

VMware Aria Automation 8.18

Table of Contents

VMware Aria Automation Release Notes	38
Release Versions	38
About VMware Aria Automation	38
Before you begin.....	38
Patch and Security Advisory Information	39
VMware Aria Automation 8.18.1 What's New.....	39
Automation Orchestrator 8.18.1 What's New	42
Resolved Issues.....	42
Known Issues.....	43
VMware Aria Automation 8.18 What's New.....	45
Automation Orchestrator 8.18 What's New	48
Resolved Issues.....	48
Known Issues.....	49
VMware Aria Automation 8.17 What's New.....	50
Automation Orchestrator 8.17 What's New	52
Resolved Issues.....	53
Known Issues.....	53
API Documentation and Versioning	54
VMware Aria Automation 8.18.1 October 2024 API Changes.....	54
VMware Aria Automation 8.18 July 2024 API Changes	56
Previous Known Issues.....	57
Getting Started with VMware Aria Automation	63
What is Automation Assembler	63
What is Automation Service Broker.....	63
What is Automation Pipelines	64
What is Automation Orchestrator	64
Before you begin with VMware Aria Automation	64
Required overall credentials	64
vCenter cloud account credentials	64
Amazon Web Services (AWS) cloud account credentials	67
Microsoft Azure cloud account credentials	70
Google Cloud Platform (GCP) cloud account credentials	73
NSX-T cloud account credentials	78
NSX-V cloud account credentials	79
VMware Cloud on AWS (VMC on AWS) cloud account credentials	79
VMware Cloud Director (vCD) cloud account credentials	79
VMware Aria Operations integration credentials	81

NSX integration with Microsoft Azure VMware Solution (AVS) for VMware Aria Automation.....	81
Automation Service Broker prerequisites	81
Automation Pipelines prerequisites	82
How do I navigate between VMware Aria Automation services	83
How do I access VMware Aria Automation services	83
What does Automation Assembler do	85
How do I get started with Automation Assembler using the VMware Aria Automation Launchpad.....	85
What does the Launchpad do	86
How do I use the Home page dashboard	86
Add a vCenter cloud account.....	87
Publish content to the Automation Service Broker catalog	88
Create a lease expiration policy for deployments	89
How do you get started with Automation Assembler using the QuickStart.....	89
How do you get started with VMware Aria Automation using the VMware vCenter Server Quickstart.....	90
How do you get started with VMware Aria Automation using the VMware Cloud Foundation Quickstart	97
How do you get started with Private AI Automation Services in VMware Aria Automation using the Catalog Setup Wizard	106
How do you get started with Automation Assembler using the Guided Setup	112
What does Automation Service Broker do	121
How do I set up Automation Service Broker.....	122
What does Automation Pipelines do.....	127
Why You Use Automation Pipelines	129
How Do I Set Up Automation Pipelines	130
What else can I do with VMware Aria Automation	133
More resources for administrators.....	133
More resources for developers.....	133
.....	133
Using Automation Assembler	134
How to use Automation Assembler	134
How does Automation Assembler work	135
Automation Assembler Tutorials.....	136
Accessing user assistance	136
Tutorial: Deploying a virtual machine in Automation Assembler.....	138
Before you begin	138
Step 1: Add a cloud account	139
Step 2: Create a project	139
Step 3: Create and deploy a virtual machine	140
Step 4: Manage the new virtual machine as a deployment	142
Step 5: Manage the new virtual machine as a resource	143
Tutorial: Setting up and testing vSphere infrastructure and deployments in Automation Assembler	145

What to do first	146
Step 1: Add the vCenter and NSX cloud accounts	146
Step 2: Define the cloud zone compute resources	149
Step 3: Configure the possible resources that are available for the account/region	150
Step 4: Create a project	154
Step 5: Design and deploy a basic cloud template	156
Tutorial results	161
Tutorial: Configuring Automation Assembler to provision a production workload	161
Before you begin	161
Customize the machine names	161
Create Active Directory machine records	164
Set your network DNS and internal IP range	166
Tutorial: Using tags in Automation Assembler to manage vSphere resources	169
Quick introduction to tags	169
Before you begin	170
Using tags to manage Workload placement	170
Adding tags as labels that you can use in vCenter Server and NSX-T	175
Tutorial: Adding an Automation Assembler cloud template to the Automation Service Broker catalog with a custom request form	181
What to do first	181
Step 1: Add inputs to the cloud template	183
Step 2: Version and release the cloud template	186
Step 3: Add the cloud template to the Automation Service Broker catalog	187
Step 4: Create a custom form for the template	189
Step 5: Control the cloud template versions in the catalog	193
Tutorial: Onboarding and managing vSphere resources in VMware Aria Automation	194
What to do first	194
Step 1: Verify that Automation Assembler discovered the resources	194
Step 2: Create a target project	195
Step 3: Create and run an onboarding plan	196
Step 4: Resize a deployment	198
Step 5: Applying approval policies	200
Step 6: Request a resize request as a user	202
Step 7: Respond to an approval request	202
Tutorial: Setting up and testing multi-cloud infrastructure and deployments in Automation Assembler	204
Part 1: Configure the example Automation Assembler infrastructure	204
Part 2: Create the example Automation Assembler project	209
Part 3: Design and deploy the example Automation Assembler template	210
Tutorial: Configuring VMware Cloud on AWS for VMware Aria Automation	231
Configure a basic VMware Cloud on AWS workflow in VMware Aria Automation	232

Configure an isolated network in VMware Cloud on AWS workflow in VMware Aria Automation.....	242
Tutorial: Configuring a provider-specific external IPAM integration for VMware Aria Automation	245
Add required extensible attributes in the Infoblox application for integration with VMware Aria Automation.....	246
Download and deploy an external IPAM provider package for use in VMware Aria Automation	246
Create a running environment for an IPAM integration point in VMware Aria Automation.....	248
Add an external IPAM integration for Infoblox in VMware Aria Automation	249
Configure a network and network profile to use external IPAM for an existing network in VMware Aria Automation	251
Define and deploy a cloud template that uses an external IPAM provider range assignment in VMware Aria Automation	253
Using Infoblox-specific properties and extensible attributes for IPAM integrations in VMware Aria Automation cloud templates	255
Control network data collection by using Infoblox filters in VMware Aria Automation	259
Setting up Automation Assembler for your organization	260
What are the VMware Aria Automation user roles.....	261
General role descriptions	261
Organization and service user roles in VMware Aria Automation	262
Custom user roles in VMware Aria Automation.....	287
Use cases: How can user roles help me control access in VMware Aria Automation	291
How do I assign the Automation Assembler Infrastructure Administrator built-in role to a user	306
Adding cloud accounts to Automation Assembler	308
Monitoring the cloud account health	309
Credentials required for working with cloud accounts in VMware Aria Automation	309
Create a Microsoft Azure cloud account in VMware Aria Automation	329
Create an Amazon Web Services cloud account in VMware Aria Automation	336
Create a Google Cloud Platform cloud account in VMware Aria Automation	338
Create a basic vCenter cloud account in VMware Aria Automation.....	350
Convert a traditional vCenter cloud account to one based on a VMware Aria Automation extensibility (vREx) proxy.....	351
Create an NSX-V cloud account in VMware Aria Automation.....	352
Create an NSX-T cloud account in VMware Aria Automation	353
Create a VMware Cloud on AWS cloud account in VMware Aria Automation	356
Create a VMware Cloud Foundation cloud account	356
Create a VMware Cloud Director cloud account in VMware Aria Automation.....	357
Create a VMware Avi Load Balancer cloud account.....	362
Integrating VMware Aria Automation with other applications	363
How do I use Git integration in Automation Assembler	363
How to upgrade to a newer external IPAM integration package in VMware Aria Automation	364
Configure an Automation Orchestrator integration in Automation Assembler.....	365
How do I work with Kubernetes in Automation Assembler.....	368
Automating Kubernetes-based workloads in Automation Assembler	389

What Is configuration management in Automation Assembler	420
Integrating with vRealize Operations Manager	424
What are onboarding plans in Automation Assembler	439
Onboarding examples	440
Onboarding event subscriptions.....	441
IP allocation during onboarding.....	441
Troubleshooting.....	441
Example: Onboard selected machines as a single deployment in Automation Assembler	441
Example: Onboard machines with template and mapping.....	444
Advanced configuration for the Automation Assembler environment.....	445
How do I set my preferences for VMware Aria Automation.....	446
How do I configure an Internet proxy server for VMware Aria Automation	447
Sample Squid configuration	449
Configure workload mobility in VMware Aria Automation.....	451
How can I configure and use a VMware Aria Automation Extensibility proxy with a vCenter cloud account for improved VMware Aria Automation performance across datacenters	452
What can I do with NSX-T mapping to multiple vCenters in VMware Aria Automation.....	456
What happens if I remove an NSX cloud account association in VMware Aria Automation	456
How do I use the IPAM SDK to create a provider-specific external IPAM integration package for VMware Aria Automation	457
Using VMware Aria Automation with Azure VMware Solution	458
Using VMware Aria Automation with Google Cloud VMware Engine.....	458
Using VMware Aria Automation with Oracle Cloud VMware Solution.....	458
Using VMware Aria Automation with VMware Cloud on Dell EMC	459
Building your Automation Assembler resource infrastructure.....	459
How to add cloud zones that define Automation Assembler target placement regions or data centers	459
Learn more about Automation Assembler cloud zones	460
How to add flavor mappings in VMware Aria Automation to specify common machine sizings	464
Learn more about flavor mappings in VMware Aria Automation	464
How to add image mapping in VMware Aria Automation to access common operating systems	465
Learn more about image mappings in VMware Aria Automation	465
How to add network profiles in VMware Aria Automation	472
Learn more about network profiles in VMware Aria Automation	472
Using network settings in network profiles and cloud templates in VMware Aria Automation	478
Using security group settings in network profiles and cloud template designs in VMware Aria Automation.....	482
Using load balancer settings in network profiles in VMware Aria Automation.....	482
How do I configure a network profile to support an on-demand network for an external IPAM integration in VMware Aria Automation	483
How do I configure a network profile to support an existing network for an external IPAM integration in VMware Aria Automation	486
NSX Projects and VPCs in network profiles	486

How to add Automation Assembler storage profiles that account for different requirements	488
Learn more about storage profiles in VMware Aria Automation.....	488
How to use Pricing Cards in VMware Aria Automation.....	491
How is price calculated	492
How do I estimate the price of my deployments and projects.....	492
How to create pricing cards for vSphere and VMware Cloud on AWS in VMware Aria Automation	493
How to use tags to manage Cloud Assembly resources and deployments.....	497
Creating a tagging strategy	497
Using capability tags in Automation Assembler	498
Using constraint tags in Automation Assembler.....	500
Standard tags.....	501
How Automation Assembler processes tags.....	502
How do I set up a simple tagging structure	502
How to work with resources in VMware Aria Automation	504
Compute resources in VMware Aria Automation	504
Network resources in VMware Aria Automation.....	504
Security resources in VMware Aria Automation	507
Storage resources in VMware Aria Automation	509
Learn more about resources in Automation Assembler	509
How to reuse VMware Aria Automation networking and security resources in Automation Assembler	530
How to manage infrastructure capacity for VMware Aria Automation	530
What to do first.....	531
Prevent memory overallocation.....	531
Set memory allocation limits	531
Ignore powered off VMs when calculating allocated memory	532
Prevent storage overallocation of datastores.....	532
Set storage allocation limits	533
Prevent CPU overallocation	533
Set CPU allocation limits	534
Ignore powered off VMs when calculating allocated CPUs	534
How to work with audit logs in VMware Aria Automation.....	535
Searching, displaying, and exporting an audit log	535
How to apply governance to your resources using Automation Assembler and Automation Service Broker	535
Background management of deployments	535
Configuring Multi-provider tenant resources with VMware Aria Automation.....	536
How do I create a Virtual Private Zone for VMware Aria Automation.....	536
Manage Virtual Private Zone configuration for VMware Aria Automation tenants	539
Create global image and flavor mapping for VMware Aria Automation tenants.....	539
Configure tenant specific image and flavor mappings for VMware Aria Automation.....	542
Create extensibility subscriptions for providers or tenants.....	542

Working with legacy Virtual Private Zones in newer versions of VMware Aria Automation	543
Adding and managing Automation Assembler projects	544
How do I add a project for my Automation Assembler development team.....	544
Learn more about Automation Assembler projects	546
Using Automation Assembler project tags and custom properties	546
Using cloud zone resource limits in Automation Assembler projects.....	547
How do project-level placement policies affect resource allocation in VMware Aria Automation.....	548
What are the project prices in Automation Assembler	553
How do Automation Assembler projects work at deployment time	554
Designing your Automation Assembler deployments	555
How cloud templates work	555
Before you create a cloud template	555
Ready to design?	555
Getting started with creating and designing cloud templates in VMware Aria Automation.....	556
How to use the Design page	556
Selecting and adding resources to the design canvas	557
Connecting resources	557
Editing cloud template code	559
Video - Creating and designing cloud templates.....	560
Getting code completion help in your Automation Assembler template	560
Creating bindings and dependencies between resources in Automation Assembler.....	563
Explicit dependencies	564
Property bindings	564
Versioning your Automation Assembler template	565
Capturing a cloud template version	565
Restoring an older version	565
Releasing a version to Automation Service Broker.....	566
Reimporting the version in Automation Service Broker	566
Comparing cloud template versions.....	566
Cloning a cloud template.....	567
Specifying formatVersion in your Automation Assembler cloud template	567
How do I use the metadata template specification	568
How do I use the variables template specification	568
How do I use the outputs template specification.....	569
Where do template specifications appear in the UI	572
User input in VMware Aria Automation requests	573
How inputs work	573
Adding input parameters	574
Referencing input parameters.....	576
Nested input	577

Optional versus required input	578
Sending inputs to VMware Aria Automation Orchestrator.....	581
List of input properties.....	582
Additional examples	583
VMware Aria Automation Orchestrator actions as inputs	586
Reusing a group of properties in Automation Assembler	592
Input property groups in Automation Assembler.....	592
Constant property groups in Automation Assembler.....	607
Learn more about Automation Assembler property groups	609
Automation Assembler resource flags for requests.....	611
Automation Assembler expressions	613
How expressions work	613
Examples	613
Complete cloud template	617
Automation Assembler expression syntax	619
Secret Automation Assembler properties	626
Creating a secret property.....	626
Adding a secret property to a cloud template	627
Remote access to an Automation Assembler deployment.....	628
Generate a key pair at provisioning time	628
Supply your own public-private key pair	629
Supply an AWS key pair.....	630
Supply a username and password.....	630
SCSI disk placement with Automation Assembler.....	631
SCSI controller and LUN disk properties	631
Option 1: Set both SCSI controller and unit number.....	631
Option 2: Set only the SCSI controller	632
Option 3: Omit both properties	633
Not an option: LUN only	634
Using inputs to set the SCSI controller and LUN	634
Machine initialization in Automation Assembler	636
How commands and customization specifications work	636
Commands and customization specifications might not mix	636
vSphere customization specifications in Automation Assembler templates.....	636
Configuration commands in Automation Assembler templates.....	637
vSphere static IP addresses in Automation Assembler	640
Delayed deployment in Automation Assembler	658
Windows guest customization in Automation Assembler.....	659
Machine and disk clusters in Automation Assembler	663
Two machines that share a disk cluster	663

Variable number of machines with one disk each.....	664
Variable number of machines with two disks each.....	665
Set disk sizes at request time	665
Custom naming deployed resources in Automation Assembler	666
Why are there two custom naming methods.....	666
How do I enroll	667
Create global custom naming for deployed resources in Automation Assembler.....	669
Create project-by-project custom names for deployed resources in Automation Assembler	681
How to add the SaltStack Config resource in Automation Assembler designs	684
Before you start.....	684
Troubleshoot minion deployments	685
Add the Salt minion to deployments in air-gapped environments.....	685
Terraform configurations in Automation Assembler	687
Preparing an Automation Assembler Terraform runtime environment	688
Designing for Terraform configurations in Automation Assembler	695
Learn more about Terraform configurations in VMware Aria Automation.....	701
Custom resource types for Automation Assembler cloud templates	703
Custom resource name and resource type	704
Extensibility action custom resources	704
Lifecycle actions for extensibility action custom resources	704
Automation Orchestrator custom resources	704
Automation Orchestrator custom resource external type.....	705
Automation Orchestrator lifecycle action validation	705
Custom resource property schema	705
Day 2 Operation Custom Request Forms	706
Day 2 Operation Request Form Validation.....	706
Adding Automation Orchestrator actions as input properties.....	707
How to create an Automation Assembler template that adds users to Active Directory	707
How to create an Automation Assembler template that includes SSH	711
Automation Assembler designs that prepare for day 2 changes	714
How to use cloud template inputs for VMware Aria Automation day 2 updates	715
How to create an Automation Assembler resource action to vMotion a virtual machine	716
Virtual Machine reconciliation after vMotion migration.....	725
More Automation Assembler template examples	727
Network, security group, and load balancer resource examples in Automation Assembler	727
Using VMware Avi Load Balancer resources	756
vSphere resource examples in Automation Assembler	811
Documented Automation Assembler template example	825
Attaching an existing disk in Automation Assembler.....	838
Cores per socket and CPU count in Automation Assembler.....	838

Puppet-enabled cloud template with username and password access	839
vCenter username and password YAML code	840
Special Automation Assembler properties.....	851
Other ways to create Automation Assembler templates.....	852
Cloud template cloning	852
Uploading and downloading	852
Integrating Automation Assembler with a repository	852
Extending and automating application life cycles with extensibility.....	852
Extensibility Actions.....	852
Automation Orchestrator Workflows	853
Extensibility action subscriptions.....	853
Extensibility workflow subscriptions	879
Learn more about extensibility subscriptions	886
Managing deployments and resources in Automation Assembler.....	898
Managing Automation Assembler deployments	898
Working with deployment cards and the deployment list	899
Working with selected deployment filters	900
How do I monitor deployments in Automation Assembler.....	901
What can I do if an Automation Assembler deployment fails	903
How do I manage the life cycle of a completed Automation Assembler deployment.....	905
Managing resources in Automation Assembler	909
Viewing billable objects	909
Working with the resource lists	910
List of managed resources by origin	911
What is the resource details view.....	912
What day 2 actions can I run on resources.....	912
How do I work with individual resources in Automation Assembler	913
How do I work with discovered resources in Automation Assembler	915
What actions can I run on Automation Assembler deployments or supported resources	919
Deployment properties that you cannot update using day 2 actions in VMware Aria Automation	934
Using Automation Service Broker	936
How does Automation Service Broker work	936
Setting up Automation Service Broker for your organization.....	938
What are the Automation Service Broker user roles	938
User Roles	938
Service Broker Service Roles	938
Adding Content to the Automation Service Broker Catalog	947
Add Automation Assembler templates to the Automation Service Broker catalog.....	947
Add CloudFormation templates to the Automation Service Broker catalog	949
Add Automation Orchestrator workflows to the Automation Service Broker catalog	952

Add extensibility actions to the Automation Service Broker catalog	954
Add Automation Pipelines pipelines to the Automation Service Broker catalog	955
Setting up Automation Service Broker policies	957
Getting started with policies	957
How do I configure Automation Service Broker approval policies	958
How do I entitle deployment users to Automation Service Broker day 2 actions using policies	967
How do I configure Automation Service Broker deployment leases using policies.....	970
How do I configure Automation Service Broker resource quotas using policies.....	974
How do I limit deployment resources using Automation Service Broker policies.....	978
How do I configure Automation Service Broker content sharing policies.....	981
How do I configure deployment criteria in Automation Service Broker policies.....	984
How are Automation Service Broker policies processed	992
Customize an Automation Service Broker icon and request form.....	996
Learn more about Service Broker custom forms	1000
Send email notifications to Automation Service Broker users.....	1019
Add an email server in Automation Service Broker to send notifications.....	1020
Working with the Infrastructure options in Automation Service Broker	1021
How do I deploy an Automation Service Broker catalog item.....	1022
Learn more about the Automation Service Broker catalog items	1022
Using the filter and search to locate a catalog item	1023
My Resource Usage dashboard.....	1023
How do I deploy VMware Private AI Foundation catalog items in the Automation Service Broker	1024
Before you begin	1025
How do I access the Private AI Automation Services catalog items	1025
How do I monitor my Private AI deployments	1025
Deploy a GPU-accelerated Tanzu Kubernetes Grid cluster.....	1025
Managing deployments and resources in Automation Service Broker.....	1026
How do I manage my Automation Service Broker deployments	1026
Working with deployment cards and the deployment list	1027
Working with selected deployment filters	1028
Working with deployment details.....	1030
How do I monitor Automation Service Broker deployments.....	1031
What can I do if a Automation Service Broker deployment fails	1033
How do I track and respond to requests that require approval in Automation Service Broker	1034
How do I track and respond to requests that require user input in Automation Service Broker	1036
How do I manage resources in Automation Service Broker.....	1037
Viewing billable objects	1037
Working with the resource lists	1038
List of managed resources by origin	1039
What is the resource details view.....	1040

What day 2 actions can I run on resources.....	1040
How do I work with individual resources in Automation Service Broker	1041
How do I work with discovered resources in Automation Service Broker	1044
What actions can I run on Automation Service Broker deployments or supported resources	1048
How to move a deployed machine to another network	715
Deployment properties that you cannot update using day 2 actions in VMware Aria Automation	934
Working with the Cloud Consumption Interface.....	1066
Getting Started with the Cloud Consumption Interface in Automation Service Broker.....	1067
Create a Supervisor Namespace	1068
Working with the Virtual Machine service	1071
Working with the Tanzu Kubernetes Grid service	1072
Working with the Volume service	1073
Other CCI Command Line Interface options	1073
Create Supervisor Namespaces and infrastructure resources using kubectl	1073
Kubernetes API Reference for the Cloud Consumption Interface.....	1080
Using Automation Pipelines.....	1091
How Administrators use Automation Pipelines	1092
How Developers Use Automation Pipelines.....	1093
Find more documentation in the In-product Support panel	1094
Setting up Automation Pipelines to model my release process	1094
How do I add a project in Automation Pipelines	1099
How do I manage user access and approvals in Automation Pipelines.....	1100
What are Roles in Automation Pipelines.....	1100
Custom roles and permissions in Automation Pipelines	1102
If you have the Administrator role.....	1105
If you have the Developer role	1105
If you have the User role	1105
If you have the Viewer role.....	1105
If you have the Executor role	1106
How do I assign and update roles.....	1106
What are user operations and approvals in Automation Pipelines.....	1107
Creating and using pipelines in Automation Pipelines	1108
What are Pipelines in Automation Pipelines.....	1108
Creating Pipelines	1108
Approving pipelines	1109
Triggering pipelines	1109
How do I run a pipeline and see results	1110
What types of tasks are available in Automation Pipelines	1114
Creating and using shared pipelines in Automation Pipelines	1119
Why is a shared pipeline useful	1119

How do I share a pipeline.....	1120
How do I run a shared pipeline	1120
How do I add a shared pipeline to another pipeline.....	1121
How do I use a shared pipeline for rollback	1122
How do I use a shared template in a pipeline	1122
How do I delete or stop sharing a pipeline	1123
How do I use variable bindings in Automation Pipelines pipelines.....	1124
How to apply dollar bindings to cloud template variables in a cloud template task	1124
How to pass a parameter to a pipeline when it runs	1127
How to bind two pipeline tasks by creating input and output parameters	1128
How do I learn more about variables and expressions	1133
How do I use variable bindings in a condition task to run or stop a pipeline in Automation Pipelines	1133
What variables and expressions can I use when binding pipeline tasks in Automation Pipelines	1135
Pipelines can run simple or complex software delivery solutions	1135
Using dollar expressions with scopes and keys to bind pipeline tasks	1136
Default Expressions	1139
Using SCOPE and KEY in pipeline tasks.....	1140
How to use a variable binding between tasks	1154
To learn more	1154
How do I send notifications about my pipeline in Automation Pipelines.....	1154
How do I create a Jira ticket in Automation Pipelines when a pipeline task fails	1156
How do I roll back my deployment in Automation Pipelines.....	1158
Planning to natively build, integrate, and deliver your code in Automation Pipelines.....	1164
Configuring the Pipeline Workspace	1164
Planning a CICD native build in Automation Pipelines before using the smart pipeline template.....	1167
Planning the Continuous Integration (CI) stage	1167
Planning the Continuous Delivery (CD) stage	1168
How you'll create the CICD pipeline by using the smart pipeline template	1172
Planning a continuous integration native build in Automation Pipelines before using the smart pipeline template.....	1174
Planning a continuous delivery native build in Automation Pipelines before using the smart pipeline template....	1176
Planning a CICD native build in Automation Pipelines before manually adding tasks	1177
Planning the external and internal requirements	1177
How you'll create the CICD pipeline and configure the workspace	1178
How to enable and run your pipeline	1183
Planning for rollback in Automation Pipelines	1184
How do I configure rollback.....	1184
What happens if my deployment pipeline has multiple tasks or stages with rollback	1185
Tutorials for using Automation Pipelines.....	1186
How do I continuously integrate code from my GitHub or GitLab repository into my pipeline in Automation Pipelines	1187

How do I automate the release of an application that I deploy from a YAML cloud template in Automation Pipelines	1191
How do I automate the release of an application in Automation Pipelines to a Kubernetes cluster	1199
Example pipeline YAML that deploys an application to a Kubernetes cluster	1205
How do I deploy my application in Automation Pipelines to my Blue-Green deployment	1207
Example YAML code for some Blue-Green Deployment Tasks.....	1209
How do I integrate my own build, test, and deploy tools with Automation Pipelines	1211
How do I use the resource properties of a cloud template task in my next task	1222
How do I use a REST API to integrate Automation Pipelines with other applications	1226
How do I leverage pipeline as code in Automation Pipelines.....	1230
Example YAML code for a pipeline and endpoints	1231
How do I use Search in Automation Pipelines	1236
What can I search	1236
How does search work.....	1236
How do I save a favorite search	1239
Can I save a favorite pipeline	1240
Connecting Automation Pipelines to endpoints.....	1240
What are Endpoints in Automation Pipelines	1241
Example YAML code for a GitHub endpoint.....	1242
How do I integrate Automation Pipelines with Jenkins	1243
Example YAML for a Jenkins build task.....	1248
How do I integrate Automation Pipelines with Git	1249
How do I integrate Automation Pipelines with Gerrit	1251
How do I integrate Automation Pipelines with VMware Aria Automation Orchestrator.....	1254
Orchestrator task output format.....	1259
Triggering pipelines in Automation Pipelines	1259
How do I use the Docker trigger in Automation Pipelines to run a continuous delivery pipeline.....	1259
How do I use the Git trigger in Automation Pipelines to run a pipeline	1267
How do I use the Gerrit trigger in Automation Pipelines to run a pipeline	1273
Monitoring pipelines in Automation Pipelines	1279

VMware Aria Automation Release Notes

This document contains the following sections

- [Release Versions](#)
- [About VMware Aria Automation](#)
- [Before you begin](#)
- [Patch and Security Advisory Information](#)
- [VMware Aria Automation 8.18.1 What's New](#)
- [VMware Aria Automation 8.18 What's New](#)
- [VMware Aria Automation 8.17 What's New](#)
- [API Documentation and Versioning](#)
- [Previous Known Issues](#)

Release Versions

VMware Aria Automation October 2024
VMware Aria Automation 8.18.1 October 09 2024
<ul style="list-style-type: none"> • VMware Aria Automation build 24282366 • VMware Aria Automation Easy Installer build 24286787 • VMware Aria Automation Cloud Extensibility Proxy build 24282368 • VMware Aria Automation Orchestrator build 24281602

Updates made to this document

Date	Description of update	Type
October 9th 2024	Initial publishing for VMware Aria Automation 8.18.1	

For more information, see our [blogs about the VMware Aria Automation releases](#).

Note: VMware has announced the End of Availability (EoA) of the VMware Aria SaaS services, including VMware Aria Automation SaaS, as of February 2024 and the services will cease to exist from December 6th 2024.

Note: The VMware Aria Automation Cloud Extensibility Proxy build specified above is only applicable for on-prem VMware Aria Automation deployments. The last applicable cloud extensibility proxy build for VMware Aria Automation SaaS is 23103969.

About VMware Aria Automation

You can find information about these new features and more at [VMware Aria Automation](#) and in the signpost and tooltip help in the user interface. Even more information is available when you open the in-product support panel where you can read and search for related topics, and view community posts and KBs, that appear for the active user interface page.

Notice: For information earlier VMware Aria Automation releases, go to the [release note archive](#).

Before you begin

Familiarize yourself with the supporting documents.

VMware Aria Automation 8.18	Automation Orchestrator 8.18
<ul style="list-style-type: none"> • Installing VMware Aria Automation with Easy Installer • Administering VMware Aria Automation • VMware Aria Automation Transition Guide <p>After installing VMware Aria Automation and setting up your users, you can use the <i>Getting Started</i> and <i>Using and Managing</i> guides for each of the included services. The <i>Getting Started</i> guides include an end-to-end proof of concept. The <i>Using and Managing</i> guides provide more in-depth information that supports your exploration of the available features. Additional information is also available in VMware Aria Automation product documentation.</p> <ul style="list-style-type: none"> • Getting Started with VMware Aria Automation • Using Automation Assembler • Using Automation Pipelines • Using Automation Service Broker 	<ul style="list-style-type: none"> • Installing and Configuring Automation Orchestrator • Upgrading Automation Orchestrator • Using Automation Orchestrator • Using Automation Orchestrator Plug-ins

Patch and Security Advisory Information

Release Date	Details
January 7th 2025	<p>VMware Aria Automation 8.18.1 Patch 1 is now available. Patch 1 resolves various issues in VMware Aria Automation and Automation Orchestrator. For more information on resolved issues and how to install the patch, go to KB385294.</p> <p>This patch also resolves CVE-2025-22215. For more information on that vulnerability and its impact on VMware products, see VMSA-2025-0001.</p>
December 6th 2024	<p>VMware Aria Automation 8.18.0 Patch 2 is now available. Patch 2 is a cumulative update that fixes various issues in VMware Aria Automation and Automation Orchestrator. For more information on resolved issues and how to install the patch, go to KB383323.</p>
July 10th 2024	<p>A new security advisory is published for VMware Aria Automation. For more information, go to VMSA-2024-0017 and KB325790. Apply the necessary patch at the earliest convenience.</p>

VMware Aria Automation 8.18.1 What's New

Full name display in UI

Full usernames for Resources, Deployments and Policy are now available in the VMware Aria Automation UI in addition to user IDs. Enable the visibility of this settings under the administration and user columns from the **Manage Column** button on the left lower corner. The same support for Catalog, Content Source, and Content is available through the API.

Removed migration support for VMware Aria Automation 7.x to 8.x and NSX-V to NSX-T

Following the previous announcement of deprecation, this release officially removes the migration assistant and as a result, the following capabilities are no longer supported:

1. Migration from vRealize Automation 7.x to VMware Aria Automation 8.x
2. Migration from NSX-V to NSX-T

Include DCGM Exporter by default in Deep Learning VM

Starting with the current release, the DCGM-Exporter will be included by default as part of the Deep Learning VM (DLVM) image. DCGM-Exporter is an exporter for Prometheus that monitors the company health and retrieves metrics from the GPUs. It leverages DCGM using Go bindings to collect GPU telemetry and exposes GPU metrics to Prometheus using an HTTP endpoint (/metrics).

Support for Data Services Manager Private AI Automation Services

Starting this release, the Catalog Setup Wizard will generate three additional items.

- DSM (Data Services Manager) Database: deploys a new instance of the PostgreSQL cluster which can be used as a datastore for RAG applications.
- AI RAG Workstation with DSM: installs a GPU-enabled deep learning VM with the necessary NVIDIA software and a PostgreSQL database to run RAG workflows.
 - Connect to a remote PostgreSQL Database instance
 - Instantiate a new PostgreSQL database instance through DSM
- AI Kubernetes RAG Cluster with DSM: installs a GPU-enabled Tanzu Kubernetes Grid (TKG) Cluster with the necessary NVIDIA software and a PostgreSQL database to run RAG workflows.
- Users of "AI RAG Workstation with DSM" and "AI Kubernetes RAG Cluster with DSM" catalog items can either connect to an existing PostgreSQL database or create a new database.

For detailed instructions on using the Catalog Setup Wizard and deploying the three new catalog items, see the [product documentation](#).

Pick TKR versions in PAIF QS

Starting this release, the Catalog Setup Wizard will allow users to pick from up to three supported versions of Tanzu Kubernetes Runtimes (TKR) to be used in Catalog items. For detailed instructions on picking the TKR runtimes, see the [product documentation](#).

Updates to the supervisor namespace classes and regions

This feature introduces the ability to create, update, and delete supervisor namespace classes in the VMware Aria Automation Assembler UI. Supervisor namespace classes are used to create supervisor namespaces used for the Cloud Consumption Interface in VMware Aria Automation Service Broker. You can also use Automation Assembler to delete supervisor regions. Supervisor regions are used to group multiple supervisors. Previously, this was only possible through the K8S CLI.

Ability to control the placement of on-demand NSX security groups by using tag constraints

This feature provides an ability to provision on-demand NSX security groups and explicitly control placement of those groups in specific NSX managers by using tag constraints.

NSX network and security group automation with discovered resources from NSX Projects and VPCs

This release supports discovery of networking and security resources from NSX environments configured with multi-tenancy including networks and security groups from NSX projects and VPCs.

Administrators can then assign these resources to network profiles and subsequently leverage them in VMware Aria Automation cloud templates to support network and multi-tier application automation use cases.

Note: There is no change in credentials required to connect to the NSX manager.

Onboarding of vSphere namespaces to be used in the Cloud Consumption Interface

In VMware Aria Automation Assembler, administrators can now onboard vSphere namespaces from discovered supervisor clusters under connected vCenter cloud accounts. These are the namespaces that are not created by VMware Aria Automation.

When vSphere namespaces are onboarded, all running services and objects (VM, TKGs cluster, Volume, images, and so on) become visible in the Cloud Consumption Interface under VMware Aria Automation Service Broker.

Handle reconciliation for VMs that are part of a vMotion migration within and across vCenter instances

VMware Aria Automation now automatically reconciles the changes to your virtual machines after vMotion migration. The supported scenarios include:

- Migration within the same vCenter
- Migration across different vCenter instances
- Migration across NSX-T networks

VMware Aria Automation now also includes a new event topic **Compute post migration reconcile status**, which is initiated after a VM is reconciled. The event topic includes the status of the VM reconciliation in VMware Aria Automation and the destination details of the migrated VM.

Audit logging in VMware Aria Automation with CSV export

You can now export an CSV file containing your audit log. You can search the audit log for specific events, event type, and date ranges and save events as a CSV file.

The following are the restrictions in downloading the CSV file:

- CSV download (0 byte file) might not work if the file size is greater than 300 MB. However, you can still access this file from the log bundle. The location of the log bundle is `/services-logs/prelude/ebs-app/file-logs/`. Larger CSV files should be accessed from the VMware Aria Automation CLI log.
- The date range for the CSV file download is kept at 12 months maximum to avoid larger file sizes.
- Because the CSV file generation is a resource intensive task, only one file generation job can be submitted at a given time. After this job is completed, the next job can be submitted.

Code Stream availability notice for VCF 9.0

Code Stream is continuous integration and continuous delivery (CI/CD) tool used to build pipelines that model the software release process in DevOps lifecycle. Code Stream is part of the VMware Aria Automation suite. Starting with VCF 9.0, Code Stream will no longer be available. There is no equivalent functionality in VCF and it is recommended that customers leverage open source tools.

Improvements to the cloud template designer

The following enhancements are made to cloud template designer:

- **Collapse / expand** – YAML code in right panel (code panel). The right panel is larger by default.
- **Search** – you can now search for anything and highlight matches.

Improvements to the cloud template designer for handling supervisor resources

With the addition of supervisor resources, cloud templates are becoming more and more complex. Many resources are nested within each other. The cloud template designer has the following enhancements for supervisor resources:

- Provide resource nesting view to show parent/child relations.
- Visualize nesting parent/child layout for resources in the topology.
- Highlight related bound inputs/variables when selecting a resource.

Improvements to disk ordering in the storage view

Previously, the disk ordering in the VMware Aria Automation deployment storage view were listed in a random order rather than being sorted by unit number.

This approach could create problematic scenarios particularly when virtual machines (VMs) have a large number of disks, as the disk with the last unit number might be shown in the list.

This feature provides ability to:

- Sort the disks by unit number by default.
- Provide sorting on each column so disks can also be sorted by name, capacity, type, encryption, and controller key unit number.

Support 64 disks on Paravirtual SCSI (PVSCSI) controller

VMware Aria Automation had a limitation when attempting to deploy certain application types that need a large number of disks or add disks. This is because VMware Aria Automation only supports up to 14 disks per controller, while Virtual Center supports up to 64 disks.

Now VMware Aria Automation supports up to 64 disks per controller at the deployment phase and for adding disks.

Automation Orchestrator 8.18.1 What's New

Control Center is removed

With the Automation Orchestrator 8.18.1 release, the Control Center is removed. To configure your Automation Orchestrator deployment, use the command line interface of the appliance.

Improve the usability of the log messages pane for workflow, action, and policy runs

This release introduces search by terms in the logs view for the Automation Orchestrator workflows, actions, and policy runs. The usability of the logs pane is also improved by keeping the context while switching content tabs, tailing running workflows, and so on.

Bump PowerShell runtime images to Photon 5

The PowerCLI 12 with PowerShell 7.2 runtime is removed. Scripts depending on it are automatically run on the latest PowerCLI 13 with PowerShell 7.4 runtime.

Resolved Issues

Workflows fail with invalid login credentials for the service account

vSphere and Multi-Node plug-in workflows can randomly fail with an "Invalid credentials" error. This is caused by access tokens being reused internally in the Automation Orchestrator server even after token expiration.

This issue is now resolved by limiting the time access tokens are cached.

Loss of feature access after upgrading to Automation Orchestrator 8.18

After upgrading to Automation Orchestrator 8.18, workflows show the following error: ""Polyglot scripting is not supported with the current license"".

VMware Aria Automation is unable to work with non-English keyboards when using the Remote Console

When using the Remote Console through VMware Aria Automation 8.18, the console lists the correct language keyboard and layout but it gives the wrong special characters and keys when inputting.

Added an option to email notifications that prevents automatic STARTTLS connection upgrades

When email notifications are configured with a Connection Security setting of "None", the connection to the email server automatically upgrades to an encrypted connection through STARTTLS if the email server indicates support. In a FIPS environment, this can cause issues if the SMTP server does not support FIPS-compatible ciphers. A new option, "Enable insecure connection upgrade with STARTTLS" is added to disable connection upgrades and forces unencrypted connections to the email server.

Integration with NSX Federation is not supported in VMware Aria Automation for NSX releases 3.2.2 and later

When using NSX-T Federation, NSX-T Global Manager enumeration fails for NSX version 3.2.2 and later when used in VMware Aria Automation 8.17 and 8.18.

The failure causes the following error message to appear:

The requested URI: /api/v1/transport-nodes could not be found

This issue does not impact non-federated environments. To resolve this issue, users must either use NSX version 3.1.x or upgrade to VMware Aria Automation 8.18.1.

Cannot download PowerShell dependencies from the custom repository

Automation Orchestrator trusted certificates are now imported in non-Java runtimes (Python, PowerShell, PowerCLI, and NodeJS).

This resolves the issue with downloading dependencies from repositories which use customer certificate authorities. Additionally, it is no longer required to use insecure connections to endpoints using self-signed or custom CA certificates.

Known Issues

Storage profile constraints are not applicable for Virtual Private Zones (VPZs)

VPZs are not supported and constraint tags alone do not handle the placement of datastores without specifying the specific datastore in the storage page for the VPZ.

Workaround: Use cloud zones instead of VPZs.

Filtering information about workflows through the API does not work

Filtering information about workflows which were run in the last 24 hours does not work.

No workaround.

Issue with policies that include more than 10 items

For policies with more than 10 items, the **Add Items** window is not showing all existing items as selected on the previous page.

No workaround.

After upgrading to VMware Aria Automation 8.18.1, users cannot create TKG cluster resources by using CCI templates

The deployment fails with a "Failed to publish resource" error for any TKG level resource defined in the template, such as Kubernetes namespaces, cluster node binding, and others.

No workaround.

Unable to run custom day 2 actions for Service Broker

Users cannot run day 2 actions for resources in a deployment, when the deployment is expanded on the main UI page. This is caused by the deployment ID not being provided to the action.

No workaround.

After upgrading to Automation Orchestrator 8.18.1, workflows that use VM Guest Operations fail

Workflows that use VMware Guest Operations, such as the workflow to change to local admin password, fail.

No workaround.

VMware Aria Automation attempting to connect to http://bellevue-ci.eng.vmware.com

Appliance logs show VMware Aria Automation repeatedly making failed attempts to send service metrics to the internal http://bellevue-ci.eng.vmware.com address.

No workaround.

After plug-in installation, data collection for workflows and actions related to this plug-in does not occur in VMware Aria Automation

You cannot use workflows and actions in VMware Aria Automation after data collection that are part of the content of a new plug-in in Automation Orchestrator.

Workaround: Make any content changes, such as creating a dummy workflow and then delete the change. Run the data collection manually or wait for the next scheduled data collection run. The new workflows and actions are now available for use in VMware Aria Automation.

After upgrading VMware Aria Automation, all new day 2 actions, for deployments that were pending approval during the upgrade, are stuck in the In Progress state

The day 2 actions impacted by this issue are stuck in the In Progress state and the associated deployment tasks cannot be canceled.

No workaround.

After upgrading Automation Orchestrator, you cannot see the authentication details when running the vracli vro authentication command

The command vracli vro authentication returns 'No authentication provider configured' although the authentication is not broken.

The issue is observed after upgrade to 8.18.1 or newer versions of Automation Orchestrator and is caused by the move to configuring authentication with commands. There is no impact. After update of the authentication using the command the issue is fixed

No workaround.

Field for assigning groups to a workflow or action is missing

The field used to assign groups is missing from the **General** view of the workflow or action if you have a Workflow Designer role.

Workaround: Use the Administrator role or use API calls to assign group permissions to your workflow or action. To use API calls:

1. Retrieve a list of the groups available to the current user by using the `GET /authorization-groups` API call.
2. Retrieve the value of the "id" attribute of the group.
3. Perform a `PUT /authorization-groups/{groupId}/{objectType}/{objectId}` API call. The `{groupId}` must be replaced with the ID you retrieved in the previous step. `{objectType}` must be replaced with `Workflow or Action` and `{objectId}` must be replaced with the ID of the workflow or action, which you can retrieve from the editor in the Automation Orchestrator Client.

Intermittent failures of running workflows and actions with an exception - "ClientResponse has erroneous status code: 403 Forbidden"

Intermittent failures of running workflows and actions with an exception - "ClientResponse has erroneous status code: 403 Forbidden" on Automation Orchestrator deployments authenticated with VMware Aria Automation.

Workaround: Run the following command to apply the license check system property:

```
vracli vro properties set --key com.vmware.o1ln.license.check.automation-endpoint.enabled
--value false
```

Deprecate solutions users and migrate to service accounts

When using a standalone Automation Orchestrator with vSphere authentication, the authentication provider must be re-registered after upgrading to 8.18.1 in order to upgrade the deprecated vSphere solution user (certificate based authentication) to vSphere service account (client id / client secret based authentication).

No workaround.

VMware Aria Automation 8.18.1 is not compatible with NSX-V when operating in FIPS mode

When VMware Aria Automation 8.18.1 is operating in FIPS mode it is not compatible with NSX-V.

No workaround.

Cannot perform day 2 operations in the Deployments view/Resources or Machine view

Day 2 operations performed outside the deployment might not work properly and you can encounter the following error message:

```
"404 NOT_FOUND "Failed to validate form source due to: "; nested exception is  
org.springframework.web.server.ResponseStatusException: 404 NOT_FOUND"
```

Workaround: Click the deployment link to enter the single-deployment view and run the day 2 action, rather than expanding the deployment parent-child view.

VMware Aria Automation 8.18 What's New

The VMware Remote Control Application (VMRC) console proxy is updated to support WebMKS

Previously, you could not use VMRC day 2 actions from VMware Aria Automation on-prem to communicate with vSphere 8+ instances. This is because vSphere 8+ only supports communication over WebMKS while MKS, used by older vSphere versions, is deprecated. For more information, go to [KB 93070](#).

Starting with this release, VMware Aria Automation on-prem will use WebMKS as the default communication method between VMRC and vSphere 7+ and 8+ instances. The console proxy abstracts the underlying vCenter as the connections are now proxied. The workaround for on-prem instances mentioned in the above KB article is no longer needed. It is recommended that users start planning their upgrade to the current product version along with upgrading to vSphere 8+.

Content library filtering improvements to the Catalog Setup Wizard

Starting this release, Catalog Setup Wizard has made the following improvements that provide a better VM image browsing experience.

- Users can now filter the list of available Deep Learning VM images by specifying a content library name.
- Content related to Tanzu Kubernetes Grid (TKG) is now excluded from the search results which reduces the search term clutter.

Split catalog items for the Catalog Setup Wizard

Starting this release, the Catalog Setup Wizard creates five catalog items for better usability.

- AI Workstation: Installs a GPU-enabled deep learning VM.
- AI RAG Workstation: Installs a GPU-enabled deep learning VM with all necessary NVIDIA software to run a RAG workflow.
- Triton Inferencing Server: Installs a GPU-enabled deep learning VM with NVIDIA Triton Inferencing Server.
- AI Kubernetes Cluster: Installs a GPU-enabled Tanzu Kubernetes Grid (TKG) Cluster.
- AI Kubernetes RAG Cluster: Installs a GPU-enabled Tanzu Kubernetes Grid (TKG) Cluster with all necessary NVIDIA software to run a RAG workflow in production.

For detailed instructions on using the Catalog Setup Wizard and deploying the five catalog items, see the [product documentation](#).

Automatic installation of the TKG RAG operator

Starting from this release, the AI Kubernetes Cluster catalog item will automatically install the NVIDIA Retrieval Augmented Generation (RAG) Kubernetes operator in addition to the NVIDIA GPU operator. Catalog users now have access to a fully functional Tanzu Kubernetes Cluster that is capable of running RAG workloads. Users will be required to manually install any sample RAG applications.

Air-gapped support for Non-RAG workloads on DLVM

Starting this release, the Catalog Setup Wizard now provides options to configure a private registry and specify HTTP/HTTPs proxy configurations. Non-RAG NVIDIA containers and vGPU drivers can now be stored in locations that are not accessible through the internet. This capability enables the deployment of the following catalog items on a deep learning VM in air-gapped environments:

- PyTorch
- TensorFlow
- Triton Inference Server
- CUDA samples

For detailed instructions on using the Catalog Setup Wizard and using air-gapped environments, see the [product documentation](#).

New workflow for the Launchpad in VMware Aria Automation

A new workflow is available to help users getting started or use as shortcuts in VMware Aria Automation. You can leverage this workflow to increase time-to-value by skipping the manual required steps to publish VM images from vCenter to catalog items for end user consumption.

- Auto-discover images from a cloud account
- Automatically associate cloud zone to a project
- Automatically create cloud templates based on the discovered image
- Automatically version and release cloud templates
- Automatically create a content source
- Automatically validate a project to pull catalog updates
- Automatically create a content sharing policy based on user choice of project name
- Assign users to a project or catalog
- Optional step to select network and storage for the VM (if skipped, network and storage will be allocated randomly)

For detailed instructions on using the Launchpad in VMware Aria Automation, see the [product documentation](#).

Set the storage priority for storage profiles and datastores

You can now set the priority for storage profiles and datastores to specify the order of datastores to be picked among all the eligible datastores. This allows users to place VMs in a specific cluster based on the set priority. This feature modifies the current behavior where multiple datastores eligible for placement are selected based on the available capacity.

Cloud template assignment with compliance for onboarding deployments

A new feature in onboarding plans allows cloud administrators to assign a template to an onboarded deployment. There are three ways to associate a cloud template to an onboarded deployment:

1. No cloud template associated.
2. For visual only, to allow a cloud template link on the deployment but not assigned with compliance.
3. Fully assigned by each virtual machine with compliance and can operate the update action using the assigned template.

To assign the cloud template and make the onboarded deployment compliant, follow the steps below:

1. Select a relevant cloud template.

2. Map every machine resource in the template to a VM by selecting discovered VMs from the machine selection page.
3. Validate and run the onboarding plan.

Note: Onboarding compliance only supports `Cloud.Machine` and `Cloud.vSphere.Machine` resource types and their attached disks and networks. Onboarding no longer supports automatic generation of cloud templates. Administrators can either onboard with an existing template or without a template.

For more information about onboarding, go to [What are onboarding plans in Automation Assembler](#).

Dark mode added in VMware Aria Automation

A beta version of Dark mode is now available for VMware Aria Automation Identity and Access Management. You can switch between Light and Dark mode from the preferences under the **My account** page. For more information, go to [How do I set my preferences for VMware Aria Automation](#).

Reduced set of languages for localization

Beginning with the next major release, we will be reducing the number of supported localization languages. The three supported languages will be:

- Japanese
- Spanish
- French

The following languages will no longer be supported:

- Italian
- German
- Brazilian
- Portuguese
- Traditional Chinese
- Korean
- Simplified Chinese

Impact:

- Customers who were using the deprecated languages will no longer receive updates or support in these languages.
- All user interfaces, help documentation, and customer support will be available only in English or in the three supported languages mentioned above.

Update Provisioning Service to call Active Directory (AD) during project change

In previous releases, users who delete a project or use the Change Project feature while having an active AD integration would receive a 403 Forbidden error. These scenarios occur because Active Directory does not listen for events coming from the Project Service. The AD integration is now updated to track these project changes.

New location of the default runtime container image in the Terraform runtime integration

In the Terraform runtime integration, the location of the default runtime container image is being changed. The new image location is `projects.packages.broadcom.com/vra/terraform:latest`. The previous location `projects.registry.vmware.com/vra/terraform:latest` will be inaccessible.

Only the location is changing. The content of the image remains the same.

If you are running any instances of VMware Aria Automation with an existing Terraform runtime integration, you must change the image location to `projects.packages.broadcom.com/vra/terraform:latest` or the runtime integration will fail.

Deprecation in Storage Profiles properties

The storage profiles properties 'Shares' and 'Limit IOPS' are being deprecated to align with deprecation strategy in vSphere. These properties will be removed in a future release.

Automation Orchestrator 8.18 What's New

- **Plug-in and log level configuration are moved from the Control Center to the System settings section in the Automation Orchestrator Client**

Plug-in and log configuration are now performed from the **System Settings** page of the Automation Orchestrator Client. New REST APIs for managing plug-ins and log levels are also introduced. You can find more information about the Automation Orchestrator REST API in the Swagger UI located at https://<your_orchestrator_FQDN>/vco/api/docs/.

- **Control Center will be removed from Automation Orchestrator in the next release**

Automation Orchestrator configuration will be done through the command line interface. For more information, see the [product documentation](#).

Resolved Issues

The vco pod experiences multiple restarts and Java heap dumps

This issue occurs when you have a very large vSphere infrastructure with a large amount of VMs and uses the `VcPlugin.getAllVirtualMachines()` method frequently. In such scenarios, the Automation Orchestrator pod or pods experience multiple restarts and Java heap dumps.

To resolve this issue, the vCenter plug-in was optimized and made configurable for different use case scenarios. The relevant changes are:

- Default objects (main and live) cache sizes - changed from 100 000 000 entries to 20 000 entries for each vCenter attached to to plug-in.
- Default objects (main and live) cache expiration times - changed from 14 440 seconds to 600 seconds.

The vCenter plug-in cache can be configured through the following system properties:

- `com.vmware.vmo.plugin.vi4.cache.main.max.size` - Sets the maximum number of entries the cache can contain. This property controls the size of the main and the live objects cache. If set to zero, elements are removed immediately after being loaded into cache. This can be useful in testing, or to disable caching temporarily without a code change. The default value is 20 000 entries.
- `com.vmware.vmo.plugin.vi4.cache.main.expirationSeconds` - Sets the main cache expiration time in. Specifies that each entry should be automatically removed from the cache after a fixed duration has elapsed from the time of the entry's creation, or the most recent replacement of the entry value. The default value is 600 seconds.
- `com.vmware.vmo.plugin.vi4.cache.live.objects.expirationSeconds` - Sets the live object cache expiration. Specifies that each entry should be automatically removed from the cache after a fixed duration has elapsed from the time of the entry's creation, or the most recent replacement of the entry value. The default value is 600 seconds.
- `com.vmware.vmo.plugin.vi4.cache.clearOnSessionRefresh` - Controls whether to clear all caches (main and live objects) on session refresh. The default value is false.

Cloud Consumption Interface (CCI) does not support sAMAccountName (short AD username)

When adding a new directory in vIDM, the admin user has the choice of two directory-search attributes. This choice impacts the format of usernames in the associated on-prem Aria Automation deployment. The possible values are:

- **sAMAccountName** - usually the user name without a domain, resulting in a short name in VMware Aria Automation, which does not include the domain. This is the default when setting up a new directory.
- **userPrincipalName** - usually the user name with a domain, resulting in a long or full username in VMware Aria Automation, which includes the domain.

CCI uses the usernames available in the project data to construct the vCenter access lists for the supervisor namespaces it manages. In systems configured with short user names, these project user names are domain-less and vCenter appears to discard them without error during project-sync, leaving users without the ability to access the supervisor namespace that they created from CCI.

Spread by memory does not consider managed machines even after onboarding the machines

Spread by memory placement policy is not calculated properly the memory ratio as described in the documentation.

Obsolete log4j library removed from the SNMP plug-in

In previous releases, the SNMP plug-in for Automation Orchestrator used an outdated version of the log4j library. This library is no longer needed and as such is removed from the SNMP plug-in starting with the current release.

"LoadBalancerDescription" objects are created with an expiration time of nine days and are getting cleaned up causing regressions

Your load balancer is recreated when iterative deployment is performed on the deployment without any changes to load balancer.

"LoadBalancerDescription" does not get deleted with the rest of the load balancer components

When deleting a load balancer from your deployment, the "LoadBalancerDescription" property is not removed.

Usage of outdated hashes might lead to collision attacks

The default certificate thumbprint digest algorithm is changed from SHA-1 to SHA-256. This change might impact Automation Orchestrator plug-ins which use the `IKeystoreCache#getThumbprints` plug-in SDK method for custom certificate validations.

Known Issues

Storage profile constraints are not applicable for Virtual Private Zones (VPZs)

VPZs are not supported and constraint tags alone do not handle the placement of datastores without specifying the specific datastore in the storage page for the VPZ.

Workaround: Use cloud zones instead of VPZs.

After plug-in installation, data collection for workflows and actions related to this plug-in does not occur in VMware Aria Automation

You cannot use workflows and actions in VMware Aria Automation after data collection that are part of the content of a new plug-in in Automation Orchestrator.

Workaround: Make any content changes, such as creating a dummy workflow and then delete the change. Run the data collection manually or wait for the next scheduled data collection run. The new workflows and actions are now available for use in VMware Aria Automation.

Integration with NSX Federation is not supported in VMware Aria Automation for NSX releases 3.2.2 and later

When using NSX-T Federation, NSX-T Global Manager enumeration fails for NSX version 3.2.2 and later when used in VMware Aria Automation.

The failure causes the following error message to appear:

The requested URI: /api/v1/transport-nodes could not be found

This issue does not impact non-federated environments

Workaround: Use NSX version 3.1.x.

It's not possible to execute day 2 operation in Deployments view/Resources or Machine view.

The day 2 operations executed outside of deployment may not work properly.

Execute day 2 operation from the deployment.

You encounter an issue when attempting to connect to the VMware Remote Control Application (VMRC) console proxy

After upgrading to VMware Aria Automation 8.18, you encounter a certification issue when attempting to connect to the VMRC console proxy. This issue is encountered in VMware Aria Automation deployments where the `acceptSelfSignedCertificate` property for cloud accounts set to **true**.

Workaround: Use the procedure described in [KB 374614](#).

Loss of feature access after upgrading to Automation Orchestrator 8.18

After upgrading an Automation Orchestrator deployment that uses an Advanced license, access to advanced features such as Git integration and multi-language support is lost.

Workaround: Use the procedure described in [KB 375928](#).

You receive a 502 Bad Gateway error when attempting to play videos from the Launchpad

The following videos cannot be played when started from the Launchpad in VMware Aria Automation:

- Publish a template to the Service Broker Catalog with the VCF Automation Launchpad
- Create a lease policy with the VCF Automation Launchpad
- Add a Cloud Account with the VCF Automation Launchpad

Workaround: Play the videos directly from YouTube.

VM is not placed in the correct storage profile based on the applied priority and constraint tags

When storage profile level priority is used and your cloud template contains a storage constraint tag, based on all the allocation filters if multiple storage profiles are eligible, storage profile with the priority might not be selected as expected. Instead another storage profile is selected.

No workaround, make sure that only one eligible storage profile remains at the end of allocation.

You encounter an issue when attempting to export a DCGM Exporter Catalog item

The Catalog Setup Wizard does not create the DCGM Exporter Catalog item.

Workaround:

Log in to the deep learning VM over SSH and run the following commands:

- `docker run -d --gpus all --cap-add SYS_ADMIN --rm -p 9400:9400 registry-URI-path/nvidia/k8s/dcgm-exporter:ngc_image_tag`

For example, to run `dcgm-exporter:3.2.5-3.1.8-ubuntu22.04` from the NVIDIA NGC catalog, run the following command:

- `docker run -d --gpus all --cap-add SYS_ADMIN --rm -p 9400:9400 nvcr.io/nvidia/k8s/dcgm-exporter:dcgm-exporter:3.2.5-3.1.8-ubuntu22.04`

For more information on the DCGM Exporter, go to [Add DCGM Exporter for DL workload monitoring](#).

VMware Aria Automation 8.17 What's New

New VMware Aria Automation home page

A new user dashboard is now part of the VMware Aria Automation home page to help users navigate through complex architectures as part of Automation Assembler for administrators. Whether a user is new to VMware Aria products, or they are a seasoned VMware Aria Automation user, they can find the dashboard useful for the following scenarios:

- Provide an overview for cloud environments by segment and VM status.
- Visualize an inventory summary broken down by cloud zone and projects.
- Visualize a deployment summary with upcoming lease policy changes and recently expired policies.
- Review recent in-product notifications and respond to requests directly.

Note: The home page is the default landing page for Automation Assembler only if the administrator does not have a cloud account in the organization. Otherwise, the default landing page is the **Resources** page in Automation Assembler. For more information, go to [How do I get started with Automation Assembler using the VMware Aria Automation Launchpad](#).

New Launchpad added to the VMware Aria Automation home page

A new Launchpad is now available for users who are getting started with VMware Aria Automation or want shortcut access to commonly used actions. You can perform easy-to-learn use cases using the two guided workflows. The Launchpad covers the following use cases:

- Add a cloud account: use your credentials to validate and link cloud accounts.
- Apply lease expiration: create a lease policy to enforce resource expiration.

For more information, go to [How do I get started with Automation Assembler using the VMware Aria Automation Launchpad](#).

Cloud Consumption Interface (CCI) Supervisor namespace, TKG, and other resource support in the Automation Assembler design canvas

CCI on-prem was released in VMware Aria Automation 8.16.1. The current release introduces support for defining multi-tier applications in Automation Assembler templates by leveraging Supervisor namespaces, TKG clusters, and any other CCI resources. You can now run a catalog item containing CCI resources that was prepared by an administrator. This capability brings together CCI and the rest of VMware Aria Automation capabilities around Infrastructure as Code (IaC) and governance with policies. For more information, go to [Automating Kubernetes-based workloads in Automation Assembler](#).

Integrating a single VMware Aria Operations on-prem instance with multiple VMware Aria Automation on-prem tenants

A single VMware Aria Operations instance can now integrate with multiple VMware Aria Automation tenants running on the same on-premises appliance.

Day 2 action for unregistering a cluster of VMs

Unregister day2 action is supported for cluster of VMs. Note that the action is unavailable on a single VM within a cluster that shares disk or disk cluster with other VMs.

Increased number of private cloud accounts in VMware Aria Automation

With this release, we are increasing the number of supported private cloud accounts in VMware Aria Automation from 50 to 100. For more information, go to [Scalability and Concurrency Maximums](#).

Content sharing policy now supports scope at the organization level and also enables role-based access control

Starting this release, the content-sharing policy supports two enhancements:

1. The ability to share content across the entire organization by setting the scope as **Organization**. The organization-scoped policies only affect shared VMware cloud templates (VCT).
2. A Role-based access entitlement. This feature allows for content sharing between users based on their set roles. The roles can be project administrators, project members, and named custom roles.

These enhancements significantly streamline content sharing and access control within the organization. For more information, go to [How do I configure Automation Service Broker content sharing policies](#).

New Active Directory (AD) error messages when changing projects

When invoking the **Change Project** action on a deployment that is associated with an Active Directory integration, there are certain scenarios that will cause validation errors.

When the source project is associated with an AD integration, but the target project is not associated with an AD integration. In such cases, you receive the following error message:

"Target project is not associated with AD integration".

To resolve this error, the target project must be associated with an AD integration that has the same organizational unit.

Another possible scenario occurs when both the source project and the target project are associated with an AD integration, but the AD integration is not part of the same organizational unit. In such cases you receive the following error message:

"The properties (OU, BaseDN) associated with the project did not match the project".

To resolve this error, the organizational unit of the target project must be changed, or a new AD integration must be made to associate with the same organization unit.

Announcing intent to deprecate specific Kubernetes automation capabilities

VMware by Broadcom is announcing the planned deprecation of Kubernetes integration capabilities, including the TKG integration and TMC integration documented under [How do I work with Kubernetes in Automation Assembler](#). The actual deprecation and removal of these capabilities from the product will happen in a future release. Customers are encouraged to adopt the Cloud Consumption interface (CCI) and vSphere TKG IaaS service. For more information on CCI, go to [Getting Started with the Cloud Consumption Interface in Automation Service Broker](#).

Announcing intent to remove deprecated automation capabilities

VMware by Broadcom wants to remind customers that the following capabilities are deprecated and scheduled to be removed from VMware Aria Automation in a future release:

- Support for NSX-V
- Support for NSX-T Manager Mode
- Support for NSX-V to NSX-T migration
- Migration Assistant for vRealize Automation 7.6 to VMware Aria Automation 8.0 and later
- Migration Assistant for NSX-V to NSX-T
- Support for the [VMware Aria Automation integration with vCloud Director](#)

Any customer currently leveraging these capabilities in VMware Aria Automation should make plans to stop using the relevant functionality.

Announcing intent to remove support of vCenter 6.x

VMware by Broadcom wants to remind customers that the support for vCenter 6.x will be removed from VMware Aria Automation in a future release. Any customer currently using vCenter 6.x cloud accounts in VMware Aria Automation should make plans to upgrade to a supported version of vCenter.

Automation Orchestrator 8.17 What's New

License management is moved from the Control Center to the Automation Orchestrator Client

License management for your external Automation Orchestrator deployment is now done from the [Licensing](#) page of the Automation Orchestrator Client. This page includes information about your currently applied license and the option to manually add a license. For more information, go to [Automation Orchestrator feature enablement with licenses](#). As it is set to match the license in VMware Aria Automation, the [Licensing](#) page is unavailable in embedded Automation Orchestrator deployments.

The Command scripting object is removed

The Command scripting object is removed and the 'execute' and 'executeAndLog' methods are deactivated. If these methods are invoked, they throw an exception. If your actions or workflows have scriptable task items that use this scripting object or methods, these scripts must be updated.

Resolved Issues

Unable to add a VMware Cloud Foundation (VCF) cloud account domain in VMware Aria Automation

When attempting to add a VCF cloud account domain to VMware Aria Automation, you receive the following error message:

"Something went wrong in a backend service."

This error occurs when a user is adding a VCF cloud account domain in VMware Aria Automation while another domain creation is in progress in the SDDC Manager.

Rebuild fails with an error if the original VM image is no longer available

Previously, a rebuild day 2 operation fails if the underlying image has been deleted at the endpoint. This is an issue for users who are unaware that the image is missing at the endpoint and the rebuild operation is blocked unless a new image reference is manually added from the back end for the machine.

This issue is now resolved. When triggering the rebuild resource level day 2 action, if the image is missing, the user is prompted to select an image from the available list of image templates to rebuild the machine.

However, in case of the rebuild being performed at the deployment level, an available image must be manually patched on the machine properties and then the rebuild day 2 action can be attempted on the deployment. To do this, users must use the "__resolvedImageLink" and "__imageRef" input properties along with the relevant image value. Alternatively, users can trigger a resource level rebuild operation for that particular VM which will enable the user to select an image and rebuild the machine from the UI.

Actions/{id}/bundle added to Swagger

The actions/{id}/bundle REST API endpoint is added to the Automation Orchestrator Swagger documentation.

Known Issues

After plug-in installation, data collection for workflows and actions related to this plug-in does not occur in VMware Aria Automation

You cannot use workflows and actions in VMware Aria Automation after data collection that are part of the content of a new plug-in in Automation Orchestrator.

Workaround: Make any content changes, such as creating a dummy workflow and then delete the change. Run the data collection manually or wait for the next scheduled data collection run. The new workflows and actions are now available for use in VMware Aria Automation.

Integration with NSX Federation is not supported in VMware Aria Automation for NSX releases 3.2.2 and later

When using NSX-T Federation, NSX-T Global Manager enumeration fails for NSX version 3.2.2 and later when used in VMware Aria Automation.

The failure causes the following error message to appear:

The requested URI: /api/v1/transport-nodes could not be found

This issue does not impact non-federated environments

Workaround: Use NSX version 3.1.x.

Branding application issue after upgrading VMware Aria Automation

After upgrading from VMware Aria Automation 8.16 to 8.17, you are unable to apply Branding changes in the UI as the **Apply** button is grayed out.

Workaround: Select **Restore Defaults** and then attempt to make the changes.

Disk resize cannot be performed on "VMname" because the state of the resource has changed and an error appears when the user tries to perform resize disk day 2 action on VM

If the user is not using SCSI controller key=1000 and unit number=0 in the configuration of virtual devices that are attached to the VM, then a resize disk action error will appear.

Workaround: Ensure that among disks attached to the VM, one disk is always configured with SCSI controller key=1000 and unit number=0. See KB <https://knowledge.broadcom.com/external/article/369794>

API Documentation and Versioning

Notice: For information earlier VMware Aria Automation releases, go to the [release note archive](#).

API documentation is available with the product. To access all Swagger documents from a single landing page, go to:

- <https://<appliance.domain.com>/automation-ui/api-docs> for vRealize Automation 8.x, where *appliance.domain.com* is your vRealize Automation appliance.

Before using the API, consider the latest API updates and changes for this release, and note any changes to the API services that you use. If you have not locked your API using the `apiVersion` variable before, you might encounter a change in an API response. Any API updates and changes are provided in the What's New section for each release.

For unlocked APIs, the default behavior varies depending upon the API.

- For Cloud Assembly IaaS APIs, all requests which are executed without the `apiVersion` parameter will be redirected to the first version which is 2019-01-15. This redirect will allow every user who did not previously specify the `apiVersion` parameter to transition smoothly to the latest version without experiencing breaking changes.

Note: For the Automation Assembly IaaS APIs, the latest version is `apiVersion=2021-07-15`. If left unlocked, IaaS API requests will be redirected to the first version which is 2019-01-15. The first version is deprecated and will be supported for 24 months. To ensure a smooth transition to the new version, lock your IaaS API requests with the `apiVersion` parameter assigned to 2021-07-15.

- For other APIs, your API requests will default to the latest version. If you select one of the earlier version dates listed for the Swagger spec, the API behavior will reflect APIs that were in effect as of that date and any date until the next most recent version date. APIs are not versioned for every vRealize Automation release and not all APIs support the `apiVersion` parameter.

For more information about using the `apiVersion` parameter, see the Programming Guides listed in:

- [Aria Automation APIs and CLI](#)
- [vRealize Automation APIs and CLI](#)

API updates and changes for each release are covered in the following sections:

VMware Aria Automation 8.18.1 | October 2024 API Changes

Service Name	Service Description	API Updates and Changes
Catalog	Access Service Broker catalog items and catalog sources, including content sharing and the request of catalog items.	<p>New input parameter <code>expand</code> option <code>expand=user</code> and new object type parameter in response to show full user names for the following endpoints:</p> <ul style="list-style-type: none"> • GET /catalog/api/items • GET /catalog/api/items/{id}

Table continued on next page

Continued from previous page

Service Name	Service Description	API Updates and Changes
		<ul style="list-style-type: none"> • GET /catalog/api/admin/sources • GET /catalog/api/admin/sources/{sourceId} <p>For information about the response, see the explanation in Show full user names in deployment details below.</p>
Custom Forms	Define dynamic form rendering and customization behavior in Automation Service Broker and Automation Assembler.	<p>Only Service Broker administrators or users with the Manage Content custom role can access the following endpoints:</p> <ul style="list-style-type: none"> • POST /form-service/api/forms/designer/elements • POST /form-service/api/forms/designer/request <p>For information about custom roles, see Custom user roles in VMware Aria Automation</p>
Deployment	Access deployment objects and platforms or blueprints that have been deployed into the system.	<p>New input parameter expand option expand=user and new object type parameter in response to show full user names for the following endpoints:</p> <ul style="list-style-type: none"> • GET /deployment/api/deployments • GET /deployment/api/deployments/{deploymentId} • GET /deployment/api/resources • GET /deployment/api/resources/{resourceId} <p>For information about the response, see the explanation in Show full user names in deployment details below.</p>
Pipelines	Create and run pipelines for continuous delivery of your applications to production.	<p>The response of the following endpoint no longer lists SHA-1 as a fingerprints certificate.</p> <p>GET /codestream/api/endpoint-certificate</p>
Policies	Interact with policies created in Service Broker.	<p>New input parameter expand option expand=user and new object type parameter in response to show full</p>

Table continued on next page

Continued from previous page

Service Name	Service Description	API Updates and Changes
		<p>user names for the following endpoints:</p> <ul style="list-style-type: none"> • GET /policy/api/policies • GET /policy/api/policies/{id} <p>For information about the response, see the explanation in Show full user names in deployment details below.</p>

Show full user names in deployment details

The following information applies to certain endpoints in the catalog, deployment, and policies API services.

When `expand=user` is passed as input and the Admin settings "show name of users" is enabled, a new object type parameter is returned for each AD ID type output parameter.

AD ID type output parameter	New object type parameter
<code>createdBy</code>	<code>creator</code>
<code>lastUpdatedBy</code>	<code>lastUpdater</code>
<code>ownedBy</code>	<code>owner</code>

Each object type has five fields: `id`, `firstname`, `lastname`, `email`, and `type` as in the following example. Only non-null fields are included in the object.

```
"creator": {
    "id": "euser@mycompany.com",

```

VMware Aria Automation 8.18 | July 2024 API Changes

Service Name	Service Description	API Updates and Changes
Relocation	Define policy and plans for bringing existing VMs from any cloud under management.	Payload of <code>POST /relocation/onboarding/task/create-deployment-bulk</code> updated to add a <code>template</code> field that supports onboarding with a cloud template.

Table continued on next page

Continued from previous page

Service Name	Service Description	API Updates and Changes
		<p>Snippet of a sample payload shows a template field with resource mapping that includes:</p> <ul style="list-style-type: none"> • Name of the cloud template • Link to the cloud template ID • VMs to be onboarded, mapped to machines in the cloud template <pre>"template": { "name": "cloud_template_name", "link": "/blueprint/api/blueprints/template_ID_string", "components": { "/resources/compute/resource_ID_string_1": "Cloud_vSphere_Machine_1", "/resources/compute/resource_ID_string2": "Cloud_vSphere_Machine_2" } }</pre>

Previous Known Issues

The following is a list of known issues documented in earlier releases of VMware Aria Automation. For more detailed information about the relevant releases where these issues were first documented, go to the [VMware Aria Automation Release Notes Archive \(8.12-8.16.2\)](#).

Password length issue when using Kerberos authentication

After Automation Orchestrator is upgraded, if the deployment is in FIPS mode, some plug-in endpoints configured with Kerberos authentication stop working and you receive the following error message in the logs:

```
org.bouncycastle.crypto.fips.FipsUnapprovedOperationException: password must be at least 112 bits
```

Workaround: Use longer and stronger passwords, with at least 14 characters, to satisfy the FIPS requirements.

Issues with importing Automation Orchestrator workflows

You can experience issues importing an Automation Orchestrator workflow into the VMware Aria Automation catalog content sources if the workflow inputs or fields include the "project" ID element as it is a system property. Having the ID added to the workflow inputs or fields can cause you to receive an error message similar to the following: "Error downloading catalog item '/workflow/<workflowId>' (Error: Content provider error).".

Note: This issue is only valid for "project" ID elements manually added to workflows. It does not relate to automatically generated project fields created when a workflow or cloud template is imported into Service Broker.

Workaround: Remove the "project" ID element from the workflow inputs or fields.

You receive a error status code 500 when a extensibility action content source has its "shared" field value as NULL

When your project includes extensibility actions, the number of items shown on the **Content Source** page includes fewer actions than the total number of actions included in the project. For example, you might see five out of ten actions shown in the **Number of items** field and red exclamation mark next to it. This means that not all actions are synchronized in the content source and that the problematic actions are not available for use in the Catalog.

Workaround: See [KB 93437](#).

Unsupported Kerberos authentication for the PowerShell plug-in

The PowerShell Plug-in for VMware Aria Automation Orchestrator does not support Kerberos authentication when used in FIPS mode because of security restrictions on the required security provider.

When used with older versions of Automation Orchestrator in FIPS mode, using Kerberos authentication in the PowerShell plug-in is not recommended as it can break the FIPS compliance.

Workaround: Use the **Run Script In Guest** workflow to run a PowerShell script inside the virtual machine.

Using Python scripts with the latest version of the requests library or urllib3 v2 client causes extensibility actions to fail with a "urllib3 v2.0 only supports OpenSSL 1.1.1+" error.

The latest version of requests library and urllib3 v2 currently cannot be used in extensibility actions, as these dependencies require an OpenSSL version later than 1.1.1.

Workaround: In the dependencies text box of the extensibility action editor, specify a version of the request library that is earlier than 2.29.0, or if you are using urllib3, specify a version that is earlier than 2.

Service and role names are replaced with old values when deploy.sh is ran for second time

This important issue has been identified with the Aria Automation 8.12 release. Refer to [KB 92018](#) for more details before upgrading or installing.

You might receive a error if your custom form field includes regex constrains

If your custom form includes one or more fields with a regex constraint, you can receive a error message similar to the following: "Some data cannot be retrieved. If the problem persists, contact your system administrator. Failed request: <action name>".

Workaround: Ensure that the regex adheres to both Java and JavaScript compliance standards. When this adjustment is made, the issue is resolved.

Complex custom forms do not load take more than 10 minutes to load

For complex custom forms with hundreds of fields and complicated default value rules, there might be a slow down to render the form. In most cases the longer rendering time is not noticeable, while the more complex the form is, the slow down can be significant.

No workaround.

After upgrading, if the deployment specifies a boot disk size that is less than the image boot disk size, the deployment will fail.

This known issue occurs when upgrading to 8.11.1 and later.

Some services are not accessible after associating a tenant with Aria Automation 8.12 through LCM

After associating a tenant with VMware Aria Automation 8.12 through LCM, users may not be able to access the following services:

- Assembler
- Migration Assistant
- Pipelines
- Config

Workaround:

1. Login to the tenant as a user with Organization Owner privileges.
2. Under Identity & Access Management, click the Active Users tab.

3. Select the affected user and click Edit Roles.
4. To grant the user access to Assembler and Migration Assistant, click Add Service Access and select Cloud Assembly.
5. To grant the user access to Pipelines, click Add Service Access and select Code Stream.
6. To grant the user access to Config, click Add Service Access and select SaltStack Config.

Delete operation for day 2 actions fails when deleting a pool from a deployment that depends on a virtual service

If an Avi load balancer resource, such as a health monitor, is used by two pools in different deployments, deleting the health monitor from one of the deployments will fail with a "false" error.

The failure to delete the resource is valid as the health monitor is referenced by multiple pools. However, the error displayed in VMware Aria Automation is not descriptive. The error displayed in the Avi load balancer is more detailed and shows why the delete operation failed.

No workaround.

You receive a validation error when an action input is bound to the Project field

When a catalog item with custom forms has an external action that has the **Project** field as an input, this can cause an error. Opening the catalog item, the action run fails with the one of the following error messages: "Cannot execute external actions due to validation errors [Request info field with name: 'project' does not exist.];" or Some data cannot be retrieved. If the problem persists, contact your system administrator. Failed request: <action name>.

Workaround: Do not explicitly pass the project field as an action input. When an Automation Orchestrator action run is started, the project ID is implicitly passed as a context parameter. Instead of having an input for the project in the action, use the "_projectId" context parameter.

For example, if the Automation Orchestrator action receives one input called "project":

1. Remove that input, and in the action script, create a variable called "project" and assign it with the following context parameter value: `var project = System.getContext().getParameter("_projectId")`.
2. Save the action.
3. In the catalog item custom form designer, re-select the updated action.
4. Save the modified custom form.

The CMX agent needs to support all Spring Boot supported metrics so that alerts can be created

Now that the CMX service has moved to Spring Boot, it needs to support all metrics, particularly "system_cpu_usage", and needs to push them to Wavefront. Without this, alerts cannot be created in Wavefront when the CPU usage crosses the threshold.

No workaround.

The Change Project process fails for multi-tenant environments in deployments with remote access

This issue can occur if your deployment includes remote access with an authentication type other than **publicPrivateKey**. Other authentication types store their authentication credentials link and during the change project action, the remote access credentials are set with the tenant organization. The compute description is patched but with the owner context (because of `reenterWithOwnerAuthContext` logic) and have a provider organization. The authentication credentials are set in the tenant organization, but it is changed to the provider organization and the patch request fails with `IllegalAccess` exception.

Workaround:

A potential workaround is to update the cloud templates from which the deployments are created to use **publicPrivateKey** authentication type for remote access.

```

remoteAccess:
  authentication: publicPrivateKey
  sshKey: ${input.sshKey}
  username: root

```

Workflows for Aria Automation user interaction times out if there is no response for a long time

Manual user interactions cannot be answered from Aria Automation if more than 24 hours have passed, however, they can still be answered from Automation Orchestrator. On an attempt to answer the manual user interaction from Aria Automation, this error message appears:

"Could not process request due to: Could not find information about request ID: '<request id>' for resource: '<resource id>'"

The Automation Orchestrator debugger does not step into sub-actions

The Automation Orchestrator action debugger does not step into inner actions called using the `System.getModule(module).action()` method.

Workaround: Use the root action as the only element in a new workflow and debug the workflow using the workflow debugger.

Intermittent behavior where servers are not added to a pool when using existing security groups

When associating an NSX security group to an Avi load balancer pool, the reference to this security group must be the full path of the security group as seen in NSX.

No workaround.

Deploying an NSX Load Balancer with persistence configuration fails if values for required fields are not specified

When deploying an NSX load balancer with a route that includes persistence configuration, the VMware Aria Automation Template displays all possible fields under `properties > routes > persistenceConfig`. You must specify values for all required fields as follows:

- For `PersistenceConfig.type = COOKIE`, specify values for the following fields:
 - cookieMode
 - cookieGarble
- For `PersistenceConfig.type = SOURCE_IP`, specify a value for `ipPurge`.
- Do not use `PersistenceConfig.type = NONE`.

If a value is missing for any required field, the deployment will fail.

For more information about resource schema for the `Cloud.NSX.LoadBalancer > routes > persistenceConfig`, go to [Aria Automation SaaS Resource Type Schema](#).

No workaround.

The "sseapi-config auth" command throws errors in VMware Aria Automation Config SaaS

The "sseapi-config auth" command can be used to view the fingerprint IDs of the Master Key. Currently, this command does not work for VMware Aria Automation Config SaaS.

No workaround.

Drop-down menu values do not get reset to the last selected value if the action is re-triggered

In cases where the `valueOptions` (`dropdown`, `multiSelect`, `dualList`, `checkbox`, and others) are controlled by an external source, you might encounter this situation:

1. You select a value from the drop-down menu.
2. An action triggers, causing the menu to have zero options.
3. The originally selected value is cleared from the UI control but is available on request.

Workaround: Explicitly select the empty value if available.

Virtual Machine (VM) deployments fail with "Getting virtual machine on NSX-T policy endpoint"

Special characters cannot be used in the name of a VM when NSX tags are used.

No workaround.

When creating an instance, creating disks with labels fails due to unexpected snake case transformation

This is a bug that is a part of a very unlikely scenario.

On instance creation, when a user attempts to create an instance with disks, using initialize_params and assigns labels to that disk that contain snake case format (ex. "first_key": "first_value"), the key will be converted to "firstKey" which is not a valid label format.

It is recommended to add the labels separately using the disk resource, or use an underscore in the label key.

Inconsistent performance tier information for Azure machine when managed disk is resized using day 2 actions

When an Azure disk with a Premium managed disk is resized with day 2 actions in Aria Automation, the baseline performance tier is updated accordingly in the Azure portal. However, the performance tier remains the same in the template in the Aria Automation custom properties. This leads to inconsistent performance tier information.

No workaround.

Deleted actions appear for helpers

Unsupported delete actions appear for helpers such as CloudZoneAllocationHelper and CustomNamingHelper.

No workaround.

vCenter machines are showing with an Automatic Private IP Addressing (APIPA) IP as the primary IP

The APIPA IP is an IPv4 address that is assigned to a machine when the DHCP server in the system is not reachable. The address is within the following range: from 169.254.0.1 through 169.254.255.254. When this occurs, the VMware Aria Automation algorithm is incorrectly selecting the APIPA IP address as the primary IP address for the machine that appears in the VMware Aria Automation UI. This is true for both discovered and deployed machines.

VMware Aria Automation shows the APIPA IP as the primary IP address of the vCenter machine because the algorithm for determining the primary IP address failed to filter out these IPs.

No workaround.

Integrate plug-in version 0.21.0 into project Flagman

In cloud templates for **idem.gcp** resources, users should use **type_** and not **type**.

There are two different identified cases:

In **instance -> network_interfaces**, the property **type_** can easily be mistaken and written as **type**. If **type** is used, VMware Aria Automation does not notify the user (as expected), but the property is skipped over and the wanted value is not set.

```
network_interfaces:
  - access_configs:
    - kind: compute#accessConfig
      name: External NAT
```

```

    network_tier: PREMIUM
    set_public_ptr: false
    type_: ONE_TO_ONE_NAT
  kind: compute#networkInterface
  name: nic0
  network: https://www.googleapis.com/compute/v1/projects/tango-gcp/global/networks/default
  stack_type: IPV4_ONLY
  subnetwork: https://www.googleapis.com/compute/v1/projects/tango-gcp/regions/us-central1/subnetworks/default

```

The other use case is in **disk**. The last property **type_** can easily be mistaken and written as **type**. This leads to the same result as described above - the user is not notified in any way, the property is skipped over, and the value is set to the default value, not the specified value in the cloud template.

```

Idem_GCP_COMPUTE_DISK_2:
  type: Idem.GCP.COMPUTE.DISK
  properties:
    name: e2e-idem-disk-2-${input.UUID}
    account: ${resource.Allocations_Compute_1.selectedCloudAccount.name}
    size_gb: 1
    project: ${resource.Allocations_Flavor_1.selectedCloudAccount.additionalProperties.gcp.project}
    zone: ${resource.Allocations_Compute_1.selectedPlacementCompute.name}
    type_: ${'/projects/' + resource.Allocations_Flavor_1.selectedCloudAccount.additionalProperties.gcp.project + '/zones/' + resource.Allocations_Compute_1.selectedPlacementCompute.id + '/diskTypes/pd-ssd'}

```

No workaround.

Python packages not downloading from private registries that require setuptools

When using a private python repository that is based on setuptools package, the dependencies cannot be downloaded.

Creating instance with status other than RUNNING does not get applied

When a new VM instance is created, the Google Compute Engine automatically provisions it in a RUNNING state, even when the deployment template specifies another desired runtime status (eg. TERMINATED).

Getting Started with VMware Aria Automation

VMware Aria Automation is an automation platform where you build and manage modern applications.

Depending on your user role, you use different components, or services, of VMware Aria Automation for your automation tasks.

The screenshot shows the VMware Aria Automation Cloud Services Console interface. On the left, there's a sidebar with 'Services' expanded, showing 'Identity & Access Management' with 'Active Users' and 'Enterprise Groups' listed, and 'Branding'. The main content area has a 'Quickstart' section titled 'Quickstart For VMware Aria Automation'. It contains a brief description: 'Get up and running fast. Quickstart will help you set up your on-prem SDDC for provisioning with VMware Aria Automation, populate the self-service catalog and deploy your first Template.' Below this is a note: 'Time to complete: Approx. 10 minutes' and a blue 'LAUNCH QUICKSTART' button. To the right of the text is an illustration of two people looking at a large server tower with clouds and network connections. Below the quickstart section is a 'My Services' section with five service icons: Assembler, Orchestrator, Pipelines, Service Broker, and Migration Assistant.

What is Automation Assembler

You use VMware Aria Automation Assembler to create and deploy machines, applications, and services to your cloud infrastructure.

As a cloud administrator, you can:

- Configure the cloud vendor infrastructure to which your users deploy their cloud templates.
- Set up projects to link the service users with the infrastructure resources.
- Delegate the user management and deployment infrastructure to project managers, freeing you up to focus on your cloud resources.

As a cloud template developer, you can:

- Create and iterate on templates until they meet your development needs.
- Deploy templates to the supporting cloud vendors based on your project membership.
- Manage the deployed resources throughout the development life cycle.

What is Automation Service Broker

VMware Aria Automation Service Broker provides a single point where you can request and manage catalog items.

As a cloud administrator, you create catalog items by importing released Automation Assembler templates and Amazon Web Services CloudFormation templates that your users can deploy to your cloud vendor regions or datastores.

As a user, you can request and monitor the provisioning process. After deployment, you manage the deployed catalog items throughout the deployment lifecycle.

What is Automation Pipelines

VMware Aria Automation Pipelines is continuous integration and continuous delivery (CI/CD) software that supports deploying monolithic legacy applications, and uses Docker containers and Kubernetes containers running on multiple clouds.

With Automation Pipelines, you create pipelines that automate your entire DevOps lifecycle while using existing development tools such as Git and Jenkins.

Automation Pipelines simplifies the ability to build, test, and deploy your applications, and increases your productivity as you release source code from the development repository, through testing, to production. Automation Pipelines supports custom and commercial applications, and objects such as Templates in Automation Assembler.

What is Automation Orchestrator

VMware Aria Automation Orchestrator is a development- and process-automation platform that provides a library of extensible workflows.

Automation Orchestrator automates management and operational tasks of both VMware and third-party applications such as service desks, change management systems, and IT asset management systems.

For more information about setting up Automation Orchestrator, see [Configure an Automation Orchestrator integration in Automation Assembler](#).

Before you begin with VMware Aria Automation

Before you begin

Before you start working in VMware Aria Automation as a cloud administrator, you must gather information about your public and private cloud accounts. Use this checklist to help you set up before you begin on-boarding to the services.

Required overall credentials

To...	You need...
Sign up for and log in to Automation Assembler	A VMware ID. <ul style="list-style-type: none"> • Set up a My VMware account by using your corporate email address at VMware Customer Connect.
Connect to VMware Aria Automation services	HTTPS port 443 open to outgoing traffic with access through the firewall to: <ul style="list-style-type: none"> • *.vmwareidentity.com • gaz.csp-vidm-prod.com • *.vmware.com For more information about ports and protocols, see VMware Ports and Protocols . For more information about ports and protocols, see Port Requirements in the Reference Architecture help.

vCenter cloud account credentials

This section describes the credentials that are required to add a vCenter cloud account.

Privileges are required for the vSphere agent to manage the vCenter instance. Provide an account with the following read and write privileges:

- vCenter IP address or FQDN

The permissions needed to manage VMware Cloud on AWS and vCenter cloud accounts are listed. Permissions must be enabled for all clusters in the vCenter, not just clusters that host endpoints.

To support control of VMware's Virtual Trusted Platform Module (vTPM) when deploying Windows 11 VMs, you must have the cryptographic operations -> direct access privilege in vCenter. Without this privilege, console access from VMware Aria Automation to Windows 11 VMs is not possible. For related information, see [Virtual Trusted Platform Module Overview](#).

For all vCenter-based cloud accounts - including NSX-V, NSX-T, vCenter, and VMware Cloud on AWS - the administrator must have vSphere endpoint credentials, or the credentials under which the agent service runs in vCenter, that provide administrative access to the host vCenter.

For more information about agent requirements, see [VMware vSphere product documentation](#).

Setting	Selection
Content library To assign a privilege on a content library, an administrator must grant the privilege to the user as a global privilege. For related information, see Hierarchical Inheritance of Permissions for Content Libraries in vSphere Virtual Machine Administration at VMware vSphere Documentation .	<ul style="list-style-type: none"> • Add library item • Create local library • Create subscribed library • Delete library item • Delete local library • Delete subscribed library • Download files • Evict library item • Probe subscription information • Read storage • Sync library item • Sync subscribed library • Type introspection • Update configuration settings • Update files • Update library • Update library item • Update local library • Update subscribed library • View configuration settings
Datastore	<ul style="list-style-type: none"> • Allocate space • Browse datastore • Low level file operations
Datastore cluster	<ul style="list-style-type: none"> • Configure a datastore cluster
Folder	<ul style="list-style-type: none"> • Create folder • Delete folder
Global	<ul style="list-style-type: none"> • Manage custom attributes • Set custom attribute
Network	<ul style="list-style-type: none"> • Assign network
Permissions	<ul style="list-style-type: none"> • Modify permission
Profile-driven storage	<ul style="list-style-type: none"> • Profile-driven storage view

Table continued on next page

Continued from previous page

Setting	Selection
	To return a list of storage policies that can be mapped to a storage profile, grant the StorageProfile.View privilege to all accounts that connect VMware Aria Automation to vCenter.
Resource	<ul style="list-style-type: none"> • Assign virtual machine to resource pool • Migrate powered off virtual machine • Migrate powered on virtual machine
vApp	<ul style="list-style-type: none"> • Import • vApp application configuration The vApp.Import application configuration is required for OVF templates and to provision VMs from the content library. • The vApp.vApp application configuration is required when using cloud-init for cloud configuration scripting. This setting allows for modification of a vApp's internal structure, such as its product information and properties.
Virtual machine	<ul style="list-style-type: none"> Change Configuration <ul style="list-style-type: none"> • Add existing disk • Add new disk • Add or remove device • Advanced configuration • Change CPU count • Change memory • Change settings • Change Swapfile placement • Change resource • Extend virtual disk • Modify device settings • Remove disk • Rename • Set annotation • Toggle disk change tracking Edit Inventory <ul style="list-style-type: none"> • Create from existing • Create new • Move • Remove Interaction <ul style="list-style-type: none"> • Configure CD media • Connect devices • Console interaction

Setting	Selection
	<ul style="list-style-type: none"> • Install VMware tools • Power off • Power on • Reset • Suspend <p>Provisioning</p> <ul style="list-style-type: none"> • Clone template • Clone virtual machine • Customize guest • Deploy template • Read customization specifications <p>Snapshot management</p> <ul style="list-style-type: none"> • Create snapshot • Remove snapshot • Revert to snapshot
vSphere Tagging	<ul style="list-style-type: none"> • Assign or unassign vSphere tag • Assign or unassign vSphere tag on object • Create vSphere tag • Create vSphere tag category • Delete vSphere tag • Delete vSphere tag category • Edit vSphere tag • Edit vSphere tag category • Modify UsedBy field for category • Modify UsedBy field for tag

Amazon Web Services (AWS) cloud account credentials

This section describes the credentials that are required to add a Amazon Web Services cloud account. See the above *vCenter cloud account credentials* section for addition credential requirements.

Provide a power user account with read and write privileges. The user account must be a member of the power access policy (PowerUserAccess) in the AWS Identity and Access Management (IAM) system.

Enable the 20-digit Access Key ID and corresponding Secret Access Key access.

If you are using an external HTTP Internet proxy, it must be configured for IPv4.

VMware Aria Automation actions-based extensibility (ABX) and external IPAM integration may require additional permissions.

Setting	Selection
Autoscaling actions	The following AWS permissions are suggested to allow autoscaling functions:

Table continued on next page

Continued from previous page

Setting	Selection
	<ul style="list-style-type: none"> • autoscaling:DescribeAutoScalingInstances • autoscaling:AttachInstances • autoscaling>DeleteLaunchConfiguration • autoscaling:DescribeAutoScalingGroups • autoscaling>CreateAutoScalingGroup • autoscaling:UpdateAutoScalingGroup • autoscaling>DeleteAutoScalingGroup • autoscaling:DescribeLoadBalancers
Autoscaling resources	<p>The following permissions are required to allow autoscaling resource permissions:</p> <ul style="list-style-type: none"> • * <p>Provide all autoscaling resource permissions.</p>
AWS Security Token Service (AWS STS) resources	<p>The following permissions are required to allow AWS Security Token Service (AWS STS) functions to support temporary, limited-privilege credentials for AWS identity and access:</p> <ul style="list-style-type: none"> • * <p>Provide all STS resource permissions.</p>
EC2 actions	<p>The following AWS permissions are required to allow EC2 functions:</p> <ul style="list-style-type: none"> • ec2:AttachVolume • ec2:AuthorizeSecurityGroupIngress • ec2>DeleteSubnet • ec2>DeleteSnapshot • ec2:DescribeInstances • ec2:DeleteTags • ec2:DescribeRegions • ec2:DescribeVolumesModifications • ec2>CreateVpc • ec2:DescribeSnapshots • ec2:DescribeInternetGateways • ec2>DeleteVolume • ec2:DescribeNetworkInterfaces • ec2:StartInstances • ec2:DescribeAvailabilityZones • ec2>CreateInternetGateway • ec2>CreateSecurityGroup • ec2:DescribeVolumes • ec2>CreateSnapshot • ec2:ModifyInstanceAttribute • ec2:DescribeRouteTables • ec2:DescribeInstanceTypes

Microsoft Azure cloud account credentials

This section describes the credentials that are required to add a Microsoft Azure cloud account.

Configure a Microsoft Azure instance and obtain a valid Microsoft Azure subscription from which you can use the subscription ID.

Create an Active Directory application as described in [How to: Use the portal to create an Azure AD application and service principal that can access resources](#) in Microsoft Azure product documentation.

If you are using an external HTTP Internet proxy, it must be configured for IPv4.

- General settings

The following overall settings are required.

Setting	Description
Subscription ID	Allows you to access to your Microsoft Azure subscriptions.
Tenant ID	The authorization endpoint for the Active Directory applications you create in your Microsoft Azure account.
Client application ID	Provides access to Microsoft Active Directory in your Microsoft Azure individual account.
Client application secret key	The unique secret key generated to pair with your client application ID.

- Settings for creating and validating cloud accounts

The following permissions are needed for creating and validating Microsoft Azure cloud accounts.

Setting	Selection
Microsoft Compute	<ul style="list-style-type: none"> • Microsoft.Compute/virtualMachines/extensions/write • Microsoft.Compute/virtualMachines/extensions/read • Microsoft.Compute/virtualMachines/extensions/delete • Microsoft.Compute/virtualMachines/deallocate/action • Microsoft.Compute/virtualMachines/delete • Microsoft.Compute/virtualMachines/powerOff/action • Microsoft.Compute/virtualMachines/read • Microsoft.Compute/virtualMachines/restart/action • Microsoft.Compute/virtualMachines/start/action • Microsoft.Compute/virtualMachines/write • Microsoft.Compute/availabilitySets/write • Microsoft.Compute/availabilitySets/read • Microsoft.Compute/availabilitySets/delete • Microsoft.Compute/disks/delete • Microsoft.Compute/disks/read • Microsoft.Compute/disks/write
Microsoft Network	<ul style="list-style-type: none"> • Microsoft.Network/loadBalancers/backendAddressPools/join/action • Microsoft.Network/loadBalancers/delete • Microsoft.Network/loadBalancers/read • Microsoft.Network/loadBalancers/write • Microsoft.Network/networkInterfaces/join/action • Microsoft.Network/networkInterfaces/read • Microsoft.Network/networkInterfaces/write • Microsoft.Network/networkInterfaces/delete • Microsoft.Network/networkSecurityGroups/join/action • Microsoft.Network/networkSecurityGroups/read • Microsoft.Network/networkSecurityGroups/write • Microsoft.Network/networkSecurityGroups/delete • Microsoft.Network/publicIPAddresses/delete • Microsoft.Network/publicIPAddresses/join/action • Microsoft.Network/publicIPAddresses/read • Microsoft.Network/publicIPAddresses/write • Microsoft.Network/virtualNetworks/read • Microsoft.Network/virtualNetworks/subnets/delete • Microsoft.Network/virtualNetworks/subnets/join/action • Microsoft.Network/virtualNetworks/subnets/read • Microsoft.Network/virtualNetworks/subnets/write • Microsoft.Network/virtualNetworks/write
Microsoft Resources	<ul style="list-style-type: none"> • Microsoft.Resources/subscriptions/resourcegroups/delete

Table continued on next page

Continued from previous page

Setting	Selection
	<ul style="list-style-type: none"> • Microsoft.Resources/subscriptions/resourcegroups/read • Microsoft.Resources/subscriptions/resourcegroups/write
Microsoft Storage	<ul style="list-style-type: none"> • Microsoft.Storage/storageAccounts/delete • Microsoft.Storage/storageAccounts/read • Microsoft.Storage/storageAccounts/write • Microsoft.Storage/storageAccounts/listKeys/action is not generally required, but may be needed by users to view storage accounts.
Microsoft Web	<ul style="list-style-type: none"> • Microsoft.Web/sites/read • Microsoft.Web/sites/write • Microsoft.Web/sites/delete • Microsoft.Web/sites/config/read • Microsoft.Web/sites/config/write • Microsoft.Web/sites/config/list/action • Microsoft.Web/sites/publishxml/action • Microsoft.Web/serverfarms/write • Microsoft.Web/serverfarms/delete • Microsoft.Web/sites/hostruntime/functions/keys/read • Microsoft.Web/sites/hostruntime/host/read • Microsoft.web/sites/functions/masterkey/read

- Settings for action-based extensibility

If you are using Microsoft Azure with action-based extensibility, the following permissions are required, in addition to the minimal permissions.

Setting	Selection

Google Cloud Platform (GCP) cloud account credentials

This section describes the credentials that are required to add a Google Cloud Platform cloud account.

The Google Cloud Platform cloud account interacts with the Google Cloud Platform compute engine.

The Project Admin and Owner credentials are required for creating and validating Google Cloud Platform cloud accounts.

If you are using an external HTTP Internet proxy, it must be configured for IPv4.

The compute engine service must be enabled. When creating the cloud account in VMware Aria Automation, use the service account that was created when the compute engine was initialized.

The following compute engine permissions are also needed, depending on the actions that the user can take.

Setting	Selection
roles/compute.admin	Provides full control of all compute engine resources.
roles/iam.serviceAccountUse	<p>Provides access to users who manage virtual machine instances that are configured to run as a service account. Grant access to the following resources and services:</p> <ul style="list-style-type: none"> compute.* resourcemanager.projects.get resourcemanager.projects.list serviceusage.quotas.get serviceusage.services.get serviceusage.services.list
roles/compute.imageUser	<p>Provides permission to list and read images without having other permissions on the image. Granting the compute.imageUser role at the project level gives users the ability to list all images in the project. It also allows</p>

NSX-T cloud account credentials

This section describes the credentials that are required to add an NSX-T cloud account.

As of NSX-T Data Center 3.1, custom roles are supported.

Provide an account with the following read and write privileges.

- NSX-T IP address or FQDN
- NSX-T user name and password

Associate the user with both the **Audit** role and the custom role, which has the specified privileges outlined below. Add this user to VMware Aria Automation as a cloud account for seamless authentication with NSX-T.

The following lists the minimum privileges required for the custom role.

Category/Subcategory	Permission
Networking - Tier-0 Gateways	Read-only
Networking - Tier-0 Gateways -> OSPF	None
Networking - Tier-1 Gateways	Full Access
Networking - Segments	Full Access
Networking - VPN	None
Networking - NAT	Full Access
Networking - Load Balancing	Full Access
Networking - Forwarding Policy	None
Networking - Statistics	None
Networking - DNS	None
Networking - DHCP	Full Access
Networking - IP Address Pools	None
Networking - Profiles	Read-only
Security - Threat Detection & Response	None
Security - Distributed Firewall	Full Access

Table continued on next page

Continued from previous page

Category/Subcategory	Permission
Security - IDS/IPS & Malware Prevention	None
Security - TLS Inspection	None
Security - Identity Firewall	None
Security - Gateway Firewall	None
Security - Service Chain Management	None
Security - Firewall Time Window	None
Security - Profiles	None
Security - Service Profiles	None
Security - Firewall Settings	Full Access
Security - Gateway Security Settings	None
Inventory	Full Access
Troubleshooting	None
System	None

Administrators also require access to the vCenter as described in the *vCenter cloud account credentials* section of this topic.

NSX-V cloud account credentials

This section describes the credentials that are required to add an NSX-V cloud account.

Provide an account with the following read and write privileges:

- NSX-V Enterprise Administrator role and access credentials
- NSX-V IP address or FQDN

Administrators also require access to the vCenter as described in the *Add a vCenter cloud account* section of this table.

VMware Cloud on AWS (VMC on AWS) cloud account credentials

This section describes the credentials that are required to add an VMware Cloud on AWS (VMC on AWS) cloud account.

Provide an account with the following read and write privileges:

- The `cloudadmin@vmc.local` account or any user account in the CloudAdmin group
- NSX Enterprise Administrator role and access credentials
- NSX Cloud Admin access to your organization's VMware Cloud on AWS SDDC environment
- Administrator access to your organization's VMware Cloud on AWS SDDC environment
- The VMware Cloud on AWS API token for your VMware Cloud on AWS environment in your organization's VMware Cloud on AWS service
- vCenter IP address or FQDN

Administrators *also* require access to the vCenter as described in the *Add a vCenter cloud account* section of this table.

For more information about the permissions needed to create and use VMware Cloud on AWS cloud accounts, see *Managing the VMware Cloud on AWS Data Center* in [VMware Cloud on AWS product documentation](#).

VMware Cloud Director (vCD) cloud account credentials

This section describes the credentials that are required to add a VMware Cloud Director (vCD) cloud account.

Creating a VMware Cloud Director cloud account in VMware Aria Automation requires that you provide account credentials for a VMware Cloud Director user with the Organization Administrator role. Specifically, the following subset of the Organization Administrator role, available in VMware Cloud Director, is needed for creating and validating VMware Cloud Director cloud accounts in VMware Aria Automation:

Setting	Selection
Access All Organization vDCs	All
Catalog	<ul style="list-style-type: none"> • Add vApp from My Cloud • View Private and Shared Catalogs • View Published Catalogs
General	<ul style="list-style-type: none"> • Administrator Control • Administrator View
Metadata File Entry	Create/Modify
Organization Network	<ul style="list-style-type: none"> • Edit Properties • View
Organization vDC Gateway	<ul style="list-style-type: none"> • View • Edit Properties • View Properties
Organization vDC	<ul style="list-style-type: none"> • View • View CPU and Memory Reservation
Organization	<ul style="list-style-type: none"> • Edit Properties • View
Quota Policy Capabilities	View
VDC Template	<ul style="list-style-type: none"> • Instantiate • View
vApp Template / Media	<ul style="list-style-type: none"> • Copy • Create/Upload • Edit • View • VAPP_VM_METADATA_TO_VCENTER
vApp Template	<ul style="list-style-type: none"> • Change Owner • Checkout • Download •
vApp	<ul style="list-style-type: none"> • Change Owner • Copy • Create / Reconfigure • Delete • Download • Edit Properties • Edit VM CPU • Edit VM CPU and Memory reservation settings in all VDC types • Edit VM Hard Disk • Edit VM Memory

Table continued on next page

Setting	Selection
	<ul style="list-style-type: none"> • Edit VM Network • Edit VM Properties • Manage VM Password Settings • Power Operations • Sharing • Snapshot Operations • Upload • Use Console • VM Boot Options • View ACL • View VM metrics
vDC Group	<ul style="list-style-type: none"> • Configure • Configure Logging • View

Creating and using a VMware Cloud Director cloud account in VMware Aria Automation is not supported if VMware Aria Automation has FIPS enabled.

VMware Aria Operations integration credentials

This section describes the credentials that are required to integrate with VMware Aria Operations. Note that these credentials are established and configured in VMware Aria Operations, not in VMware Aria Automation.

Provide a local or non-local login account to VMware Aria Operations with the following read privileges.

- Adapter Instance vCenter Adapter > VC Adapter Instance for *vCenter-FQDN*

A non-local account might need to be imported first, before you can assign its read-only role.

NSX integration with Microsoft Azure VMware Solution (AVS) for VMware Aria Automation

For information about connecting NSX running on Microsoft Azure VMware Solution (AVS) to VMware Aria Automation, including configuring custom roles, see [NSX-T Data Center clouadmin user permissions](#) in the Microsoft product documentation.

Automation Service Broker prerequisites

To...	You need...
Add an Automation Assembler template content source.	<p>You can import Automation Assembler templates from an associated instance.</p> <ul style="list-style-type: none"> • Projects - Know who is a member of which projects in Automation Assembler. Projects determine who can see the imported templates.
Add an Amazon CloudFormation template source.	<p>You can import Amazon CloudFormation templates that are stored in Amazon S3 buckets.</p> <ul style="list-style-type: none"> • Projects - Know who is a member of which projects in Automation Assembler. Projects determine who can see the imported templates.

Table continued on next page

Continued from previous page

To...	You need...
Add an Amazon Web Services cloud account as a target region when you deploy a template.	<ul style="list-style-type: none"> Bucket name - You must know the name of the Amazon S3 buckets where the Amazon CloudFormation templates are stored. Bucket access key and secret key - If you are adding templates from private buckets, you must know the keys. Deployment target accounts and regions - You must know the cloud accounts and regions configured in Automation Assembler to which the templates are deployed. <p>Provide a power user account with read and write privileges.</p> <ul style="list-style-type: none"> 20-digit Access Key ID and corresponding Secret Access Key.

Automation Pipelines prerequisites

To...	You need...
Create endpoints so that you can ensure that working instances are available for developers.	<p>For example, your developers might need to connect their pipeline tasks to a data source, repository, or notification system. These components provide data for their pipelines to run.</p> <p>You can also integrate Automation Pipelines with other VMware Aria Automation components.</p> <ul style="list-style-type: none"> Use Automation Assembler to deploy VMware Cloud Templates. Use Automation Service Broker to publish pipelines and trigger them.
Use Automation Pipelines to build and run pipelines, and monitor pipeline activity on the dashboards.	<p>Provide developers with the <code>User</code> role.</p> <p>After you run a pipeline, you'll want to know whether:</p> <ul style="list-style-type: none"> Your code succeeded through all stages of your pipeline. Results appear in pipeline executions. Your pipeline failed and what caused the failure. Key errors appear in pipeline dashboards.
Use the smart pipeline templates.	<p>To save time when you create a pipeline that natively builds, tests, and deploys your application, use the smart pipeline templates. Each smart pipeline template asks you several questions, and creates a pipeline based on how you answer the questions about:</p> <ul style="list-style-type: none"> Your build goals, environments, and where your source code resides. Your deployment goals, and where you intend to deploy your application. For example, the smart pipeline template identifies your existing Kubernetes

Table continued on next page

Continued from previous page

To...	You need...
	<p>clusters. You can then select a cluster to use when you build and deploy your application.</p> <p>After the smart pipeline template creates the pipeline, you can modify the pipeline further to make it even more specific to your needs.</p> <p>For more information about planning your native build and use the smart pipeline templates, see Planning a continuous integration native build in Automation Pipelines before using the smart pipeline template.</p>

How do I navigate between VMware Aria Automation services

How do I navigate between services

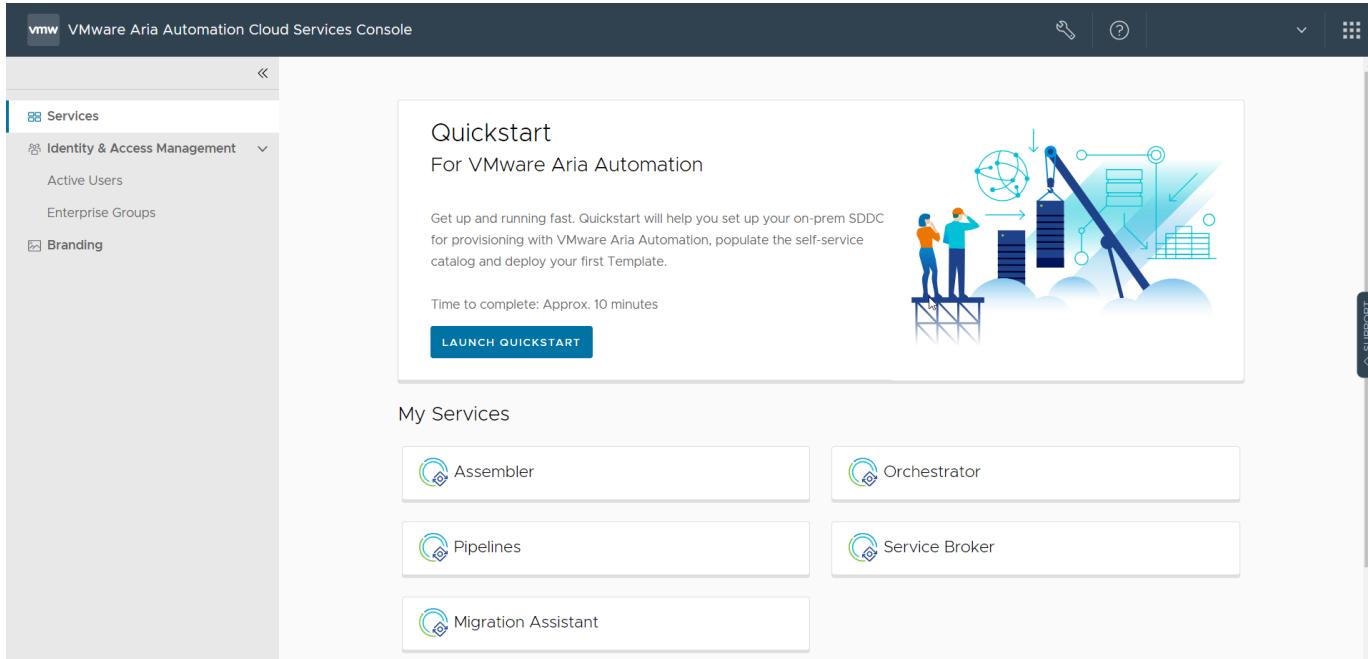

The VMware Aria Automation landing page is your main point of access to the different automation services, such as Automation Assembler, Automation Service Broker, and Automation Pipelines. Which automation services you can access depends on your user permissions.

How do I access VMware Aria Automation services

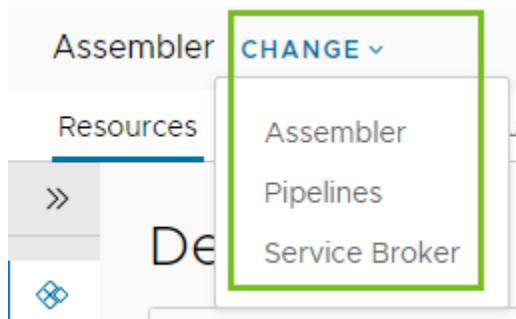

This procedure assumes that you are a cloud administrator or a user with permissions defined by your administrator.

1. On the VMware Aria Automation landing page, select the service that you want to access.
You can only access the services that your administrator gave you permission to.

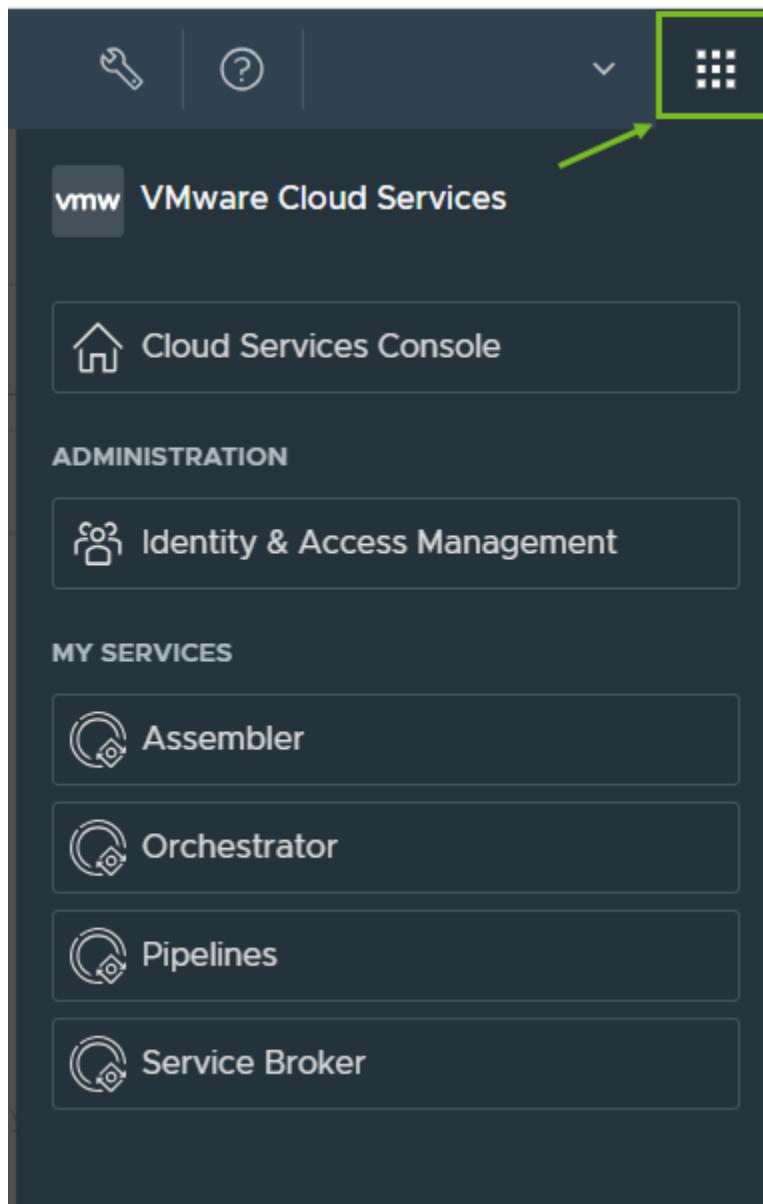

If you have permissions to only one service, you skip this step. For example, if you only have access to Automation Assembler, when you launch VMware Aria Automation in the console, you go directly to Automation Assembler.

2. To switch between VMware Aria Automation child services, use the drop-down menu located in each service.

3. To access other VMware services, you use the applications menu in the upper-right corner, where you can select your service or go back to the VMware Cloud Service console.

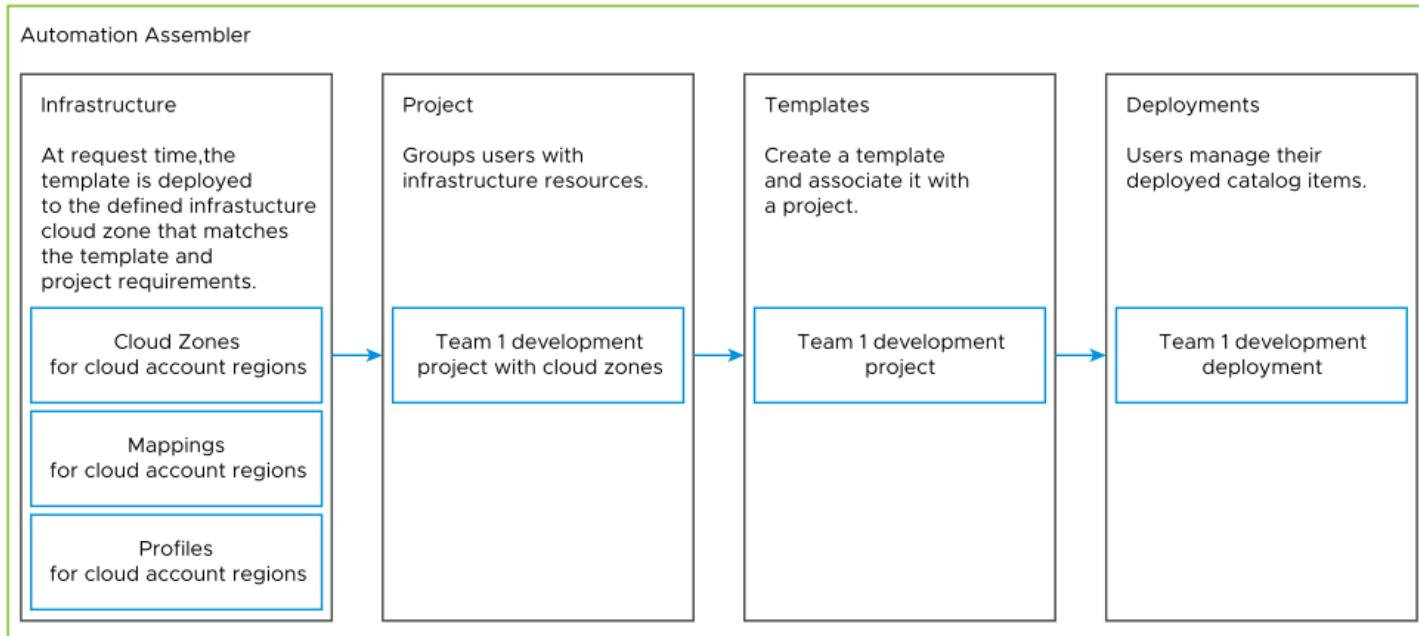

4. To return to the main landing page, click the VMware Aria Automation product name in the header.

What does Automation Assembler do

What does Automation Assembler do

Automation Assembler provides an automation service where your development teams can iteratively develop and deploy VMware cloud templates to designated cloud vendors.

The primary purpose of Automation Assembler is to create cloud templates, and then deploy the templates.

As a Automation Assembler administrator, generally referred to as a cloud administrator, you configure the infrastructure to support template development and deployment. The infrastructure begins with cloud vendors, then you add Automation Assembler users as project members and link them to the cloud account regions as projects. At this point, you can continue to develop templates, or you can turn over development to the project administrators and members.

As a project member, use Automation Assembler as you iteratively develop and deploy templates, until you have a production-worthy product. The deployment locations are configured by your cloud administrator as part of the infrastructure. The administrator has the best understanding of your organizations resources and budget.

How do I get started with Automation Assembler using the VMware Aria Automation Launchpad

As a cloud administrator using VMware Aria Automation for the first time, you can use the Launchpad in Automation Assembler to quickly set up a cloud account, add items to the Automation Service Broker catalog, and apply a lease policy to the catalog items. You can then use the dashboard on the Home tab to review usage and consumption details about your organization.

The screenshot shows the VMware Aria Automation 8.18 Home page. At the top, there's a navigation bar with links for Assembler (selected), CHANGE, Home, Resources, Design, Infrastructure, Extensibility, Tenant Management, and Migration. A dark mode toggle is also present. Below the navigation is the "Your Launchpad" section, which lists three recommended steps for success: "Add Cloud Account", "Publish to Catalog", and "Apply Lease Expiration". Each step has a "MARK AS DONE" button. To the right of the Launchpad are several dashboard widgets: "Cloud Accounts & VMs" (showing 3 cloud accounts, 378 VMs, and a status ring), "Deployments" (showing 0 expired last 7 days and 1 expiring next 7 days), "Inventory Summary" (showing 4 cloud zones and 7 projects), and a "Notifications" section with a lease expiring in 3 days. A "1 WEEK" dropdown is also visible.

What does the Launchpad do

Using the Launchpad, you do the following tasks in Automation Assembler.

- Add a vCenter cloud account. Cloud accounts are the credentials that are used to collect data from and deploy resources to your vCenter instance.
- Share content in the Automation Service Broker catalog.
- Create a lease policy. Lease policies control how long a deployment is active.

When you run the Launchpad for the first time, you start by adding a cloud account. You can then perform the procedures as needed and in any order.

Once you complete the Launchpad, you can continue to use it whenever you need to add a cloud account, add catalog items, or create a lease policy quickly. If you want to revisit any of the procedures, they also appear as quick links at the top of the Home page.

NOTE

If you want to permanently hide the Launchpad, click **Mark as done**.

How do I use the Home page dashboard

You use the Home page dashboard to view a summary of your VMs, deployments, and other inventory, such as cloud accounts, cloud zones, and projects, that are currently managed by VMware Aria Automation.

Clicking the numbers in the dashboard widgets takes you to the respective pages in Automation Assembler. For example, click the VMs count in the Cloud Accounts & VMs widget to view a full list of discovered virtual machines.

You can use the Notifications widget to track and manage approval requests for deployments or day 2 actions, deployment status updates, and expiring deployment leases. For more information about notifications, see *Send email notifications to Automation Service Broker users*.

Add a vCenter cloud account

The screenshot shows the 'New Cloud Account' configuration dialog and the 'Your Launchpad' sidebar.

New Cloud Account Dialog:

- Type:** vCenter Server
- Name:** vcenter-cloud-account
- Description:** My first vCenter cloud account.
- Credentials:**
 - IP address / FQDN: w4-hs3-octo-vc-wld01.eng.vmware.com
 - Username: administrator@vsphere.local
 - Password: [REDACTED]
 - VALIDATE button
 - Credentials validated successfully message
- Configuration:**
 - Allow provisioning to these datacenters: gpu-wld-DC
- Capabilities:**
 - Capability tags: vccenter
 - Enter capability tags input field

Your Launchpad Sidebar:

- Add Cloud Account:** Add a cloud account that connects to one of your end points.
- Publish to Catalog:** Discover reusable templates to publish to catalog and empower devops.
- Apply Lease Expiration:** Apply resource leases so that you can automate the process of reclaiming resources on your provider account platforms.

1. Navigate to the **Home** tab in Automation Assembler.
 2. On the **Add Cloud Account** card, click **Add cloud account**.
 3. Enter a name and description for the cloud account.
 4. Provide credentials.
 - a. Enter the vCenter server host IP address or fully-qualified domain name.
 - b. Enter your vCenter server administrator username and password.
 5. Click **Validate**.
 6. If you need to add tags to support a tagging strategy, enter capability tags.
You can use tags to distinguish between multiple vCenter cloud accounts when designing a template.
- You can add or remove capability tags later. See [How do I use tags to manage Automation Assembler resources and deployments](#) and [Creating a tagging strategy](#).

7. Click **Add**.

You added a vCenter cloud account. To view your cloud accounts, click the green banner in the Launchpad.

Publish content to the Automation Service Broker catalog

The screenshot shows the 'Your Launchpad' interface. On the left, there are three cards: 'Add Cloud Account', 'Publish to Catalog', and 'Apply Lease Expiration'. The 'Publish to Catalog' card is highlighted with a green checkmark and has a tooltip: 'Discover reusable templates to publish to catalog and empower devops.' Below it is a 'MARK AS DONE' button. The main area is titled 'Publish to Catalog' with the sub-instruction: 'Select VM templates from your associated cloud accounts and enable catalog self-service for your end users.' It shows a 'Template Location' section with an account selected ('vcenter-cloud-account / gpu-wld-DC') and a search bar. Below is a table titled 'Available VM Templates' with one item listed:

Name	Description
ubuntu-2004-kube-v1.26.8+vmware.tkg.1	ubuntu-2004-kube-v1.26.8+vmware.tkg.1

At the bottom, there's a 'Configuration' section for setting network and storage profiles, a 'Project' dropdown set to 'Project 1', and a 'SELECT NETWORK & STORAGE' button. At the very bottom are 'PUBLISH' and 'CANCEL' buttons.

1. Click the **Publish to Catalog** card.
2. Select a cloud account.
3. Select the VM templates that you want to make available to your users.
You can select up to 10 VM templates at a time. You can select from VM templates that are associated with the cloud account.
4. Select a project.
If no projects exist, you can create one in this step.

The project links your users with cloud account regions, so that they can deploy application templates with networks and storage resources to your vCenter instance.

5. (Optional) Set a preferred network and storage for deploying catalog items.
If you don't set a preference, catalog items are deployed to the network and storage profile that are configured for the cloud zone. If no network and storage profile exist in the cloud zone, then the catalog items are deployed at random.

The selected network and storage must be in the same cluster. Otherwise, the VM template will not provision.

You added VM templates to the Automation Service Broker catalog where users from your project can request them. To view the catalog, click the green banner in the Launchpad.

Create a lease expiration policy for deployments

The screenshot shows the VMware Aria Automation 8.18 interface. On the left, the 'Your Launchpad' screen displays three cards: 'Add Cloud Account', 'Publish to Catalog', and 'Apply Lease Expiration'. The 'Apply Lease Expiration' card is highlighted with a green checkmark and a 'MARK AS DONE' button. On the right, the 'Apply Lease Expiration' configuration screen is open. It includes fields for 'Lease name' (LeasePolicy1), 'Lease description' (empty), 'Maximum lease (days)' (15), 'Grace period (days)' (3), a project selection dropdown ('Project 1'), and three buttons at the bottom: 'CREATE', 'PREVIEW', and 'CANCEL'.

1. Click the **Apply Lease Expiration** card.
2. Enter a name and description for the lease policy.
3. Define the lease.
 - **Maximum lease** is the number of days that the deployment resources are active without being renewed. If they are not renewed, the lease expires and the deployment is destroyed. If a grace period is specified, the user can renew the lease for up to the same number of days that the lease has been active.
 - **Grace period** is the number of days the user has to renew an expired lease before the deployment is destroyed. If you don't define a grace period, it defaults to 1 day.
4. Select a project.
If no projects exist, you can create one in this step. The project links your users with cloud account regions, so that they can deploy application templates with networks and storage resources to your vCenter instance.

The deployments that are associated with the specified project are managed based on the defined lease. Other projects are not affected.

5. To preview which resources in the selected project the lease policy will impact, click **Preview**.
6. Click **Create**.

The lease policy is applied to deployments. You can click the green banner to access your lease policy.

How do you get started with Automation Assembler using the QuickStart

How do you get started using the QuickStart

To set up and verify your Automation Assembler instance, you can use a quick start wizard and a guided setup. The wizard asks you to provide values that are used to configure Automation Assembler and Automation Service Broker. The guided setup provides instructions in a support panel that guide you through an Automation Assembler configuration process in the user interface.

How do you get started with VMware Aria Automation using the VMware vCenter Server Quickstart

How do you get started using the vCenter Server Quickstart

If you are new to VMware Aria Automation, the Quickstart is a great way to get started. The Quickstart helps you, the cloud administrator, set up your on-premises vCenter Server so that you can provision resources using VMware Aria Automation, populate the self-service catalog, and deploy your first cloud template to your vSphere instance.

- Verify that you have the IP address or FQDN for the vCenter that you are adding as a cloud account. You must also have the credentials for a vCenter user account with the necessary permissions. See the vCenter Server requirements in [Before you begin with VMware Aria Automation](#).
- Verify that you have the IP address or FQDN for the NSX-V or NSX-T instance that you are adding as a cloud account. You must also have the credentials for a user account that has create, read, edit, and delete permission. See the NSX requirements in [Before you begin with VMware Aria Automation](#).

Using the vCenter Server Quickstart, you do the following tasks in Automation Assembler and Automation Service Broker.

- Add a vCenter cloud account. Cloud accounts are the credentials that are used to collect data from and deploy resources to your vCenter instance.
- Add an NSX-T or NSX-V cloud account and associate it with the vCenter account. The NSX cloud accounts are the credentials that are used to create and deploy NSX network resources.
- Select a datacenter. The datacenter is added as a cloud account region.
- Create a sample machine template that you can deploy.
- Create a project. The project links your users with cloud account regions, so that they can deploy application templates with networks and storage resources to your vCenter instance.
- Create lease and machine naming policies. The lease policy controls how long a deployment is active. The naming policy provides a standardized naming convention for the resources.
- Add the templates to the catalog.
- Deploy a machine from the catalog.

After you run the Quickstart the first time, the Quickstart is added as a tile on the console services page. You can run it again to add new vCenter Server or Cloud Foundation instances.

Much of this terminology might be new to you. As you go through the Quickstart and the tour, we explain the new concepts in more detail. After you run the Quickstart, use the [Take me on a tour of to see what the Quickstart did](#) to tour the results. The Quickstart is not an option under the following circumstances.

- If you do not use vSphere and want to add a different type of cloud account, you can use the Guided Setup as your first-time guide to the process.
- You can only run the Quickstart once. You cannot run it a second time. Consider using the Guided Setup.
- For more about the Guided Setup, see [How do you get started with using the Guided Setup](#).

In this procedure, we provide sample values to illustrate the workflow. Substitute these samples with values that are relevant to your environment.

1. After you install VMware Aria Automation and log in for the first time, click **Launch Quickstart**.

Quickstart

For VMware Aria Automation

Get up and running fast. Quickstart will help you set up your on-prem SDDC for provisioning with VMware Aria Automation, populate the self-service catalog and deploy your first Template.

Time to complete: Approx. 10 minutes

LAUNCH QUICKSTART

My Services

- Assembler
- Orchestrator
- Pipelines
- Service Broker
- Migration Assistant

2. On the VMware vCenter Server card, click **Start**.
3. Add your vCenter.

Quickstart

1 vCenter Server Add a vCenter Server and enable datacenters for provisioning

Add a new vCenter Server account

Username * ⓘ

Password *

VALIDATE

CREATE AND GO TO NEXT STEP

> 2 NSX Add the NSX Manager that is registered with your vCenter Server instance

> 3 Content Populate the cloud with VM template images

> 4 Project Create a project, or select an existing project

Remember that all values here are use case samples. Your account values depend on your environment.

Avoid any beginning or trailing spaces when you enter the values.

- If you are adding your first account, select **Add a new vCenter Server account**.
If you are adding additional accounts using the wizard, select **Use an existing vCenter Server account**.
- Enter the address and credentials.
- Click **Validate**.
If your certificates are not configured, a warning appears regarding the untrusted certificate. You can resolve the trust or you can click **Accept** and continue.
- After successful validation, select the data centers that you want to deploy to.

1 vCenter Server Add a vCenter Server and enable datacenters for provisioning

Add a new vCenter Server account

vCenter Server IP address/FQDN *

nsxt-vc.sqa.local

Datacenter

CREATE AND GO TO NEXT STEP

Each data center is added as an account region cloud zone in VMware Aria Automation.

- Click **Create and go to next step**.
- Add the NSX instance that is associated with your vCenter.

For this example, the values are for NSX-T.

▼ 2 NSX Add the NSX Manager that is registered with your vCenter Server instance

Configuring an NSX instance enables out-of-the-box provider infrastructure as code as well as on-demand network and security services.

NSX Version * NSX-T NSX-V None [\(i\)](#)

NSX-T IP address/FQDN * nsxt-mgr-1.sqa.local [\(i\)](#)

Username * admin [\(i\)](#)

Password * [\(i\)](#)

NSX Mode Policy [\(i\)](#)

[VALIDATE AND CREATE](#) ✓ Endpoint created successfully [X](#)

[NEXT STEP](#)

a) Select the NSX version.

Select the NSX version that you use. If you do not have NSX, select **None**.

b) Enter the address and credentials.

c) Select the **NSX Mode** with the capabilities that you want to use to manage the endpoint.

You cannot change the mode after the account is created.

d) Review the information, and then click **Validate and Create**.

e) Click **Next step**.

5. Set up the content of your first templates and where they are deployed.

This process sets up the elements in your infrastructure and creates your first VMware cloud templates that are made available in the Automation Service Broker catalog. The terms that are used in Automation Assembler and

Automation Service Broker are provided so that you become familiar with them and how they are used in the UI.

▼ **3 Content** Populate the cloud with VM template images

Add content to your cloud. Items added here are used to populate the service catalog.

Datacenter * i

VM templates

Discovered templates 10 Selected templates 2 SELECT TEMPLATES

Create and deploy your first cloud template

Provide information needed to create a cloud template, add it to the catalog, and deploy it.

Template * i

IP assignment type DHCP i CONFIGURE

Also add sample NSX cloud templates to the catalog

Provide information needed to create a network profile that supports sample NSX on-demand infrastructure cloud templates.

Tier-0 logical router * i

Edge cluster * i

NEXT STEP

- a) Click in the text box to select the **Datacenter**.

The other possible values on this page are collected from your vCenter instance based on the provided credentials. This data center becomes a cloud zone in Automation Assembler.

- b) To add one or more templates that exist on your vCenter to your catalog, select **VM templates** and select the templates.

These templates are virtual machine templates on your vCenter Server instance.

- c) To deploy a template, click **Select Templates** and locate the template that you want to deploy.
- d) Select the **Datastore / cluster**.

This datastore becomes a storage profile.

- e) To add a **Network**, click **Browse** and select the network.

If you are configuring NSX, select the NSX network, not the vCenter Server network. This network becomes a cloud zone that supports the network profile.

- f) To select and configure a DHCP or static IP connection type, click **Configure** and provide the values specific to your environment.

The network connection that you configure becomes a network profile.

- g) To add NSX templates, click **Also add sample NSX cloud templates to the catalog** and select the **Tier-0 logical router** and the **Edge cluster**.

- h) Click **Next Step**.

As part of this configuration process, a Quickstart cloud zone is defined for you and vCenter templates are added as cloud templates and catalog items.

6. Create a project and assign users.

Projects are used to manage people, assigned resources, cloud templates, and deployments. They can operate a business group to manage access and costs.

4 Project Create a project, or select an existing project

Create or select a project that will have access to resources from this cloud account. You can add additional projects later.

Name * vCenter Server Quickstart Project 1

Description First project created using the vCenter Server wizard.

Administrators sylvia (i)
Search users

Members connie (i)
tony

NEXT STEP

- a) If this is your first time using the Quickstart, select **Create a new project**.

If you are using the Quickstart to add more templates to a project, select **Use an existing project**.

- b) If you are making these templates available to others, add an **Administrator** and **Members**.

Administrators have more permissions than the members have.

- c) Click **Next Step**.

7. Provide the starting policies and a machine naming policy so that all the deployments have the same approval requirements and lease time, and so that they follow a standard naming convention.

5 Policies

Configure governance policies for self service applications

Configure governance policies for your project. Additional policies can be created later.

The screenshot shows a list of three governance policies:

- Approval:** Approval required, Approval policy for deployments and. **EDIT** button.
- Lease:** Lease, 2 weeks, Configure the how long the Quickstart. **EDIT** button.
- Machine:** Machine, Project - Requestor -, Configure how the deployed machines are. **EDIT** button.

NEXT STEP

These policies are applied to deployments associated with the Quickstart project. The Quickstart creates the project for you. You define the policies.

- Edit the approval policy and assign it to yourself.

The approval policy requires the assigned user to approve the deployment request before the resources are deployed. If you assign it to someone else, you must change your custom permissions to give yourself the ability to approve the request.

- Edit the lease and select the time after which the resources are destroyed if not renewed by the user.

Lease**X**

Remove deployments after a specified duration unless the lease is renewed.

This policy is applied at the project level

RUN QUICKSTART

- Click **Run Quickstart**.

Take a tour of Automation Assembler and Automation Service Broker to discover more about how you manage your infrastructure, create templates, and deploy and manage resources. See [Take me on a tour of to see what the Quickstart did](#).

How do you get started with VMware Aria Automation using the VMware Cloud Foundation Quickstart

How do you get started using the VMware Cloud Foundation Quickstart

If you use VMware Cloud Foundation to manage your SDDC, the Quickstart helps you connect it to VMware Aria Automation so that you can provision resources and then manage the life cycle of those resources.

- Verify that you have the IP address or FQDN for the Cloud Foundation SDDC Manager that you are adding as a cloud account. You must also have the credentials for a SDDC Manager user account with the necessary permissions.

- Verify that the following exists in your Cloud Foundation instance.
 - A deployed NSX-T Edge
 - A tier-0 router
- Verify that you have a deployable virtual machine template that VMware Aria Automation can deploy as part of the Quickstart.

Using the Cloud Foundation Quickstart, you do the following Automation Assembler and Automation Service Broker tasks that are used in this procedure.

- Add a vCenter cloud account for the vCenter instance associated with the selected SDDC Manager workload domain. Cloud accounts are the credentials that are used to collect data from and deploy resources to your vCenter instance.
- Add an NSX-T cloud account. The NSX cloud accounts are the credentials that are used to create and deploy NSX network resources.
- Select a datacenter. The datacenter is added as a cloud account region.
- Create a sample machine cloud template that you can deploy.
- Create a project. The project links your users with cloud account regions, so that they can deploy cloud templates with networks and storage resources to your vCenter instance.
- Create lease and machine naming policies. The lease policy controls how long a deployment is active. The naming policy provides a standardized naming convention for the resources.
- Add the templates to the catalog.
- Deploy a machine from the catalog.

After you run the Quickstart the first time, the Quickstart is added as a tile on the console services page. You can run it again to add new vCenter Server or Cloud Foundation instances.

Much of this terminology might be new to you. As you finish the Quickstart, review the tour. Although the tour is based on the vCenter Server Quickstart, the tour applies to Cloud Foundation. In the tour, you are introduced to the new concepts in more detail. For more information, see [Take me on a tour of to see what the Quickstart did](#).

1. After you install VMware Aria Automation and log in for the first time, click **Launch Quickstart**.

Quickstart For VMware Aria Automation

Get up and running fast. Quickstart will help you set up your on-prem SDDC for provisioning with VMware Aria Automation, populate the self-service catalog and deploy your first Template.

Time to complete: Approx. 10 minutes

LAUNCH QUICKSTART

My Services

NSX password *	*****
NSX Mode	Policy (1)
	<input type="button" value="VALIDATE"/> ✓ Credentials validated successfully.
Configuration	
Allow provisioning to these datacenters *	<input checked="" type="checkbox"/> SDDC-Datacenter
CREATE AND GO TO NEXT STEP	

- a) Review the information, provide the credentials, and then click **Validate and Create**.
 - b) Select the data centers that you want to deploy to.
Each data center is added as an account region cloud zone in VMware Aria Automation.
 - c) Click **Create and go to next step**.
5. Verify the NSX-T associated with the workload domain, and then select the router and Edge.

Quickstart

3 NSX Add the NSX Manager that is registered with your vCenter Server instance

The NSX Manager is added as a cloud account with the API credentials that were generated when you connected to the SDDC Manager.

Workload domain	MGMT
NSX-T	cmbuvcfnsxmgr.eng.vmware.com
	<input type="button" value="VALIDATE AND CREATE"/> Endpoint created successfully
Tier-0 logical router *	<input type="text" value="vra-vcf-tier-0"/> (i)
Edge cluster *	<input type="text" value="EdgeCluster"/> (i)
<input type="button" value="NEXT STEP"/>	

4 Blueprint Select the blueprint configuration and deployment options

- a) Review the information, and then click **Validate and Create**.
 - b) Select the **Tier 0 Router** and the **Edge Cluster** that you want to use in your network profile.
 - c) Click **Next Step**.
6. Set up your cloud template.

This process sets up the elements in your infrastructure. The terms that are used in Automation Assembler and Automation Service Broker are provided so that you become familiar with them and how they are used in the UI.

3 Content Populate the cloud with VM template images

Add content to your cloud. Items added here are used to populate the service catalog.

Datacenter * [i](#)

VM templates

Discovered templates 2 Selected templates 1 [SELECT TEMPLATES](#)

Create and deploy your first cloud template

Provide information needed to create a cloud template, add it to the catalog, and deploy it.

Template * [i](#)

Datastore / cluster [i](#)

Network * [i](#) [BROWSE](#)

IP assignment type DHCP [i](#) [CONFIGURE](#)

Also add sample NSX cloud templates to the catalog

Provide information needed to create a network profile that supports sample NSX on-demand infrastructure cloud templates.

Tier-0 logical router * [i](#)

Edge cluster * [i](#)

[NEXT STEP](#)

- a) Click in the text box to select the **Datacenter**.

The other possible values on this page are collected from your vCenter instance based on the provided credentials. This data center becomes a cloud zone in Automation Assembler.

- b) To add one or more templates that exist on your vCenter to your catalog, select **VM templates** and select the templates.

These templates are virtual machine templates on your vCenter Server instance.

- c) To deploy a template, click **Select Templates** and locate the template that you want to deploy.
d) Select the **Datastore / cluster**.

This datastore becomes a storage profile.

- e) To add a **Network**, click **Browse** and select the network.
If you are configuring NSX, select the NSX network, not the vCenter Server network.

This network becomes a cloud zone that supports the network profile.

- f) To select and configure a DHCP or static IP connection type, click **Configure** and provide the values specific to your environment.

The network connection that you configure becomes a network profile.

- g) To add NSX templates, click **Also add sample NSX cloud tempaltes to the catalog** and select the **Tier-0 logical router** and the **Edge cluster**.

- h) Click **Next Step**.

As part of this configuration process, a Quickstart project is defined for you. The project eventually links your users, infrastructure, and provisioning templates. You can see the project in the tour.

7. Create a project and assign users.

Projects are used to manage people, assigned resources, cloud templates, and deployments. They can operate a business group to manage access and costs.

The screenshot shows the 'Project' creation interface. At the top, it says '4 Project' and 'Create a project, or select an existing project'. Below that, a note says 'Create or select a project that will have access to resources from this cloud account. You can add additional projects later.' The 'Name *' field contains 'VCF Quickstart Project 2'. The 'Description' field is empty. Under 'Administrators', there is a list with 'connie X' and a 'Search users' input field. Under 'Members', there is a 'Search users' input field. At the bottom is a blue 'NEXT STEP' button.

- a) If this is your first time using the Quickstart, select **Create a new project**.

If you are using the Quickstart to add more templates to a project, select **Use an existing project**.

- b) If you are making these templates available to others, add an **Administrator** and **Members**.

Administrators have more permissions than the members have.

- c) Click **Next Step**.

8. Provide the starting policies and a machine naming policy so that all the deployments have the same approval requirements and lease time, and so that they follow a standard naming convention.

5 Policies Configure governance policies for self service applications

Configure governance policies for your project. Additional policies can be created later.

Approval	None	Approval policy for deployments and actions	EDIT
Lease	1 week	Configure the how long the Quickstart deployments are active.	EDIT
Machine Name	Project - Requestor - 001	Configure how the deployed machines are named.	EDIT

[NEXT STEP](#)

These policies are applied to deployments associated with the Quickstart project. The Quickstart creates the project for you based on the default name or one that you provide. You define the policies.

- Edit the approval policy and assign it to yourself.

The approval policy requires the assigned user to approve the deployment request before the resources are deployed. If you assign it to someone else, you must change your custom permissions to give yourself the ability to approve the request.

- Edit the lease and select the time after which the resources are destroyed if not renewed by the user.

Lease

Remove deployments after a specified duration unless the lease is renewed.

This policy is applied at the project level

Take a tour of Automation Assembler and Automation Service Broker to discover more about how you manage your infrastructure, create cloud templates, and deploy and manage resources. See [Take me on a tour of to see what the Quickstart did..](#)

How do you get started with Private AI Automation Services in VMware Aria Automation using the Catalog Setup Wizard

How do you get started with Private AI Automation Services using the Catalog Setup Wizard
As a cloud administrator, you can utilize your VMware Cloud Foundation stack to manage GPU-enabled infrastructure and AI/ML workload domains. In VMware Aria Automation, you can set up and provide GPU-enabled deep learning virtual machines (DL VM) and Tanzu Kubernetes Grid (TKG) clusters as catalog items that data scientists and DevOps teams in your organization can request in the self-service Automation Service Broker catalog.

NOTE

This documentation is based on VMware Aria Automation 8.18. For information about the VMware Private AI Foundation functionality in VMware Aria Automation 8.18.1, see [Set Up VMware Aria Automation for VMware Private AI Foundation with NVIDIA](#) in the VMware Private AI Foundation with NVIDIA documentation.

What is VMware Private AI Foundation?

VMware Private AI Foundation with NVIDIA provides a platform for provisioning AI workloads on VMware Cloud Foundation with NVIDIA GPUs. In addition, running AI workloads based on NVIDIA GPU Cloud (NGC) containers is specifically validated by VMware by Broadcom. To learn more, see [What is VMware Private AI Foundation with NVIDIA](#).

Private AI Automation Services is the collective name for all VMware Private AI Foundation features that are available in VMware Aria Automation.

To get started with Private AI Automation Services, you run the Catalog Setup Wizard in VMware Aria Automation. The wizard helps you connect VMware Private AI Foundation to VMware Aria Automation.

How does the Catalog Setup Wizard work?**IMPORTANT**

The Catalog Setup Wizard is not enabled by default. Contact VMware by Broadcom Professional Services to activate the wizard for your organization.

Using the Catalog Setup Wizard, you do the following tasks:

1. Add a cloud account. Cloud accounts are the credentials that are used to collect data from and deploy resources to your vCenter instance.
2. Add an NVIDIA license.
3. Select content to add to the Automation Service Broker catalog.
4. Create a project. The project links your users with cloud account regions, so that they can deploy cloud templates with networks and storage resources to your vCenter instance.

After you run the Catalog Setup Wizard the first time, the following catalog items are created in the Automation Service Broker catalog that become available for users in your organization to deploy:

- **AI Workstation** – a GPU-enabled virtual machine that can be configured with desired vCPU, vGPU, memory, and the option to pre-install AI/ML frameworks like PyTorch, CUDA Samples, and TensorFlow.
- **AI RAG Workstation** – a GPU-enabled virtual machine with Retrieval Augmented Generation (RAG) reference solution.
- **Triton Inference Server** – a GPU-enabled virtual machine with Triton Inference Server.
- **AI Kubernetes Cluster** – a VMware Tanzu Kubernetes Grid Cluster with GPU-capable worker nodes to run AI/ML cloud-native workloads.
- **AI Kubernetes RAG Cluster** – a VMware Tanzu Kubernetes Grid Cluster with GPU-capable worker nodes to run a reference RAG solution.

You can run the wizard again multiple times if you need to change any of the settings that you provided, like changes in licensing, or if you want to create AI catalog items for other projects. Each time you run the wizard, five new catalog items are created for you in addition to any previously created items.

You can modify the templates for the catalog items that the wizard created to meet the specific needs of your organization.

Before you begin

- Verify that you are running VMware Aria Automation 8.18.
- Verify that you are running VMware Cloud Foundation 5.1.1 or later, which includes vCenter 8.0 Update U2b or later.

- Verify that you have a vCenter cloud account in VMware Aria Automation.
- Verify that you have an NVIDIA GPU Cloud Enterprise organization with a premium cloud service subscription.
- Verify that you have a configured GPU-enabled Supervisor cluster via workload management..
- Configure VMware Aria Automation for VMware Private AI Foundation with NVIDIA. See [Set Up VMware Aria Automation for VMware Private AI Foundation with NVIDIA](#).
- Complete the VMware Cloud Foundation Quickstart before running the Catalog Setup Wizard. Your SDDC and Supervisor clusters must be registered with VMware Aria Automation. See [How do you get started with VMware Aria Automation using the VMware Cloud Foundation Quickstart](#) .
- Verify that you have generated the client configuration token from the NVIDIA licensing server and that you have your NVIDIA NGC Portal API key. The NVIDIA NGC Portal Access key is used to download and install vGPU drivers.
- Configure Single Sign-On (SSO) for Cloud Consumption Interface (CCI). See [Setting Up Single Sign-On for CCI](#).
- Verify that you are subscribed to the content library at <https://packages.vmware.com/dl-vm/lib.json>.

Procedure

1. After you install VMware Aria Automation and log in for the first time, click **Launch Quickstart**.

Quickstart
For VMware Aria Automation

Get up and running fast. Quickstart will help you set up your on-prem SDDC for provisioning with VMware Aria Automation, populate the self-service catalog and deploy your first Template.

Time to complete: Approx. 10 minutes

LAUNCH QUICKSTART

My Services

 Assembler	 Orchestrator	 Pipelines
 Service Broker	 Migration Assistant	

2. On the **Private AI Automation Services** card, click **Start**.
3. Select the cloud account to provision access to.

1 Select Cloud Account

Select the Private AI Foundation to provision access to

Cloud account *

Select supervisor *

Region name * (i)

NEXT STEP

Remember that all values here are use case samples. Your account values depend on your environment.

- Select a vCenter cloud account.
- Select a GPU-enabled supervisor.
- Enter a region name.

A region is automatically selected if the supervisor is already configured with a region.

If the supervisor is not associated with a region, you add one in this step. Consider using a descriptive name for your region that helps your users distinguish GPU-enabled regions from other available regions.

- Click **Next Step**.

4. Provide information about your NVIDIA license server.

2 Licensing and Drivers

Provide details for your NVIDIA client configuration token and vGPU guest driver location

NVIDIA client configuration token *

NVIDIA vGPU guest driver location * Cloud - NVIDIA Licensing Portal Local - self hosted

NVIDIA licensing portal API key * (i)

NEXT STEP

- Copy and paste the contents of the NVIDIA client configuration token.
The client configuration token is needed to enable full capabilities of the vGPU driver.
- Select the location of the NVIDIA vGPU drivers.
 - Cloud – the NVIDIA vGPU driver is hosted on the NVIDIA Licensing Portal.
You must provide the NVIDIA Licensing Portal API key, which is used to evaluate if a user has the right entitlement to download the NVIDIA vGPU drivers. The API key must be a UUID.

NOTE

The API key that you generate from the NVIDIA Licensing Portal is not the same as the NVAIE API Key.

- Local – the NVIDIA vGPU driver is hosted on-premises and is accessed from a private network. You must provide the location of the vGPU guest drivers for VMs.

For air-gapped environments, the vGPU driver must be available on your private network or data center.

For more information, see the [NVIDIA License System documentation](#).

- Click **Next Step**.

5. Configure the catalog items.

This workflow will create some catalog items which your organization's users can use to consume this infrastructure in a self-service manner. Enter the details required to set up those catalog items.

VM image name * dl-vm-content-library / common-container-nv-vgpu-ubuntu-2204-v20240119

VM classes * Select the VM classes to make available for selection for your users. Select at least one GPU-capable and one non-GPU-capable VM class. Non-GPU capable VM classes will be used for nodes that do not need GPUs, like Kubernetes control plane nodes.

GPU-capable(1)	Non-GPU-capable(3)					
<input type="checkbox"/>	VM class	CPU count	Memory	GPU model	GPU count	GPU memory
<input checked="" type="checkbox"/>	mig-a100-2-10c	8	12 GB	grid_a100	1	10 GB
<input type="checkbox"/>	vikas-gpu-10c-class	4	16 GB	grid_a100	1	10 GB
<input type="checkbox"/>	vikas-gpu-5c-profile	4	16 GB	grid_a100	1	5 GB

Manage Columns 1 - 3 of 3 VM classes

Storage policy * Management Storage Policy - Regular

Container registry for NVIDIA containers * Cloud - NVIDIA NGC Catalog Local - self-hosted registry

NEXT STEP

- Select the content library that contains the deep learning VM image.

You can access only one content library at a time. If the content library contains Kubernetes images, those images are filtered out.

- Select the VM image you want to use to create the workstation VM.

- Select the VM classes you want to make available to your catalog users.

You must add at least one GPU-capable and one non-GPU-capable class.

- GPU-enabled VM classes are used for the deep learning VM and for the worker nodes of the TKG cluster. When the catalog item is deployed, the TKG cluster is created with the selected VM classes.
- Non-GPU-capable nodes are required to run the Kubernetes control planes.

- Select the storage policy to apply to the virtual machines.

- Specify the container registry where you want to pull NVIDIA GPU Cloud resources.

- Cloud – the container images are pulled from the NVIDIA NGC catalog.

- Local – for air-gapped environments, the containers are pulled from a private registry.

You must provide the location of the self-hosted registry. If the registry requires authentication, you must also provide login credentials.

You can use Harbor as a local registry for container images from the NVIDIA NGC catalog. See [Setting Up a Private Harbor Registry in VMware Private AI Foundation with NVIDIA](#).

- (Optional) Configure a proxy server.

In environments without direct Internet access, the proxy server is used to download the vGPU driver and pull the non-RAG AI Workstation containers.

NOTE

Support for air-gapped environments is available for the AI Workstation and Triton Inference Server catalog items. The AI RAG Workstation and AI Kubernetes Cluster items do not support air-gapped environments and need Internet connectivity.

- g. Click **Next Step**.
6. Configure access to the catalog items by creating a project and assigning users.

4 Configure Access

Create a Project in which these Catalog items will reside, and configure access to this project

Name *	vpaif-quickstart-1
Description	My Private AI Foundation project
Administrators	<input type="text" value="administrator@vpaif-quickstart-1.com"/> (i) Search Users
Members	<input type="text" value="gloria@vpaif-quickstart-1.com tony@vpaif-quickstart-1.com"/> (i) Search Users

NEXT STEP

Projects are used to manage people, assigned resources, cloud templates, and deployments.

- a. Enter a name and description for the project.
The project name must contain only lowercase alphanumeric characters or hyphens (-).
- b. To make the catalog items available to others, add an **Administrator** and **Members**.
Administrators have more permissions than the members have. For more information, see [What are the VMware Aria Automation user roles](#).
- c. Click **Next Step**.
7. Verify your configuration on the **Summary** page.
Consider saving the details for your configuration before running the wizard.
8. Click **Run Quickstart**.

Results

Five catalog items – **AI Workstation**, **AI RAG Workstation**, **Triton Inferencing Server**, **AI Kubernetes Cluster**, and **AI Kubernetes RAG Cluster**, are created in the Automation Service Broker catalog and users in your organization can now deploy them.

The screenshot shows the VMware Aria Automation Service Broker Catalog interface. The left sidebar includes tabs for 'Service Broker' (selected), 'CHANGE', 'Consume', 'Content & Policies', 'Infrastructure', and 'Inbox'. Under 'Catalog', there are sections for 'Projects' (Showing all) and 'Deployments' (with sub-options: Deployments, Resources, Virtual Machines, Volumes, Networking & Security, Supervisor Namespaces). The main area displays five catalog items:

- AI Kubernetes Cluster**: Deploy a VMware Tanzu Kubernetes Cluster with customizable, GPU capable worker nodes to run AI/ML cloud-native workloads. The cluster will run Kubernetes version 1.26.5 with Ubuntu nodes.
- AI Kubernetes RAG Cluster**: Deploy a VMware Tanzu Kubernetes Cluster with customizable, GPU capable worker nodes to run AI/ML cloud-native workloads. The cluster will run Kubernetes version 1.26.5 with Ubuntu nodes.
- AI RAG Workstation**: This reference solution demonstrates how to find business value in generative AI by augmenting an existing foundational LLM to fit your business use case. This is done using retrieval augmented generation (RAG) which...
- AI Workstation**: Workstation (VM) with preconfigured GPU capabilities, and options to pre-install selectable customizations during deployment.
- Triton Inferencing Server**: Triton Inference Server provides a cloud and edge inferencing solution optimized for both CPUs and GPUs. Triton supports an HTTP/REST and GRPC protocol that allows remote clients to request inferencing for any...

Each item card includes 'Projects' (vpaif-quickstart-1) and 'REQUEST' buttons.

What to do next

- Verify that the templates are available in the catalog to the members of the selected projects with whom you shared the content and monitor the provisioning process to ensure successful deployment. See [How do I deploy PAIF catalog items](#).
- If you want to control how long a deployment can exist, create a lease. See [Setting up Automation Service Broker policies](#).
- To modify user inputs at request time, you can create a custom form. See [Customize an Automation Service Broker icon and request form](#).

Troubleshooting

- If the Catalog Setup Wizard fails, run the wizard again for a different project.

How do you get started with Automation Assembler using the Guided Setup

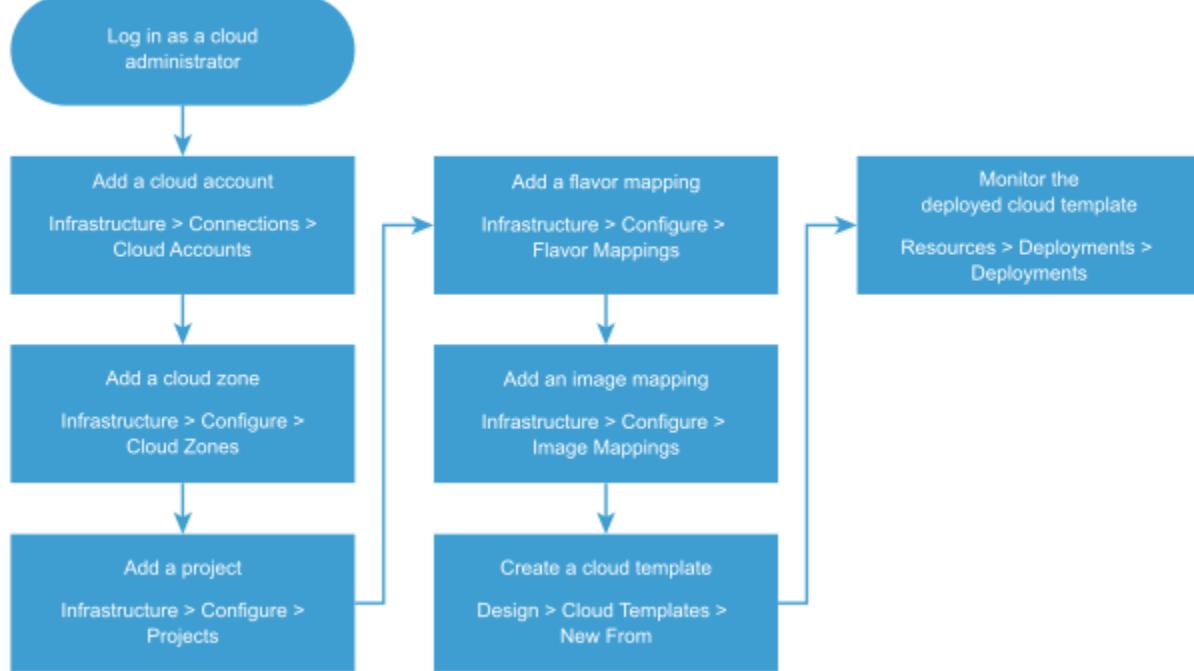

How do I set up Automation Assembler

To set up and verify your Automation Assembler instance, you configure the infrastructure based on the cloud accounts, and then you create and deploy cloud templates to ensure that everything is flowing through the system.

- Log in as a cloud administrator.
- Verify that you have the credentials required to connect to the cloud account. If you have an Amazon Web Services account, consider using those credentials. See [Before you begin with VMware Aria Automation](#) for details.

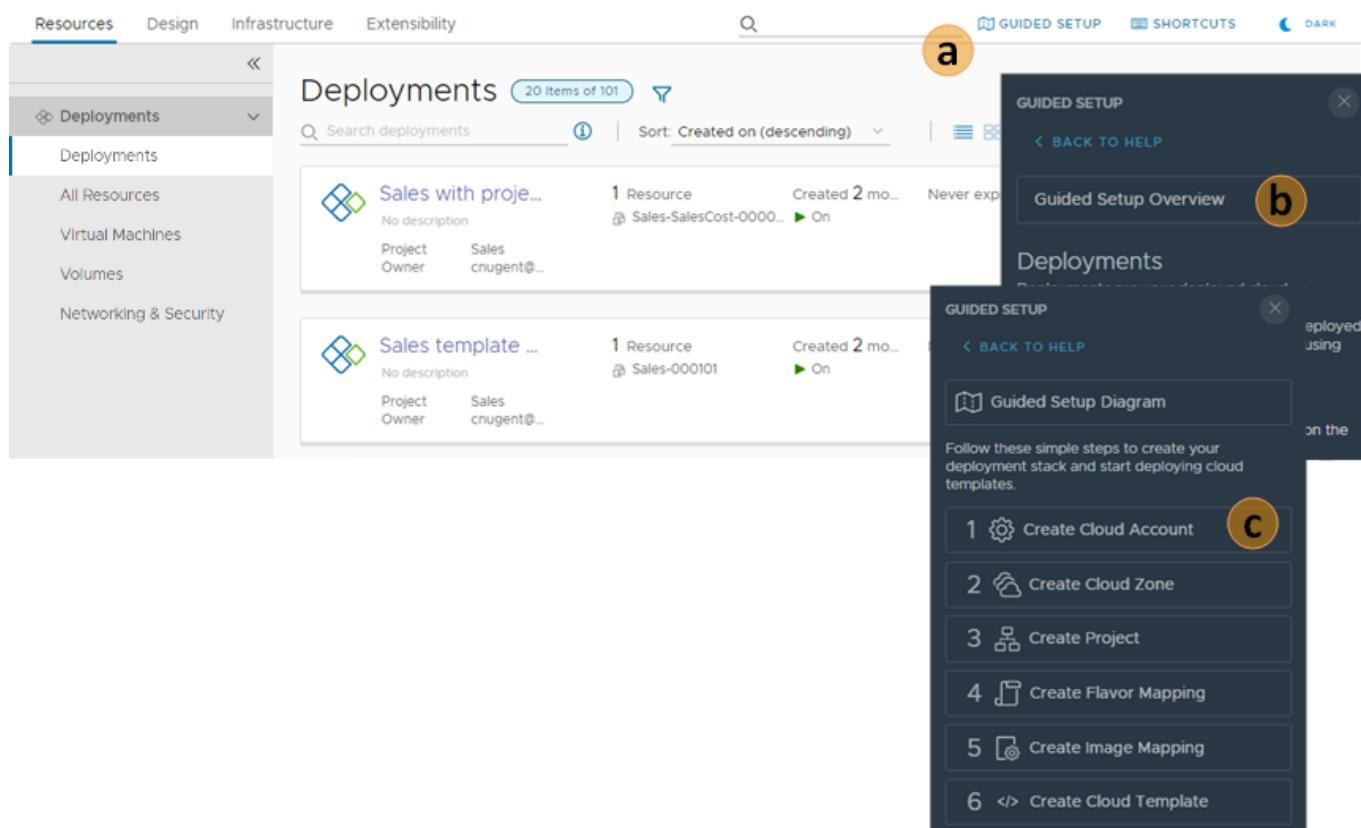

This use case helps you, a cloud administrator, through your first time using Automation Assembler. You add an Amazon Web Services cloud account and configure the infrastructure related to that account. The infrastructure consists of a cloud

account region, a project to link users to the region, and some size and image mapping that you use at deployment time. To test the infrastructure, you next create and deploy a simple cloud template.

To help you with this getting started process, the instructions are available as a Guided Setup in the user interface. The first time that you log in to Automation Assembler, you might encounter the Guided Setup Diagram. The diagram illustrates how the components that you configure process a cloud template at request time. Click **Continue** and configure your cloud account.

1. Open the **Guided Setup**.

- Click **Guided Setup** on the tab bar.
- In the support panel, click **Guided Setup Overview**.

The Guided Setup is contextually sensitive to the page that you are on in the user interface. The initial Guided Setup topic that opens depends on the page you are on in the user interface. The link to the Guided Setup overview is at the top of each getting started topic.

- In the step list, click **Create Cloud Account** to begin.
The guided opens the cloud account topic and opens the page in the UI.

Use the information in the support panel and the provided workflow to set up your infrastructure, create a cloud template, and deploy the template.

- Add a cloud account.

The screenshot shows the VMware Aria Automation interface. On the left, there's a sidebar with icons for Resources, Design, Infrastructure (which is selected), and Extensibility. Below the sidebar, the main area displays 'Cloud Accounts' with 10 items. Two accounts are visible: 'nsxt-manager' and 'nsxv-manager-new'. Each account card shows its status (OK), identifier, manager type (Local), and NSX mode (Manager). An 'OPEN' button is at the bottom of each card. To the right of the main content is a 'GUIDED SETUP' window titled 'Guided Setup Overview'. It contains five numbered steps: 1. Click Add Cloud Account. 2. Select the account type you would like to add. 3. Enter cloud credentials and click Validate. 4. Enter cloud account name and description. 5. Add applicable capability tags. Step 5 includes a note about using 'dev' tags to indicate a development environment.

Cloud Account	Status	Identifier	Manager type	NSX mode
nsxt-manager	OK	cmbu-w01-nsx10.eng.vmware.com	Local	Manager
nsxv-manager-new	OK	eso-vra-vc03-nsxmgr01.eng.vmware.com		

Cloud Accounts
Cloud accounts allow you to bring your public cloud and on-prem data centers under management.

- 1 Click **Add Cloud Account**.
- 2 Select the account type you would like to add.
- 3 Enter cloud credentials and click **Validate**.
- 4 Enter cloud account name and description.
- 5 Add applicable capability tags.
Add capability tags, which match this cloud account to cloud template constraints during provisioning. For example you might tag an account as `dev` to indicate that it's matched with cloud templates intended for a development environment. If you are not ready to define tags, you can return to the cloud account and add tags later.

3. Create a cloud zone for one of your Amazon Web Services regions.

Cloud Zones (7 items)

GUIDED SETUP

Cloud Zones

Cloud zones associate compute resources with projects and account/regions to form the basis of deployable virtual machines. In addition, they enable you to define capabilities that Cloud Assembly matches with cloud template constraints to define where and how resources are configured for deployments.

- Click **New Cloud Zone** or use one of the existing Cloud Zones.
- Select an account/region and enter a name and description.
- Select a placement policy that defines how provisioned resources are distributed among hosts in this cloud zone.
- Add applicable capability tags. Add capability tags, which match this cloud zone to cloud template constraints during provisioning. For example you might tag a zone as **dev** to indicate that it's matched with cloud templates intended for a development environment. If you are not ready to define tags, you can return to the cloud zone and add tags later.
- Click the **Compute** tab and view the compute resources in this cloud zone. If you don't want to use all the compute

4. Create a project with users and the cloud zone.

The screenshot shows the VMware Aria Automation interface. On the left, there's a sidebar with icons for Resources, Design, Infrastructure (which is selected), and Extensibility. Below the sidebar, the main area has a header "Projects" with "10 items". It includes buttons for "+ NEW PROJECT" and "TEST CONFIGURATION". There's also a search bar labeled "Filter..." and some filtering icons. The main content area displays two project entries:

- AmazonCloudGrp** (Summary tab):
 - Administrators: 1
 - Zones: 1
 - Cloud templates: 1
 Buttons: OPEN, DELETE
- CustomFormsGroup** (Summary tab):
 - Administrators: 2
 Buttons: OPEN, DELETE

To the right, a dark sidebar titled "Guided Setup Overview" provides instructions for creating a new project:

- 1 Click **New Project**.
- 2 Enter project information on the **Summary** tab. For this setup example, the project name is *dev-basic*.
- 3 Click the **Users** tab and add one or more users. Project users must be existing active service organization users.
- 4 Click the **Provisioning** tab and add one or more zones. The selected zones must have the appropriate infrastructure resources to support the project goals. If you are just getting started, ignore Constraints and Custom Properties for now. You can go back and add them later if necessary.
- 5 Click **Create**.

NEXT: CREATE FLAVOR MAPPING

5. Create a small flavor mapping.

The screenshot shows two main sections: 'Flavor Mappings' and 'Guided Setup Overview'.

Flavor Mappings:

- small:** Account / regions: 18. Actions: OPEN, DELETE.
- v-medium:** Account / regions: 1. Actions: OPEN, DELETE.
- v-small:** Account / regions: 4. Actions: OPEN, DELETE.

Guided Setup Overview:

Flavor Mappings

Cloud vendors use flavors, or instance types, to express standard deployment sizings such as small (1 CPU, 2 GB RAM) or large (2 CPU, 8 GB RAM) for compute resources. When you build a cloud template, you pick a flavor that fits your needs.

Map a flavor name to a value for each account/region.

- 1 Click **New Flavor Mapping**.
- 2 Enter a new **Flavor name**, such as *StdSmall_1_2*.
- 3 Click in **Account/Region** and select one of the available cloud account/regions.
- 4 Specify a compute value.
 - For Microsoft Azure: Click or type in **Value** and select *Standard_B1ms*.
 - For AWS: Click or type in **Value** and select *t2.small*.
 - For vSphere or NSX-V/T: Specify 1

6. Create an `ubuntu-16` image mapping.

Image Mappings (14 items)

TinyCentOS

Account / region: 5

centos

Account / region: 3

jieaaptestvcMapping

GUIDED SETUP

Guided Setup Overview

Image Mappings

Cloud vendors use images to configure a VM based on OS settings, such as an ubuntu-16 configuration. When you build a cloud template, you pick an image that fits your needs. Map an image name to a value for each account/region. You can also add constraints and configuration scripts to further control resource placement.

Map an image name to a value for each account/region.

- 1 Click **New Image Mapping**.
- 2 Enter a new **Image name**, such as *ubuntu-16*.
- 3 Click in **Account/Region** and select one of the available cloud account/regions.
- 4 Click in **Value** and start to type **ubuntu-16**. Select one of the available ubuntu-16 configurations to complete the first map row. If you are just getting started, ignore **Constraints** and **CloudConfig** for now. You can go back and add them later if necessary.

7. Create a simple template that deploys a small machine with the ubuntu-16 operating system.

The screenshot shows the VMware Aria Automation interface. At the top, there are tabs: Resources, Design (which is selected), Infrastructure, and Extensibility. Below the tabs, there's a 'GUIDED SETUP' button. The main area is titled 'Templates' with a sub-section 'New Template'. The 'New Template' dialog box is open, prompting for a 'Name' (e.g. Template1), a 'Description' (empty), and a 'Project' (Search for a project). It also includes sharing options: 'Share only with this project' (selected) and 'Allow an administrator to share with any project in this organization'. At the bottom of the dialog are 'CANCEL' and 'CREATE' buttons. To the right of the dialog, a 'GUIDED SETUP' sidebar provides an overview of templates, steps for creating a new template, and a YAML code example.

GUIDED SETUP

TEMPLATES

Templates are specifications for the resources that you deploy. You can continuously improve a Template after you deploy it.

- 1 Click **New from - blank canvas**.
- 2 Enter a name, select a project, and click **Create**.
The Template and project examples in this setup are *CloudTemplate-1* and *dev-basic*.
- 3 Drag components to the canvas.
For example, a **Cloud Agnostic > Machine** is a cloud-neutral virtual machine that can deploy to any cloud vendor.
- 4 Edit the code to configure properties.
For example, the YAML code below adds a flavor size and operating system image to the cloud-neutral virtual machine.

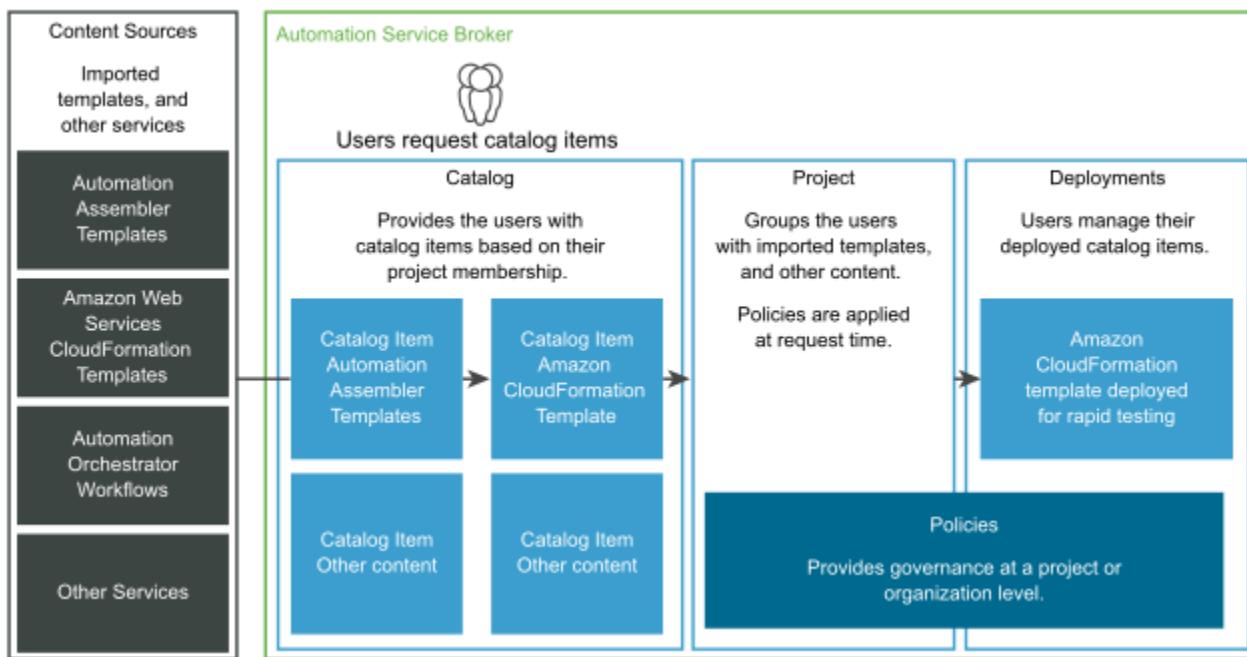

```
resources:
  Cloud_Machine_1:
    type: Cloud.Machine
    properties:
      flavor: StdSmall_1_2
      image: ubuntu-16
```

8. Check on your deployed cloud template.

The screenshot shows the VMware Aria Automation interface. On the left, there's a navigation bar with tabs: Resources (selected), Design, Infrastructure, and Extensibility. Below the navigation is a sidebar with icons for search, refresh, and deployment status. The main area is titled "Deployments" and shows a list of 30 items out of 303. The list includes entries like "tes ldap", "aws-vm-with-new-disk-and-network_58baa...", and "aws-disk-2". Each entry has a small icon, a name, and an address. A search bar at the top says "Search deployments". To the right, a modal window titled "Guided Setup Overview" is open, showing a section titled "Deployments" which describes how to monitor request status, troubleshoot failed requests, and manage deployed resources.

What does Automation Service Broker do

Automation Service Broker provides a simplified and efficient catalog that you provide to your users. You use the catalog to manage the available catalog items and how and where they are deployed.

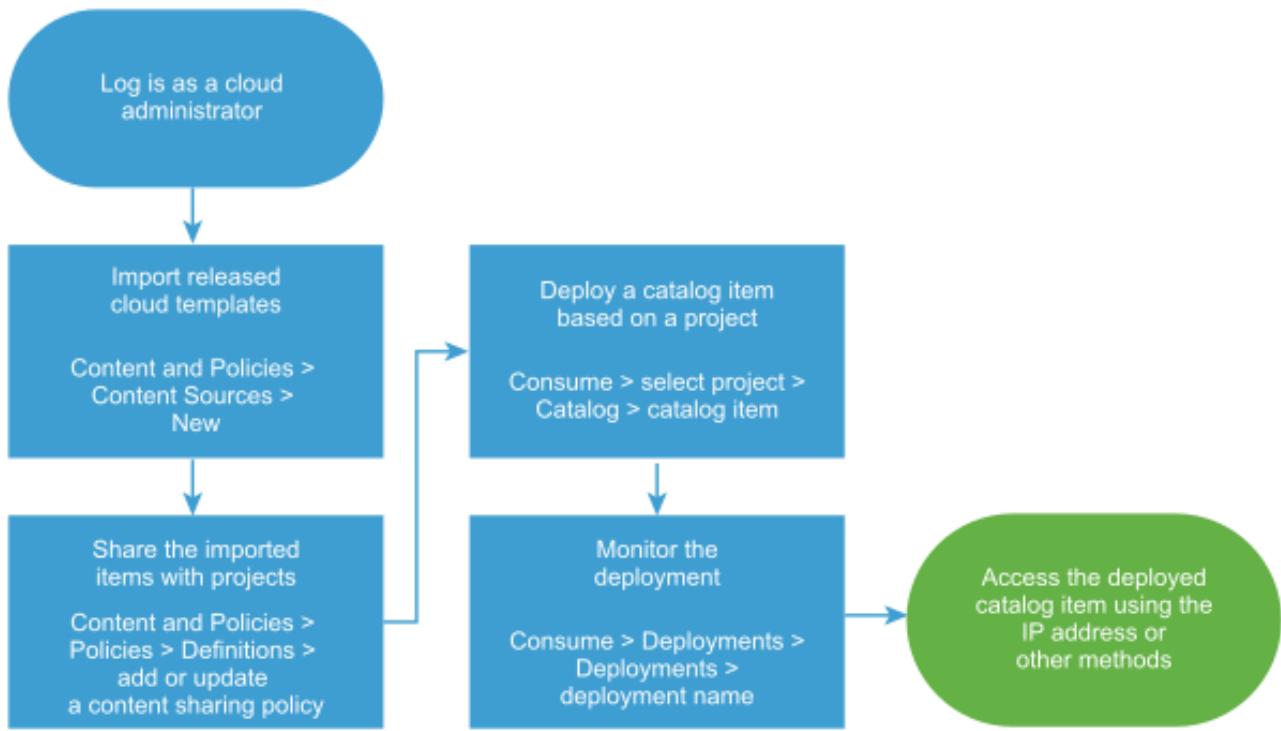

For an Automation Service Broker administrator, generally referred to as a cloud administrator, Automation Service Broker is the streamlined user interface that you provide to your development operations and other teams. You import the machine and application templates that you need, and add governance in the form of projects to control who can deploy what resources, and to control where the resources are deployed.

How do I set up Automation Service Broker

To set up and verify your Automation Service Broker instance, you import known working content from outside sources to make them available in the catalog, and then deploy catalog items to ensure that they are working.

- Log in as a cloud administrator.
- Verify that the templates that you are importing are deployable and released in Automation Assembler before you import it. See [How to save different versions of a cloud template](#) in *Using Automation Assembler*.

As a cloud administrator, this is your first time using Automation Service Broker and you want to set it up, import content, and then deploy the content to ensure that you can connect to your cloud vendors before fully populating the catalog and inviting other users to join the service.

In this use case, you import released Automation Assembler templates. You can also import Amazon CloudFormation templates, but the process is not presented here. See [Add CloudFormation Templates to the Automation Service Broker Catalog](#) in *Using Automation Service Broker*.

1. Import templates.

The screenshot shows the 'Content & Policies' section of the VMware Aria Automation interface. On the left, a sidebar lists 'Content Sources', 'Content', 'Policies' (with 'Definitions' and 'Enforcement' sub-options), and 'Notifications' (with 'Email Server' and 'Scenarios' sub-options). The main area is titled 'New Content Source'. It has fields for 'Type' (set to 'VMware Cloud Templates'), 'Name' ('PersonnelAppImport'), and 'Description'. Below these, a section titled 'Get cloud templates from' includes a 'Source project' dropdown set to 'PersonnelAppDev'. A validation message box indicates 'Content source validated successfully. 2 items found.' At the bottom, there are 'CREATE & IMPORT' and 'CANCEL' buttons.

- a) Select **Content and Policies** > **Content Sources**, and then click **New**.
 - b) Click **Template** and enter a name for the source.
 - c) Select the **Source Project** that is associated with your Automation Assembler templates and click **Validate**.
The process verifies the connection and tells you the number of templates that will be imported
 - d) Click **Create and Import**.
2. Share the imported templates with a project.

Automation Assembler templates are associated with projects when they are created in Automation Assembler. Projects include a group of users and the account regions where the templates are deployed. In Automation Service Broker, you can share the templates with other users, but you must ensure that the target projects include

the account regions with the cloud resources to support the deployment.

New Policy

Content sharing policies control users access to catalog items. ⓘ

After you create or modify this policy, enforcement can take up to five minutes.

Type: Content Sharing

Name *: Content Sharing Policy for PersonnelApp 2.b

Description:

Scope *: PersonnelAppDev 2.c

Content sharing *: + ADD ITEMS X REMOVE ? 2.d

No items added

Share Items with PersonnelAppDev

Select the templates to share with the project members. ⓘ

ALL CONTENT 2.e	Filter...	
<input type="checkbox"/> Name	Description	Content Source
<input type="checkbox"/> Basic Linux machine for testing		PersonnelAppImport
<input checked="" type="checkbox"/> WebApp for Personnel 2.f		PersonnelAppImport
1 items selected of 2 items		

CANCEL SAVE

- a) Select **Content and Policies** > **Policies** > **Definitions**, and create a new content sharing policy.
 - b) Enter a name for the content sharing policy.
 - c) In the **Scope** list, select the target project.
 - d) In the **Content sharing** section, click **Add Items**.
 - e) To select only particular templates, select **All Content** in the **Content Sources** drop-down menu.
 - f) Select the templates to share with the project, and click **Save**.
 - g) In the **Users** section, select the users and user groups that you want to have access to the templates.
 - h) Click **Create**.
- The list for the project now includes the templates and the imported templates are available in the catalog.

3. Deploy an imported template.

Catalog Items 20 items of many

SUBMIT **CANCEL**

- a) Click **Consume > Catalog**.
- b) Locate the card for the template that you want to deploy and click **Request** on the card.
- c) Complete the request form and click **Submit**.

The deployment process begins.

4. Monitor the deployment.

The screenshot shows the VMware Aria Automation interface. At the top, there's a navigation bar with 'Deployments' and a search bar. Below it, a deployment card for 'webApp for Perso...' is shown, indicating 'Create - In Progress' with 5 / 7 Tasks completed, submitted 13 minutes ago. This card is part of a larger 'Deployments' list. A modal window titled 'Deployments' shows the successful creation of the deployment with 2 Resources (Cloud_Machine_1-mcm3...) and a status of 'On'. The main view then displays the details of the deployment, including its summary (Requestor: fritz, Project: PersonnelAppDev, Cloud Template: Web App dev), topology (a network diagram with nodes like 'Cloud_Network...' and 'Cloud_Machine_1'), and a detailed view of the machine 'Cloud_Machine_1' with fields like Resource name, Account / Region, Status, Address, and Compute host.

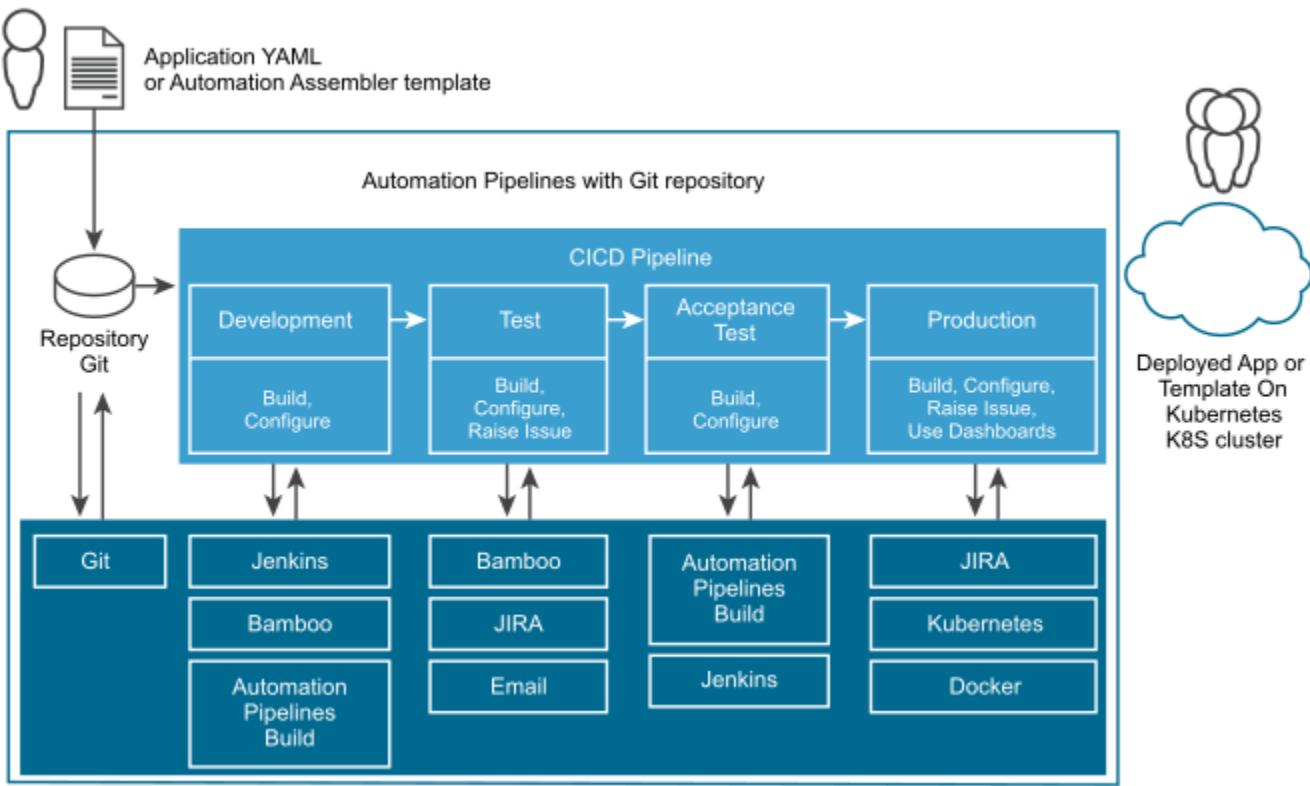

- Select **Consume** > **Deployments** > **Deployments**, and then use the search and filter options to locate the deployed catalog item.
 - When the deployment is completed, locate the IP address on the card or by clicking the name and viewing the details.
5. Access the deployed workload and verify that it is working.

The deployment might be an application or a single machine.

What does Automation Pipelines do

Automation Pipelines models the tasks in your software release process, automates the development and test of developer code, and releases it to your production environment.

It integrates your release process with developer tools to accomplish specific tasks, and tracks all code artifacts and versions.

You create a pipeline that runs actions to build, deploy, test, and release your software. Automation Pipelines runs your software through each stage of the pipeline until it is ready to be released to production.

You integrate your pipeline with one or more DevOps tools such as data sources, repositories, or notification systems, which provide data for the pipeline to run.

For example, you might need to use several endpoints in a pipeline that downloads and deploys a Kubernetes application from GitHub to a Kubernetes cluster.

The screenshot shows the VMware Aria Automation 8.18 Pipelines interface. At the top left, it says "Pipelines 45 items". Below that are "NEW PIPELINE" and "IMPORT" buttons. To the right is a search bar with a magnifying glass icon and a refresh/circular arrow icon.

The main area contains 12 pipeline cards arranged in three rows of four:

- Row 1:**
 - RestPipeline**: Status: Enabled. No description. Updated By: j. Created By: j. 2 EXECUTIONS (dot progress bar). RUN OPEN ACTIONS ▾.
 - Blue-GreenDeployment**: Status: Enabled. No description. Updated By: j. Created By: j. 0 EXECUTIONS. RUN OPEN ACTIONS ▾.
 - Canary-Deployment-Strategy**: Status: Enabled. No description. Updated By: j. Created By: j. 0 EXECUTIONS. RUN OPEN ACTIONS ▾.
 - RollingUpdate Deployment**: Status: Enabled. No description. Updated By: j. Created By: j. 0 EXECUTIONS. RUN OPEN ACTIONS ▾.
- Row 2:**
 - MyKubeApp**: Status: Enabled. No description. Updated By: ker. Created By: ker. 1 EXECUTIONS (dot progress bar). RUN OPEN ACTIONS ▾.
 - TestBlueprint**: Status: Enabled. No description. Updated By: s. Created By: s. 3 EXECUTIONS (dot progress bar). RUN OPEN ACTIONS ▾.
 - Test_m**: Status: Disabled. No description. Updated By: -. Created By: m. 0 EXECUTIONS. ENABLE OPEN ACTIONS ▾.
 - भया**: Status: Enabled. No description. Updated By: b. Created By: b. 12 EXECUTIONS (dot progress bar). RUN OPEN ACTIONS ▾.
- Row 3:**
 - test-pipeline**: Status: Enabled. No description. Updated By: tan. Created By: tan. 0 EXECUTIONS. RUN OPEN ACTIONS ▾.
 - M_Test_PL1**: Status: Enabled. No description. Updated By: tan. Created By: tan. 0 EXECUTIONS. RUN OPEN ACTIONS ▾.
 - K8s-Test-1**: Status: Enabled. No description. Updated By: tan. Created By: tan. 0 EXECUTIONS. RUN OPEN ACTIONS ▾.
 - pipeline-service-master**: Status: Disabled. 1 EXECUTION (dot progress bar). tan. RUN OPEN ACTIONS ▾.

Automation Pipelines integrates with various endpoint types.

Table 1: Automation Pipelines Integrates with DevOps Tools

Endpoint	What it does
Git	Pulls developer code from the repository and works with the Git trigger to trigger pipelines when developers check in code.
Kubernetes	Automates the steps to deploy, scale, and manage containerized applications.
Automation Pipelines Build	Creates native builds for continuous integration instead of using third-party integrations.
Jenkins	Builds code artifacts.
Email	Sends notifications to users.
JIRA	Creates a ticket when a pipeline fails.
Bugzilla	Creates and tracks bugs.

Why You Use Automation Pipelines

As a Automation Pipelines administrator or developer, you use Automation Pipelines to automate your entire DevOps release lifecycle, while you continue to use your existing development tools. Automation Pipelines gives you:

- Easy automation
- Out-of-the-box plug-ins that work without open source
- Simple modeling experience and pipeline as code

- Straightforward integration with VMware Tanzu Kubernetes Grid Integrated Edition (formerly known as VMware Enterprise PKS)
- Reporting and insights
- End-to-end visibility with detailed dashboards
- Custom dashboards
- DevOps metrics and insights
- Governance
- Role-based access
- Secret and restricted variables, and approvals
- Projects

Automation Pipelines simplifies the deployment of software applications as your source code runs through the development and test phases, and is released to production. It also increases your productivity by using the Git trigger. When a developer checks in code, Automation Pipelines can trigger the pipeline and automate the build, test, and deployment of your application.

You can use Automation Pipelines with other VMware Aria Automation components.

- Deploy a Automation Assembler cloud template, and use the parameter values that the cloud template exposes.
- Publish your pipeline to Automation Service Broker so that other members of your team can request and deploy it to their cloud regions.

How Do I Set Up Automation Pipelines

How Do I Set It Up

As an administrator who sets up Automation Pipelines, after you log in, you can add endpoints, create and run pipelines, and view the results.

- Verify that a GitLab repository or a GitHub repository exists on premises, and contains the code that your pipeline will use.

Automation Pipelines connects to endpoints to obtain data for your pipelines to run. In this use case, Automation Pipelines connects to a GitLab repository so that your pipeline can download a Kubernetes file.

A getting started process is also available as a guided setup in the Automation Pipelines user interface. Click the **Help** icon and click **Guided Setup**.

1. Add a Git endpoint that connects Automation Pipelines to your on-premises GitLab repository.
 - a) Click **Endpoints**.
 - b) Select the Git endpoint type, and enter a name and description.
 - c) Enter the remaining information.
 - d) To test the connection to the endpoint, click **Validate**, then save the endpoint.
2. Click **Pipelines**, create a pipeline, and add a task that uses the Git endpoint. You can optionally add an email notification.

MyKubeApp4 Disabled

SAVE RUN CLOSE Last saved: a year ago

- Save your pipeline, then click **Enable**, which enables it to run.

4. After you enable the pipeline, click **Run**.
5. Click **Executions**, and observe your pipeline as it runs.

6. If the pipeline fails, correct the problem and run it again.
7. Click **Dashboards**, and select your pipeline dashboard so that you can monitor the pipeline activity.

Your pipeline ran, and downloaded the developer file from a GitLab instance. The pipeline task deployed the application to a Kubernetes cluster, and you monitored all the activity on the pipeline dashboard.

To learn more about using Automation Pipelines, see [What is Automation Pipelines and how does it work](#).

If you don't find the information you need here, you can get more help in the product.

- To get the context-specific information, when and where you need it, click and read the signposts and tooltips in the user interface.
- Open the In-product support panel and read the topics that appear for the active user interface page. To get answers to questions, you can also search in the panel.

What else can I do with VMware Aria Automation

What else can I do

As a cloud administrator or developer, you can learn more about VMware Aria Automation services.

More resources for administrators

As a cloud administrator, you:

- Provide cloud templates to your developers and manage cloud resources in Automation Assembler. If it suits your organization, you can delegate the cloud template creation to project members, or you can create them yourself.
- Provide a catalog of resources in Automation Service Broker that your developers use to create development, test, and production environments.
- Create more complex pipelines that model and automate the steps in your DevOps release lifecycle in Automation Pipelines.

Using Automation Assembler

You use VMware Aria Automation Assembler to connect to your public and private cloud providers so that you can deploy machines, applications, and services that you create to those resources. You and your teams develop cloud-templates-as-code in an environment that supports an iterative workflow, from development to testing to production. At provisioning time, you can deploy across a range of cloud vendors. The service is a managed VMware SaaS and NaaS-based framework.

How to use Automation Assembler

An overview of Automation Assembler includes the following basic functions.

- The Home tab shows a summary of your resources, deployments, and other inventory currently managed by VMware Aria Automation, as well as pending notifications and action items. This tab is available to Assembler Administrators only.
- The Resources tab shows the current status of your provisioned, discovered, onboarded, and other resources. You can access resource details and day 2 actions that you use to manage your resources.
- The Design tab is your development home. You use the canvas and the YAML editor to develop and then deploy your machines and applications.
- The Infrastructure tab is where you add and organize your cloud vendor resources and users. This tab also provides information about deployed cloud templates.
- The Extensibility tab is where you can extend and automate your application life cycles. You can subscribe to events that are used to trigger extensibility actions or VMware Aria Automation Orchestrator workflows.
- An Alerts tab provides notifications regarding capacity, performance, and availability for your infrastructure resources. You must have a configured integration with VMware Aria Operations to see and use the alerts.
- The Tenant Management tab shows the different tenants that you configured if you are a service provider and enables you allocate or de-allocate virtual private zones.

How does Automation Assembler work

Automation Assembler is a cloud template development and deployment service. You and your teams use the service to deploy machines, applications, and services to your cloud vendor resources.

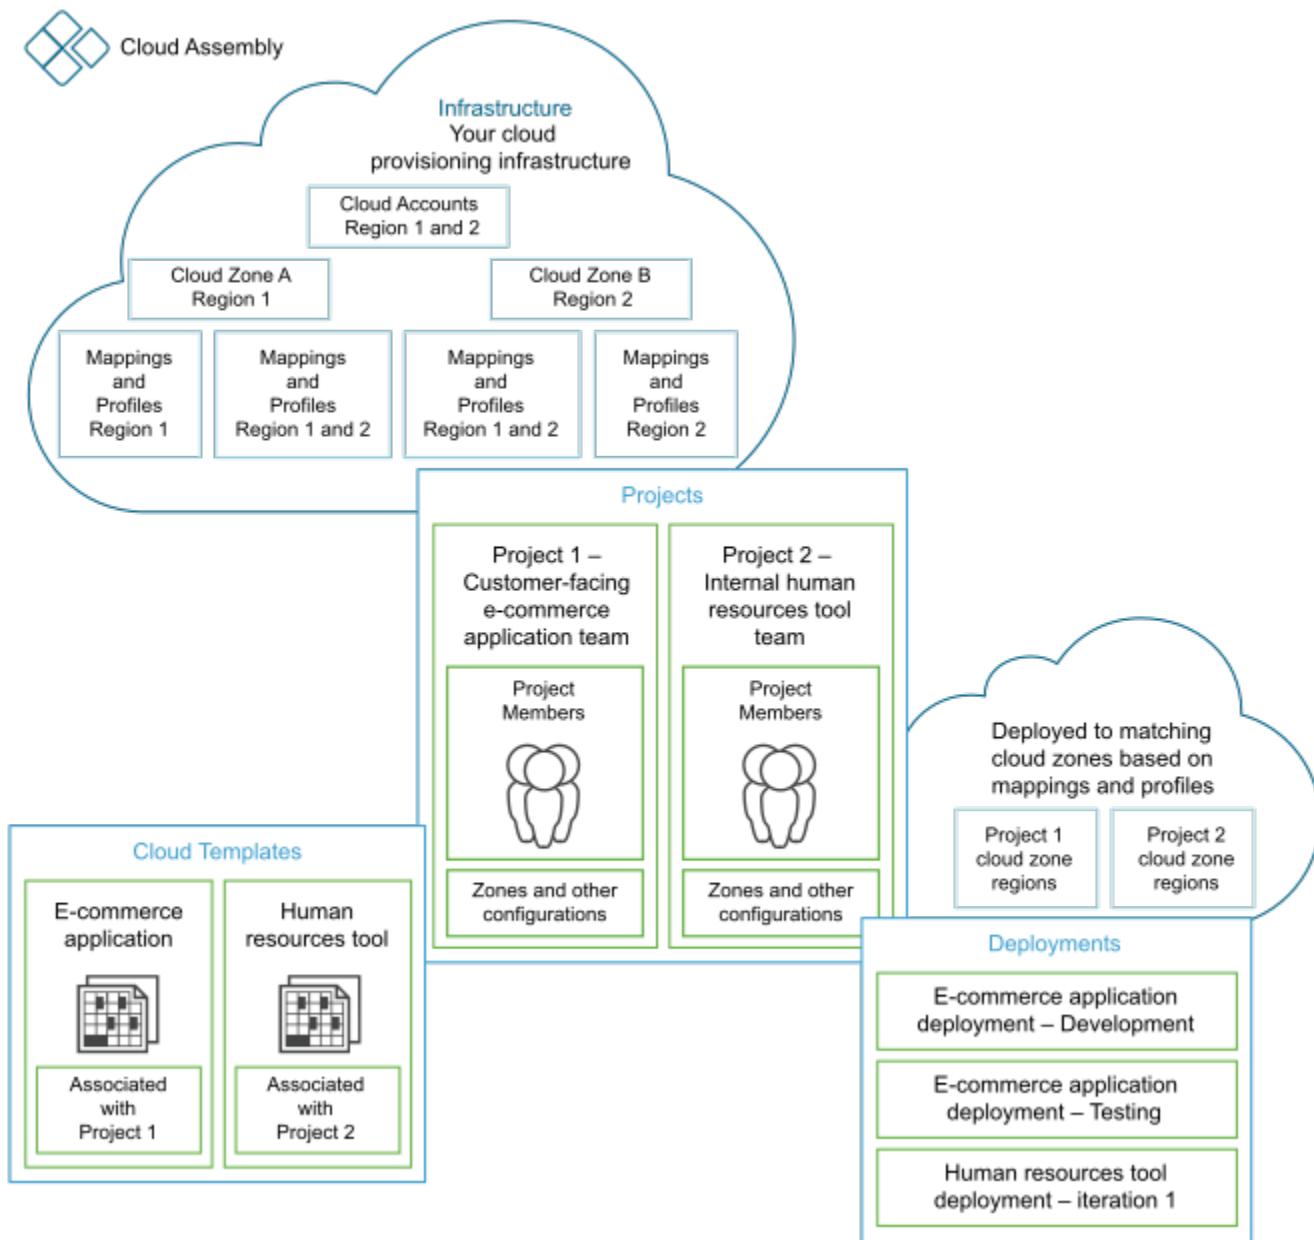

As an Automation Assembler administrator, generally referred to as a cloud administrator, you set up the provisioning infrastructure and create the projects that group users and resources.

- Add your cloud vendor accounts. See [Adding cloud accounts to](#).
- Determine which regions or datastores are the cloud zones that you want your developers deploying to. See [Learn more about cloud zones](#).
- Create policies that define the cloud zones. See [Building your resource infrastructure](#).
- Create projects that group the developers with the cloud zones. See [Using project tags and custom properties](#).

As a cloud template developer, you are a member of one or more projects. You create and deploy templates to the cloud zones associated with one of your projects.

- Develop cloud templates for projects by using the design canvas. See [Getting started with creating and designing cloud templates in](#).
- Deploy your cloud templates to project cloud zones based on policies and constraints.
- Manage your deployments, including deleting unused applications. See [Managing deployments](#).

Welcome to Automation Assembler. If you want an example of how to define the infrastructure, and then create and deploy a cloud template, see [Tutorial: Setting up and testing multi-cloud infrastructure and deployments in](#).

Automation Assembler Tutorials

Tutorials

The tutorials show you how to perform common tasks that help you become proficient with Automation Assembler.

As you begin, a reminder that in addition to the steps in the tutorials, there is additional information in this guide. Links are provided to relevant topics.

Accessing user assistance

Equally important, user assistance is provided throughout the application. The user assistance helps you understand features and provides information that helps you make decisions about how to populate text boxes. The external documentation provides greater depth, code samples, and use cases.

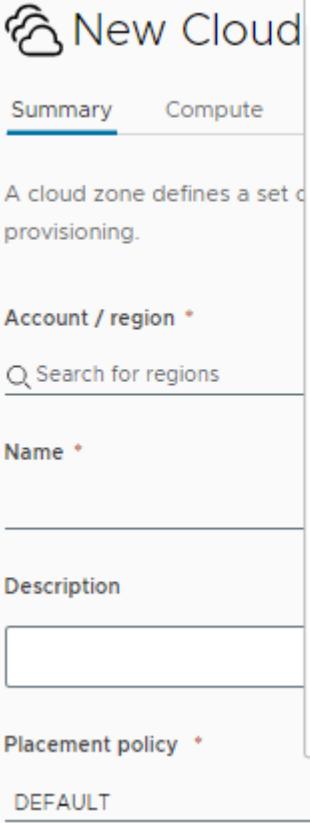

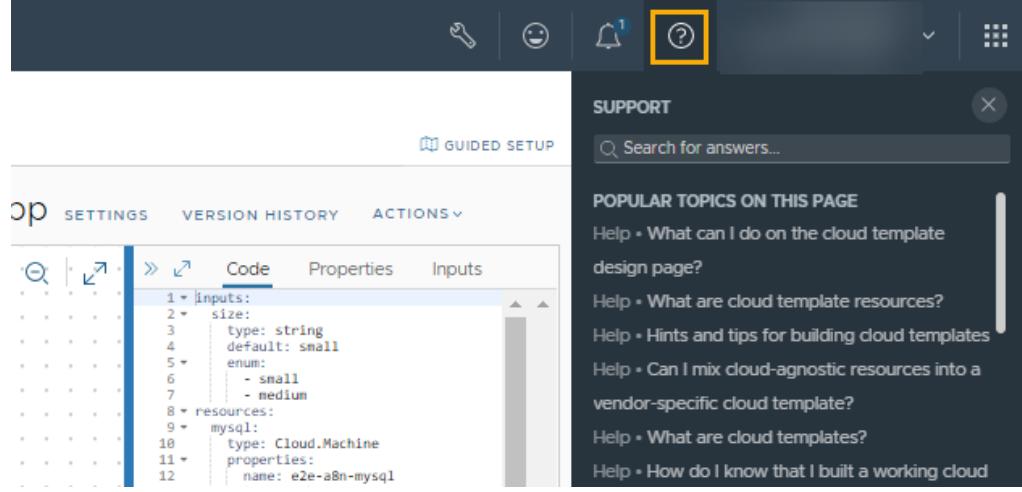

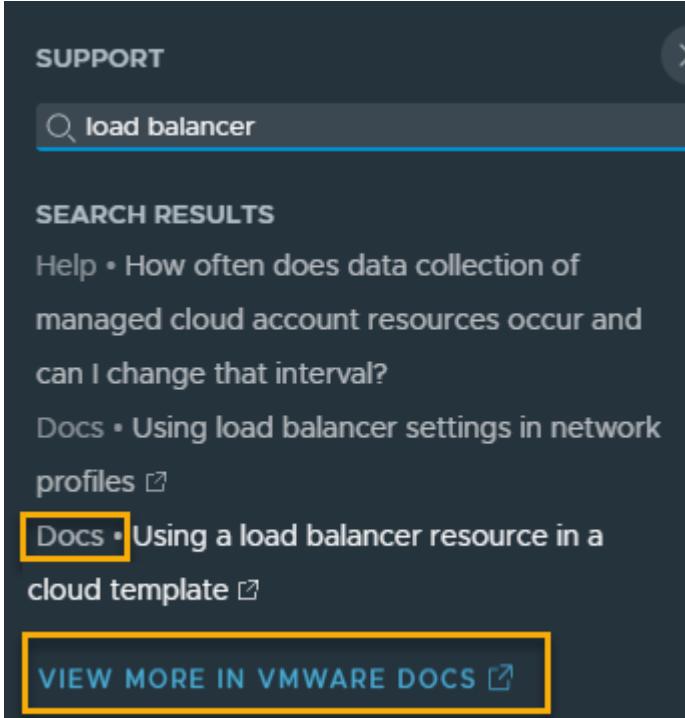

Assistance type	How to access assistance	Example
Field-level signpost help	Click the Info icon (ⓘ) beside a field.	 <p>The screenshot shows the 'New Cloud' configuration page. The 'Placement policy' dropdown is open, displaying a tooltip with the title 'Placement Policy'. The tooltip contains instructions on applying placement strategies and a list of options: DEFAULT, BINPACK, SPREAD, and SPREAD BY MEMORY. The 'DEFAULT' option is selected.</p>
Contextual support panel help	Click the Help icon (ⓘ) beside your name and organization.	 <p>The screenshot shows the VMware Aria Automation interface. At the top, there is a dark header bar with several icons, including a question mark icon. Below the header is a 'GUIDED SETUP' section. On the right side, there is a 'SUPPORT' panel titled 'POPULAR TOPICS ON THIS PAGE' with a search bar and a list of links related to cloud templates and resources.</p>

Table continued on next page

Continued from previous page

Assistance type	How to access assistance	Example
Access the external documentation	Click an article title that is labeled Docs or click the View More in VMware Docs.	 <p>The screenshot shows the VMware Aria Automation support interface. At the top, it says "SUPPORT". Below that is a search bar with the text "load balancer". Under "SEARCH RESULTS", there are two items: "Help • How often does data collection of managed cloud account resources occur and can I change that interval?" and "Docs • Using load balancer settings in network profiles". The second item is highlighted with a yellow box. Below that is another item: "Docs • Using a load balancer resource in a cloud template". This item is also highlighted with a yellow box. At the bottom, there is a button labeled "VIEW MORE IN VMWARE DOCS" with a yellow border.</p>

Tutorial: Deploying a virtual machine in Automation Assembler

Deploying a virtual machine

As an Automation Assembler administrator, you can deploy a simple virtual machine that does not require that you know how to create a cloud template. If you are new to Automation Assembler this tutorial guides you through the set up process, creating the virtual machine, and shows you where to manage the deployed machine.

This method is an easy way to quickly deploy a machine based on image templates, sizing flavors, storage, and networks defined by the cloud provider. It is a quick test of your cloud account and projects.

You can create a virtual machine for any of the following cloud services providers.

- Amazon Web Services
- Google Cloud Platform
- Microsoft Azure
- vCenter Server
- VMware Cloud on AWS

The Google Cloud Platform is the example in this tutorial.

Before you begin

- Verify that you have the Assembler Administrator role. See [Organization and service user roles](#). If you do not have this user role, you do not even see the option create a new VM.
- Verify that catalog users can deploy simple virtual machines. The Create New Resource option on the **Infrastructure** > **Settings** page must be activated.

Step 1: Add a cloud account

The cloud accounts provide the credentials that Automation Assembler uses to connect to the cloud provider.

1. Select **Infrastructure > Connections > Cloud Accounts**.
2. Click **Add Cloud Account** and select the account type.

You can access the configuration details using the following links.

- Amazon Web Services
- Google Cloud Platform
- Microsoft Azure
- vCenter Server
- Cloud on AWS

After you add the cloud account, Automation Assembler collects resource information from the target cloud provider account that you later use to deploy a virtual machine.

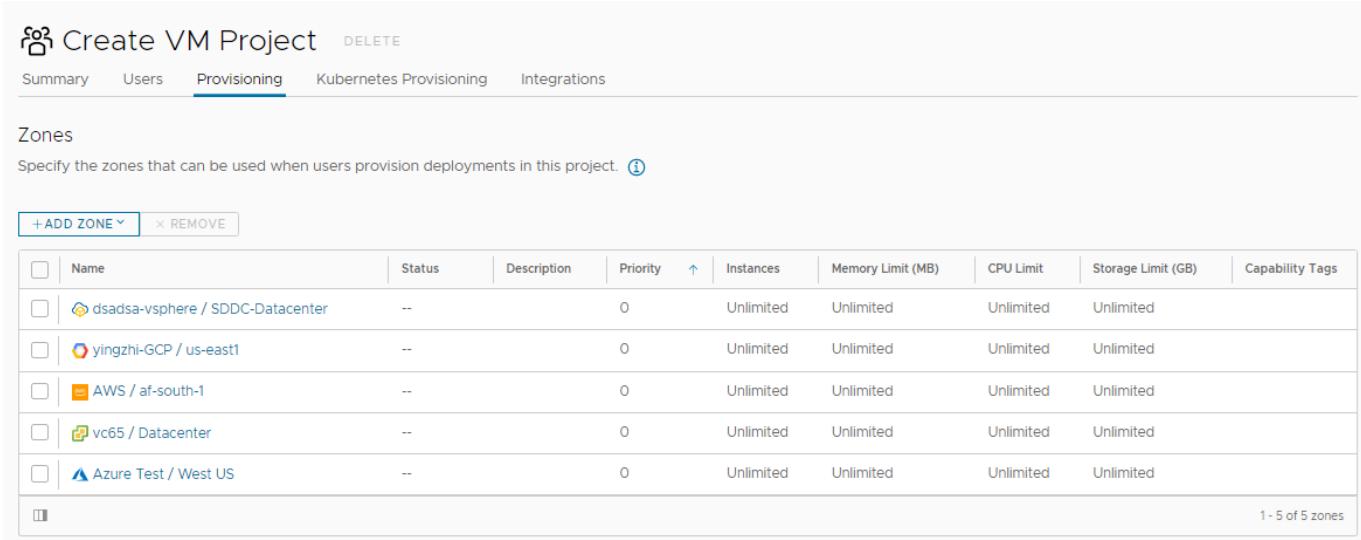

Step 2: Create a project

The project associates the users and the cloud account cloud zones.

In this tutorial, the project name is Create VM Project. This project is a demonstration project that includes cloud zones for all the supported platforms.

1. Select **Infrastructure > Administration > Projects**.
2. Click **New Project**.
3. Enter a name.
In this tutorial, the name is Create VM Project.
4. If you want other to use this project, click the **Users** tab and add any users to the project.
5. Click the **Provisioning** tab and click **Add Zone** to add at least one cloud zone for the cloud accounts that you are deploying to.

Remember, this is a demonstration project that includes a cloud zone for each support cloud vendor platform.

The screenshot shows the 'Create VM Project' interface. At the top, there are tabs for Summary, Users, **Provisioning**, Kubernetes Provisioning, and Integrations. The Provisioning tab is selected. Below the tabs, there's a section titled 'Zones' with the sub-instruction: 'Specify the zones that can be used when users provision deployments in this project.' There are two buttons: '+ADD ZONE' and 'REMOVE'. A table lists five cloud zones:

Name	Status	Description	Priority	Instances	Memory Limit (MB)	CPU Limit	Storage Limit (GB)	Capability Tags
dsadsa-vsphere / SDDC-Datacenter	--		0	Unlimited	Unlimited	Unlimited	Unlimited	
yingzhi-GCP / us-east1	--		0	Unlimited	Unlimited	Unlimited	Unlimited	
AWS / af-south-1	--		0	Unlimited	Unlimited	Unlimited	Unlimited	
vc65 / Datacenter	--		0	Unlimited	Unlimited	Unlimited	Unlimited	
Azure Test / West US	--		0	Unlimited	Unlimited	Unlimited	Unlimited	

At the bottom right of the table, it says '1 - 5 of 5 zones'.

6. Click **Create**.

Step 3: Create and deploy a virtual machine

1. Select **Resources** > **Virtual Machines** > **Managed**, and then click **New VM**.
2. Configure the required settings on the General page of the wizard and click **Next**.

This tutorial uses Google Cloud Platform as the cloud account where you want to deploy the virtual machine.

The screenshot shows the 'General' configuration page for creating a new VM. It includes fields for Name (Google Cloud Create VM), Project (Create VM Project), Cloud zone (yingzhi-GCP / us-east1), and Tags. Below each field is a brief description. At the bottom are 'NEXT' and 'CANCEL' buttons.

Setting	Sample Value
Name	Google Cloud Create VM
Project	Create VM Project
Cloud zone	yingzhi-GCP/us-east1

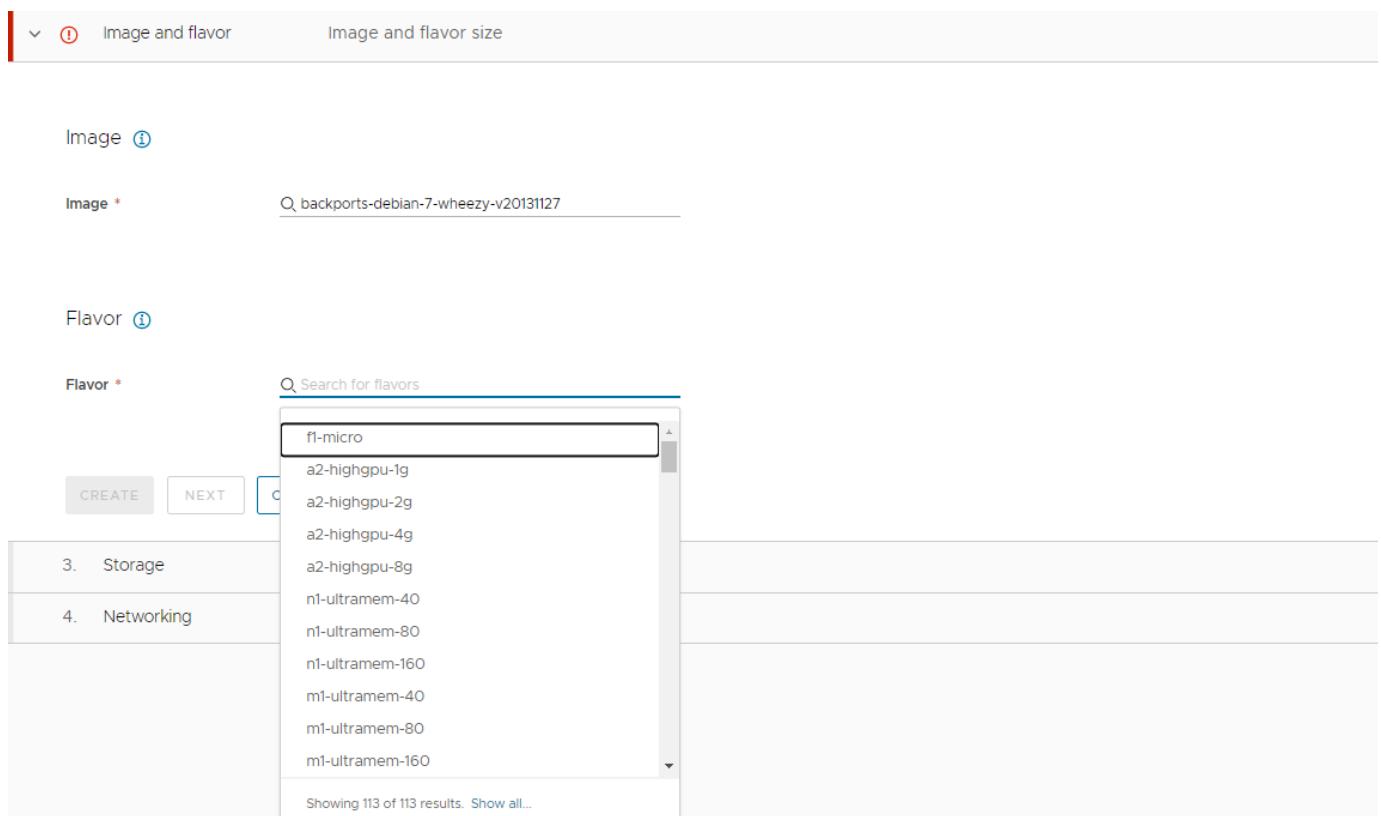

Remember that these values are samples only. Your values must be specific to your environment.

Table 2: Sample values for the first wizard page

Setting	Sample Value
Name	Google Cloud Create VM
Project	Create VM Project
Cloud zone	yingzhi-GCP/us-east1

3. Select the image and flavor that are used to create the virtual machine.

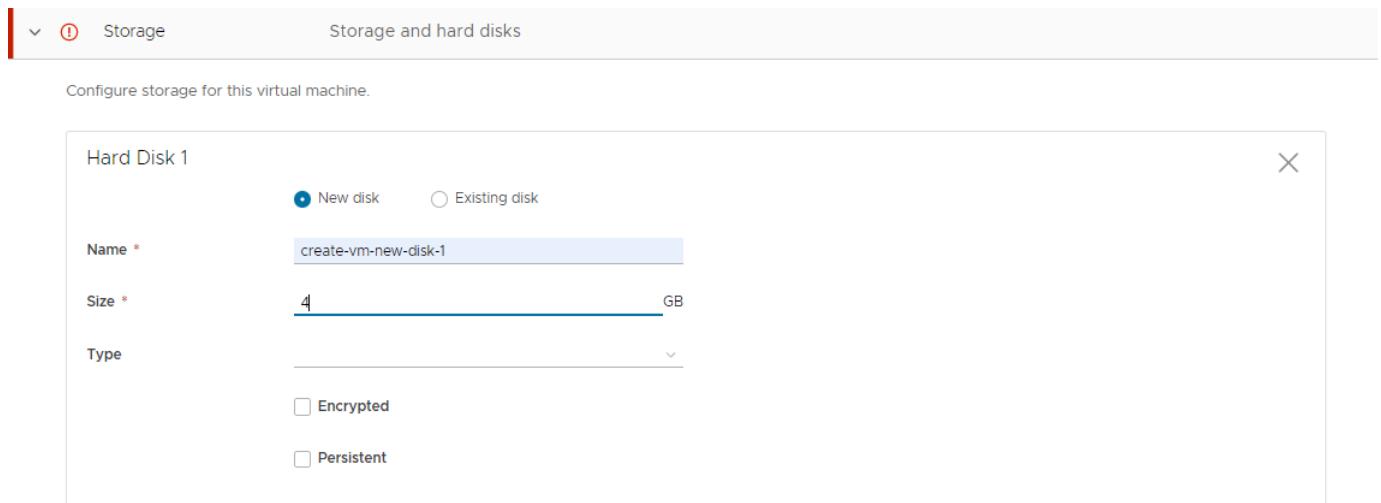

The available values are collected from the target cloud zone. The image is the operating system and the flavor is the defined size options. Some target provider types require you to specify the CPU and memory. This target requires you to select from the defined options.

4. Click **Next**.

To deploy only the machine, click **Create**. For this tutorial, click **Next** to add the optional storage and network for this virtual machine.

5. To add a new disk, click **Add hard disk** and enter a **Name** and **Size**.

6. Click **Next**.

7. To add a network adapter, click **Add network adapter**.

8. Select from the search results.

Configure networking for your virtual machine.

Network Adapter 1

Network * default

Advanced

+ ADD NETWORK ADAPTER

CREATE **CANCEL**

9. Click **Create**.

Your view switches to the Deployments page so that you can monitor the progress of the deployment.

Step 4: Manage the new virtual machine as a deployment

When the deployment process is completed successfully, you can begin managing the deployment.

For more about managing your deployments, see [Managing deployments](#).

For a list of all possible day 2 actions on all resource types, see [What actions can I run on deployments or supported resources](#).

1. Select **Resources > Deployments** and locate your virtual machine.

In this tutorial, the deployment name is Google Cloud Create VM.

2. To run an allowed deployment-level action on the deployment from this view, click the vertical ellipsis and select the action.

	Name	Address	Owner	Project	Status	Expires on	Price
>	gcp_811d09ff-efe1-4da4-a949-5be9ab62c...	@vmware.com	Create VM Project	Never			
>	Google Cloud Create VM_6f6d0315-ddc8-4...	@vmware.com	Create VM Project	Never			
>	Actions						
>	Change Lease						
>	Change Owner						
>	Change Project						
>	e-f792-43d5-885d-2b45e...	@vmware.com	Create VM Project	Never			
>	-South	@vmware.com	Sales	Never			
>		@vmware.com	Sales	Never			

3. To learn more about the deployment, including the topology, click the deployment name.

Notice that the topology of this deployment is simple. More complex deployments also provide the complete topology that might include machines, load balancers, network connections, and other components.

You can also view the deployment history, which is a log of all the actions on the deployment components, and run allowed machine-level actions.

The screenshot shows the VMware Aria Automation interface for managing a virtual machine. At the top, there's a header with the title "Google Cloud Create VM_6f6d0315-ddc8-4f5d..." and a "Create Successful" button. Below the header, there's a summary section with details like Owner (cnugent@vmware.com), Requestor, Project (Create VM Project), and timestamps for Last updated and Created on. The main area is divided into Topology and History tabs, with the Topology tab selected. On the right, there's a detailed view of the VM's General and Storage sections. The General section includes fields for Resource name (mcm-20211203215331-000020), Account / Region (yingzhi-GCP/us-east1), Status (On), Address (34.74.168.22), and Compute host (us-east1-b). The Storage section lists two disk volumes: "create-vm-new-disk-1-524598563851" (Capacity 4 GB, Type HDD, Encrypted true) and "mcm-20211203215331-000020" (Capacity 10 GB, Type HDD, Encrypted true). A large green box highlights the "Actions" dropdown menu on the right side of the screen, which contains options like Add Disk, Create Snapshot, Delete, Power Off, Resize, and Resize Boot Disk. A cursor is pointing at the "Resize" option.

Step 5: Manage the new virtual machine as a resource

In addition to managing the virtual machine as a deployment, you can also manage it along with the other resources. Resources can include deployed, discovered, and onboarded virtual machines, storage volumes, and network and security resources.

Discovered resources are those that are collected from the cloud instance. You can manage discovered resources with a limited set of day 2 actions, such as power on and power off. For more information about working with discovered resources, see [How do I work with discovered resources](#).

Onboarded resources are discovered resources that you brought under full management. They can be managed with the more robust day 2 action options. For more information about how to onboard discovered resources, see [What are onboarding plans in](#).

As you work with this deployed machine, it is eligible for more day 2 actions. The availability of the actions depends on the state of the machine and what day 2 actions you have permission to run.

1. Select **Resources > Virtual Machines > Managed**.
2. Locate the machine.

Virtual Machines ▾

Discovered Managed

Managed machines are those under full VMware Aria Automation management so that you can run day 2 actions. The managed machines included onboarded or deployed machines. Click New VM if you want to deploy a VM based on your current cloud provider OS image and size flavors.

	Name	Deployment	VM State	Account / Region	Address	Project
»	vm-administrator-VL... [⋮]		▶ On	https://cmbu-w01-vc08.eng.vmware.com / w01-vc08...

Tutorial: Setting up and testing vSphere infrastructure and deployments in Automation Assembler

Setting up and testing vSphere infrastructure and deployments

If you are new to VMware Aria Automation or only need a refresher course, this tutorial guides you through the Automation Assembler configuration process. You add cloud vSphere account endpoints, define the infrastructure, add users to projects, and then design and deploy a workload by using VMware Cloud Templates based on vSphere resource types, learning the process along the way.

Although this tutorial is just the beginning, you are on the path to delivering self-service automation and iterative development that works across multiple public and private clouds. This tutorial focuses on VMware vCenter and NSX-T. After you finish this workflow, you can apply what you've learned to add more types of cloud accounts and deliver more sophisticated cloud templates.

As you work your way through the steps, we provide data examples. Replace the examples with values that work in your environment.

You perform all the steps in this tutorial in Automation Assembler.

This configuration process is the foundation of your Automation Assembler development experience. As you build your infrastructure and mature your cloud template development skills, you will repeat and expand on this workflow.

What to do first

- Verify that you have the Automation Assembler Administrator role. See [Organization and service user roles in](#) .
- If you have not used the VMware vCenter or the VMware Cloud Foundation Quickstart wizards in the Automation console, you can do so now.

These wizard-driven workflows include most but not all of the configuration in this tutorial.

This tutorial is a hands-on experience that adds to your understanding of how to put together a working infrastructure and deploy a workload.

See [How do I set up Automation Assembler](#) in the *Getting Started* guide.

- If you have not yet used the guided setup that is available in Automation Assembler, you can do it now. The guided setup takes you through most but not all of the procedures that you do in this tutorial. To open the guided setup, click **Guided Setup** on the right side of the tab bar.
- Ensure that you have vCenter Server and NSX credentials. For more information about the permissions that the credentials must have, see [Credentials required for working with cloud accounts in](#) . If you plan to add additional users to projects, verify that they are members of the Automation Assembler service.

Step 1: Add the vCenter and NSX cloud accounts

The cloud accounts provide the credentials that VMware Aria Automation uses to connect to vCenter and the associated NSX server.

1. Add the vCenter Server cloud account.

The vCenter Server cloud account provides the vCenter credentials that Automation Assembler uses to discover resources and deploy cloud templates.

For additional information about vCenter cloud accounts, see [Create a basic cloud account in](#) .

- a. Select **Infrastructure > Connections > Cloud Accounts**.
- b. Click **Add Cloud Account** and select **vCenter**.
- c. Enter the values.

New Cloud Account

Name * vCenter Server Account

Description

vCenter Server Credentials

vCenter IP address / FQDN * sc2vc05.cmbu.local

Username * mgmt@cmbu.local

Password *

VALIDATE Credentials validated successfully. X

Configuration

Allow provisioning to these datacenters *

- wld01-DC
- Create a cloud zone for the selected datacenters

NSX cloud account Search for cloud accounts

Capabilities

ADD CANCEL

Remember that these values are only examples. Your values will be specific to your environment.

Setting	Sample Value
Name	vCenter Account
vCenter IP address / FQDN	your-dev-vcenter.company.com
Username and Password	vCenterCredentials@yourCompany.com

- d. To verify the credentials, click **Validate**.
 - e. To **Allow provisioning to these datacenters**, select one or more data centers.
 - f. Skip the NSX cloud account. We'll configure that later, linking the vCenter account to the NSX cloud account.
 - g. Click **Add**.
2. Add an associated NSX cloud account.
The NSX-T cloud account provides the NSX-T credentials that Automation Assembler uses to discover network resources and deploy networks with cloud templates.

For more information about NSX-T cloud accounts, see [Create a basic cloud account in](#) .

- a. Select **Infrastructure > Connections > Cloud Accounts**.
- b. Click **Add Cloud Account** and select either NSX-T or NSX-V. This tutorial uses **NSX-T**.
- c. Enter the values.

New Cloud Account

Name * NSX-T Account

Description

NSX-T Credentials

NSX-T IP address / FQDN * sc2vc05-vip-nsx-mgmt.cmbu.local 

Username * mgmt@cmbu.local

Capability tags 

ADD **CANCEL**

These values are only examples. Your values will be specific to your environment.

Setting	Sample Value
Name	NSX-T Account
vCenter IP address / FQDN	your-dev-NSX-vcenter.company.com
Username and Password	NSXCredentials@yourCompany.com
NSX mode	<p>Don't know what to select?</p> <p>Here's a great opportunity to use the in-product help. Click the information icon to the right of field. Notice that the field-level help includes information that can help you configure the option.</p> <p>In this example, select Policy.</p>

- d. To verify the credentials, click **Validate**.
- e. To associate the vCenter cloud account you created in the previous step, click **Add** and then select the **vCenter Account**.
This vCenter cloud account association ensures network security.
- f. On the NSX cloud account page, click **Add**.

Step 2: Define the cloud zone compute resources

The cloud zones are groups of compute resources in an account/region that are then made available to projects. The project members deploy cloud templates by using the resources in the assigned cloud zones. If you want to have more granular control over where project cloud templates are deployed, you can create multiple cloud zones with different compute resources.

Account/regions are how cloud vendors tie resources to isolated regions or datastores. The account indicates the cloud account type and the region indicates the region or datastore. vCenter uses datastores and the provisioning resources are the selected clusters and resource pools.

For this tutorial, you must ensure that the cloud zones include the resources that support the goals of the project development team, and your budget and management requirements.

For more information about cloud zones, see [Learn more about cloud zones](#).

1. Select **Infrastructure > Configure > Cloud Zones**.
2. Click the cloud zone that was added for your vCenter Server instance and enter the values.

vCenter Account Cloud Zone DELETE

Summary Compute Projects

A cloud zone defines a set of compute resources that can be used for provisioning.

Account / region *	vCenter Account / wld01-DC
Name *	vCenter Account Cloud Zone
Description	(Empty text area)
Placement policy *	DEFAULT
Folder	Select folder

Capabilities

Capability tags are effectively applied to all compute resources in this cloud zone, but only in the context of this cloud zone.

Capability tags	Enter capability tags	(Info icon)
-----------------	-----------------------	-------------

SAVE **CANCEL**

Setting	Sample Value
Account / region	vCenter Account / data center name
Name	vCenter Cloud Zone

Table continued on next page

Continued from previous page

Setting	Sample Value
	This value cannot be changed after you create it. If you want to configure a different data center for a different vCenter, you must create a new cloud zone where you can select the account/region.
Description	All vCenter compute resources for development.
Policy	Default Don't forget to consult the help if you have questions about a field value.

Remember that all values are only examples. Your zone specifics will be specific to your environment.

3. Click the **Compute** tab and verify that the compute resources are all present.
If you need to exclude one, switch to **Manually select compute** and add only the ones you want to include in the cloud zone.

Account / Region	Type	Tags
vCenter Account / wld01-DC	Supervisor Cluster	
vCenter Account / wld01-DC	Resource Pool	
vCenter Account / wld01-DC	Resource Pool	
vCenter Account / wld01-DC	Resource Pool	
wld01-clu01 / VCF-edge_edge-wldclu-01_ResourcePool_ffa14b18-82b5-4261-b546-aef86a1db2d9	Resource Pool	

4. Click **Save**.
5. Repeat the process for any additional cloud zones, but you must ensure unique zone names.

Step 3: Configure the possible resources that are available for the account/region

You added the account/region to the cloud zone. Now you define the possible machine sizes (flavor mappings), image mappings, network profiles, and storage profiles for the cloud account. The mapping and profile definitions are evaluated for a match when you deploy a cloud template, ensuring that the workload includes the appropriate machine size (flavor), image, networks, and storage.

1. Configure the flavor mappings for the account/regions.
Flavors are sometimes referred to as t-shirt sizing. Depending on how your cloud template is configured, the applied flavor mapping determines the number of CPUs and memory.

For more information about flavor mappings, see [Learn more about flavor mappings in .](#)

- a. Select **Infrastructure > Configure > Flavor Mappings**.

- b. Click **New Flavor Mapping** and enter values that define small, medium, and large machines. Remember, these are sample values. You must select relevant account/regions and define the sizing.

Allows you to define flavors by name in a cloud-agnostic way. ⓘ

Flavor name *	small
Configuration *	Account / Region
	vCenter Account / wld01-DC
	Value
	2
	1
	GB
	<input type="button" value="–"/> <input type="button" value="+"/>

Setting	Sample Value
Flavor name	small
Account/region	vCenter Account / data center
CPU value	2
Memory value	1 GB

- c. Click **Create**.
d. To create additional sizes, configure medium and large flavor mappings for the account/region.

Setting	Sample Value
Flavor name	medium
Account/region	vCenter Account / Datacenter
CPU value	4
Memory value	2 GB
Flavor name	large
Account/region	vCenter Account / Datacenter
CPU value	8
Memory value	4 GB

2. Configure the image mappings for the account/regions. The images are the operating system for machines in the cloud template. When you are working with vCenter images, you select vCenter templates.

For more information about image mappings, see [Learn more about image mappings in .](#)

- Select **Infrastructure > Configure > Image Mappings**.
- Click **New Image Mapping** and search for the images for the account/region. Remember, these are sample values. You must select relevant images that were discovered in your account/region.

Allows you to define images or machine templates by name in a cloud-agnostic way. ⓘ

Image name *	centos
Configuration *	Account / Region Image Constraints Cloud Configuration <input type="text" value="vCenter Account / wld"/> <input type="text" value="centos7"/> Example: !license:none: ⓘ + ADD - +

Setting	Sample Value
Image name	centos
Account/region	vCenter Account
Image	centos7

- c. Click **Create**.
- d. Repeat the process to create additional image mappings. For example, an ubuntu mapping for the account/region.

3. Configure network profiles.

Network profiles define the networks and network settings that are available for an account/region. The profiles must support the target deployment environments.

This task provides the minimum configuration information for success. If you want more information about network profiles, start with [Learn more about network profiles in](#).

- a. Select **Infrastructure > Configure > Network Profile**.
- b. Click **New Network Profile** and create a profile for the vCenter Account / Datacenter account/region.

A network profile defines a group of networks and network settings used when machines are provisioned.

Account / region	<input type="text" value="vCenter Account / wld01-DC"/>
Name *	Network Profile
Description	Networks for development teams.
Capabilities	Capability tags listed here are matched to constraint tags in the cloud template.
Capability tags	<input type="text" value="Enter capability tags"/> ⓘ

Setting	Sample Value
Account/region	vCenter Account / Datacenter
Name	Network Profile
Description	Networks for development teams.

- c. Click the **Networks** tab and click **Add Network**.

Name	Account / Region	Zone	Network Domain	CIDR	Support Public IP	Default for Zone	Origin	Tags
DevProject-004	NSX-T Account		overlay-tz-sc2vc05-vip-nsx-mgmt.cmbu.local	192.168.1.64/27	--	--	Deployed	
External-mcm1373520-150877845350	NSX-T Account		overlay-tz-sc2vc05-vip-nsx-mgmt.cmbu.local	172.16.1.64/28	--	--	Discovered	
seq-domain-c8-e2a5580e-2772-43f5-9ea-eddc05e35996-vmware-system-nsx-0	NSX-T Account		overlay-tz-sc2vc05-vip-nsx-mgmt.cmbu.local	10.244.0.0/28	--	--	Discovered	external_id... ncp/project_u... ncp/cluster_d... ncp/version:1... ncp/project_v...

- d. Select the NSX networks that you want to make available for the application development team.
In this example, we had an NSX-T network named DevProject-004.
- e. Click the **Network Policies** tab and create a policy.

Setting	Sample Value
Isolation policy	None
Tier-0 logical router	Tier-0-router
Edge cluster	EdgeCluster

- f. Click **Create**.

4. Configure storage profiles.

Storage profiles define the disks for an account/region. The profiles must support the target deployment environments.

If you want more information about storage profiles, see with [Learn more about storage profiles in .](#)

- Select **Infrastructure > Configure > Storage Profile**.
- Click **New Storage Profile** and create a profile for the vCenter Server/Datacenter account/region. Unless specified in the table, keep the default values.

Storage Profile

Account / region: vCenter Account / wld01-DC

Name *: Storage Profile

Description:

Disk type *: Standard disk (FCD)

Storage policy: Datastore default

Datastore / cluster: wld01-sc2vc05-wld01-clu01-vsan01

Provisioning type: Unspecified

Shares: Unspecified

Limit IOPS:

Disk mode: Dependent

Supports encryption

Preferred storage for this region

Capability tags: Enter capability tags

SAVE **CANCEL**

Setting	Sample Value
Account/region	vCenter Account / Datacenter
Name	Storage Profile
Datastore/cluster	Selected a datastore with sufficient capacity and that is accessible to all the hosts.
Preferred storage for this region	Select the check box.

- Click **Create**.

Step 4: Create a project

This is where you really begin thinking about the project goals.

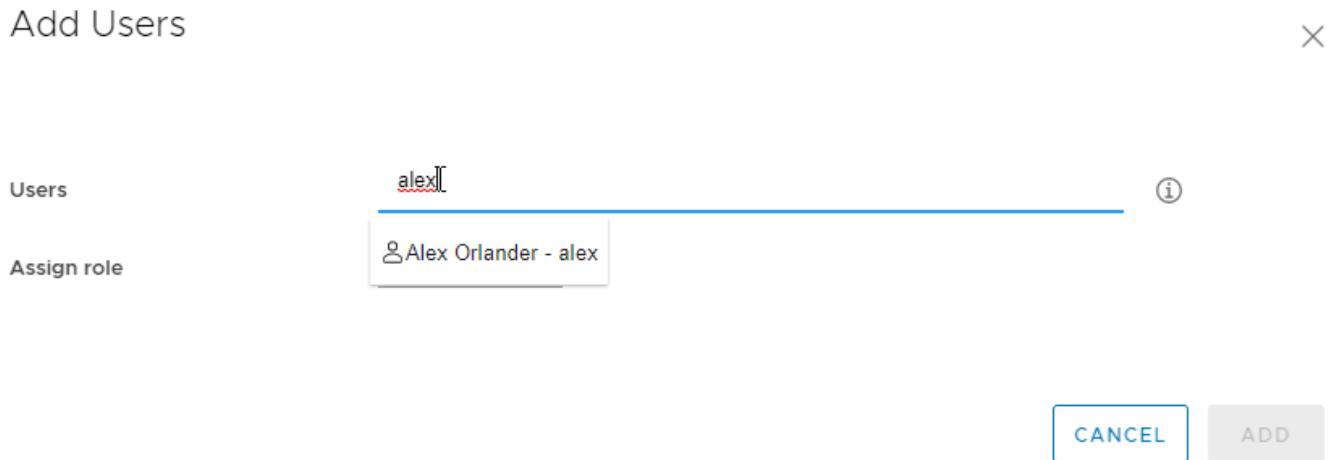

- What users need access to the compute resources so that they can create and deploy an application cloud template? For more information about what the different project roles can see and do, see [Organization and service user roles in .](#)
- Will the members of the project be creating applications that go from development to production? What are the necessary resources?

- What cloud zones do they need? What priority and limits should be placed on each zone for the project?

For this tutorial, we are going to support the Development team as they create and extend an in-house software application.

This task provides the minimum configuration information for success. If you want more information about projects, start with [Learn more about projects](#).

1. Select **Infrastructure > Administration > Projects**.
2. Click **New Project** and enter the name **Development Project**.
3. Click the **Users** tab, and then click **Add Users**.
You are not required to add users at the time. But if you want other users to work with cloud templates, they must be a member of the project.
4. Enter email addresses to add users as project members or administrators, depending on what permissions you want each individual to have.

5. Click **Provisioning** and click **Add Zones > Cloud Zone**.

6. Add the cloud zones that the users can deploy to.

You can also set resource limits for the cloud zone in the project. In the future, you can set different limits for other projects.

Add Cloud Zone

X

Add a cloud zone that can be used by this project.

Cloud zone *	<input type="text" value="vCenter Server Account / vld01-DC"/>
Provisioning priority	1
Instances limit	5
Memory limit (MB)	0
CPU limit	0
Storage limit (GB)	0

CANCEL ADD

Project Cloud Zone Setting	Sample Value
Cloud Zone	vCenter Account Cloud Zone
Provisioning priority	1
Instance limit	5

7. Add any additional cloud zones to the project.
8. Click **Create**.
9. To verify that the project was added to the cloud zone, select **Infrastructure > Configure > Cloud Zones** and open the vCenter Account Zone cloud Zone card so that you can examine the **Projects** tab. You should see the Development Project.

Step 5: Design and deploy a basic cloud template

You design and deploy the cloud template to ensure that your infrastructure is properly configured to support the template. Later you can build on the template as you create an application that meets your project needs.

The best way to build a cloud template is component-by-component, verifying that it deploys between each change. This tutorial starts with a simple machine and then iteratively adds more resources.

The examples in this procedure use the YAML code editor. It is an easier way of providing you with code snippets. However, if you prefer a use dialog box-driven user interface, click **Inputs**.

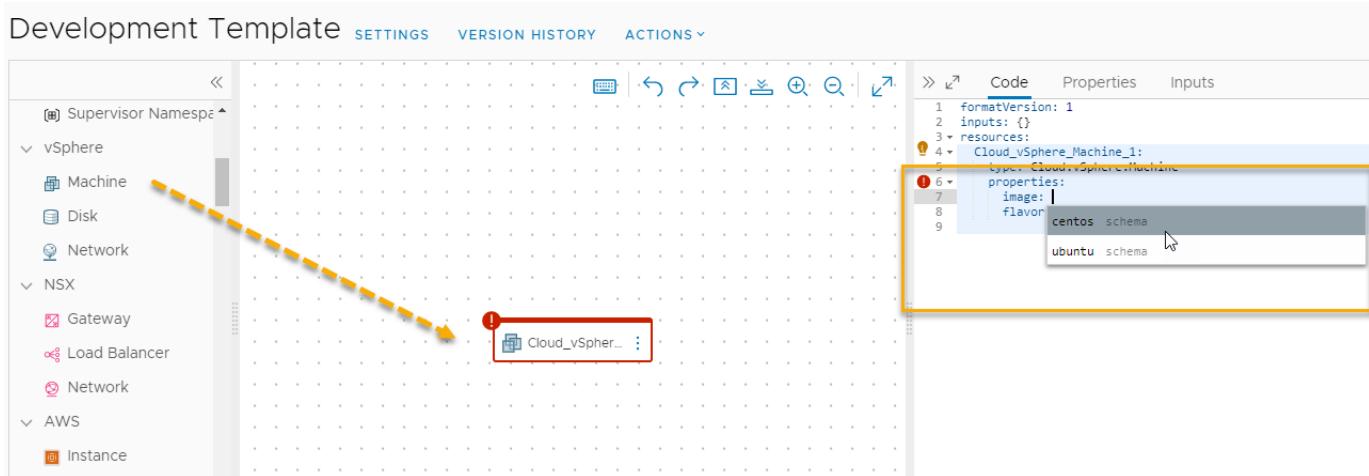

There is so much more that you can do with cloud templates than is provided in this tutorial. If you want more information, start with [Designing your deployments](#).

This tutorial uses vSphere and NSX resource types. These resource types can be deployed only on vCenter cloud account endpoints. You can also use the cloud agnostic resource types to create cloud templates that can be deployed on any endpoint. For an example of how to configure the infrastructure and design the template for any endpoint, see [Tutorial: Setting up and testing multi-cloud infrastructure and deployments in](#).

For a video that illustrates the basic steps in this procedure, see [How to design and deploy a basic cloud template](#).

1. Select **Design > Cloud Templates**.
2. Select **New From > Blank Canvas**.
3. Enter the **Name** Development Template, select the **Project** Development Project, and click **Create**.
4. Add a vSphere machine to the design canvas, test, and deploy.

- a. From the resource type pane, drag a **vSphere Machine** to the canvas.

Notice that the **Code** pane shows the YAML for the machine, with an empty value for image and predefined CPU and memory properties. You are going to make this template able to support flexible sizing.

- b. To select an image value, put your pointer between the single quotes for `image` and select **centos** from the list of images that you configured.
Remember, these are sample values. If you did not configure a centos image, select an image that you did configure.
- c. Create a line below the `image` property and enter or select `flavor`, then select the **small** from the list.
- d. Delete `cpuCount` and `totalMemory`.

Your YAML should look similar to this example.

```

formatVersion: 1
inputs: {}
resources:
  Cloud_vSphere_Machine_1:
    type: Cloud.vSphere.Machine
    properties:
      image: centos
      flavor: small
  
```

- e. Click **Test**.

Test allows you to validate the syntax and placement of your cloud template. A successful test does not mean that you can deploy the template without errors.

Test Result for Development Template

Successful

This simulation only tests syntax, placement and basic validity

1 Info

Provisioning Diagram

Cloud_vSphere_Machine_1

LINE 4

If the test fails, click **Provisioning Diagram** and look for the failure points. For more information about using the diagram to troubleshoot, see [Test a basic cloud template](#).

- f. Click **Deploy**.
- g. Enter **Deployment Name** as DevTemplate – machine and click **Deploy**.

You can track the progress of the deployment on the DevTemplate deployment details page or on the Deployments page. Select **Resources > Deployments**.

If the deployment fails, you can troubleshoot the problem and revise your template. See [What can I do if an deployment fails](#).

A successful deployment looks similar to this example on the Deployments page.

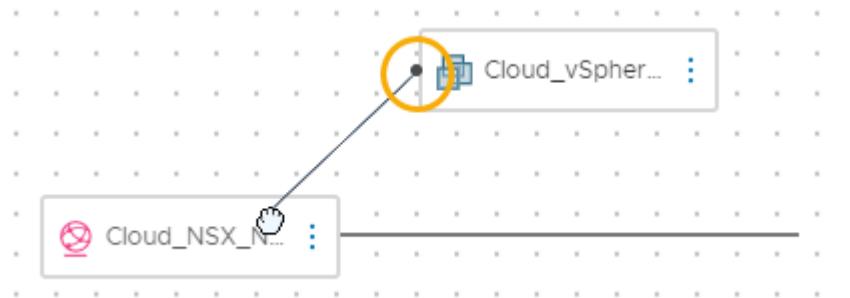

Property	Value
Resource name	DevProject--030
Account / Region	vCenter Account/wld01-DC
Status	On

5. Version the template and add a network.

Versioning a cloud template is required to make it available in the Automation Service Broker catalog, but it is useful to have a good version to revert to during development.

- a. Open the template in the design canvas.
- b. Click **Version**, enter a **Description** similar to Simple deployable machine, and click **Create**.
- c. From the resource type pane, drag an **NSX Network** resource type to the canvas.
- d. Connect the machine to the network.

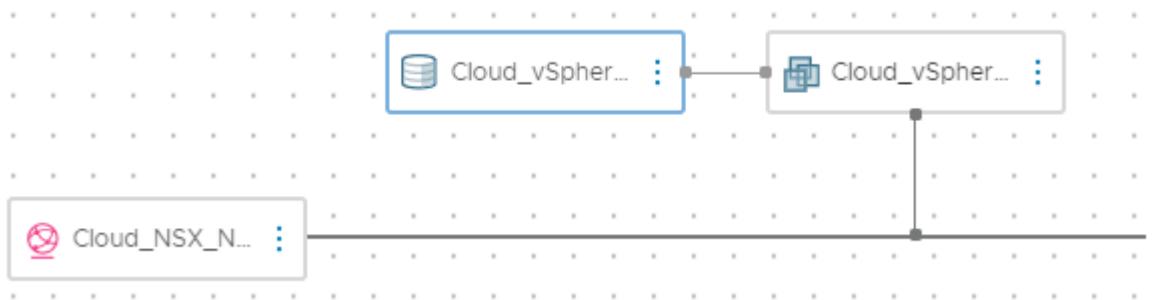

Click the small circle on the machine component and drag the connection to the network.

Notice that the YAML now looks similar to this example.

```
formatVersion: 1
inputs: {}
resources:
  Cloud_vSphere_Machine_1:
    type: Cloud.vSphere.Machine
    properties:
      image: centos
      flavor: small
      networks:
        - network: '${resource.Cloud_NSX_Network_1.id}'
  attachedDisks: []
Cloud_NSX_Network_1:
  type: Cloud.NSX.Network
  properties:
    networkType: existing
```

- e. Click **Test** to validate the template.
 - f. Click **Deploy**.
 - g. Enter the name **DevTemplate** – machine – network and click **Deploy**.
 - h. Track the progress and review the successful deployment.
6. Version the template and add data disk.
- a. Open the template in the design canvas.
 - b. Version the template.
Enter **Machine with existing network** as the description.
 - c. From the resource type pane, drag an **vSphere Disk** resource type to the canvas.
 - d. Connect the disk to the machine.

Notice that the YAML now looks similar to this example.

```

formatVersion: 1
inputs: {}
resources:
  Cloud_vSphere_Disk_1:
    type: Cloud.vSphere.Disk
    properties:
      capacityGb: 1
  Cloud_vSphere_Machine_1:
    type: Cloud.vSphere.Machine
    properties:
      image: centos
      flavor: small
    networks:
      - network: '${resource.Cloud_NSX_Network_1.id}'
    attachedDisks:
      - source: '${resource.Cloud_vSphere_Disk_1.id}'
  Cloud_NSX_Network_1:
    type: Cloud.NSX.Network
    properties:
      networkType: existing
  
```

- e. Test the template.
- f. Deploy the template using the name DevTemplate – machine – network – storage.
- g. Track the progress and review the successful deployment.
- h. Version the template.

Enter Machine with existing network and storage disk as the description.

This final version ensures that you can add a working template to the Automation Service Broker catalog.

Tutorial results

You completed the workflow that configured Automation Assembler as a working system. You are now familiar with the following concepts.

- Cloud accounts are the credentials that connect Automation Assembler to your cloud vendor endpoints.
- Cloud zones are the selected compute resources in account/regions that you then assign to different projects based on the project needs and your goals for managing costs.
- Infrastructure resources are definitions of resources associated with account/regions that are used in cloud templates.
- Projects are how you give your users access to the cloud zones based on the project's application development goals.
- Cloud templates are the definitions of your application workloads that you iteratively develop and deploy.

This tutorial is the foundation of your Automation Assembler development experience. You can use this process to build your infrastructure and mature your cloud template development skills.

Tutorial: Configuring Automation Assembler to provision a production workload

Configuring and provisioning a production workload

As a cloud administrator, you want to automate the deployment process for a project so that when the cloud template designers are creating and deploying templates, Automation Assembler does the work for you. For example, the workloads are deployed with a particular custom machine naming pattern, the machines are added to a specific Active Directory organizational unit, and specific DNS and IP ranges are used.

By automating the process for the project deployments, you can more easily manage multiple projects across various data centers and cloud environments.

You are not required to complete all of the tasks provided here. You can mix and match any of these tasks, depending on your management goals.

Before you begin

This tutorial requires you to have your infrastructure configured and to have successfully deployed a cloud template with a machine and a network. Verify that the following are already configured on your system.

- You successfully performed all of the steps specified in the infrastructure tutorial. See [Tutorial: Setting up and testing vSphere infrastructure and deployments in](#).
- You have the Automation Assembler Administrator role. See [Organization and service user roles in](#).

Customize the machine names

The goal of this task is to ensure that the deployed machines for the a project are named based on the project, the operating system that the user selects at deployment time, and that it is incremented to ensure uniqueness. For example, DevProject-centos-021.

You can adapt this example to your naming requirements.

1. Create a project.
For this tutorial, the project name is DevProject.

For more about projects, see [Adding and managing projects](#).

- a. Select **Infrastructure > Projects** and click **Add Project**.
- b. Enter the name **DevProject**.
- c. Click the **Users** tab and add the users who are members of this project.
- d. Click the Provisioning tab and click **Add Zone** to add cloud zones that support your deployments.
- e. Click **Save**.

2. Create a custom naming templates.

The custom naming templates allow you to create templates that you can assign to more than one project. To assist with template management, the templates are managed in one location and the templates reduce the number that you must manage.

For this tutorial, enter ProjectName-OS.

For additional examples, see [Create global custom naming templates](#).

- a. Select **Infrastructure > Administration > Custom Names** and click **New Custom Name**.
- b. Enter the name `ProjectName-OS`.
- c. Click **New Naming Template** and configure the following values.

Option	Value
Resource type	<code>machine</code>
Template format	<code> \${project.name}-\${resource.name}-#\${#####}</code>
Starting counter value	<code>1</code>
Increment step	<code>1</code>

- d. Click **Assign Projects** and select DevProject.

You can also assign the template to other projects where the templates support the template.

- e. Click **Save**.

3. Update the cloud template with an input value for the operating system type.

Input values are the direct way that you can customize the deployment request form for users and simplify your development process. By creating input values, you can use a single cloud template to deploy workloads with different configurations. For example, size or operating system.

This example uses the Development Template from a previous tutorial. See [Step 5: Design and deploy a basic cloud template](#).

- a. Select **Design** and open the Development Template.
- b. In the Code pane, update the YAML with the following changes.
 - In the `Inputs` section, add `installedOS`.
In the next step you can see that `installedOS` input is also used to specify the image. When you add the strings in the `enum` section, the values, in this example they are `centos` and `ubuntu`, must match the image names that you defined in **Infrastructure > Configure > Image Mappings**. For example, if your image mapping name is `CentOS` rather than `centos`, you should use `CentOS` in the inputs section.
 - In the `Cloud_vSphere_Machine_1` section, update the `image` to an `installedOS` input parameter (`$(input.installedOS)`) and add `name` custom property with the same input parameter.

```

inputs:

  installedOS:
    type: string
    title: OS Type
    description: Select the operating system.

    enum:
      - centos

```

```

      - ubuntu

resources:

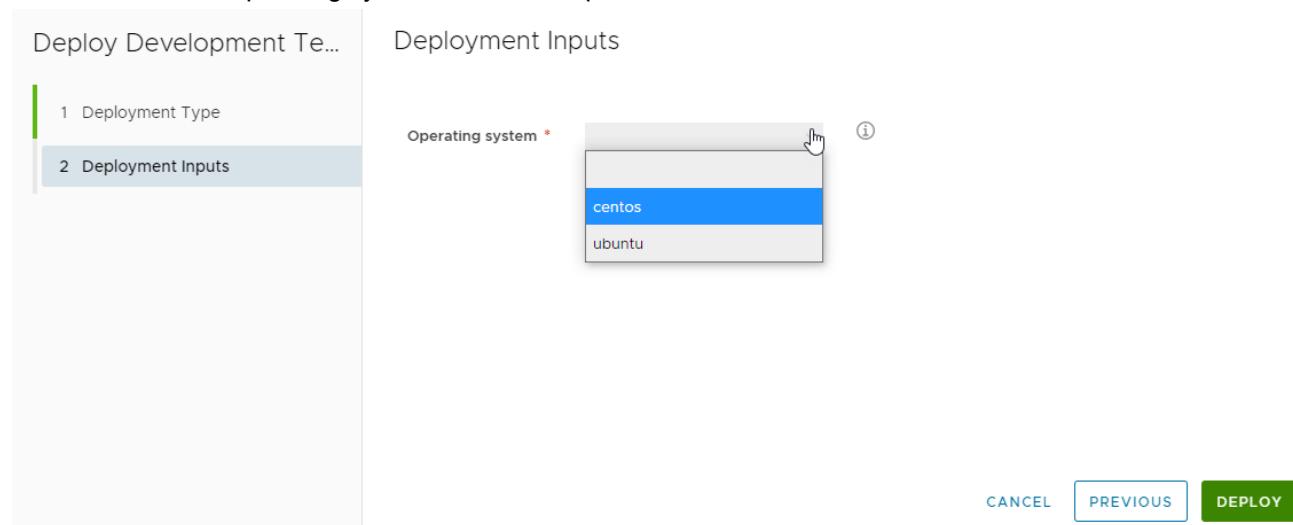

Cloud_vSphere_Disk_1:
  type: Cloud.vSphere.Disk
  properties:
    capacityGb: 1

Cloud_vSphere_Machine_1:
  type: Cloud.vSphere.Machine
  properties:
    image: ${input.installedOS}
    name: ${input.installedOS}
    flavor: small
  networks:
    - network: '${resource.Cloud_NSX_Network_1.id}'
  attachedDisks:
    - source: '${resource.Cloud_vSphere_Disk_1.id}'

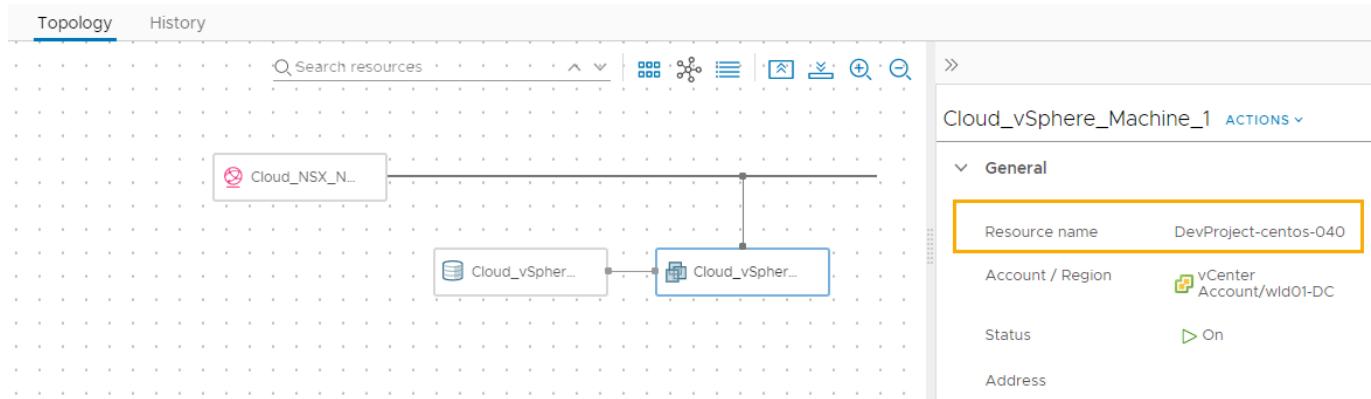

Cloud_NSX_Network_1:
  type: Cloud.NSX.Network
  properties:
    networkType: existing

```

- c. Click **Deploy** and enter the name **Custom name deployment test**.
- d. Click **Next**.
- e. Select the **centos** operating system from the drop-down menu.

- f. Click **Deploy**.
4. Track the progress and review the successful deployment.
The machine name in this example is DevProject-centos-026. Just a reminder, this example is based on the tutorial referenced at the beginning of this task.

Create Active Directory machine records

When you provision a workload, you can create machine records in Active Directory. By configuring Automation Assembler to perform this task automatically for a project deployments, you have lightened your own workload as the cloud administrator.

1. Add an Active Directory integration.
 - a. Select **Infrastructure > Connections > Integrations**.
These steps cover the basic Active Directory configuration that is related to this AD machine records tutorial.
For more about the Active Directory integration, see [how-do-i-create-an-active-directory-integration-in-cloud-assembly.dita#GUID-011A34E3-9548-4180-8171-16AEDA27089A-en](#).
 - b. Click **Add Integration** and click and click **Active Directory**.

The screenshot shows the 'Active Directory Integration' configuration page. On the left, there's a sidebar with navigation links: Image Mappings, Network Profiles, Storage Profiles, Pricing Cards, Terraform Versions, Tags, Resources (Compute, Networks, Security, Storage, Machines, Volumes, Kubernetes), Activity (Requests, Events Log), and Connections. The main area has tabs for Summary (selected) and Projects. Under 'Summary', there's a 'Status' section showing 'OK' and an 'Activate integration' toggle switch which is turned on. Below that are fields for 'Name' (Active Directory Integration) and 'Description'. The 'Active Directory Credentials' section contains fields for 'LDAP host / IP' (ldap://cmbu-sc2dc-01.cmbu.local:389), 'Running environment' (embedded-ABX-onprem), 'Username' (cmbu\administrator), and 'Password'. The 'Base DN' field (ou=AppDev,dc=cmbu,dc=local) is highlighted with a yellow border. At the bottom right, there's a 'VALIDATE' button and a note: 'Validate credentials before making changes.'

- c. Enter the name that you are using for this integration.
 - d. Enter the **LDAP host / IP** and the associated credentials.
 - e. Enter the **Base DN**.
In this tutorial the example is `ou=AppDev,dc=cmbu,dc=local`. AppDev is the parent OU for the computer OU that you will add for the project.
 - f. Click **Add**.
2. Add the project to the integration.
 3. In the Active Directory integration, click the **Projects** tab and click **Add Project**.

Add Projects

Select a project and the OU it will be mapped to by adding its relative DN. The effective DN is created by appending the RDN to the integration base DN (`dc=cmbu,dc=local`).

Project *

Relative DN * (i)

Overrides * Allow cloud template to override relative DN path (i)

Ignores * Allow cloud template to skip adding machines to Active Directory (i)

Constraints
The policy is applied only when at least one of the following criteria is matched

Tags (i)

Matching zones

CANCEL ADD

- a. Select the App Development project.
 - b. Enter the relative DNs. For example, `OU=AppDev-Computers`.
 - c. Leave the Overrides and Ignores switches turned off.
This procedure is focused on automating the process for a project. It is not about customizations that you can do in templates.
 - d. Click **Add**.
4. To save your changes to the integration, click **Save**.
 5. Deploy a cloud template for the project and verify that the machine added to the correct Active Directory OU.

Set your network DNS and internal IP range

Add or update a network profile to include your DNS servers and internal IP ranges.

You must have already created a cloud account for vSphere, NSX-V, or NSX-T. See [Tutorial: Setting up and testing vSphere infrastructure and deployments in](#) or [Adding cloud accounts to](#) .

1. Select **Infrastructure > Configure > Network Profiles**.
2. Select an existing profile or create one.
3. On the **Summary** tab, select an **Account/region** and enter a name.
For this tutorial, the network profile name is Network Profile.
4. Add networks.
 - a. Click the **Networks** tab.

- b. Click **Add Network**.
 - c. Add one or more NSX or vSphere networks.
 - d. Click **Add**.
5. Configure the DNS servers.

- a. In the networks list on the **Networks** tab, click the network name.

The screenshot shows the 'Networks' tab in the VMware Aria Automation interface. At the top, there are tabs for 'Summary', 'Networks' (which is underlined), 'Network Policies', 'Load Balancers', and 'Security'. Below the tabs, a message says 'Networks listed here are used when provisioning to existing, on-demand, or private clouds.' There are four buttons at the top of the list: '+ ADD NETWORK', 'TAGS', 'MANAGE IP RANGES', and 'REMOVE'. The list itself has columns for 'Name' (with a sorting arrow), 'Account / Region', 'Zone', 'Network Domain', and 'CIDR'. The 'DevProject--004' network is selected, indicated by a checked checkbox and highlighted with a yellow box around its row. Its details are shown in the columns: Account/Region is 'NSX-T', Zone is 'sc2vc05', Network Domain is 'vip-nsx-mgmt.cmb.u.local', and CIDR is '192.168.1.64/27'.

- b. Enter the DNS server IP addresses you want this network to use.

The screenshot shows the 'DNS Servers' configuration dialog for the 'DevProject--004' network. It has two main sections: 'DNS servers' containing '192.168.1.22' and '192.168.1.23', and 'DNS search domains' containing 'company.local'. A tooltip for the 'DNS servers' section says 'Use a comma separated list or new lines.' A small 'i' icon is next to each input field.

- c. Click **Save**.

6. Specify the IP range for the network.

- a. In the networks list, select the check box next to the network name.

Network Profile DELETE

Summary **Networks** Network Policies Load Balancers Security Groups

Networks listed here are used when provisioning to existing, on-demand, or public networks. (i)

+ ADD NETWORK TAGS MANAGE IP RANGES REMOVE

<input type="checkbox"/>	Name	Account / Region	Zone	Network Domain	CIDR	Subnets
<input type="checkbox"/>	External-mcm1343745-148168716643	NSX-T Account		overlay-tz-sc2vc05-vip-nsx-mgmt.cmbu.local	172.16.12.64/28	
<input type="checkbox"/>	NSX-mcm1376447-151082888186	NSX-T Account		overlay-tz-sc2vc05-vip-nsx-mgmt.cmbu.local	192.168.100.32/28	
<input checked="" type="checkbox"/>	NSX-mcm39835-146434698964	NSX-T Account		overlay-tz-sc2vc05-vip-nsx-mgmt.cmbu.local	192.168.1.0/27	

1 New IP Range

- b. Click **Manage IP Ranges**.
- c. In the Manage IP Ranges dialog box, click **New IP Range**.

New IP Range

Network *	NSX-mcm1376447-151082888186
Source	<input checked="" type="radio"/> Internal <input type="radio"/> External
Name *	DevProject Range
Description	
CIDR	192.168.100.32/28
Start IP address *	192.168.100.34
End IP address *	192.168.100.46

d. Enter a name.

For example, DevProject Range.

e. To define the range, enter the **Start IP address** and **End IP address**.

f. Click **Add**.

g. Add additional ranges or click **Close**.

7. Add the cloud zone containing the associated network account/region that you configured to your Development project.
8. Deploy a cloud template for the project and verify that the machine is provisioned within the specified IP range.

Tutorial: Using tags in Automation Assembler to manage vSphere resources

Using tags to manage vSphere resources

Tags are powerful metadata that you can associate with resources and include in templates. You can use tags in a variety of management scenarios, including workload placement and resource labeling.

Quick introduction to tags

This section is a simple introduction to tags as they apply to the provided steps. For more in-depth information about tags, see [maphead-how-to-use-tags.dita#GUID-1F1FD968-2EA1-404E-B081-E13383392061-en](#).

- Capability and constraint tags

You can use of tags to control deployments based on resource capabilities. For example, as a cloud administrator you want the iteratively developed cloud templates to deploy to a development-specific resource pool and the production worthy templates to deploy to a different resource pool.

- Capability tags are added to resources, defining their capabilities.
- Constraint tags are used in cloud templates, defining what resources you want the deployed resources to consume.
- Label tags
To manage resources, you can add tags as object labels or descriptions. The management possibilities include better resources searching results, differentiating between similar objects, annotating objects with custom information, providing information to third-party systems, creating security grouping membership criteria, ensuring consistency across linked SDDC domains.

Before you begin

- Review the resources and cloud template defined in [Tutorial: Setting up and testing vSphere infrastructure and deployments in](#). The sample values used in that tutorial are used here.

Using tags to manage Workload placement

This simple example uses development and production environment tags to demonstrate how to use capability and constraint tags. First, you add capability tags on vCenter Server resource pool compute resources, and then you include the tags in the cloud template. The cloud template example demonstrates how to use inputs to let the deploying user select whether to deploy it to a development or to a production resource pool.

For an example of how to use the same tags to define placement in a multi-cloud environment, see [Tutorial: Setting up and testing multi-cloud infrastructure and deployments in](#).

1. Add capability tags to resource pools.

- a. Select **Infrastructure > Resources > Compute**.
- b. Open the cloud zone and click **Compute**.

Name	Account / Region	Type	Tags
10.176.152.27	vCenter Account / wid01-DC	Host	
wid01-clu01	vCenter Account / wid01-DC	Supervisor Cluster	
wid01-clu01 / Development	vCenter Account / wid01-DC	Resource Pool	
wid01-clu01 / Production	vCenter Account / wid01-DC	Resource Pool	
wid01-clu01 / Training-Org	vCenter Account / wid01-DC	Resource Pool	
wid01-clu01 / VCF-edge_edge-widclu-01_ResourcePool_ffa14b18-82b5-4261-b546-aef86a1db2d9	vCenter Account / wid01-DC	Resource Pool	

- c. Locate and click the resource pool that you want to deploy development workloads to.

This tutorial uses the following sample values. Remember that these values are only examples. Your values will be specific to your environment.

Sample resource pool	Sample tag
wid01-clu01 / Development	env:dev
wid01-clu01 / Production	env:prod

- d. Add the tag `env.dev` and click **Save**.

wld01-clu01 / Development

Account / region vCenter Account / wld01-DC

Name wld01-clu01 / Development

Type VM_HOST

Tags env:dev X Enter a new tag

SAVE **CANCEL**

- e. Repeat the process for the resource pool that you want to deploy production workloads to and add the env:prod tag.
2. Verify that the capability tags were added to the resource pools in your cloud zone.
 - a. Select **Infrastructure > Configure > Cloud Zones**.
 - b. Open the cloud zone associated with the project and click **Compute**.

In this example, the cloud zone is vCenter Account Cloud Zone and the tags were added to the two resource pools, wid01-clu01 / Development and wid01-clu01 / Production.

Name	Account / Region	Type	Tags
10.176.152.27	vCenter Account / wld01-DC	Host	
wld01-clu01	vCenter Account / wld01-DC	Supervisor Cluster	
wld01-clu01 / Development	vCenter Account / wld01-DC	Resource Pool	env:dev
wld01-clu01 / Production	vCenter Account / wld01-DC	Resource Pool	env:prod
wld01-clu01 / Training-Org	vCenter Account / wld01-DC	Resource Pool	
wld01-clu01 / VCF-edge_edge-wldclu-01_ResourcePool_ffa14b18-82b5-4261-b546-aef86a1db2d9	vCenter Account / wld01-DC	Resource Pool	

3. Add constraint tags to the cloud template.
- Constraint tags are used to limit where the template is deployed.
- a. Select **Design > Cloud Templates** and then open your template.
- In this tutorial, the template name is Development Template.

- b. Review the YAML for the template in the Code pane.
 This YAML is the starting point for this tutorial.

```

formatVersion: 1

inputs: {}

resources:

  Cloud_vSphere_Machine_1:
    type: Cloud.vSphere.Machine
    properties:
      image: centos
      flavor: medium
    networks:
      - network: '${resource.Cloud_NSX_Network_1.id}'
    attachedDisks:
      - source: '${resource.Cloud_vSphere_Disk_1.id}'

  Cloud_vSphere_Disk_1:
    type: Cloud.vSphere.Disk
    properties:
      capacityGb: 5

  Cloud_NSX_Network_1:
    type: Cloud.NSX.Network
    properties:
      networkType: existing

```

- c. Add the constraint tag to the Cloud_vSphere_Machine_1 resource using \${input.placement} as a variable.

```

resources:

  Cloud_vSphere_Machine_1:
    type: Cloud.vSphere.Machine
    properties:
      image: centos
      flavor: medium
    constraints:

```

```

    - tag: '${input.placement}'

networks:
    - network: '${resource.Cloud_NSX_Network_1.id}'

attachedDisks:
    - source: '${resource.Cloud_vSphere_Disk_1.id}'

```

d. Define the placement variable in the Inputs section.

```

inputs:
  placement:
    type: string
    enum:
      - env:dev
      - env:prod
    default: env:dev
    title: Select Placement for Deployment
    description: Target Environment

```

e. Verify that the final YAML looks similar to the following example.

```

formatVersion: 1

inputs:
  placement:
    type: string
    enum:
      - 'env:dev'
      - 'env:prod'
    default: 'env:dev'
    title: Select Placement for Deployment
    description: Target Environment

resources:
  Cloud_vSphere_Machine_1:
    type: Cloud.vSphere.Machine
    properties:
      image: centos
      flavor: small

```

```

constraints:
  - tag: '${input.placement}'

networks:
  - network: '${resource.Cloud_NSX_Network_1.id}'

attachedDisks:
  - source: '${resource.Cloud_vSphere_Disk_1.id}'

Cloud_vSphere_Disk_1:
  type: Cloud.vSphere.Disk

  properties:
    capacityGb: 5

Cloud_NSX_Network_1:
  type: Cloud.NSX.Network

  properties:
    networkType: existing

```

- f. To try out the tag variable against the available resources, click **Test** and then select `env:dev`.

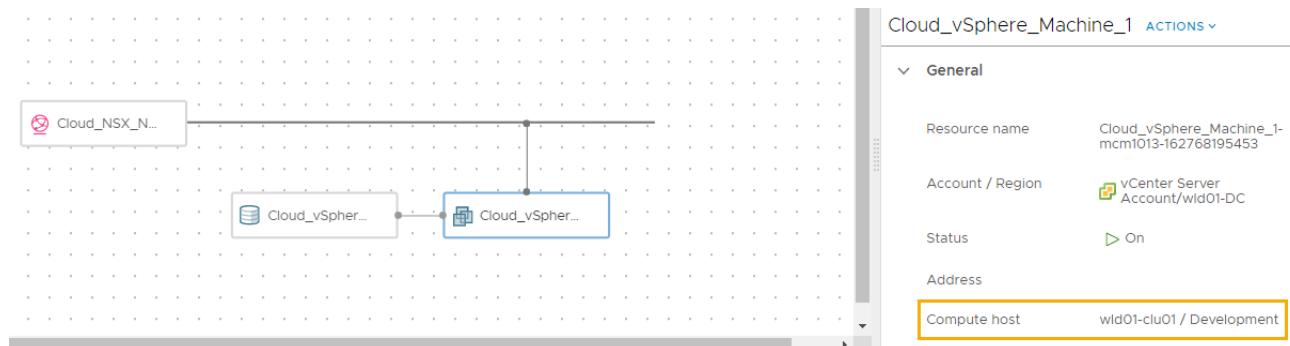

Repeat the test using `env:prod`. When both tests are successful, confirm that the template works by deploying it.

4. Deploy the template to test the workload placement.
 - a. In the cloud template designer, click **Deploy**.
 - b. Enter `Deployment Tag Dev` as the **Deployment Name** and click **Next**.
 - c. Select `env:dev` in the **Select Placement for Deployment** drop-down menu and click **Deploy**.
5. Verify that the template deployed the resources to the selected resource pool.
 - a. Select **Resources > Deployments** and locate the `Deployment Tag Dev` deployment.
 - b. Open the deployment details and click **Topology**.
 - c. Click the vSphere machine and expand the machine information in the right pane.

- d. In the **General** section, locate **Compute host** and verify that the value matches the resource pool that matches your env:dev tag.

In this example, the value is wid01-clu01 / Development, illustrating that the workload was deployed to correct resource pool based on the selected constraint tag.

- e. Repeat the deployment process, this time select env:prod.

Adding tags as labels that you can use in vCenter Server and NSX-T

You can add tags to deployments that you can then use to manage resources.

In this example, you add tags to identify the MySQL machine and network. You also add a tag to identify the web network. Due to how tags work on existing networks compared to on-demand networks, you have two choices.

- If you use the existing network profile that you used in the previous section, the NGINX:web tag is not added to existing objects in NSX-T. So you can ignore the verification steps regarding this tag in NSX-T.
- If you create an on-demand network profile, you can update the network in the YAML to use the routed/on-demand network. The on-demand network is used in this example so that we can demonstrate the NGINX:web tag on the new object in NSX-T.

The following YAML is from the previous example except that it uses a routed on-demand networkType. It includes the constraint tags.

This tutorial uses the following sample values. Remember that these values are only examples. Your values will be specific to your environment.

```

formatVersion: 1

inputs:

placement:
  type: string
  enum:
    - 'env:dev'
    - 'env:prod'
  default: 'env:dev'
  title: Select Placement for Deployment
  description: Target Environment

resources:
  Cloud_vSphere_Machine_1:

```

```

type: Cloud.vSphere.Machine
properties:
  image: centos
  flavor: small
constraints:
  - tag: '${input.placement}'
networks:
  - network: '${resource.Cloud_NSX_Network_1.id}'
attachedDisks:
  - source: '${resource.Cloud_vSphere_Disk_1.id}'
Cloud_vSphere_Disk_1:
  type: Cloud.vSphere.Disk
  properties:
    capacityGb: 5
Cloud_NSX_Network_1:
  type: Cloud.NSX.Network
  properties:
    networkType: routed
  constraints:
    - tag: 'net:od'

```

1. Select **Design > Cloud Templates** and then open your template.
2. In the Cloud_vSphere_Machine_properties, add the following tag.

```

tags:
  - key: db
    value: mysql

```

3. Add VM NIC tags.

```

tags:
  - key: db
    value: mysql

```

4. Add NSX logical switch/segment tags.

```
tags:  
  - key: NGINX  
    value: web
```

5. Verify that the YAML looks similar to the following example.

```
formatVersion: 1  
  
inputs:  
  placement:  
    type: string  
    enum:  
      - 'env:dev'  
      - 'env:prod'  
    default: 'env:dev'  
    title: Select Placement for Deployment  
    description: Target Environment  
  
resources:  
  Cloud_vSphere_Machine_1:  
    type: Cloud.vSphere.Machine  
    properties:  
      image: centos  
      flavor: small  
      constraints:  
        - tag: '${input.placement}'  
    tags:  
      - key: db  
        value: mysql  
    networks:  
      - network: '${resource.Cloud_NSX_Network_1.id}'  
    tags:  
      - key: db  
        value: mysql
```

```
attachedDisks:  
  - source: '${resource.Cloud_vSphere_Disk_1.id}'  
  
Cloud_vSphere_Disk_1:  
  type: Cloud.vSphere.Disk  
  
  properties:  
    capacityGb: 5  
  
Cloud_NSX_Network_1:  
  type: Cloud.NSX.Network  
  
  properties:  
    networkType: routed  
  
  constraints:  
    - tag: 'net:od'  
  
  tags:  
    - key: NGINX  
      value: web
```

6. Deploy the template.

This example uses the name Development template w tags.

7. To verify the tags in the deployment, open the deployment and click the **Topology** tab.

- a. Click the machine in the topology.
- b. Expand the **General** section for the machine and locate the Tags label.
The tag value is db:mysql.
- c. Expend the **Network** section and locate the network Tags column.
The tag value is db:mysql.

The screenshot shows the VMware Aria Automation interface. On the left, there is a 'Topology' view displaying a network diagram with nodes labeled 'Cloud_NSX_N...', 'Cloud_vSphere...', and 'Cloud_vSphere...'. On the right, a detailed view of a resource named 'Cloud_vSphere_Machine_1' is shown under the 'General' section. The 'Tags' field contains the value 'db:mysql', which is highlighted with a yellow box. Below this, under the 'Network' section, there is a table with one row. The table has columns for Index, Name, Address, Assignment Type, Security Groups, and Tags. The 'Tags' column for the single entry also contains 'db:mysql' and is highlighted with a yellow box.

- d. Click the network in the topology and expand the **General** section to locate the Tag label.
The tag value is NGINX : web.

The screenshot shows the VMware Aria Automation interface. On the left, there is a 'Topology' view displaying a network diagram with nodes labeled 'Cloud_NSX_N...', 'Cloud_vSphere...', and 'Cloud_vSphere...'. On the right, a detailed view of a resource named 'Cloud_NSX_Network_1' is shown under the 'General' section. The 'Tags' field contains the value 'NGINX:web', which is highlighted with a yellow box. Below this, under the 'Custom properties' section, there is a table with one row. The table has columns for Name, Value, and Type. The 'Type' column for the entry shows 'String' and is highlighted with a yellow box.

8. To verify the tags in vCenter Server, log in to the vCenter Server instance where this workload was deployed.
a. Locate the virtual machine and locate the Tags pane.

Cloud_vSphere_Machine_1-mcm1294-163799945783

Tags

Assigned Tag	Category	Description
mysql	db	mysql

vSphere HA

Failure	Response
Host failure	Restart VMs
Proactive HA	Disabled
Host Isolation	Power off and restart VMs
Datastore with Permanent Dev...	Power off and restart VMs
Datastore with All Paths Down	Power off and restart VMs
Guest not heartbeating	Reset VMs

- To verify the tags in NSX-T, log in to the NSX-T instance where this network is configured.
The network tags and machine tags are added to NSX-T.

- Click **Policy** in the upper right corner.
- To locate the db:mysql tag associated with the NIC, search for mysql.
- Click **Logical Ports** and locate the deployed vSphere machine.
- Click the number in the Tags column.

The Scope and Tag are db and mysql respectively.

Tutorial: Adding an Automation Assembler cloud template to the Automation Service Broker catalog with a custom request form

Adding a cloud template to the Automation Service Broker catalog with a custom request form. During the iterative development of your cloud templates or when you have a final template, you can make the templates available to consumers in the Automation Service Broker self-service catalog. To further enhance the user experience, you can create a custom request form. The customized form is more powerful than the simple template input options.

What to do first

- Verify that you have the infrastructure that supports your template. If you do not, start with [Tutorial: Setting up and testing vSphere infrastructure and deployments in](#) and continue with the other tutorials.
- Verify that you tagged some resource pools as `env:dev` and `env:prod`. For more information, see [Tutorial: Using tags in to manage vSphere resources](#).
- Ensure that you have a deployable cloud template, similar to the one below. This tutorial starts with the following template.

```
formatVersion: 1

inputs:

  installedOS:
    type: string
    title: Operating System
    description: Select the operating system.

  enum:
    - centos
    - ubuntu

  placement:
    type: string
    enum:
      - 'env:dev'
```

```
- 'env:prod'

default: 'env:dev'

title: Select Placement for Deployment

description: Target Environment

resources:

Cloud_vSphere_Disk_1:
  type: Cloud.vSphere.Disk

  properties:
    capacityGb: 1

Cloud_vSphere_Machine_1:
  type: Cloud.vSphere.Machine

  properties:
    image: '${input.installedOS}'
    installedOS: '${input.installedOS}'
    flavor: small

  constraints:
    - tag: '${input.placement}'

  tags:
    - key: db
      value: mysql

networks:
  - network: '${resource.Cloud_NSX_Network_1.id}'

  tags:
    - key: db
      value: mysql

attachedDisks:
  - source: '${resource.Cloud_vSphere_Disk_1.id}'

Cloud_NSX_Network_1:
  type: Cloud.NSX.Network

  properties:
    networkType: existing

  tags:
```

```

- key: NGINX
  value: web

```

Step 1: Add inputs to the cloud template

In addition to the existing OS type input, this procedure updates the placement input and adds a size input. When you customize the request form in Automation Service Broker, these are the three fields on the request form that are customized.

1. In Automation Assembler, select **Design > Templates** and create or open the template provided above. The sample template is used to explain the different options and includes sample values. Adapt it to your environment.
2. Add the size variable and define the sizes in the Inputs section.
 - a. In the Cloud_vSphere_Machine_1 section, add a variable to the `flavor` property.
`flavor: '${input.size}'`
 - b. In the Inputs section, add a user input name size so that the user can select the size of the deployment. This is sometimes referred to as the t-shirt size that you defined for the cloud zones.

```

size:
  type: string
  title: Deployment size
  description: Select the the deployment t-shirt size.
  enum:
    - small
    - medium
    - large

```

3. Update placement inputs with a descriptive term rather than the tag strings. These constraint tags will be matched with the capability tags that you added in [Tutorial: Using tags in to manage vSphere resources](#).
 - a. In the Inputs section, add a user input named `placement` so that the user can select development or production as the deployment placement. This example uses the `oneOf` attribute, which allows you to present a natural language label while still submitting strings that the deployment process requires. For example, the `env:dev` and `env:prod` tags.

```

placement:
  type: string
  oneOf:
    - title: Development
      const: 'env:dev'

```

```
- title: Production  
  const: 'env:prod'  
  default: 'env:dev'  
  title: Select Deployment Placement  
  description: Target Environment
```

4. Review the full YAML to ensure that it looks similar to the following example.

```
formatVersion: 1  
  
inputs:  
  
  installedOS:  
    type: string  
    title: Operating system  
    description: Select the operating system.  
  
    enum:  
      - centos  
      - ubuntu  
  
  placement:  
    type: string  
  
  oneOf:  
    - title: Development  
      const: 'env:dev'  
    - title: Production  
      const: 'env:prod'  
  
  default: 'env:dev'  
  title: Select Deployment Placement  
  description: Target Environment  
  
size:  
  type: string  
  title: Deployment size  
  description: Select the deployment t-shirt size.  
  
  enum:  
    - small  
    - medium  
    - large
```

```

resources:

Cloud_vSphere_Disk_1:
  type: Cloud.vSphere.Disk
  properties:
    capacityGb: 1

Cloud_vSphere_Machine_1:
  type: Cloud.vSphere.Machine
  properties:
    image: '${input.installedOS}'
    installedOS: '${input.installedOS}'
    flavor: '${input.size}'
  constraints:
    - tag: '${input.placement}'
  tags:
    - key: db
      value: mysql
  networks:
    - network: '${resource.Cloud_NSX_Network_1.id}'
      tags:
        - key: db
          value: mysql
  attachedDisks:
    - source: '${resource.Cloud_vSphere_Disk_1.id}'

Cloud_NSX_Network_1:
  type: Cloud.NSX.Network
  properties:
    networkType: existing
  tags:
    - key: NGINX
      value: web

```

5. Click **Deploy**, verify that the second page of the request looks similar to the following example, and then you can verify that the deployment is in the selected development or production resource pool after deployment.

The screenshot shows the 'Deployment Inputs' step of a deployment wizard. On the left, a sidebar lists '1 Deployment Type' and '2 Deployment Inputs' (which is currently selected). The main area contains three input fields: 'Operating system *' set to 'centos', 'Select Deployment Placement' set to 'Development', and a dropdown menu for 'Deployment size *' with options 'small', 'medium', and 'large', where 'small' is highlighted in blue. At the bottom right are three buttons: 'CANCEL', 'PREVIOUS', and a large green 'DEPLOY' button.

Step 2: Version and release the cloud template

When you have a deployable template, you can now make it available in the Automation Service Broker catalog for other uses to deploy. To make the cloud template discoverable so that you can add it to the catalog, you must release it. In this procedure we will version it, to capture a snapshot of the template, and then release the template.

1. Select **Design > Templates** and open the template in the design canvas.
2. Click **Version** and enter a description.

Creating Version

X
Version *

7

Last Version: 6
Description

 Placement inputs added
and tested.

Change Log**Release**
 Release this version to the catalog

This cloud template is restricted to this project in the catalog. Edit shareability in cloud template level settings.

CANCEL
CREATE

3. Select the **Release** check box and click **Create**.

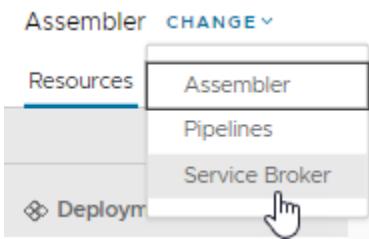

Releasing the cloud template does not automatically add it to Automation Service Broker. Releasing it makes it discoverable so you can add it to the catalog.

Step 3: Add the cloud template to the Automation Service Broker catalog

You can use the Automation Service Broker catalog to provide cloud templates to other consumers in your organization where they don't need to have any awareness of how to create a template. The catalog allows them to deploy the template.

Before you can add the template as a catalog item, you must import it into Automation Service Broker. You can only import released cloud templates.

1. To open Automation Service Broker from Automation Assembler, click the service drop-down menu in the upper left corner.

2. Click **Service Broker**.
 3. Import the cloud template.
 - a. In Automation Service Broker, select **Content and Policies > Content Sources**.
 - b. Click **New** and then select **Template**.
 - c. Enter a **Name**.
For this tutorial, enter Automation Assembler DevProject.
 - d. For the **Project**, select the Development Project that you created in Automation Assembler.
 - e. Click **Validate**.
The system must indicate that it found at least one item.
 - f. When validated, click **Create and Import**.
Automation Assembler DevProject is added to the list as a content source.
 4. Make the cloud template available in the catalog.
 - a. Select **Content and Policies > Policies > Definitions**.
 - b. Click **New Policy**, and then click **Content Sharing Policy**.
 - c. Enter a Name.
For this tutorial, enter DevProject Policy.
 - d. In the **Scope** list, select Development Project.
 - e. In the **Content sharing** section, click **Add Items**.
 - f. In the **Share Items** dialog box, select Automation Assembler DevProject and click **Save**.
 - g. In the **Users** section, select the project users and groups that you want to see the item in the catalog.
 - h. Click **Create**.
 5. To verify that the Development Template was added to the catalog, click **Consume > Catalog**.
 6. Click **Request** on the Development Template card.
- Notice that the inputs that you saw on the cloud template are provided here. The next step is to customize the request form.

New Request

The screenshot shows the 'New Request' interface for a 'Development Template' at version 8. The form includes the following fields:

- Project ***: Development Project
- Deployment Name ***: (empty)
- Operating system ***: (empty) with an information icon (i)
- Select Deployment**: Development
 - Placement**: (empty) with an information icon (i)
- Deployment size ***: (empty) with an information icon (i)

Step 4: Create a custom form for the template

The goal for this custom form is to provide a form where the user selects the operating system and placement based on the env:dev or env:prod tags. Then the env:dev option allows the user to select small or medium, large is not an option. However, if the user selects env:prod, there is no option to select large, the size is hidden from the user but is included in the request.

1. To create a custom form in Automation Service Broker, select **Content and Policies** > **Content**.
2. Click the vertical ellipsis to the left of the Development Template entry and click **Customize form**.
3. Customize the input option.

- a. In the canvas, click fields in the canvas and configure the Properties as specified in the following table.

Canvas field name	Appearance	Values	Constraints
Operating system	Label and type <ul style="list-style-type: none"> Label = Operating system 	Value options <ul style="list-style-type: none"> Value options = Constant Value source = centos 	

Table continued on next page

Continued from previous page

Canvas field name	Appearance	Values	Constraints
		<p>CentOS, ubuntu Ubuntu</p> <p>This example uses the value options to customize the all lower case operating system names with the preferred OS name.</p>	
Select Deployment Placement		<p>Value options</p> <ul style="list-style-type: none"> • Value options = Constant • Value source = env:dev Development, env: prod Production 	
Deployment Size	<p>Visibility</p> <ul style="list-style-type: none"> • Value source = Conditional value • Set value = Yes if Select Deployment Placement Equals env:dev 	<p>Default value</p> <ul style="list-style-type: none"> • Value source = Conditional value • Set value = large if Select Deployment Equals env:prod <p>Value options</p> <ul style="list-style-type: none"> • Value options = Constant • Value source = small Small, medium Medium <p>Notice that the value source does not include large. Large is excluded because it is only available for Production and is the required value. The large value is included in deployment request without a user-initiated action.</p>	

- b. To turn on the form in the catalog, click **Enable**.
 - c. Click **Save**.
4. To ensure the correct results by submitting at least a Development Small and a Production request, test the form in the catalog.
 Use following examples to verify the results.
- a. Test the Development Small request form by providing a name, Test small in this example, and selecting CentOS, Development, and Small for the options.

New Request

 Development Template Version 8 ▾

Project *	Development Project
Deployment Name *	Test small
Operating system *	CentOS
Select Deployment Placement	Development
Deployment size *	Small

- b. To verify the Development Small deployment, Select **Consume > Deployments > Deployments** and click the Test small deployment.
- c. On the Topology tab, click the Cloud_vSphere_Machine, and then locate the Custom Properties section in the right pane.
A few of the values to review include cpuCount = 2 and flavor = small.

Topology History

Search resources: Cloud_NSX_N... Cloud_vSphere... Cloud_vSphere...

Properties:

- costCenter: DevProject
- cpuCount: 2
- datastoreName: wld01-sc2vc05-wld01-clu
- endpointId: d827e01c-df9e-4c80-9f1d
- flavor: small
- image: centos

- d. Test the Production request form by entering a name, Test large in this example, and select CentOS and Production for the options.

Remember, you configured the form to neither display nor require the user to select the size.

New Request

Development Template Version 3

Project *	Development Project
Deployment Name *	Test large
Operating System *	CentOS
Select Deployment Placement	Production

- e. To verify the Production deployment, select **Consume > Deployments > Deployments** and click the Test large deployment.

- f. On the Topology tab, click the Cloud_vSphere_Machine, and then locate the Custom Properties section in the right pane.
A few of the values to review include cpuCount = 8 and flavor = large.

costCenter	DevProject
cpuCount	8
datastoreName	wld01-scvc05-wld01-clu
endpointId	d827e01c-df9e-4c80-9f1d
flavor	large
image	centos
imageId	centos7

Step 5: Control the cloud template versions in the catalog

In most cases, you want to make only the latest cloud templates available in the Automation Service Broker catalog. The following procedure supports iterative development, where you release a version of template and add it to the catalog, but now you improved the template and want to replace the current version with the newer version.

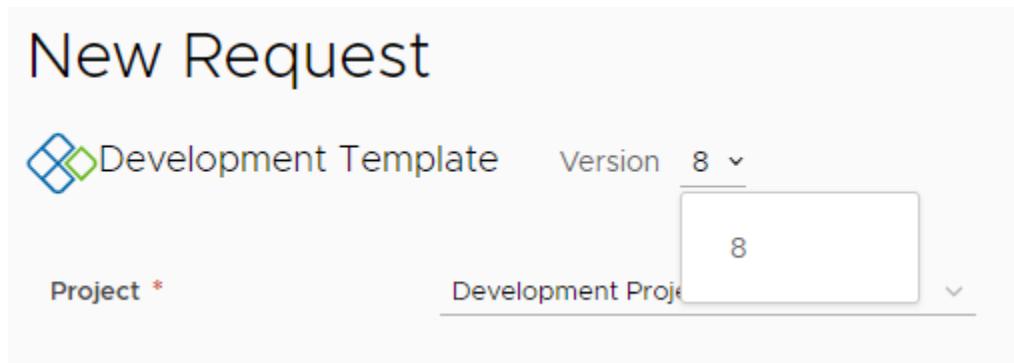

In step 2, you versioned and released a template, so you are familiar with the process. In step 3, you added it to the catalog. The procedure ties the two steps together as you do iterative development and update the catalog with the latest version.

You do have the option to make multiple versions available in the catalog.

1. In Automation Assembler, version the template that you now want to make available in the catalog.
 - a. Select **Design > Templates** and open the template in the design canvas.
 - b. Click **Version History**.
 - c. Locate the version that you want to add to the catalog and click **Version**.
 - d. Enter a **Description**, select the **Release** check box, and click **Create**.
At this point, you have the option to keep the old version in the catalog. If you want multiple versions, ignore the next step where you Unrelease a version.
 - e. To make only one version of the template available in the catalog, review the version history list and click **Unrelease** on every version that you don't want in the catalog.
2. To update the Automation Service Broker catalog with the latest version, and to replace any old version, you must collect the new version.
 - a. In Automation Service Broker, select **Content and Policies > Content Sources**.
 - b. Click the Automation Assembler DevProject content source that is used in this tutorial.

- c. Click **Validate**.
You should see a message that an item is found.
 - d. Click **Save and Import**.
3. Verify that the catalog displays the needed versions or no versions.
- a. In Automation Service Broker, click **Consume > Catalog**.
 - b. Locate the catalog item and click **Request**.
 - c. At the top of the request form, click the **Version** and verify the version or versions.

The following screenshot shows 8.

Tutorial: Onboarding and managing vSphere resources in VMware Aria Automation

Onboarding and managing vSphere resources

As a cloud administrator who has recently added a new cloud account, you want to begin managing some of the vCenter workloads using Automation Assembler and Automation Service Broker. This tutorial guides you through the onboarding process and how to set up a few of the management options for your existing vSphere workloads.

The sample management tasks include adding the resources to a project, creating and applying an approval policy in Automation Service Broker, and running a few day 2 actions on the resources to demonstrate the life cycle management tools and to trigger the approval policy.

This tutorial assumes that although you might be relatively new to Automation Assembler, you already configured a new vSphere cloud account. When you add the cloud account, Automation Assembler discovers the currently unmanaged resources on your vSphere instance.

What to do first

- Add your new vCenter account. For additional instructions, see [Create a basic cloud account in](#) .
- Verify that your user account has at least Automation Assembler Administrator and Automation Service Broker Administrator service roles. See [What are the user roles](#).
- To properly test the approval policy from the perspective of one of your users, verify that you have a user account that has only the following user roles. In this tutorial, the user is named Sylvia.
 - Organization Member
 - Automation Assembler User
 - Automation Service Broker User

For more information about user roles, see [What are the user roles](#).

Step 1: Verify that Automation Assembler discovered the resources

When you add a vCenter account, Automation Assembler discovers the resources on the vCenter instance. You can verify that the machines that you want to begin managing are available to onboard.

1. In Automation Assembler, select **Resources > Virtual Machines > Discovered**.

2. In the grid, review the **Account/Region** column.

The Discovered page lists all machines that are discovered on your vSphere instance rather than deployed by VMware Aria Automation or already onboarded.

Virtual Machines

[Discovered](#) [Managed](#)

Discovered machines are identified when you add cloud accounts. You can run simple day 2 actions on the machines or click Onboard to bring the selected machines under full management, including robust day 2 management actions. You can only include 50 machines each time you run an onboarding action.

Name	Status	Account / Region	Address	Project	Owner	Creation Time	Origin	Tags
DevProject-116	► On	vCenter Account / wld01-DC	N/A			Jul 26, 2021, 2:29:15 PM	Discoverd	
DevProject-centos-010	► On	vCenter Account / wld01-DC	N/A	Onboarding Project	fritz	Jul 26, 2021, 2:29:18 PM	Discoverd	db:mysql
DevProject-centos-012	► On	vCenter Account / wld01-DC	N/A			Jul 26, 2021, 2:29:18 PM	Discoverd	
DevProject-centos-013	► On	vCenter Account / wld01-DC	N/A			Jul 26, 2021, 2:29:15 PM	Discoverd	db:mysql
DevProject-centos-016	► On	vCenter Account / wld01-DC	N/A	Onboarding Project	sylvia	Jul 26, 2021, 2:29:15 PM	Discoverd	db:mysql

Step 2: Create a target project

Create a project that you can assign the onboarded machines to. To manage the resources, they must be part of a project that includes the source cloud zone on which they were originally deployed.

To test this tutorial, you must have another user who is not an administrator. In this step, as an administrator, you add Sylvia as the project member.

For more information about projects, see [Adding and managing projects](#).

1. In Automation Assembler, select **Infrastructure > Administration > Projects**.
2. On the Projects page, click **New Project**.
3. Enter the project **Name**.
In this tutorial, the project name is **Onboarding Project**.
4. Click the **Users** tab.
 - a. Click **Add Users** and add at least one user and assign them at least a project member role.
In this tutorial, you add **Sylvia**.
 - b. Click **Add**.
5. Click **Provisioning**.
 - a. Click **Add Zone > Cloud Zone**.
 - b. Select the account/region you identified in Step 1.
In this tutorial, the sample value is **vCenter Account / wld01-DC**.

Specify the zones that can be used when users provision deployments in this project. [\(i\)](#)

Zones

<input type="checkbox"/>	Name	Status	Description	Priority	Instances	Memory Limit (MB)	CPU Limit	Storage Limit (GB)	Capability Tags
<input type="checkbox"/>	vCenter Account / wld01-DC	--	0	Unlimited	Unlimited	Unlimited	Unlimited	Unlimited	

1 - of 1 zones

Specify the placement policy that will be applied when selecting a cloud zone for provisioning.

Placement policy: DEFAULT [\(i\)](#)

c. Click **Add**.

6. Click **Create**.

Step 3: Create and run an onboarding plan

As a cloud administrator, you onboard discovered machines from your vSphere instance so that you can apply governance and manage the resources with day 2 actions.

For more information about onboarding plans, see [What are onboarding plans in](#).

1. In Automation Assembler, select **Infrastructure > Onboarding**, and then click **New**.
2. Enter the onboarding information.

Setting	Sample Value
Plan name	wld01-DC Onboarding Plan
Cloud account	vCenter Account
Default project	Onboarding Project

3. Click **Create**.

4. Add the machines that you want to onboard.

Do not run the onboarding plan until you complete all of the following steps.

- a. Click **Deployments > New**, and then click **Without Cloud Template**.
- b. In the Create Deployments dialog box, select **Create a deployment for each selected machine**. You select this option when you want the machines as individual deployments so that you can manage them as individual resources.
- c. Select the machines that you want to include in the plan, and then click **Create**. For this tutorial, only two machines are selected.
- d. The selected machines are added to the list.

wld01-DC Onboarding Plan

Summary **Deployments** Machines

These deployments will be created or updated when the plan runs. By default each added machine is placed in its own Assembler deployment.

NEW	RENAME	EDIT OWNER	TEMPLATE	REMOVE	Deployment Name	Status	Template	Resource Mapping	Owner	Components
<input type="checkbox"/>	»	Deployment-04b178c5-6063-4c62-b418-419dc0921db4	Ready to run						1	
<input type="checkbox"/>	»	Deployment-1f9776e7-f8df-46d5-b4b1-3d62e5deb305	Ready to run						1	

5. Rename the deployments.

- To change the generated deployment name, select a deployment and click **Rename**.
- Enter the new name, and then click **Save**.
For example, Onboarded machine 1.
- Repeat as needed.

6. Assign an owner to the deployments.

If you do not assign an owner, you become the owner. The owner must be a member of the target project.

This tutorial assigns all the deployments to the same owner. Optionally, you can assign different deployments to different owners.

- Select all the deployments and click **Edit Owner**.
- Select the owner and click **Save**.

Review the deployment name changes in the grid.

wld01-DC Onboarding Plan

Summary **Deployments** Machines

These deployments will be created or updated when the plan runs. By default each added machine is placed in its own Assembler deployment.

NEW	RENAME	EDIT OWNER	TEMPLATE	REMOVE	Deployment Name	Status	Template	Resource Mapping	Owner	Components
<input type="checkbox"/>	»	Onboarded machine 1	Ready to run						sylvia	1
<input type="checkbox"/>	»	Onboarded machine 2	Ready to run						sylvia	1

7. Click **Run**.

After you run the onboarding plan, you cannot modify the name or assign owners. If you add more machines to the plan, you can modify the name or the owner.

8. Review the resources that you onboarded as deployments.

- Select **Resources > Deployments**.
- To locate deployments, you can search by deployment name, project, or owner.

Resource Name	Status	Resource Type
Hard disk 2		Cloud.vSphere.Disk
w1-hs4-vcf-maq-118-142-NSXM420-24020326	► On	Cloud.vSphere.Machine
VM Network		Cloud.vSphere.Network

Now that you have brought machines into VMware Aria Automation, you can begin managing them.

Step 4: Resize a deployment

Perform this step as a cloud administrator and familiarize yourself with how day 2 actions work. The changes that you can make to deployments are referred to as day 2 actions. Using day 2 actions are the first step in managing your resources.

For this tutorial, you think that the CPU count on a machine is too high, and you want to decrease the consumed CPUs. This procedure assumes that you are running the resize action on a vSphere machine that is powered on. It also assumes that you do not have any day 2 policies that prohibit a user from running this action.

The available actions depend on the resource type, the resource state, and the day 2 policies. For more information about day 2 actions, see [What actions can I run on deployments or supported resources](#).

- In Automation Assembler, select **Resources > Deployments**, and then locate your onboarded deployments. You can use the search or filter options.
- Expand the deployment using the arrow on the left, and then click the vertical ellipsis on the machine name and click **Resize**.

Resources

Resource Name	Status	Resource Type
Hard disk 2		Cloud.vSphere.Disk
wl-hs4-vcf-mag-118-142-NSXM420-24020326	On	Cloud.vSphere.Machine
VM Network		Cloud.vSphere.Network

Manage Columns Objects per page 10 1 - 3 of 3 resources

- In the **Resize** dialog box, decrease the CPU count to 4 and click **Submit**.

The suggested value is an example, change the CPU count to a value that works in your environment.

The action runs on the machine.

- To verify that the CPU count is changed, open the deployment and check the `cpuCount` custom property for the machine.
- You can also verify the count in vCenter Server.

The screenshot shows the vSphere Client interface. In the left sidebar, under the 'vm' category, 'DevProject-centos-019' is selected. On the right, the 'Summary' tab is active for the selected VM. The 'VM Hardware' section displays various configuration details:

Hardware Component	Configuration Details
CPU	4 CPU(s), 0 MHz used
Memory	4 GB, 1 GB memory active
Hard disk 1 (of 2)	48 GB Thin Provision (i) wld01-sc2vc05-wld01-clu01-vs01
Network adapter 1	Cloud_NSX_Network_1-mcm1292- 163799928607 (connected) 00:50:56:be:5c:69
CD/DVD drive 1	Disconnected (i)

Step 5: Applying approval policies

As a cloud administrator, you can apply governance in VMware Aria Automation to limit what the users can do or to require them to have approval before they do it. This tutorial shows you how to apply approval policies to the resize action so that your users cannot reconfigure a machine, perhaps catastrophically, without your approval or the approval of another administrator.

The policies are created in Automation Service Broker. However, the policies apply to the relevant requests in Automation Assembler and Automation Service Broker.

As an approver, you must respond to the approval request in Automation Service Broker.

1. In Automation Service Broker, select **Content and Policies** > **Policies** > **Definitions**, and then click **New Policy**.
2. Click **Approval Policy**.
3. Configure the approval policy.

Resize Approval Policy

[DELETE](#)

Approval policies control who must agree to a deployment or day 2 action before the request is provisioned. [\(1\)](#)

Type	Approval									
Name *	Resize Approval Policy									
Description	<input type="text"/>									
Scope *	<input checked="" type="radio"/> Organization / Multiple Projects <small>Apply the policy to all or a selection of projects in this organization. To target multiple projects, select project based criteria.</small> <input type="radio"/> Project <small>Apply the policy to a single project in this organization.</small> Onboarding Project									
Criteria	<input type="button"/> <input type="button" value="+ (GROUP)"/>									
Approval type *	<input checked="" type="radio"/> User based <input type="radio"/> Role based									
Approver mode *	<input checked="" type="radio"/> Any <input type="radio"/> All									
Approvers *	<input type="button" value="+ ADD USERS"/> <input type="button" value="REMOVE"/> <table border="1"> <thead> <tr> <th><input type="checkbox"/> Name</th> <th><input type="checkbox"/> Email</th> <th>Type</th> </tr> </thead> <tbody> <tr> <td><input type="checkbox"/> Fritz Arbeiter</td> <td>fritz</td> <td>User</td> </tr> <tr> <td><input type="checkbox"/></td> <td></td> <td>User</td> </tr> </tbody> </table>	<input type="checkbox"/> Name	<input type="checkbox"/> Email	Type	<input type="checkbox"/> Fritz Arbeiter	fritz	User	<input type="checkbox"/>		User
<input type="checkbox"/> Name	<input type="checkbox"/> Email	Type								
<input type="checkbox"/> Fritz Arbeiter	fritz	User								
<input type="checkbox"/>		User								
Auto expiry decision *	Reject									
Auto expiry trigger *	1 days									
Actions *	<input type="button" value="DELETE"/> <input type="button" value="Search approval actions"/> <table border="1"> <thead> <tr> <th><input type="checkbox"/> Actions</th> </tr> </thead> <tbody> <tr> <td><input type="checkbox"/> Cloud.vSphere.Machine.Resize</td> </tr> </tbody> </table>	<input type="checkbox"/> Actions	<input type="checkbox"/> Cloud.vSphere.Machine.Resize							
<input type="checkbox"/> Actions										
<input type="checkbox"/> Cloud.vSphere.Machine.Resize										

The following table includes sample values that illustrate how to create the policy.

Setting	Sample value
Name	Resize Approval Policy
Scope	Select Project , and then select Onboarding Project . The approval policy is triggered when a user who is a member of the project runs a Resize day 2 action.
Approval type	User based This value allows you to name the approvers.
Approver mode	Any If you have multiple approvers, the approval request can be resolved by at least one approver.
Approvers	Add yourself as an approver.
Auto expiry decision	Reject By rejecting an unreviewed request, you reduce the risk of making a machine either unusable or over resourced.
Auto expiry trigger	1

Table continued on next page

Continued from previous page

Setting	Sample value
Actions	Select the resize action that triggers the approval policy. 1. Enter <code>machine.resize</code> in the Search. 2. Click Show all in the search results drop-down list. 3. Select <code>Cloud.vSphere.Machine.Resize</code> . For this tutorial, which is based on vSphere, you select the <code>vSphere.Machine</code> action. If you want the action policy to apply to other resource types, you can add the other <code>Machine.Resize</code> actions.

Step 6: Request a resize request as a user

In this step you log in to Automation Service Broker as an Organization member and Automation Service Broker user and run a resize day 2 request. The request creates an approval request. The user can also perform the same steps in Automation Assembler.

In the step after this one, you log in as the user who you assigned as an approver in Step 5 and approve the request.

1. Log in to Automation Service Broker as a user.

In this tutorial, the user is Sylvia.

2. Select **Consume > Deployments > Deployments** and locate Onboarded machine 1.

This deployment is the one where you ran the resize action on the machine in Step 4, changing the number of CPUs from 8 to 4. If you used a different value, modify the machine in a way that you want to test.

3. Run the **Resize** action on the machine, increasing the CPU count to 6.

4. Notice that the request is waiting for an approval.

To see the pending status, hover over the information icon in the grid or open the deployment and review the **History** tab.

The screenshot shows a table titled "Deployments" with 20 items of 24. The columns are Name, Address, Owner, Project, Status, Expires on, and Price. One row is expanded, showing sub-items: "Hard disk 2" and "DevProject-c...". A tooltip at the bottom right of the screen says "Resize – Approval Pending (0 / 2 Tasks)".

Deployments (20 Items of 24)						
	Name	Address	Owner	Project	Status	Expires on
...	Onboarded ma...	sylvia	Onboarding P...	1	Pending	Never
...	Hard disk 2					
...	DevProject-c...					
>	Onboarded ma...	sylvia	Onboarding P...			

5. As a user, the change the Sylvia requested does not proceed until it is approved.

6. Log out of Automation Service Broker as the user.

In Step 7 you log in as the assigned approver and respond to the request.

Step 7: Respond to an approval request

When a request requires an approval, and you are the approver, you receive an email message. For this tutorial, we are not waiting for the message. Instead, the process guides you through directly to responding to approval requests using the Automation Service Broker **Inbox** tab.

1. Log in to Automation Service Broker as the user you assigned as the approver in Step 5.

In this tutorial, the approver is Fritz.

2. Select **Consume > Deployments > Deployments** and locate Onboarded machine 1.

The status in the grid looks the same as it did for Sylvia.

The screenshot shows the 'Deployments' page with a table header: Name, Address, Owner, Project, Status, Expires on, Price. Below the header, there are three rows of deployment data. The third row, which corresponds to the 'Onboarded machine 1' entry from the previous screenshot, has a status of 'Approval Pending'. A tooltip 'Resize – Approval Pending (0 / 2 Tasks)' is displayed over this row. The table footer shows another row for 'Onboarded machine 1'.

3. Select **Inbox > Approvals**.

Notice that you have an approval request pending.

The screenshot shows the 'Approval Requests' page with a table header: Requestor, Action, Created on. Below the header, there is one item: 'Onboarded machine 1' (Requested by sylvia, Action: Cloud.vSphere.Machine.Resize, Created on: Jul 29, 2021, 2:44:17 PM). A tooltip 'Resize Approval Policy' is displayed next to the action details. The table footer shows another row for 'Onboarded machine 1'.

4. To view the request details, click the deployment name.

The screenshot shows the deployment details for 'Onboarded machine 1'. At the top, there are buttons for APPROVE (yellow) and REJECT (red). Below the buttons, the deployment details are listed: Requestor (sylvia), Action (Cloud.vSphere.Machine.Resize), Created on (Jul 29, 2021, 2:44:17 PM). Under 'Project', it says 'Onboarding Project'. Under 'Deployment', it says 'Onboarded machine 1'. Under 'Auto decision', it says 'Reject on Jul 30, 2021, 2:44:17 PM'. Below these details is a section titled 'Policy Details' with tabs for 'Policy Details', 'Resource Details', and 'Input Details'. The 'Policy Details' tab is selected, showing a table with columns: Policy name, Approval mode, Status, and Approvers. One row is visible: 'Resize Approval Policy', 'ANY_OF', 'Pending', and 'fritz'. A vertical support bar is on the right side of the page.

5. Click **Approve**, provide a comment, if needed, and click **Approve**.

6. Return to the **Deployments** page to see that the Sylvia's resize action is now in progress.

The screenshot shows the 'Deployments' page with a table header: Name, Address, Owner, Project, Status, Expires on, Price. Below the header, there are three rows of deployment data. The third row, which corresponds to the 'Onboarded machine 1' entry from the previous screenshots, has a status of 'In Progress'. A tooltip 'Resize – In Progress (1 / 2 Tasks)' is displayed over this row. The table footer shows another row for 'Onboarded machine 1'.

- When the resize action is completed, you can verify the number of CPUs in the deployment details and in the vSphere Client.

This tutorial guided you through the process of bringing the machines into VMware Aria Automation so that you can begin managing the life cycle of the resource.

Tutorial: Setting up and testing multi-cloud infrastructure and deployments in Automation Assembler

Multi-cloud infrastructure and deployments

This end-to-end Automation Assembler tutorial shows how you might deploy in a multiple-cloud setting. You deploy the same cloud template to more than one provider, in this case AWS and Microsoft Azure.

In this example, the application is a WordPress site. Look at the sequential setup to understand the process that brings the entire design to completion.

Remember that the names and values you see are only examples. You won't be able to use them letter-by-letter in your own environment.

To fit your own cloud infrastructure and deployment needs, consider where you would make your own substitutions for the example values.

Part 1: Configure the example Automation Assembler infrastructure

Part 1: Configure the example infrastructure

First, configure the resources where Automation Assembler engineering users can later develop, test, and put the application into production.

The infrastructure includes cloud targets, and definitions around the available machines, networks, and storage that the WordPress site will need.

Prerequisites

Log in to Automation Assembler as an Automation Assembler Administrator.

1. Add cloud accounts

In this step, the cloud administrator adds two cloud accounts. The example project expects to do development and testing work on AWS, and go to production on Azure.

- Go to **Infrastructure > Connections > Cloud Accounts**.
- Click **Add Cloud Account**, select Amazon Web Services, and enter values.

Setting	Sample Value
Access key ID	R5SDR3PXVV2ZW8B7YNSM
Secret access key	SZXAINXU4UHNAQ1E156S
Name	OurCo-AWS
Description	WordPress

Remember that all values are only examples. Your account specifics will vary.

- To verify credentials, click **Validate**.
- In **Configuration**, allow provisioning to us-east-1 and us-west-2 regions.
- (Optional) Select the option to create default cloud zones for the regions.
- Click **Add**.

7. Click **Add Cloud Account**, select Microsoft Azure, and enter values.

Setting	Sample Value
Subscription ID	ef2avpf-dfdv-zxlugui1i-g4h0-i8ep2jwp4c9arbf
Tenant ID	dso9wv3-4zgc-5nrcy5h3m-4skf-nnovp40wfxsro22r
Client application ID	bg224oq-3ptp-mbhi6aa05-q511-uf1yjr2sttyik6bs
Client application secret key	7uqx57-0wtn-kymgf9wcj-t2l7-e52e4nu5fig4pmdd
Name	OurCo-Azure
Description	WordPress

8. To verify credentials, click **Validate**.
 9. In **Configuration**, allow provisioning to the East US region.
 10. (Optional) Select the option to create a default cloud zone for the region.
 11. Click **Add**.

2. Add cloud zones

In this example step, the cloud administrator adds three cloud zones, one each for development, testing, and production.

1. Go to **Infrastructure > Configure > Cloud Zones**.
 2. Click **New Cloud Zone**, and enter values for the development environment.
 If you created a default cloud zone while adding the parent cloud account, you only need to edit the default cloud zone, not add a new one.

Cloud Zone Setting	Sample Value
Account / region	OurCo-AWS/us-east-1
Name	OurCo-AWS-US-East
Description	WordPress
Placement policy	Default
Capability tags	env:dev

Remember that all values are only examples. Your zone specifics will vary.

3. Click **Compute**, and verify that the zones you expect are there.
 4. Click **Create**.
 5. Repeat the process twice, with values for the test and production environments.

Cloud Zone Setting	Sample Value
Account / region	OurCo-AWS/us-west-2
Name	OurCo-AWS-US-West
Description	WordPress
Placement policy	Default
Capability tags	env:test

Cloud Zone Setting	Sample Value
Account / region	OurCo-Azure/East US
Name	OurCo-Azure-East-US

Table continued on next page

Continued from previous page

Cloud Zone Setting	Sample Value
Description	WordPress
Placement policy	Default
Capability tags	env:prod

3. Add flavor mappings

In this example step, the cloud administrator adds flavor mappings to account for capacity needs that might vary depending on deployment.

Flavor mapping accounts for different size machine deployments and is informally referred to as T-shirt sizing.

1. Go to **Infrastructure > Configure > Flavor Mappings**. Each cloud zone needs to allow for small, medium, and large flavors.
2. Click **New Flavor Mapping**, and enter values for the development cloud zone.

Setting	Sample Value
Flavor name	small
Account/region	OurCo-AWS/us-east-1
Value	t2.micro
Account/region	OurCo-AWS/us-west-2
Value	t2.micro
Account/region	OurCo-Azure/East US
Value	Standard_A0

Remember that all values are only examples. Your flavors will vary.

3. Click **Create**.
4. Repeat the process twice, with values for medium and large flavors.

Setting	Sample Value
Flavor name	medium
Account/region	OurCo-AWS/us-east-1
Value	t2.medium
Account/region	OurCo-AWS/us-west-2
Value	t2.medium
Account/region	OurCo-Azure/East US
Value	Standard_A3

Setting	Sample Value
Flavor name	large

Table continued on next page

Continued from previous page

Setting	Sample Value
Account/region Value	OurCo-AWS/us-east-1 t2.large
Account/region Value	OurCo-AWS/us-west-2 t2.large
Account/region Value	OurCo-Azure/East US Standard_A7

4. Add image mappings

In this example step, the cloud administrator adds an image mapping for Ubuntu, the host for the WordPress server and its MySQL database server.

Plan for the operating system by adding image mappings. Each cloud zone needs a Ubuntu image mapping.

1. Go to **Infrastructure > Configure > Image Mappings**.
2. Click **New Image Mapping**, and enter values for Ubuntu servers.

Setting	Sample Value
Image name	ubuntu
Account/region Value	OurCo-AWS/us-east-1 ubuntu-16.04-server-cloudimg-amd64
Account/region Value	OurCo-AWS/us-west-2 ubuntu-16.04-server-cloudimg-amd64
Account/region Value	OurCo-Azure/East US azul-zulu-ubuntu-1604-923eng

Remember that all values are only examples. Your images will vary.

3. Click **Create**.

5. Add network profiles

In this example step, the cloud administrator adds a network profile to each cloud zone.

In each profile, the administrator adds a network for the WordPress machines, and a second network that will sit on the other side of an eventual load balancer. The second network will be the one that users eventually connect to.

1. Go to **Infrastructure > Configure > Network Profiles**.
2. Click **New Network Profile**, and create a profile for the development cloud zone.

Network Profile Setting	Sample Value
Account / region	OurCo-AWS/us-east-1
Name	devnets

Table continued on next page

Continued from previous page

Network Profile Setting	Sample Value
Description	WordPress

3. Click **Networks**, and click **Add Network**.
4. Select wpnet, appnet-public, and click **Add**.
Remember that all values are only examples. Your network names will vary.
5. Click **Create**.
This Wordpress example does not require that you specify network policy or network security settings.
6. Repeat the process twice, to create a network profile for the Wordpress example test and production cloud zones. In each case, add the wpnet and appnet-public networks.

Network Profile Setting	Sample Value
Account / region	OurCo-AWS/us-west-2
Name	testnets
Description	WordPress

Network Profile Setting	Value
Account / region	OurCo-Azure/East US
Name	prodnets
Description	WordPress

6. Add storage profiles

In this example step, the cloud administrator adds a storage profile to each cloud zone.

The administrator places fast storage at the production zone and general storage at development and test.

1. Go to **Infrastructure > Configure > Storage Profiles**.
2. Click **New Storage Profile**, and create a profile for the development cloud zone.
Additional fields appear after you select the account/region.

Storage Profile Setting	Sample Value
Account / region	OurCo-AWS/us-east-1
Name	OurCo-AWS-US-East-Disk
Description	WordPress
Device type	EBS
Volume type	General Purpose SSD
Capability tags	storage:general

Remember that all values are only examples.

3. Click **Create**.
4. Repeat the process to create a profile for the test cloud zone.

Storage Profile Setting	Sample Value
Account / region	OurCo-AWS/us-west-2
Name	OurCo-AWS-US-West-Disk
Description	WordPress
Device type	EBS
Volume type	General Purpose SSD
Capability tags	storage:general

5. Repeat the process to create a profile for the production cloud zone, which has different settings because it is an Azure zone.

Storage Profile Setting	Sample Value
Account / region	OurCo-Azure/East US
Name	OurCo-Azure-East-US-Disk
Description	WordPress
Storage type	Managed disks
Disk type	Premium LRS
OS disk caching	Read only
Data disk caching	Read only
Capability tags	storage:fast

What to do next

Create a project to identify users, and to define provisioning settings. See [Part 2: Create the example project](#).

Part 2: Create the example Automation Assembler project

Part 2: Create the example project

The example Automation Assembler project enables the users who can provision, and configures how much provisioning is possible.

Projects define the user and provisioning settings.

- Users and their role level of permission
- Priority for deployments as they are being provisioned to a cloud zone
- Maximum number of deployment instances per cloud zone

1. Go to **Infrastructure > Administration > Projects**.

2. Click **New Project**, and enter the name WordPress.

3. Click **Users**, and click **Add Users**.

4. Add email addresses and roles for the users.

To successfully add a user, a VMware Cloud Services administrator must have enabled access to Automation Assembler for the user.

Remember that addresses shown here are only examples.

- chris.ladd@ourco.com, Member
- kerry.mott@ourco.com, Member
- pat.tubb@ourco.com, Administrator

5. Click **Provisioning**, and click **Add Cloud Zone**.

- Add the cloud zones that the users can deploy to.

Project Cloud Zone Setting	Sample Value
Cloud zone	OurCo-AWS-US-East
Provisioning priority	1
Instances limit	5
Cloud zone	OurCo-AWS-US-West
Provisioning priority	1
Instances limit	5
Cloud zone	OurCo-Azure-East-US
Provisioning priority	0
Instances limit	1

- Click **Create**.
- Go to **Infrastructure > Configure > Cloud Zones**, and open a zone that you created earlier.
- Click **Projects**, and verify that WordPress is a project that is allowed to provision to the zone.
- Check the other zones that you created.

Create a basic cloud template.

Part 3: Design and deploy the example Automation Assembler template

Part 3: Design and deploy the example cloud template

Next, you define the example application—the WordPress site—in the form of a generic cloud template. The template can be deployed to different cloud vendors without needing to change its design.

To follow along, you must be familiar with your own infrastructure values. This example uses AWS for development and test, and Azure for production. When creating your own cloud template, substitute your own values, typically set by your cloud administrator.

The example consists of a WordPress application server, MySQL database server, and supporting resources. The template starts with a few resources, and then grows as you modify them and add more resources. Here are the values from [the first part of the example](#), the infrastructure that was set by a cloud administrator:

- Two cloud accounts, AWS and Azure.
- Three cloud zone environments:
 - Development—OurCo-AWS-US-East
 - Test—OurCo-AWS-US-West
 - Production—OurCo-Azure-East-US
- Flavor mappings with small, medium, and large compute resources for each zone.
- Image mappings for Ubuntu configured in each zone.
- Network profiles with internal and external subnets for each zone.
- Storage on which to deploy; general storage for the development and test zone, and fast storage for the production zone.
- The example project includes all three cloud zone environments plus the users who can create designs.

Create a basic cloud template

Create a basic cloud template

In this Automation Assembler design example, you start with a cloud template that contains only minimal WordPress resources, such as having only one application server.

Automation Assembler is an infrastructure-as-code tool. You drag resources to the design canvas to get started. Then, you complete the details using the code editor to the right of the canvas.

The code editor allows you to type, cut, and paste code directly. If you're uncomfortable editing code, you can select a resource in the canvas, click the code editor **Properties** tab, and enter values there. Values that you enter appear in the code as if you had typed them directly.

1. Go to **Design > Cloud Templates** and click **New from > Blank canvas**.
 2. Name the cloud template `Wordpress-BP`.
 3. Select the **WordPress** project, and click **Create**.
 4. From the resources on the left of the cloud template design page, drag two cloud agnostic machines onto the canvas.
- The machines serve as WordPress application server (WebTier) and MySQL database server (DBTier).
5. On the right, edit the machine YAML code to add names, images, flavors, and constraint tags:

```
resources:
  WebTier:
    type: Cloud.Machine
    properties:
      name: wordpress
      image: ubuntu
      flavor: smallconstraints:
        - tag: env:devDBTier:
  type: Cloud.Machine
  properties:
    name: mysql
    image: ubuntu
    flavor: smallconstraints:
      - tag: env:dev
```

6. Drag a cloud agnostic network to the canvas, and edit its code:

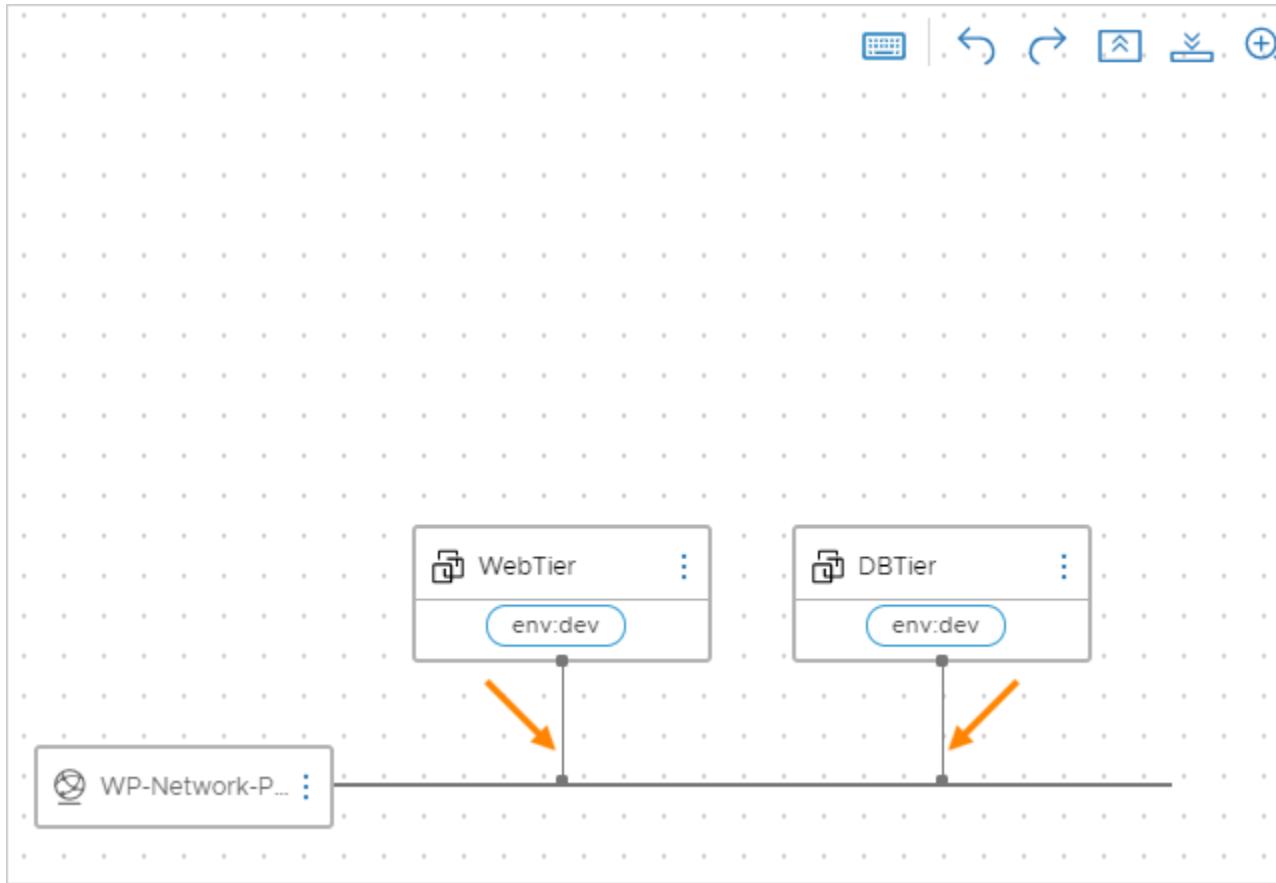

```
WP-Network-Private:
  type: Cloud.Network
  properties:
    name: WP-Network-Private
```

```
networkType: existing
```

7. Connect the machines to the network:

In the canvas, hover over the network block, click and hold the bubble where the line touches the block, drag to a machine block, and release.

When you create the connection lines, note that network code is automatically added to the machines in the editor.

8. Add user input prompting.

In some places, the example infrastructure was set up for multiple options. For example:

- Cloud zone environments for development, test, and production
- Flavor mappings for small, medium, and large machines

You might set a specific option directly in the cloud template, but a better approach is to let the user select the option at template deployment time. Prompting for user input lets you create one template that can be deployed many ways, instead of having many hard-coded templates.

- a) Create an `inputs` section in the code so that users can select machine size and target environment at deployment time. Define the selectable values:

```
inputs:
```

```
  env:
```

```

type: string
enum:
  - env:dev
  - env:prod
  - env:test
default: env:dev
title: Environment
description: Target Environment
size:
  type: string
  enum:
    - small
    - medium
    - large
  description: Size of Nodes
  title: Tier Machine Size

```

- b) In the resources section of the code, add \${input.input-name} code to prompt for the user selection:

```

resources:
  WebTier:
    type: Cloud.Machine
    properties:
      name: wordpress
      image: ubuntu
      flavor: '${input.size}'
    constraints:
      - tag: '${input.env}'
    networks:
      - network: '${resource["WP-Network-Private"].id}'
  DBTier:
    type: Cloud.Machine

```

```

properties:
  name: mysql
  image: ubuntu
  flavor: '${input.size}'
  constraints:
    - tag: '${input.env}'
networks:
  - network: '${resource["WP-Network-Private"].id}'

WP-Network-Private:
  type: Cloud.Network
  properties:
    name: WP-Network-Private
    networkType: existing

```

9. Finally, enhance the WebTier and DBTier code using the following examples. The WP-Network-Private code does not need additional changes.

Note that the enhancements include login access to the database server and deployment-time cloudConfig initialization scripts.

Component	Example

Test the cloud template by checking the syntax and deploying it.

Test a basic cloud template

Test a basic cloud template

During design, you often build a cloud template by starting with the essentials, then deploying and testing as the template grows. This example demonstrates some of the in-progress testing built into Automation Assembler.

Create the basic cloud template. See [Create a basic cloud template](#).

To be certain that a deployment works the way that you want, you might test and deploy the cloud template several times. Gradually, you add more resources, retest, and redeploy along the way.

1. Click **Cloud Templates**, and open the WordPress-BP cloud template.

The basic cloud template appears, in the design canvas and code editor.

2. To check template syntax, placement, and basic validity, click **Test** at the lower left.
3. Enter input values, and click **Test**.

Testing Basic

Environment: env:dev (i)

Tier Machine: small (i)

Size *: **Small**

Database: ouradmin

Username *: ouradmin

Database:
Password *: **.....**

CANCEL **TEST**

The test is only a simulation and does not actually deploy virtual machines or other resources.

← Test Result for Basic

Successful This simulation only tests syntax, placement and basic validity

3 Infos Provisioning Diagram

WP-Network-Private

LINE 96

DBTier

LINE 69

WebTier

The test includes a link to a **Provisioning Diagram**, where you can inspect the simulated deployment flow and see what occurred. The simulation exposes potential issues, such as not having any resource capabilities defined that match hard constraints in the cloud template. In the example error that follows, a cloud zone of capability tag `env:dev` wasn't found anywhere in the defined infrastructure.

The screenshot shows the 'Request Details' page with the title 'Request Details' and an 'EXPORT' button. Below the title are two tabs: 'NETWORK ALLOCATION' (blue) and 'MACHINE ALLOCATION' (red). The 'MACHINE ALLOCATION' tab is selected. On the left, there's a vertical sidebar labeled 'Requests'. In the main area, a red error message box contains the text: 'Request: mysql' followed by 'Error: No placement exists that satisfies all of the request requirements. See if suitable placements and cloud zones exist for the current project and they have been properly tagged.' Below this, a table lists request details:

Request type	Allocation
Flavor	small
Image	ubuntu
Constraints	<code>env:dev:hard</code>

A red arrow points from the error message to the 'env:dev:hard' constraint entry in the table. A red downward arrow points from the bottom of the table towards the dashed line at the bottom of the screen.

A successful simulation doesn't guarantee that you can deploy the template without errors.

4. After the template passes the simulation, click **Deploy** at the lower left.
5. Select **Create a new deployment**.
6. Name the deployment `WordPress for OurCo` and click **Next**.
7. Enter input values, and click **Deploy**.
8. To verify that the template successfully deployed, look under **Resources > Deployments**.

If a deployment fails, click its name, and click the **History** tab to see messages that can help you troubleshoot.

Timestamp	Status	Resource type	Resource name
Sep 8, 2020, 1...	CREATE_IN_PROGRESS	Cloud.Machine	WebTier
Sep 8, 2020, 1...	CREATE_FINISHED	Cloud.Machine	DBTier
Sep 8, 2020, 1...	CREATE_IN_PROGRESS	Cloud.Machine	DBTier
Sep 8, 2020, 1...	CREATE_FINISHED	Cloud.Network	WP-Network
Sep 8, 2020, 1...	CREATE_IN_PROGRESS	Cloud.Network	WP-Network

Some history entries might have the **Provisioning Diagram** link at the far right. The diagram is similar to the simulated one, where you inspect the flow chart of Automation Assembler decision points in the provisioning process.

More flow charts are available under **Infrastructure > Activity > Requests**.

9. To verify that the application is working, open the WordPress start page in a browser.
 - a) Wait for the WordPress servers to be fully created and initialized.
It might take 30 minutes or more for initialization, depending on the environment.
 - b) To locate the site FQDN or IP address, go to **Resources > Deployments > Topology**.
 - c) On the canvas, click the WebTier, and find the IP address in the panel on the right.
 - d) Enter the IP address as part of the full URL to the WordPress start page.
In this example, the full URL is:
`http://{IP-address}/mywordpresssite`
or
`http://{IP-address}/mywordpresssite/wp-admin/install.php`
10. After inspecting WordPress in a browser, if the application needs more work, make template changes and redeploy using the **Update an existing deployment** option.
11. Consider versioning the cloud template. You can revert to a working version if a change causes deployment to fail.
 - a) On the cloud template design page, click **Version**.
 - b) On the Creating Version page, enter `WP-1.0`.
Do not enter spaces in version names.
 - c) Click **Create**.

To review or revert to a version, on the design page, click the **Version History** tab.
12. With a basic deployment now possible, try your first deployment-time enhancement by increasing CPU and memory on the application and database servers.

Update to a medium node size for both. Using the same template, select `medium` at deployment time, redeploy, and verify the application again.

Expand the cloud template into a production-worthy application by adding even more resources.

Expand a cloud template

Expand a cloud template

After you create and test the basic Automation Assembler template for the example application, you expand it into a multiple tier application that is deployable to development, test, and eventually production.

Create the basic cloud template and test it. See [Create a basic cloud template](#) and [Test a basic cloud template](#).

To expand the cloud template, you add the following enhancements.

- An option to cluster application servers for increased capacity
- A public-facing network and load balancer in front of the application servers
- A backup server with archive storage

1. Click **Cloud Templates**, and open the WordPress-BP cloud template.

The basic template appears, in the design canvas and code editor.

2. Make additions and changes, using the code example and figure for guidance.

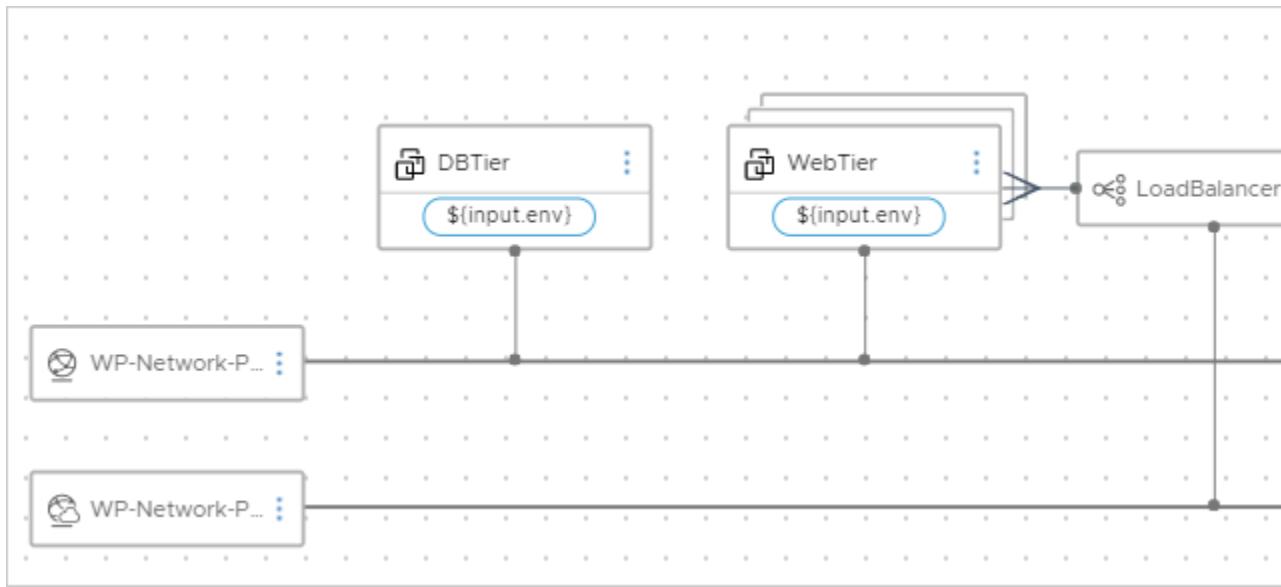

You use the GUI to drag new resources to the canvas, such as the load balancer, and then finish the configuration in the code editor.

- Add a `count` input prompt to make the WordPress application server into a cluster.
- Add a cloud agnostic load balancer.
- Connect the load balancer to the WordPress application server cluster.
- Add a cloud agnostic backup machine.
- Connect the backup machine to the private/internal network.
- Add a cloud agnostic public/external network.
- Connect the load balancer to the public network.
- Add a cloud agnostic storage volume for use as an archive disk.
- Connect the archive disk to the backup machine.
- Add an input prompt for the archive disk speed.

3. Deploy, test, and make changes in the same way that you did for the basic cloud template.

You can update existing deployments, or even deploy new instances so that you can compare deployments.

The goal is to reach a solid, repeatable template that can be used for production deployments.

Define your own infrastructure and create your own cloud templates.

See [Building your resource infrastructure](#) and [Designing your deployments](#).

Tutorial: Configuring VMware Cloud on AWS for VMware Aria Automation

Configuring VMware Cloud on AWS

This VMware Aria Automation tutorial illustrates the process of defining resource infrastructure and cloud template settings for deployment to a VMware Cloud on AWS environment.

The procedure requires that a cloud administrator has already configured your organization's VMware Cloud on AWS SDDC data center as described in *Deploying and Managing a Software-Defined Data Center in the VMware Cloud on AWS Getting Started documentation*.

Look at the sequential setup to understand the process for configuring your environment for VMware Cloud on AWS.

Configure a basic VMware Cloud on AWS workflow in VMware Aria Automation

Configure a basic VMware Cloud on AWS workflow

This use case shows the process of defining resource infrastructure and a corresponding cloud template for deployment to a VMware Cloud on AWS environment.

Before you can create and configure a VMware Cloud on AWS cloud account in Automation Assembler, you must be part of an organization in an existing VMware Cloud on AWS SDDC environment. For information about configuring the VMware Cloud on AWS service, see [VMware Cloud on AWS Documentation](#).

Note: The on-premises version of VMware Aria Automation can be configured to support either standard (commercial) VMware Cloud on AWS or VMware Cloud on AWS GovCloud (US), but not both. Configuring a VMware Aria Automation on AWS GovCloud (US) environment is outside the scope of this documented workflow.

In this procedure, you will prepare for and create a VMware Cloud on AWS cloud account in VMware Aria Automation.

Prepare your VMware Cloud on AWS SDDC to connect with VMware Cloud on AWS cloud accounts in VMware Aria Automation

Prepare your VMware Cloud on AWS SDDC to connect with VMware Cloud on AWS cloud accounts

Before you can create VMware Cloud on AWS cloud accounts, you must create a network connection and configure rules to support communication between your SDDC in vCenter and VMware Cloud on AWS cloud accounts in VMware Aria Automation.

To support communication between VMware Aria Automation and the VMware Cloud on AWS SDDC, configure the needed connections and rules. After you have configured required gateway access and firewall rules, you can continue with the process of creating a VMware Cloud on AWS cloud account.

To facilitate the needed connection between your existing VMware Cloud on AWS host SDDC in vCenter and a VMware Cloud on AWS cloud account in VMware Aria Automation Automation Assembler, you must provide a network connection, and add firewall rules, by using a VPN or similar networking means.

The VMware Cloud on AWS administrator must use the VMware Cloud on AWS SDDC console to configure management rules and firewall rules that support access to required ports and protocols.

To facilitate the needed connection between your existing VMware Cloud on AWS host SDDC in vCenter and a VMware Cloud on AWS cloud account in VMware Aria Automation, you must provide a network connection between the two elements by using a VPN or similar networking means.

1. Configure a VPN connection over the public Internet or AWS Direct connect.

See information about configuring VPN connectivity to the on-premises data center, as well as configuring AWS Direct Connect for VMware Cloud on AWS, in *VMware Cloud on AWS Networking and Security at VMware Cloud on AWS Documentation*.

2. Verify that the vCenter FQDN is resolvable at a private IP address on the management network.

See information about setting the vCenter FQDN resolution address in *VMware Cloud on AWS Networking and Security at VMware Cloud on AWS Documentation*.

3. Configure needed firewall rules.

You must configure management gateway firewall rules in the VMware Cloud on AWS SDDC console to support communication. The rules must be in the **Management Gateway** firewall rules section. Create the firewall rules by using options on the **Networking & Security** tab in the SDDC console.

- Limit network traffic to ESXi for HTTPS (TCP 443) services to the discovered IP address of the VMware Aria Automation appliance/server or VMware Aria Automation load balancer VIP.

- Limit network traffic to vCenter for ICMP (All ICMP), SSO (TCP 7444), and HTTPS (TCP 443) services to the discovered IP address of the VMware Aria Automation appliance/server or VMware Aria Automation load balancer VIP.
- Limit network traffic to the NSX Manager for HTTPS (TCP 443) services to the discovered IP address of the VMware Aria Automation appliance/server or VMware Aria Automation load balancer VIP.

The required firewall rules are summarized in the following table.

Table 3: Required Management Gateway Firewall Rules Summary

Name	Source	Destination	Service
vCenter	CIDR block of on-premises data center	vCenter	Any (All Traffic)
vCenter	Any	vCenter	ICMP (All ICMP)
NSX Manager	CIDR block of on-premises data center	NSX Manager	Any (All Traffic)
On premises to ESXi ping	CIDR block of on-premises data center	ESXi Management Only	ICMP (All ICMP)
On Premises to ESXi remote console and provisioning	CIDR block of on-premises data center	ESXi Management Only	TCP 902
On-premises to SDDC VM	CIDR block of on-premises data center	CIDR block of SDDC logical network	Any (All Traffic)
SDDC VM to on premises	CIDR block of SDDC logical network	CIDR block of on-premises data center	Any (All Traffic)

For related information, see [VMware Cloud on AWS Networking and Security](#) and [VMware Cloud on AWS Operations Guide](#) at [VMware Cloud on AWS Documentation](#).

Create a VMware Cloud on AWS cloud account in VMware Aria Automation in the workflow

You can create a VMware Cloud on AWS cloud account in VMware Aria Automation based on a source VMware Cloud on AWS SDDC.

- Verify that you have the required administrator credentials, including VMware Cloud on AWS CloudAdmin credentials for the target SDDC in vCenter and that you have enabled HTTPS access on port 443. See [Credentials required for working with cloud accounts in VMware Aria Automation](#).

Also see the *System Requirements* topic in *Installing VMware Aria*

Automation with Easy Installer

and the *Port Requirements* topic in *Reference Architecture Guide*. Both publications are available on the [VMware Aria Automation product documentation page](#).

- Verify that you have the cloud administrator user role. See [What are the user roles](#).
- To facilitate the needed connection between your existing VMware Cloud on AWS host SDDC in vCenter and a VMware Cloud on AWS cloud account in VMware Aria Automation, you must provide a network connection, and firewall rules, by using a VPN or similar networking means. See [Prepare your VMware Cloud on AWS SDDC to connect with VMware Cloud on AWS cloud accounts in VMware Aria Automation](#).
- If you do not have external Internet access, configure an Internet server proxy. See [How do I configure an Internet proxy server for VMware Aria Automation](#).

For general information about VMware Cloud on AWS, see [VMware Cloud on AWS documentation](#).

1. Select **Infrastructure > Connections > Cloud Accounts**.
2. Click **Add Cloud Account** and select the VMware Cloud on AWS tile.
3. As prompted, enter a name and description for the cloud account.

- For the API token setting, create a new token or use an existing token for your organization by using the linked **API Tokens** page as described below.

Note: Copy, download, or print the token that is generated by this workflow. After you leave the API token page you cannot retrieve the generated token information.

- Click the *i* help icon at the end of the **VMC API token** line and click **API Tokens page** in the help text box to open the **API Tokens** tab on your organization's **My Account** page.
- Click **Generate Token** to display the **Generate a New API Token** options.
- Enter a new token name, for example *myinitials_mytoken*.
- Set the **Token TTL** to **never expire**.
If you create a token that is set to expire, then the VMware Cloud on AWS operations from VMware Aria Automation will stop working when the token expires and continue to not work until you update the cloud account with a new token.
- In the **Define Scopes** section, select **All Roles**.
- Click **Generate**.
- In the generated token page, click **Copy** and click **Continue**.
- Return to the **New Cloud Account** page, paste the copied token into the **VMC API token** row, and click **Apply API token**.

The screenshot shows the 'New Cloud Account' interface. In the 'VMware Cloud on AWS Server Credentials' section, there is a field labeled 'VMC API token *' containing a redacted token value. Below the field is a blue rectangular button with the text 'APPLY API TOKEN' and a small icon.

In the **Define Scopes** section, the minimum required roles for the API token are:

- **Organizational Roles**
 - Organization Member
 - Organization Owner
- **Service Roles - VMware Cloud on AWS**
 - Administrator
 - NSX Cloud Administrator
 - NSX Cloud Auditor

Apply the generated or supplied token to connect to the available SDDC environment in your organization's VMware Cloud on AWS subscription and populate the list of SDDC names. If the VMware Aria Automation and VMware Cloud on AWS services are in different organizations, you should switch to the VMware Cloud on AWS organization and then generate the token. For more information about API tokens, see [Generate API Tokens](#).

- Click **Apply API token** to apply the API token and display the SDDC name option.
- In the **SDDC name** drop-down menu, select an SDDC from the list of available SDDCs. The list of available SDDCs is derived from your VMware Cloud on AWS subscription.

The selected SDDC name auto-populates the vCenter and NSX FQDN entries.

- In the **vCenter Server IP address/FQDN** drop-down menu, enter the IP address or FQDN of the vCenter in the specified SDDC.

The address auto-populates based on your SDDC selection. It defaults to the private IP address. Based on the type of network connectivity used to access your SDDC, the default address might be different than the IP address of the vCenter in the specified SDDC.

8. In the **NSX Manager IP address/ FQDN** drop-down menu, enter the IP address or FQDN of the NSX Manager in the specified SDDC.

The address auto-populates based on your SDDC selection. It defaults to the private IP address. Based on the type of network connectivity used to access your SDDC, the default address might be different than the IP address of the NSX Manager Server in the specified SDDC. VMware Cloud on AWS cloud accounts support NSX.

If you are creating a VMware Aria Automation on AWS GovCloud (US) cloud account in a VMware Aria Automation environment, do not use the default **NSX Manager IP address/FQDN** setting. Instead, you must specify the NSX Manager IP address that is identified in the VMware Aria Automation on AWS GovCloud (US) SDDC.

9. As prompted, enter your vCenter user name and password for the specified SDDC if it's different than the default.

The specified user requires CloudAdmin credentials. The user does not require CloudGlobalAdmin credentials.

The data centers that are available for provisioning in your specified VMware Cloud on AWS SDDC environment are listed. The list is read-only.

10. Click **Validate**.

The **Validate** option confirms your access rights to the vCenter server and NSX Manager and checks that the specified vCenter is running.

If you receive an Error updating endpoint <Name>: Endpoint already exists, a cloud account has already been associated to that SDDC.

11. In the **Configuration** section of the page, specify the SDDC data center that you wish to provision to and optionally create a new cloud zone for provisioning within that data center.

12. In the **Capabilities** section of the page, optionally specify capability tags for the cloud account.

Use tags according to your organization's tag strategy. See [maphead-how-to-use-tags.dita#GUID-1F1FD968-2EA1-404E-B081-E13383392061-en](#) and [Creating a tagging strategy](#).

13. Click **Add** to create the cloud account.

Resources such as machines and volumes are data-collected from the VMware Cloud on AWS SDDC data center and listed in the **Resources** section of the VMware Aria Automation **Infrastructure** tab.

[Create a cloud zone for deployments](#) .

Create a cloud zone for VMware Cloud on AWS deployments in VMware Aria Automation

Create a cloud zone for VMware Cloud on AWS deployments

In this step, you create a cloud zone to specify a compute resource that the CloudAdmin user can access when working with VMware Cloud on AWS in VMware Aria Automation.

- Complete the [Create a cloud account in the workflow](#) procedure.
- This procedure assumes that you have the required administrator credentials, including VMware Cloud on AWS CloudAdmin credentials for the target SDDC in vCenter. See [Credentials required for working with cloud accounts in VMware Aria Automation](#).
- This procedure assumes that you have the cloud administrator user role. See [What are the user roles](#).

In VMware Cloud on AWS, the two primary administrator credentials are CloudGlobalAdmin and CloudAdmin. Automation Assembler is designed to support the CloudAdmin user. Deploy to resources that are available to a VMware Cloud on AWS CloudAdmin user. Do not deploy to resources that require VMware Cloud on AWS CloudGlobalAdmin credentials. Cloud zones identify the compute resources onto which a project cloud template deploys machines, networks, and storage. See [Learn more about cloud zones](#).

Unless otherwise indicated, the step values that you enter in this procedure are for this example workflow only.

1. Select **Infrastructure > Configure > Cloud Zones**.
2. Click **New Cloud Zone**, and enter values for the VMware Cloud on AWS environment.

Setting	Sample Value
Account / region	OurCo-VMC / Datacenter:Datacenter-abz This is the cloud account and associated region that you defined in the previous step, Create a cloud account in the workflow .
Name	VMC_cloud_zone-1
Description	VMware Cloud on AWS resources only
Placement policy	Default
Capability tags	Leave this empty. This workflow does not use capability tags.

3. Click the **Compute** tab.
4. As shown in area 1 below, find and select a compute resource that is available to the CloudAdmin user. For this example, use the resource named `Cluster 1/ Compute-ResourcePool`.

`Cluster 1/ Compute-ResourcePool` is the default compute resource for VMware Cloud on AWS.

The screenshot shows the VMware Aria Automation interface with the 'Compute' tab selected. At the top, there are three tabs: 'Summary', 'Compute' (which is underlined), and 'Projects'. Below the tabs, a message reads: 'All compute resources listed apply to this cloud zone'. There are two main sections for filtering resources:

- Filter tags:** This section includes a 'TAGS' button (highlighted with a yellow circle labeled '1') and a text input field 'Enter tags to filter'.
- Resource list:** This section displays a table with columns: 'Name' and 'Status'. The first row, 'Cluster-1 / Compute-ResourcePool', has its checkbox checked (highlighted with a yellow box labeled '2').

5. As shown in area 2 above, add the tag name `vmc_placements_abz`.

Tags

1 object(s) selected

Add tags

vmc_placements_abz X

Enter a new tag

Remove tags

no tags (i)

6. Filter the compute resources that are used in this cloud zone by entering `vmc_placements_abz` in the **Filter tags** section.
7. Click **Save**.

<input type="checkbox"/>	Name	Account / region	Type	Tags
<input type="checkbox"/>	Cluster-1		Cluster	
<input checked="" type="checkbox"/>	Cluster-1 / Compute-ResourcePool		ResourcePool	<code>vmc placements abz</code>
<input type="checkbox"/>	Cluster-1 / Mgmt-ResourcePool		ResourcePool	
<input checked="" type="checkbox"/> 1				

For this example, only the compute resource named `Cluster 1 / Compute-ResourcePool` is available to the CloudAdmin user.

[Configure network and storage profiles for VMware Cloud on AWS deployments in VMware Aria Automation.](#)

Configure network and storage profiles for VMware Cloud on AWS deployments in VMware Aria Automation

Configure network and storage profiles for VMware Cloud on AWS deployments

In this step, you configure a network profile and a storage profile to specify resources that are available to a VMware Cloud on AWS CloudAdmin user in VMware Aria Automation.

- Create a cloud zone. See [Create a cloud zone for deployments](#).
- This procedure assumes that you have the required administrator credentials, including VMware Cloud on AWS CloudAdmin credentials for the target SDDC in vCenter. See [Credentials required for working with cloud accounts in VMware Aria Automation](#).
- This procedure assumes that you have the cloud administrator user role. See [What are the user roles](#).

While an image and a flavor value are also needed, there is nothing unique about them specific to VMware Cloud on AWS user credentials. For this example, you'll use a flavor value of `small` and an image value of `ubuntu-16` when you define the cloud template.

For general information about mappings and profiles, see [Building your resource infrastructure](#).

Unless otherwise indicated, the step values that you enter in this procedure are for this example workflow only.

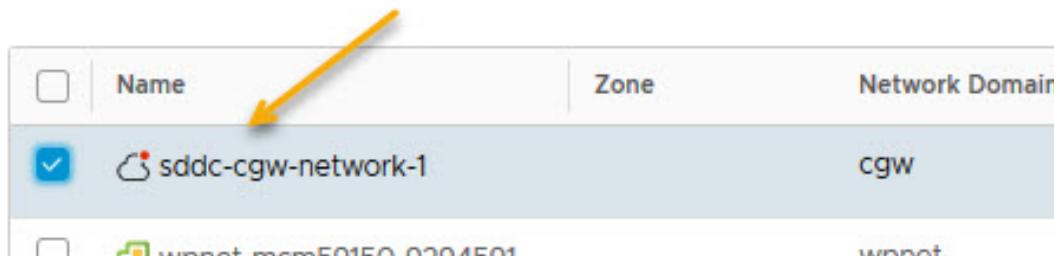

1. Define a network profile for VMware Cloud on AWS deployments.

- a) Select **Infrastructure > Configure > Network Profiles** and click **New Network Profile**.

Setting	Sample value
Account / region	OurCo-VMC / Datacenter:Datacenter-abz NOTE Select the VMware Cloud on AWS cloud account, and its matched SDDC data center, that you created in Create a cloud account in the workflow .
Name	vmc-network1
Description	Contains networks that can be accessed by cloud template administrators who have VMware Cloud on AWS CloudAdmin credentials.

- b) Click the **Network** tab and click **Add Network**.
- c) Select a network that a VMware Cloud on AWS user with CloudAdmin credentials can deploy to, for example `sddc-cgw-network-1`.

Add Network

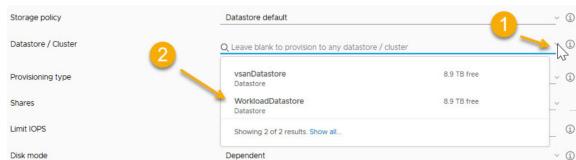

2. Save the network profile.
3. Define a storage profile for VMware Cloud on AWS deployments.

Configure a storage profile that targets a datastore/cluster that is accessible to the CloudAdmin user.

- a) Select **Infrastructure > Configure > Storage Profiles** and click new **New Storage Profile**.

Setting	Sample Value
Account / region	OurCo-VMC / Datacenter:Datacenter-abz Select the VMware Cloud on AWS cloud account, and its matched SDDC data center, that you created in Create a cloud account in the workflow .
Name	vmc-storage1
Description	Contains the datastore cluster that can be deployed to by cloud template administrators who have VMware Cloud on AWS CloudAdmin credentials.

- b) From the **Datastore / Cluster** drop-down menu, select the **WorkloadDatastore** datastore.

For VMware Cloud on AWS in Automation Assembler, the storage policy must use the **WorkloadDatastore** datastore to support VMware Cloud on AWS deployment.

4. Save the storage profile.

[Create a project to support deployments in .](#)

Create a project to support VMware Cloud on AWS deployments in Automation Assembler

Create a project to support VMware Cloud on AWS deployments

In this step, you define a Automation Assembler project that can be used to control which resources are available for VMware Cloud on AWS deployments.

- Complete the [Configure network and storage profiles for VMware Cloud on AWS deployments in VMware Aria Automation](#) procedure.
- This procedure assumes that you have the required administrator credentials, including VMware Cloud on AWS CloudAdmin credentials for the target SDDC in vCenter. See [Credentials required for working with cloud accounts in VMware Aria Automation](#).
- This procedure assumes that you have the cloud administrator user role. See [What are the user roles](#).

For information about projects, see [How do projects work at deployment time](#).

Unless otherwise indicated, the step values that you enter in this procedure are for this example workflow only.

1. Select **Infrastructure > Configure > Projects**.

2. Click **New Project** and enter the project name `VMC_proj-1_abz`.

3. Click **Users** and click **Add Users**.

The users need CloudAdmin credentials to their organization's VMware Cloud on AWS subscription.

- `chris.gray@ourco.com`, Administrator
- `kerry.white@ourco.com`, Member

4. Click **Provisioning** and then click **Add Cloud Zone**.

- Add the cloud zone that you configured in the earlier step.

Setting	Sample Value
Cloud zone	VMC_cloud_zone-1 You created this cloud zone in the earlier step, Create a cloud zone for deployments in .
Provisioning priority	1
Instances limit	3

- For this example, ignore the other options.

Create a blueprint to deploy in your VMware Cloud on AWS environment. See [Define a machine resource in a cloud template design to support deployment in](#) .

Define a vCenter machine resource in a cloud template design to support VMware Cloud on AWS deployment in VMware Aria Automation

Define a vCenter machine resource in a cloud template design to support VMware Cloud on AWS deployment. In this step, you drag a vCenter machine resource onto the design canvas and add settings for a VMware Cloud on AWS deployment in VMware Aria Automation.

- This procedure assumes that you have cloud template designer credentials. See [What are the user roles](#).
- This procedure assumes that you have VMware Cloud on AWS CloudAdmin credentials for the target SDDC in vCenter (Datacenter:Datacenter-abz). See [Credentials required for working with cloud accounts in VMware Aria Automation](#).
- Configure the resource infrastructure and project as described in the preceding sections.

Create a cloud template design that you can deploy to available VMware Cloud on AWS resources. Unless otherwise indicated, the step values that you enter in this procedure are for this example workflow only.

- Click the **Templates** tab and then click **New**.

Setting	Sample Value
Name	vmc-bp_abz
Description	1
Project	VMC_proj-1_abz This is the project that you created earlier, which supports the cloud zone that you also created earlier. The project is now associated with the cloud zone, which in turn is associated with the VMware Cloud on AWS cloud account/region that you created earlier.

- Slide a vSphere machine resource onto the canvas.
- Edit the following (bold) cloud template resource code in the machine resource.

```
formatVersion: 1
inputs: {}
resources:
  Cloud_vSphere_Machine_1:
```

```

type: Cloud.vSphere.Machine

properties:

  image: ubuntu-1604

  cpuCount: 1

  totalMemoryMB: 1024
  folderName: Workloads

```

The `image` can be any value that is appropriate to your deployment needs.

You must add the `folderName: Workloads` statement to the cloud template design code to support VMware Cloud on AWS deployment. The `folderName: Workloads` setting supports the `CloudAdmin` credentials in the VMware Cloud on AWS SDDC environment and is required.

Note: While the `folderName: Workloads` setting shown in the above code sample is required, you can add it directly in the cloud template code as shown above or you can add it in the associated cloud zone or project. If the setting is specified in more than one of these three places, the precedence is as follows:

- The project setting overrides the cloud template setting and the cloud zone setting.
- The cloud template setting overrides the cloud zone setting.

Note: You can optionally replace the `cpuCount` and `totalMemoryMB` settings with a flavor (sizing) entry, as shown below:

```

formatVersion: 1

inputs: {}

resources:

  Cloud_vSphere_Machine_1:
    type: Cloud.vSphere.Machine

    properties:

      image: ubuntu-1604

      flavor: small
      folderName: Workloads

```

If the cloud zone has the folder value set to **Workloads**, you do not need to set the `folderName` property in the cloud template, unless you want to override the cloud zone folder value.

Expand on this basic VMware Cloud on AWS workflow by adding network isolation. See [Configure an isolated network in workflow in](#).

Configure an isolated network in VMware Cloud on AWS workflow in VMware Aria Automation

Configure an isolated network in VMware Cloud on AWS

In this procedure, you add an isolated network for your VMware Cloud on AWS deployment in VMware Aria Automation.

This procedure expands on the basic VMware Cloud on AWS workflow. It uses the same cloud account and region, cloud zone, project, and network profile that you configured in the [Tutorial: Configuring for](#) workflow.

When you define your VMware Cloud on AWS cloud account, NSX-T settings configured in your VMware Cloud on AWS service are available. For information about configuring NSX-T settings in your VMware Cloud on AWS service, see [VMware Cloud on AWS product documentation](#).

VMware Aria Automation supports VMware Cloud on AWS with NSX-T. It does not support VMware Cloud on AWS with NSX-V.

VMware Aria Automation supports network isolation for VMware Cloud on AWS deployments. It does not support other network methods for VMware Cloud on AWS.

This extension of the basic VMware Cloud on AWS workflow describes the following methods of creating an isolated network for use in your cloud template:

- Configure on-demand network-based isolation.
- Configure on-demand security group-based isolation.

Define an isolated network for a VMware Cloud on AWS deployment in VMware Aria Automation

Define an isolated network for a VMware Cloud on AWS deployment

You can configure network isolation for a VMware Cloud on AWS deployment by using either of the following procedures:

- [Configure on-demand network-based isolation in](#)
- [Configure on-demand security group-based isolation in](#)

Configure on-demand network-based isolation in VMware Aria Automation

Configure network isolation by using on-demand network settings

You can configure network isolation for your VMware Cloud on AWS deployment needs by specifying and using on-demand network settings in a network profile.

- Complete the [Configure a basic workflow in](#) workflow.
- Review [Configure an isolated network in workflow in](#).
- This procedure assumes that you have the required administrator credentials, including VMware Cloud on AWS CloudAdmin credentials for the target SDDC in vCenter. See [Credentials required for working with cloud accounts in VMware Aria Automation](#).
- This procedure assumes that you have the cloud administrator user role. See [What are the user roles](#).

You can specify an isolated network by using a security group or by using on-demand network settings. In this example, you configure network isolation by specifying on-demand network settings in the network profile. Later, you access the network in a cloud template and use the cloud template in a VMware Cloud on AWS deployment.

Unless otherwise indicated, the step values that you enter in this procedure are for this example workflow only.

1. Open the network profile that you used in the basic VMware Cloud on AWS workflow, for example `vmc-network1`. See [Configure network and storage profiles for VMware Cloud on AWS deployments in VMware Aria Automation](#).
2. You do not need to make any selections on the **Networks** tab.
3. Click the **Network Policies** tab.
4. Select the **Create an on-demand network** option and select the default `cgw` network domain. Specify an appropriate CIDR and subnet size.
5. Click **Save**.

When you use this network profile, machines are deployed to a network in the default network domain. The network is isolated from other networks by using private or outbound network access.

Configure a network component in your cloud template. See [Define a network component in a cloud template to support network isolation for VMware Cloud on AWS in VMware Aria Automation](#)

Configure on-demand security group-based isolation in VMware Aria Automation

Configure network isolation by using an on-demand security group

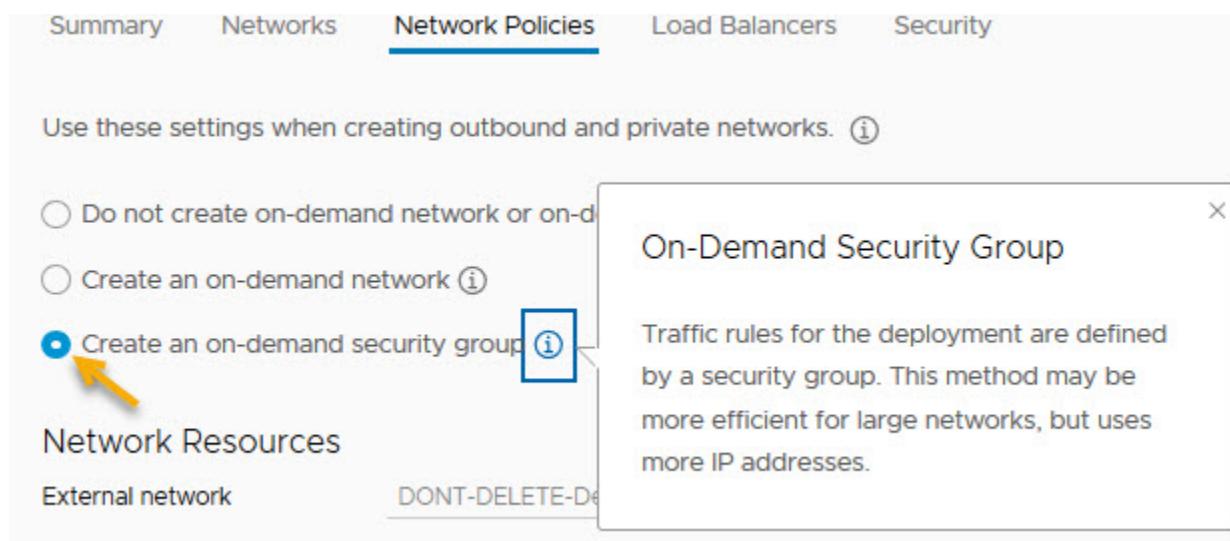

You can configure network isolation for your VMware Cloud on AWS deployment needs by specifying and using an on-demand security group in a network profile.

- Complete the [Configure a basic workflow in](#) workflow.

- Review [Configure an isolated network in workflow in](#) .
- This procedure assumes that you have the required administrator credentials, including VMware Cloud on AWS CloudAdmin credentials for the target SDDC in vCenter. See [Credentials required for working with cloud accounts in VMware Aria Automation](#).
- This procedure assumes that you have the cloud administrator user role. See [What are the user roles](#).

You can specify an isolated network by using a security group or by using on-demand network settings. In this example, you configure network isolation by specifying an on-demand security group in the network profile. Later, you specify the network in a cloud template and use the cloud template in a VMware Cloud on AWS deployment. Unless otherwise indicated, the step values that you enter in this procedure are for this example workflow only.

1. Open the network profile that you used in the basic VMware Cloud on AWS workflow, for example `vmc-network1`. See [Configure network and storage profiles for VMware Cloud on AWS deployments in VMware Aria Automation](#) .
2. Select the existing network that you used in the basic VMware Cloud on AWS workflow, for example `sddc-cgw-network-1`. See [Configure network and storage profiles for VMware Cloud on AWS deployments in VMware Aria Automation](#).
3. Click the **Network Policies** tab.
4. Select the **Create an on-demand security group** option.

5. Click **Save**.

When you use this network profile, machines are deployed to the selected network and are isolated by a new security group policy. The new security policy allows private or outbound network access.

Configure a network component in your cloud template. See [Define a network component in a cloud template to support network isolation for VMware Cloud on AWS in VMware Aria Automation](#)

Define a network component in a cloud template to support network isolation for VMware Cloud on AWS in VMware Aria Automation

Define a network component in a cloud template to support network isolation

In this step, you drag a network machine component onto a VMware Aria Automation cloud template canvas and add settings for an isolated network deployment to your target VMware Cloud on AWS environment.

- Complete the [Configure on-demand security group-based isolation in VMware Aria Automation](#) or [Configure on-demand network-based isolation in VMware Aria Automation](#) procedure.
- This procedure assumes that you have cloud template designer credentials. See [What are the user roles](#).

- This procedure assumes that you have VMware Cloud on AWS CloudAdmin credentials for the target SDDC in vCenter. See [Credentials required for working with cloud accounts in VMware Aria Automation](#).

Add network isolation to the cloud template that you created earlier. The cloud template is already associated with a project and cloud zone that support deployment to your VMware Cloud on AWS environment, as well as the network profile and network that you configured for isolation.

Unless otherwise indicated, the step values that you enter in this procedure are for this example workflow only.

- Open the cloud template that you created in the previous workflow. See [Define a vCenter machine resource in a cloud template design to support VMware Cloud on AWS deployment in VMware Aria Automation](#).
- From the components on the left of the cloud template page, drag a network component onto the canvas.
- Edit the network component YAML code to specify a network type of either `private` or `outbound`, as shown in bold.

```
resources: Cloud_Network_1:
  type: Cloud.Network
  properties:
    name: vmc_isolated
    networkType: private
```

OR

```
resources: Cloud_Network_1:
  type: Cloud.Network
  properties:
    name: vmc_isolated
    networkType: outbound
```

You are ready to deploy or close the cloud template.

Tutorial: Configuring a provider-specific external IPAM integration for VMware Aria Automation

Configuring an external IPAM integration for Infoblox

You can use an external IPAM provider to manage IP address assignments for your cloud template deployments. This tutorial describes how to configure external IPAM integration in VMware Aria Automation using Infoblox as the external IPAM provider.

In this procedure, you use an existing IPAM provider package, in this case an Infoblox package, and an existing running environment to build a provider-specific IPAM integration point. You configure an existing network and create a network profile to support IP address allocation from the external IPAM provider. Finally, you create a cloud template that is matched to the network and network profile and deploy networked machines using IP values obtained from the external IPAM provider.

Information about how to obtain and configure the IPAM provider package, and how to configure a running environment that accesses a cloud extensibility proxy to support the IPAM provider integration, is included as reference.

The values you see in this sample workflow are example values. You won't be able to use them verbatim in your environment. Think about where you would make your own substitutions to fit your organization's needs.

To reference a similar VMware Aria Automation scenario that illustrates an Infoblox IPAM integration workflow in video form, see [Infoblox IPAM Plug-in Integration](#).

Add required extensible attributes in the Infoblox application for integration with VMware Aria Automation

Add required extensible attributes in the Infoblox application before deploying the download package

Before you can download and deploy the Infoblox provider package (`infoblox.zip`) for integration with VMware Aria Automation from either the Infoblox website or from the VMware Marketplace, you must add required extensibility attributes in Infoblox.

- Verify that you have an account with [Infoblox](#) and that you have the correct access credentials to your organization's Infoblox account.
- Confirm that the Infoblox WAPI version is supported. IPAM integration with Infoblox depends on Infoblox WAPI version v2.7. Infoblox appliances that support WAPI v2.7 are supported.
- Review [Using Infoblox-specific properties and extensible attributes for IPAM integrations in VMware Aria Automation cloud templates](#).

This procedure is applicable if you are creating an external IPAM integration point for Infoblox integration with Automation Assembler.

Before you can use the `infoblox.zip` download, you must log in to your Infoblox account, using your organization account administrator credentials, and pre-create the following Infoblox extensible attributes:

- VMware NIC index
- VMware resource ID

1. Log in to your Infoblox account using administrator credentials.

These are the same administrator user name and password credentials that you specify when you create an external IPAM integration point in Automation Assembler using the **Infrastructure > Connections > Integrations** menu sequence.

2. Use the procedure described in the Infoblox documentation to create the following required extensible attributes in your Infoblox application.
 - VMware NIC index - type Integer
 - VMware resource ID - type String

The procedure is described in the *Adding Extensible Attributes* section of the Infoblox documentation topic [About Extensible Attributes](#). Also see [Managing Extensible Attributes](#).

After you add the required attributes, you can resume the process of downloading and deploying the Infoblox package as described in [Download and deploy an external IPAM provider package for use in VMware Aria Automation](#).

Download and deploy an external IPAM provider package for use in VMware Aria Automation

Download and deploy an external IPAM provider package

Before you can define an external IPAM integration point in VMware Aria Automation, you need a configured IPAM provider package.

- Verify that you have cloud administrator credentials. See [Credentials required for working with cloud accounts in VMware Aria Automation](#).
- Verify that you have the cloud administrator user role. See [What are the user roles](#).
- Verify that you have an account with the external IPAM provider, for example [Infoblox](#) or [Bluecat](#), and that you have the correct access credentials to your organization's account with the IPAM provider.
- If you are using Infoblox as your external IPAM provider, verify that you have added the required extensible attributes to your Infoblox account before continuing. See [Add required extensible attributes in the Infoblox application for integration with VMware Aria Automation](#).

NOTE

A certificate chain issue exists relative to how the Python element in the Infoblox plug-in handles SSL handshakes. For information about the issue and required actions to resolve the issue, see Knowledge Base Article [vRA Cloud Infoblox Plugin throws a certificate chain error during authentication process \(88057\)](#).

You can download a provider-specific integration package from your IPAM provider's website or the [VMware Marketplace](#).

NOTE

This example uses the VMware-supplied Infoblox package `Infoblox.zip`, which is available for download from [VMware Marketplace](#) as follows:

- [Infoblox plugin version 1.5](#) - (*Aria Automation Infoblox Plugin 1.5*) Compatible with VMware Aria Automation and vRealize Automation 8.9.1 and later and containing all the functionality of previous versions. In this version, a local Infoblox property overrides a global Infoblox property. This allows the `Infoblox.IPAM.Network.dnsSuffix` property to be configurable for multiple NICs. For related information, see [Using Infoblox-specific properties and extensible attributes for IPAM integrations in VMware Aria Automation cloud templates](#).

The Infoblox version 1.5 plug-in is supported for use with VMware Aria Automation and vRealize Automation 8.9.1 and later. It is not supported for use with vRealize Automation 8.9 or earlier.

- [Infoblox plugin version 1.4](#) - (*vRA Cloud Infoblox Plugin 1.4*) Compatible with VMware Aria Automation and vRealize Automation 8.3.x forward, and providing all the functionality of previous versions. With this version, you can use the same host name with a different DNS suffix for two NICs. See plug-in release notes for additional details.
- [Infoblox plugin version 1.3](#) - Compatible with VMware Aria Automation and vRealize Automation 8.3.x and providing additional network data collection filters. See [Control network data collection by using Infoblox filters in VMware Aria Automation](#).

The [Infoblox v1.3 plug-in](#) may be used with vRealize Automation 8.1 or 8.2, but only in select situations and with caution as described in KB article [Infoblox 1.3 Compatibility with vRealize Automation 8.x \(82142\)](#).

- [vRA Cloud Infoblox plugin version 1.2](#) - Compatible with vRealize Automation 8.1.x and 8.2.x
- [vRA Cloud Infoblox plugin version 1.1](#) - Compatible with vRealize Automation 8.1.x
- [vRA Cloud Infoblox plugin version 1.0](#) - Compatible with vRealize Automation 8.0.1.x with or without an internet connection to the global network.
- [vRA Cloud Infoblox plugin version 0.4](#) - Compatible with vRealize Automation 8.0.0.x and 8.0.1.x when there is an internet connection with the global network.

IPAM integration with Infoblox depends on Infoblox WAPI version v2.7. All Infoblox appliances that support WAPI v2.7 are supported.

For information about how to create an IPAM integration package for other IPAM providers, if one does not already exist in the [VMware Marketplace](#), see [How do I use the IPAM SDK to create a provider-specific external IPAM integration package for VMware Aria Automation](#).

The IPAM provider package contains scripts that are packaged with metadata and other configurations. The scripts contain the source code used for the operations that VMware Aria Automation performs in coordination with the external IPAM provider. Example operations include Allocate an IP address for a virtual machine, Fetch a list of IP ranges from the provider, and Update the MAC address of a host record in the provider.

1. Navigate to the correct download page for the Infoblox plug. See above for links to a specific Infoblox plug-in version.
See above for the Infoblox plugin options that are available in the [VMware Marketplace](#).
2. Log in and download the plug-in package.
3. If you have not already done so, add the required extensible attributes in Infoblox. See [Add required extensible attributes in the Infoblox application for integration with VMware Aria Automation](#).

The package is now available for you to deploy by using the **Integrations > Add Integration > IPAM > Manage Providers > Import package** menu sequence as described in [Add an external IPAM integration for Infoblox in VMware Aria Automation](#).

Create a running environment for an IPAM integration point in VMware Aria Automation

Create a running environment for an IPAM integration point

Before you can define an external IPAM integration point in VMware Aria Automation, you must create or access an existing running environment that can serve as an intermediary between the IPAM provider and VMware Aria Automation. The running environment is commonly an Amazon Web Services or Microsoft Azure cloud account or an on-premises and actions-based extensibility integration point that is associated to a cloud extensibility proxy.

- Verify that you have cloud administrator credentials. See [Credentials required for working with cloud accounts in VMware Aria Automation](#).
- Verify that you have the cloud administrator user role. See [What are the user roles](#).
- Verify that you have an account with the external IPAM provider, for example, [Infoblox](#) or [Bluecat](#), and that you have the correct access credentials to your organization's account with the IPAM provider.
- Verify that you can access a deployed integration package for your IPAM provider, such as Infoblox or BlueCat. You obtain the .zip download file from your IPAM provider website or from the [VMware Marketplace](#) and then deploy the package in Automation Assembler.

For information about how to deploy the provider package .zip file and make it available as a **Provider** value on the IPAM Integration page, see [Download and deploy an external IPAM provider package for use in VMware Aria Automation](#).

External IPAM integration requires a running environment. When you define the IPAM integration point, you create a connection between Automation Assembler and your IPAM provider by specifying an available running environment. IPAM integration uses a set of downloaded, provider-specific scripts or plug-ins in a running environment facilitated by a Feature-as-a-Services (FaaS) provider such as Amazon Web Services Lambda, Microsoft Azure Functions, or an actions-based extensibility (ABX) On-Prem Embedded integration point. The running environment is used to connect to the external IPAM provider, for example Infoblox.

NOTE

An Infoblox IPAM integration point requires an actions-based extensibility (ABX) On-Prem Embedded integration point.

Each type of runtime environment has advantages and disadvantages:

- An actions-based extensibility (ABX) integration point:
 - is free, no additional vendor usage costs.
 - can connect to IPAM vendor appliances that reside in an on-premises data center behind a NAT/firewall that is not publicly accessible, for example Infoblox.
 - is slower with slightly less available performance than commercial cloud.
- Amazon Web Services
 - has associated vendor FaaS connection/usage costs.
 - cannot connect to IPAM vendor appliances that reside in an on-premises data center behind a NAT/firewall that is not publicly accessible.
 - has fast and highly reliable performance.
- Microsoft Azure
 - has associated vendor FaaS connection/usage costs.
 - cannot connect to IPAM vendor appliances that reside in an on-premises data center behind a NAT/firewall that is not publicly accessible.
 - has fast and highly reliable performance.

1. To create an On-Prem FaaS-based extensibility action to use as an IPAM integration running environment, select **Extensibility > Library > Actions**.
2. Click **New Action**, enter an action name and description, and specify a project.

3. In the **FaaS provider** drop-down menu, select **On Prem**.
4. Complete the form to define the extensibility action.

For more information about creating extensibility actions, see [Extending and automating application life cycles with extensibility](#).

For related information about the running environment, see this [Infoblox IPAM Plug-in Integration](#) blog video at approximately 24 minutes into the video.

Add an external IPAM integration for Infoblox in VMware Aria Automation

Add an external IPAM integration for Infoblox

VMware Aria Automation supports integration with an external IPAM provider. This example uses Infoblox as the external IPAM provider.

- Verify that you have cloud administrator credentials. See [Credentials required for working with cloud accounts in VMware Aria Automation](#).
- Verify that you have the cloud administrator user role. See [What are the user roles](#).
- Verify that you have an account with external IPAM provider and that you have the correct access credentials to your organization's account with the IPAM provider.
- Verify that you have access to a deployed integration package for your IPAM provider. The deployed package is initially obtained as a .zip download from your IPAM provider website, or from the VMware solutions exchange marketplace, and then deployed to VMware Aria Automation.
For information about how to download and deploy the provider package .zip file and make it available as a **Provider** value on the IPAM Integration page, see [Download and deploy an external IPAM provider package for use in VMware Aria Automation](#).
- Verify that you have access to a configured running environment for the IPAM provider. The running environment is typically an actions-based extensibility (ABX) On-Prem Embedded integration point.
For information about running environment characteristics, see [Create a running environment for an IPAM integration point in VMware Aria Automation](#).
- Enable required extensible attributes in your Infoblox application. See [Add required extensible attributes in the Infoblox application for integration with VMware Aria Automation](#).
- If you do not have external Internet access, you can configure an Internet server proxy. See [How do I configure an Internet proxy server for VMware Aria Automation](#).
- Verify that you have the required user credentials to access and use your Infoblox IPAM product. For example, open the Administration tab in the Infoblox appliance and customize administrator, groups, and roles entries. You must be a member of a group that has administrator or superuser permissions or a custom group that has DHCP, DNS, IPAM, and Grid permissions. These settings allow access to all the functionality that is available in the Infoblox plug-in, enabling you to create an Infoblox IPAM integration and designers to use that IPAM integration in cloud templates and deployments. For more information about user permissions, see your Infoblox product documentation.

You can use a provider-specific IPAM integration point to obtain and manage IP addresses and related network characteristics for cloud template deployments.

In this example, you create an external IPAM integration point to support access to your organization's account with an external IPAM provider. In this example workflow, the IPAM provider is Infoblox and the provider-specific integration package already exists. While these instructions are specific to an Infoblox integration, they can be used as reference if creating an IPAM integration for a different external IPAM provider.

You can obtain a provider-specific integration package from your IPAM provider's website or the [VMware Marketplace](#). This example uses the VMware-supplied Infoblox package `Infoblox.zip`, which is available for download from the [VMware Marketplace](#), for example the [Aria Automation Infoblox Plugin 1.5](#). For information about the latest Infoblox plug-in versions that are available in the [VMware Marketplace](#), see [Download and deploy an external IPAM provider package for use in VMware Aria Automation](#).

1. Select **Infrastructure > Connections > Integrations** and click **Add Integration**.
2. Click **IPAM**.
3. In the **Provider** drop-down, select a configured IPAM provider package from the list, for example *Infoblox_hrg*.

If the list is empty, click **Import Provider Package**, navigate to an existing provider package .zip file, and select it. If you do not have the provider .zip file, you can obtain it from your IPAM provider's web site or from the [VMware Marketplace](#).

For information about how to deploy the provider package .zip file in vCenter and make it available as a **Provider** value on the Integration page, see [Download and deploy an external IPAM provider package for use in VMware Aria Automation](#).

For information about how to upgrade an existing IPAM integration to use a more recent version of a vendor's IPAM integration package, see [How to upgrade to a newer external IPAM integration package in VMware Aria Automation](#).

4. Enter your administrator user name and password credentials for your account with the external IPAM provider, along with all other (if any) mandatory fields, such as the host name of your provider.

In this example, you obtain the host name of your Infoblox IPAM provider using the following steps:

1. In a separate browser tab, log in to your IPAM provider account using your Infoblox administrator credentials.
2. Copy your host name URL.
3. Paste your host name URL in the **Hostname** field on the IPAM Integration page.

5. In the **Running Environment** drop-down list, select an existing on-premises actions-based extensibility integration point, for example *Infoblox_abx_intg*.

The running environment supports communication between VMware Aria Automation and the external IPAM provider.

NOTE

If you use an Amazon Web Services or Microsoft Azure cloud account as the integration running environment, be sure that the IPAM provider appliance is accessible from the Internet and is not behind a NAT or firewall and that it has a publicly resolvable DNS name. If the IPAM provider is not accessible, the Amazon Web Services Lambda or Microsoft Azure Functions cannot connect to it and the integration will fail. For related information, see [Create a running environment for an IPAM integration point in VMware Aria Automation](#).

The IPAM framework only supports an actions-based extensibility (ABX) On-Prem Embedded running environment.

NOTE

An Infoblox IPAM integration point requires an actions-based extensibility (ABX) On-Prem Embedded integration point.

The configured cloud account or integration point allows communication between VMware Aria Automation and the IPAM provider, in this example Infoblox, through an associated cloud extensibility proxy. You can select a provider that has already been created or you can create one.

For information about how to create a running environment, see [Create a running environment for an IPAM integration point in VMware Aria Automation](#).

6. Click **Validate**.

Because this example uses the on-premises actions-based extensibility integration for the running environment, you can view the validation action.

1. Click the **Extensibility** tab.
2. Click **Activity > Action Runs** and select either **All Runs** or **Integration runs** from the filter to note that an endpoint validation action is initiated and running.

7. When prompted to trust the self-signed certificate from the IPAM provider, click **Accept**.
After you accept the self-signed certificate, the validation action can continue to completion.

8. Enter a **Name** for this IPAM integration point, such as *Infoblox_Integration*, and a **Description**, such as *Infoblox IPAM with ABX integration for team HRG*.
9. Click **Add** to save the new external IPAM integration point.
A data collection action is initiated. Networks and IP ranges are data-collected from the IPAM provider. You can view the data collection action as follows:
 1. Click the **Extensibility** tab.
 2. Click **Activity > Action Runs** and note that a data collection action is initiated and running. You can open and view the action run content.
 3. If no action runs are displayed, click the **User Runs** drop-down menu and select **Integration Runs**.

The provider-specific external IPAM integration is now available for use with networks and network profiles.

Configure a network and network profile to use external IPAM for an existing network in VMware Aria Automation

Configure a network and network profile to use external IPAM for an existing network

You can define an existing network to use IP address values that are obtained from, and managed by, an external IPAM provider rather than internally from VMware Aria Automation.

This sequence of steps is shown in the context of an IPAM provider integration workflow. See [Tutorial: Configuring a provider-specific external IPAM integration for VMware Aria Automation](#).

- Verify that you have cloud administrator credentials. See [Credentials required for working with cloud accounts in VMware Aria Automation](#).
- Verify that you have the cloud administrator user role. See [What are the user roles](#).
- Verify that you have an account with the external IPAM provider, for example [Infoblox](#) or [Bluecat](#), and that you have the correct access credentials to your organization's account with the IPAM provider. In this example workflow, the IPAM provider is Infoblox.
- Verify that you have an IPAM integration point for the IPAM provider. See [Add an external IPAM integration for Infoblox in VMware Aria Automation](#).

You can define a network to access existing IP settings that you have defined in your organization's external IPAM provider account. This step expands on the Infoblox provider integration that you created in the previous step.

In this example, you configure a network profile with existing networks that were data-collected from vCenter. You then configure these networks to obtain IP information from an external IPAM provider, in this case Infoblox. Virtual machines that you provision from VMware Aria Automation that can be matched with this network profile obtain their IP and other TCP/IP related settings from the external IPAM provider.

For more information about networks, see [Network resources in VMware Aria Automation](#). For more information about network profiles, see [How to add network profiles in VMware Aria Automation](#) and [Learn more about network profiles in VMware Aria Automation](#).

For related information, see [How do I configure a network profile to support an on-demand network for an external IPAM integration in VMware Aria Automation](#).

1. To configure a network, click **Infrastructure > Resources > Networks**.
2. On the **Networks** tab, select an existing network to use with the IPAM provider integration point. In this example, the network name is *net.23.117-only-IPAM*.

Listed networks have been data-collected by VMware Aria Automation from a vCenter in your organization.

3. To obtain values from the external IPAM provider, verify that except for the **Account/region**, **Name**, and **Network domain**, all other network settings are empty, including the following:
 - Domain (See Note in step 8)
 - CIDR
 - Default gateway
 - DNS servers
 - DNS search domains
4. Click the **IP Ranges** tab and click **Add IPAM IP Range**.
5. From the **Network** menu, select the network that you just configured, for example `net.23.117-only-IPAM`.
6. From the **Provider** menu, select the *Infoblox Integration* IPAM integration point that you created earlier in the workflow.
7. From the now-visible **Address Space** drop-down menu, select one of the listed network views.

An address space in Infoblox is referred to as a network view.

The network views are obtained from your IPAM provider account. This example uses the network subnet that you just configured, for example `net.23.117-only-IPAM`, the *Infoblox Integration* integration point that you created earlier in the workflow, and an address space named `default`.

Listed address space values are obtained from the external IPAM provider.

8. From the list of displayed networks that are available for the selected address space, select one or more networks, for example select `10.23.117.0/24`.

For this example, the **Domains** and **DNS Servers** column values for the selected network contain values from Infoblox.

NOTE

If you select a network in step 3 that had a domain specified for VMware Aria Automation, and then select a network from the external IPAM provider address space that contains a domain value, the domain value in the external IPAM provider network takes precedence over the domain specified in VMware Aria Automation. If the IPAM IP range setting doesn't have a domain value, specified in either Automation Assembler or in the external IPAM provider, provisioning fails.

For Infoblox, you can use the blueprint property `Infoblox.IPAM.Network.dnsSuffix` at the machine level to overwrite the domain value. For related information, see [Using Infoblox-specific properties and extensible attributes for IPAM integrations in VMware Aria Automation cloud templates](#).

9. Click **Add** to save the IPAM IP range for the network.
The range is visible in the **IP Ranges** table.
10. Click the **IP Addresses** tab.
After you provision a machine by using the new address range from the external IPAM provider, a new record will be visible in the **IP Addresses** table.
11. To configure a network profile to use the network, click **Infrastructure > Configure > Network Profiles**.
12. Name the network profile, for example `Infoblox-NP`, and add the following sample settings.
 - Summary tab:
 - Specify a vSphere cloud account/region.
 - Add a capability tag for the network profile, for example named `infoblox_abx`.
Make note of the capability tag, as you must also use it as a cloud template constraint tag to make the provisioning association in the cloud template.

- Networks tab:
 - Add the network that you created earlier, for example `net.23.117-only-IPAM`.

13. Click **Save** to save the network profile with these settings.

The network and network profile setting are now configured for an existing network type to be used for the Infoblox IPAM integration in a cloud template.

Define and deploy a cloud template that uses an external IPAM provider range assignment in VMware Aria Automation

Define and deploy a cloud template that uses an external IPAM provider range assignment

You can define a cloud template to obtain and manage IP address assignments from your external IPAM provider. This example uses Infoblox as the external IPAM provider.

This sequence of steps is shown in the context of an external IPAM provider integration workflow. See [Tutorial: Configuring a provider-specific external IPAM integration for VMware Aria Automation](#).

- Verify that you have cloud administrator credentials. See [Credentials required for working with cloud accounts in VMware Aria Automation](#).
- Verify that you have the cloud administrator user role. See [What are the user roles](#).
- Verify that you have an account with the external IPAM provider, for example Infoblox or BlueCat, and that you have the correct access credentials to your organization's account with the IPAM provider.
- Verify that you have administrator access to the host account and any role requirements needed to display status records in the vSphere web client record for your deployed VMs in the host vCenter.
- Verify that you have an IPAM integration point for the external IPAM provider. See [Add an external IPAM integration for Infoblox in VMware Aria Automation](#).
- Verify that you have configured a VMware Aria Automation network and network profile that support external IPAM integration for your intended IPAM integration point. See [Configure a network and network profile to use external IPAM for an existing network in VMware Aria Automation](#).
- Verify that your project and cloud zone are tagged to match tags in the IPAM integration point and network or network profile. Optionally configure the project to support custom resource naming.

For more information about the role of a project and cloud zone, and the role of other infrastructure elements in your cloud template, see [Tutorial: Setting up and testing multi-cloud infrastructure and deployments in Automation Assembler](#). For more information about tagging, see [maphead-how-to-use-tags.dita#GUID-1F1FD968-2EA1-404E-B081-E13383392061-en](#).

For information about custom naming VMs by using settings in your project, see [Create project-by-project custom names for deployed resources in](#).

In this final step in the external IPAM integration workflow, you define and deploy a cloud template that connects your previously defined network and network profile to your organization's Infoblox account to obtain and manage IP address assignments for deployed VMs from the external IPAM provider rather than from VMware Aria Automation.

This workflow uses Infoblox as the external IPAM provider and in some steps, the example values are unique to Infoblox, although the intent is that the procedure can be applied to other external IPAM integrations.

NOTE

For cloud templates that use Infoblox as the external IPAM provider, you can run up to 200 concurrent deployments within a 20 minute period. This scaling factor has been tested with cloud templates that contain a single VM deployed to vCenter on a network that uses Infoblox as the external IPAM provider, as seen in the sample code below.

The [Automate IPAM and DNS for VMs using VMware vRealize Automation and Infoblox DDI](#) Infoblox blog provides related information.

After you deploy the cloud template and the VM is started, the IP address used for each VM in the deployment appears as a network entry in the **Resources > Networks** page, as a new host record in the IPAM provider network in your IPAM provider's account, and in the vSphere Web Client record for each deployed VM in the host vCenter.

1. Click **Cloud templates > New**, enter the following information in the **New cloud template** page, and click **Create**.
 - **Name** = ipam-bpa
 - **Description** = Cloud template that uses Infoblox IPAM integration
 - **Project** = 123VC
2. For this example, add a cloud agnostic machine component and a cloud agnostic network component to the cloud template canvas and connect the two components.
3. Edit the cloud template code to add a constraint tag to the network component that matches the capability tag that you added to the network profile. For this example, that tag value is *infoblox_abx*.
4. Edit the cloud template code to specify that the network assignment type is *static*.

When using an external IPAM provider, the `assignment: static` setting is required.

For this example, the specified (fictitious value) IP address `xx.yy.zzz.0` is known to be currently available in the external IPAM address space that we selected for the network in the associated network profile. While the `assignment: static` setting is required, the `address: value` setting is not. You can choose to begin external IP address selection at a particular address value, but doing so is not required. If you do not specify an `address: value` setting, the external IPAM provider selects the next available address in the external IPAM network.

5. Verify the cloud template code against the following example.

Sample code:

```
formatVersion: 1

inputs: {}

resources:

  Cloud_Network_1:
    type: Cloud.Network
    properties:
      networkType: existing
      name: ipam
    constraints:
      - tag: infoblox_abx

  Cloud_Machine_1:
    type: Cloud.Machine
    properties:
      image: ubuntu
      flavor: small
    networks:
      - network: '${resource.Cloud_Network_1.id}'
```

```
assignment: staticaddress: xx.yy.zzz.0 (fictitious value)
name: '${resource.Cloud_Network_1.name}'
```

For examples of Infoblox properties that are available for specifying DNS and DHCP settings in cloud templates, see [Using Infoblox-specific properties and extensible attributes for IPAM integrations in VMware Aria Automation cloud templates](#).

6. Click **Deploy** on the cloud template page, name the deployment *Infoblox-1*, and click **Deploy** on the **Deployment Type** page.
7. As the cloud template is being deployed, click the **Extensibility** tab and select **Activity > Action Runs** to see the *Infoblox_AllocateIP_n* extensibility action running.

After the extensibility action is completed and the machine is provisioned, the *Infoblox_Update_n* action propagates the MAC address to Infoblox.

8. You can log in to and open your Infoblox account to see the new host record for the IPAM address in the associated 10.23.117.0/24 network. You can also open the DNS tab in Infoblox to see the new DNS host record.
9. To verify that the VM is being provisioned, log in to your host vCenter and vSphere Web Client to locate the provisioned machine and view the DNS name and IP address.

After the provisioned VM is started, the MAC address is propagated to Infoblox by an *Infoblox_AllocateIP* extensibility action.

10. To view the new network record in VMware Aria Automation, select **Infrastructure > Resources > Networks** and click to open the **IP Addresses** tab.
11. If you delete the deployment, the IPAM address of VMs in the deployment are released and the IP addresses are again available to the external IPAM provider for other allocations. The extensibility action for this event in VMware Aria Automation is *Infoblox_Deallocate*.

Using Infoblox-specific properties and extensible attributes for IPAM integrations in VMware Aria Automation cloud templates

Using Infoblox-specific properties for IPAM integrations in cloud templates

You can use Infoblox-specific properties for VMware Aria Automation projects that contain external IPAM integrations for Infoblox.

The following Infoblox properties are available for use with your Infoblox IPAM integrations in cloud template designs and deployments. You can use them in VMware Aria Automation to further control IP address allocation during cloud template deployment. Use of these properties is optional.

NOTE

If you are using the Infoblox plug-in version 1.5 ([Aria Automation Infoblox Plugin 1.5](#)), a local Infoblox property overrides a global Infoblox property for `dnsSuffix`, `dnsView`, `enableDns`, and `enableDhcp` properties. For example, if you specify a local (NIC-specific) Infoblox property such as

`Infoblox.IPAM.Network1.dnsSuffix` and a global property such as

`Infoblox.IPAM.Network.dnsSuffix`, the local property overrides the global property. In this example, the local property overrides the global property for the NIC with index 1 while the global property applies to all the other NICs.

The Infoblox plug-in version 1.5 is supported for use with VMware Aria Automation and vRealize Automation 8.9.1 and later. It is not supported for use with vRealize Automation 8.9 or earlier.

If you are using the [Infoblox plug-in 1.4](#) or earlier, a global Infoblox property overrides a local Infoblox property for `dnsSuffix`, `dnsView`, `enableDns`, and `enableDhcp` properties. A global property applies to all NICs.

The following properties are available and included in the version 1.5 and later Infoblox plug-in for VMware Aria Automation. For more information about Infoblox plug-in versions and where to obtain the most recent version of the Infoblox plug-in for your IPAM integration in VMware Aria Automation, see [Download and deploy an external IPAM provider package for use in VMware Aria Automation](#).

The Infoblox v1.5 plug-in allows you to create DNS A and PTR records for your Infoblox external IPAM integration. The plug-in supports the Infoblox host record. These records help ensure proper DNS operations by logging and asset management tools that query the DNS system. DNS A and PTR records are commonly used by IPv4 DNS systems.

- **Infoblox.IPAM.createHostRecord**

This property allows you to create a host record in Infoblox. A host record is created by default for VMs, unless some of the other properties (such as Infoblox.IPAM.createFixedAddress, Infoblox.IPAM.createAddressRecord, Infoblox.IPAM.createAddressAndPtrRecords) are set to True. For non-VM resources, such as load balancers, the default value is False.

- **Infoblox.IPAM.createFixedAddress**

This property allows you to create a fixed address record in Infoblox. For VMs, the default value is False. For non-VM resources, a fixed record is created by default, unless Infoblox.IPAM.createHostRecord is set to True.

- **Infoblox.IPAM.createAddressRecord**

This property allows you to create a DNS A record in Infoblox. The default value is False. It is available with the Infoblox plug-in v1.5 forward.

- **Infoblox.IPAM.createAddressAndPtrRecords**

This property allows you to create a DNS A record and a PTR record in Infoblox. The default value is False. It is available with the Infoblox plug-in v1.5. forward.

- **Infoblox.IPAM.Network.dnsView**

This property allows you to use a DNS view when creating a host record inside Infoblox.

- **Infoblox.IPAM.Network.enableDns**

When allocating an IP in Infoblox, this property allows you to also create a DNS record. Possible values are True and False. The default value is True.

- **Infoblox.IPAM.Network.enableDhcp**

This property allows you to set the DHCP configuration for the host address. Possible values are True and False. The default value is True.

- **Infoblox.IPAM.Network.dnsSuffix**

This property allows you to overwrite the *domain* DHCP option of an Infoblox network with a new one. This capability is useful if the Infoblox network does not have the *domain* DHCP option set or if the *domain* DHCP option must be overwritten. The default value is null (empty string).

When using an external IPAM provider such as Infoblox, you must specify a DNS suffix when provisioning a machine. While the DNS suffix is required, you can specify the `Infoblox.IPAM.Network.dnsSuffix` property in the machine resource code in the VMware Aria Automation cloud template.

An example is shown below in the `Infoblox.IPAM.Network.hostnameNicSuffix` section.

`Infoblox.IPAM.Network.dnsSuffix` is only applicable if `Infoblox.IPAM.Network.enableDns` is set to True.

- **Infoblox.IPAM.Network.hostnameNicSuffix**

You can use this property to specify a NIC index suffix when generating a host name.

This allows you to provision a machine with more than one NIC such that the host names for each NIC are distinguished by a custom-defined suffix. As seen in the following example, you can provision a machine, for example *my-machine*, that has 2 NICs so that the host name suffix for the first NIC is `-nic1` and the other is `-nic2`.

You can also specify a DNS suffix as shown in the example. The `Infoblox.IPAM.Network.dnsSuffix` property is used with a value of `test.local` to result in the first NIC being named `my-machine-nic1.test.local` and the other `my-machine-nic2.test.local`.

```

formatVersion: 1

inputs: {}

resources:

  Cloud_Machine_1:
    type: Cloud.Machine

    properties:

      Infoblox.IPAM.Network.dnsSuffix: test.local
      Infoblox.IPAM.Network0.hostnameNicSuffix: -nic1
      Infoblox.IPAM.Network1.hostnameNicSuffix: -nic2

      image: ubuntu
      flavor: small

      networks:
        - network: '${resource.Cloud_Network_1.id}'
          deviceIndex: 0
        - network: '${resource.Cloud_Network_2.id}'
          deviceIndex: 1

  Cloud_Network_1:
    type: Cloud.Network

    properties:
      networkType: existing

  Cloud_Network_2:
    type: Cloud.Network

    properties:
      networkType: existing

```

This property was introduced with Infoblox plug-in version 1.3. See [Download and deploy an external IPAM provider package for use in VMware Aria Automation](#).

- You can also specify properties by using an extensibility subscription.
For related information about Infoblox extensible attributes relative to this use case, see [Add required extensible attributes in the Infoblox application for integration with VMware Aria Automation](#).

Using Infoblox properties on different machine NICs in a cloud template

The following Infoblox properties can support a different value for each machine NIC in the cloud template:

- Infoblox.IPAM.Network.enableDhcp
- Infoblox.IPAM.Network.dnsView
- Infoblox.IPAM.Network.enableDns
- Infoblox.IPAM.Network.hostnameNicSuffix

For example, to use a different Infoblox.IPAM.Network.dnsView value for each NIC, use a Infoblox.IPAM.Network<nicIndex>.dnsView entry for each NIC. The following sample shows different values Infoblox.IPAM.Network.dnsView for two NICs.

```
formatVersion: 1

inputs: {}

resources:

Cloud_Machine_1:
  type: Cloud.Machine
  properties:
    Infoblox.IPAM.Network0.dnsView: default
    Infoblox.IPAM.Network1.dnsView: my-net
  image: ubuntu
  flavor: small
  networks:
    - network: '${resource.Cloud_Network_1.id}'
      deviceIndex: 0
    - network: '${resource.Cloud_Network_2.id}'
      deviceIndex: 1

Cloud_Network_1:
  type: Cloud.Network
  properties:
    networkType: existing

Cloud_Network_2:
  type: Cloud.Network
  properties:
    networkType: existing
```

By default, the Infoblox integration creates a DNS host record in the *default* DNS view in Infoblox. If your Infoblox administrator has created *custom* DNS views, you can overwrite the default integration behavior and specify a named view by using the Infoblox.IPAM.Network.dnsView property in the machine component. For example, you can add the following property to the Cloud_Machine_1 component to specify a named DNS view in Infoblox.

```
Cloud_Machine_1:
  type: Cloud.Machine
  properties:
    image: ubuntu
    flavor: small
```

Infoblox.IPAM.Network.dnsView:<dns-view-name>

For information about configuring and using DNS views, see [DNS Views](#) in Infoblox product documentation. For examples in the Infoblox integration workflow, see [Define and deploy a cloud template that uses an external IPAM provider range assignment in VMware Aria Automation](#).

How to specify Infoblox properties

You can specify an Infoblox property using one of the following methods in Automation Assembler:

- You can specify properties in a project by using the **Custom Properties** section on your **Infrastructure > Administration > Projects** page. Using this method, the specified properties are applied to all machines that are provisioned in the scope of this project.
- You can specify properties on each machine component in a cloud template. Sample cloud template code illustrating use of the `Infoblox.IPAM.Network.dnsView` property is shown below:

```
formatVersion: 1

inputs: {}

resources:

  Cloud_vSphere_Machine_1:
    type: Cloud.vSphere.Machine
    properties:
      Infoblox.IPAM.Network.dnsView: default
      image: ubuntu
      cpuCount: 1
      totalMemoryMB: 1024
    networks:
      - network: '${resource.Cloud_Network_1.id}'

  Cloud_Network_1:
    type: Cloud.Network
    properties:
      networkType: existing
    constraints:
      - tag: mk-ipam-demo
```

Control network data collection by using Infoblox filters in VMware Aria Automation

Control network data collection by using Infoblox filters

For Infoblox, you can limit the number of data collected networks to only those networks that are needed for VMware Aria Automation operations. This reduces the amount of transferred data and enhances system performance.

VMware Aria Automation collects data every 10 minutes from the external IPAM system. For Infoblox, you can filter in several ways to discover and data-collect only a subset of networks that are used by VMware Aria Automation operations.

To filter data collection for networks that use Infoblox-generated IP addresses, use the following properties on the IPAM integration tab. The filter properties are available as you create or edit the external IPAM integration point for Infoblox.

These filters are only available with VMware Aria Automation 8.3 and later and with the [Infoblox plug-in version 1.3](#) and later (for example [Infoblox plugin version 1.4](#)).

NOTE

The [Infoblox plug-in version 1.3](#) can be used with VMware Aria Automation 8.1 or 8.2, but only in select situations and with caution as described in KB article [Infoblox 1.3 Compatibility with vRealize Automation 8.x \(82142\)](#).

- `Infoblox.IPAM.NetworkContainerFilter`
Filters on network containers.
- `Infoblox.IPAM.NetworkFilter`
Filter on networks.
- `Infoblox.IPAM.RangeFilter`
Filter on IP address ranges.

Be cautious when applying these data collection filters to networks that have already been data-collected. If you apply filters to prevent some networks from being data-collected, the networks that are not collected are assumed to be unnecessary and are deleted from VMware Aria Automation. The exception are networks that are associated to VMware Aria Automation subnets. Previously data-collected networks that are not subsequently discovered and data-collected, for example because they were filtered out of the data collection task, are deleted from the VMware Aria Automation database. However, if the previously data-collected networks are in use in VMware Aria Automation, they are not deleted.

These filters are applied as query parameters in the search requests for the different network objects. You can use any search parameters that Infoblox supports. You filter by CIDR or extensible attributes that are based on regular expressions or exact matches. The format uses the Infoblox WAPI filtration format, as described in [Infoblox WAPI documentation](#).

Methods of filtering by CIDR or extensible attributes are shown in the following examples:

- Filter based on CIDR for networks and network containers. Examples:
 - Exact match - `Infoblox.IPAM.NetworkFilter: network=192.168.0.0`
 - Match by extensible attribute - `Infoblox.IPAM.NetworkFilter: network~=192.168`
- Filter based on CIDR for IP address range. Example:
Match by regular expression and network view name - `Infoblox.IPAM.RangeFilter: network~=192.168.&network_view=my_view`
- Filter based on extensible attributes for networks, IP ranges, and network containers.
Syntax uses the `filter_name=*ext_attr=ext_attr_value` format. Examples:
 - Exact match - `*Building=Data Center`
 - Match by regular expression with '~' - `*Building~=*Center`
 - Case sensitive match with ':' - `*Building:=data center`
 - Exclude match with '!' - `*Building!=Data Center`
 - Match by regular expression (case sensitive and exclude can be combined): `*Building! ~:=Data Cent / *Building~:=center`
- Filter based on CIDR and extensible attributes using syntax from the above methods of filtering. Example:
`network=192.168.&*Building=Data Center`

For more information about using extensible attributes and regular expressions in these properties, see [Infoblox Supported Expressions for Search Parameters](#) and [Infoblox REST API Reference Guide](#).

Setting up Automation Assembler for your organization

As an Automation Assembler administrator, you must understand the user roles and set up connections with your cloud account vendor and integration applications.

When you configure the cloud accounts and integrations, you are configuring the communication between Automation Assembler and those target systems.

What are the VMware Aria Automation user roles

VMware Aria Automation has several levels of user roles. These different levels control access to the organization, the services, the projects that produce or consume the cloud templates, catalog items, and pipelines, and the ability for users to use or see individual parts of the user interface. These different levels give cloud administrators different tools to apply any level of granularity that is required by their operational needs.

General role descriptions

The user roles are defined at different levels. The service level roles are defined for each service.

More details for the service roles is provided below this table.

Role	General permissions	Where the role is defined
Organization Owner	Can access the console and add users to organization. The organization owner cannot access a service unless they have a service role. More about the Organization User Roles	Organization console
Organization Member	Can access the console. The organization member cannot access a service unless they have a service role. More about the Organization User Roles	Organization console
Service Administrator	Can access the console and has full view, update, and delete privileges in the service. <ul style="list-style-type: none"> • More about Assembler roles • More about Service Broker roles • More about Pipelines roles • More about Migration Assistant roles • More about Orchestrator roles • More about the Automation Config role 	Organization console
Service User	Can access the console and the service with limited permissions. The service member has limited user interface. What they can see or do depends on their project membership. <ul style="list-style-type: none"> • More about Assembler roles • More about Service Broker roles • More about Pipelines roles 	Organization console
Service Viewer	Can access the console and the service in a view-only mode. <ul style="list-style-type: none"> • More about Assembler roles 	Organization console

Table continued on next page

Role	General permissions	Where the role is defined
	<ul style="list-style-type: none"> • More about Service Broker roles • More about Pipelines roles • More about Migration Assistant roles • More about Orchestrator roles 	
Executor (Automation Pipelines only)	Can access the console and manage pipeline executions. More about Pipelines roles	Organization console
Orchestrator Workflow Designer (Orchestrator only)	Can create, run, edit, and delete their own Orchestrator Client content. Can add their own content to their assigned group. Does not have access to the administration and troubleshooting features of the Orchestrator Client. More about Orchestrator roles	Organization console
Project roles	Can view and manage project resources depending on project role. Project roles include administrator, member, and viewer. More about project roles	Automation Assembler, Automation Service Broker, and Automation Pipelines
Custom roles	The permissions are defined by the Automation Assembler Administrator for all the services. The user must have at least a service viewer role in the relevant services so that they can access the service. The custom roles take precedence over the service roles. More about custom roles	Automation Assembler and Automation Service Broker
Infrastructure administrator built-in role	Gives predefined permissions for tasks in VMware Aria Automation . More about the Infrastructure Administrator role	Using the API

Organization and service user roles in VMware Aria Automation

Organization and service user roles

The organization and service user roles that you defined for the Automation Assembler, Automation Service Broker, and Automation Pipelines services determine what the user can see and do in each service.

Organization User Roles

User roles are defined for the organization in the VMware Aria Automation console by an organization owner. There are two types of roles, organization roles and service roles.

The organization roles are global and apply to all services in the organization. The organization-level roles are Organization owner or Organization Member role.

For more information about the organization roles, see [Administering VMware Aria Automation](#)

The Automation Assembler service roles, which are service-specific permissions, are also assigned at the organization level in the console.

Service Roles

These service roles are assigned by the organization owner.

This article includes information about the following services.

- [Assembler Service Roles](#)
- [Service Broker Service Roles](#)
- [Pipelines Service Roles](#)
- [vRA Migration Assistant Roles](#)
- [Automation Orchestrator Roles](#)
- [Automation Config Role](#)

Assembler Service Roles

The Automation Assembler service roles determine what you can see and do in Automation Assembler. These service roles are defined in the console by an organization owner.

Table 4: Automation Assembler Service Role Descriptions

Role	Description
Assembler Administrator	A user who has read and write access to the entire user interface and API resources. This is the only user role that can see and do everything, including add cloud accounts, create new projects, and assign a project administrator.
Assembler User	A user who does not have the Assembler Administrator role. In an Automation Assembler project, the administrator adds users to projects as project members, administrators, or viewers. The administrator can also add a project administrator.
Assembler Viewer	A user who has read access to see information but cannot create, update, or delete values. This is a read-only role across all projects in all the services. Users with the viewer role can see all the information that is available to the administrator. They cannot take any action unless you make them a project administrator or a project member. If the user is affiliated with a project, they have the permissions related to the role. The project viewer would not extend their permissions the way that the administrator or member role does.

In addition to the service roles, Automation Assembler has project roles. Any project is available in all of the services.

The project roles are defined in Automation Assembler and can vary between projects.

In the following tables, which tells you what the different service and project roles can see and do, remember that the service administrators have full permission on all areas of the user interface.

The descriptions of project roles will help you decide what permissions to give your users.

- Project administrators leverage the infrastructure that is created by the service administrator to ensure that their project members have the resources they need for their development work.
- Project members work within their projects to design and deploy cloud templates. Your projects can include only resources that you own or resources that are shared with other project members.
- Project viewers are restricted to read-only access, except in a few cases where they can do non-destructive things like download cloud templates.
- Project supervisors are approvers in Automation Service Broker for their projects where an approval policy is defined with a project supervisor approver. To provide the supervisor with context for approvals, consider also granting them the project member or viewer role.

Table 5: Automation Assembler service roles and project roles

UI Context	Task	Assembler Administrator	Assembler Viewer	Assembler User User must be a project administrator or member to see and do project-related tasks.

Service Broker Service Roles

The Automation Service Broker service roles determine what you can see and do in Automation Service Broker. These service roles are defined in the console by an organization owner.

Table 6: Service Broker Service Role Descriptions

Role	Description
Service Broker Administrator	Must have read and write access to the entire user interface and API resources. This is the only user role that can perform all tasks, including creating a new project and assigning a project administrator.
Service Broker User	Any user who does not have the Automation Service Broker Administrator role. In an Automation Service Broker project, the administrator adds users to projects as project members, administrators, or viewers. The administrator can also add a project administrator.
Service Broker Viewer	A user who has read access to see information but cannot create, update, or delete values. This is a read-only role across all projects in all the services. Users with the viewer role can see all the information that is available to the administrator. They cannot take any action unless you make them a project administrator or a project member. If the user is affiliated with a project, they have the permissions related to the role. The project viewer would not extend their permissions the way that the administrator or member role does.

In addition to the service roles, Automation Service Broker has project roles. Any project is available in all of the services.

The project roles are defined in Automation Service Broker and can vary between projects.

In the following tables, which tells you what the different service and project roles can see and do, remember that the service administrators have full permission on all areas of the user interface.

Use the following descriptions of project roles will help you as you decide what permissions to give your users.

- Project administrators leverage the infrastructure that is created by the service administrator to ensure that their project members have the resources they need for their development work.
- Project members work within their projects to design and deploy cloud templates. In the following table, Your projects can include only resources that you own or resources that are shared with other project members.
- Project viewers are restricted to read-only access.
- Project supervisors are approvers in Automation Service Broker for their projects where an approval policy is defined with a project supervisor approver. To provide the supervisor with context for approvals, consider also granting them the project member or viewer role.

Pipelines Service Roles

The Automation Pipelines service roles determine what you can see and do in Automation Pipelines. These roles are defined in the console by the organization owner. Any project is available in all of the services.

Table 8: Pipelines Service Role Descriptions

Role	Description
Pipelines Administrator	A user who has read and write access to the entire user interface and API resources. This is the only user role that can see and do everything, including create projects, integrate endpoints, add triggers, create pipelines and custom dashboards, mark endpoints and variables as restricted resources, run pipelines that use restricted resources, and request that pipelines be published in Automation Service Broker.
Pipelines Developer	A user who can work with pipelines, but cannot work with restricted endpoints or variables. If a pipeline includes a restricted endpoint or variable, this user must obtain approval on the pipeline task that uses the restricted endpoint or variable.
Pipelines Executor	A user who can run pipelines and approve or reject user operation tasks. This user can resume, pause, and cancel pipeline executions, but cannot modify pipelines.
Pipelines User	A user who can access Automation Pipelines, but does not have any other privileges in Automation Pipelines.
Pipelines Viewer	A user who has read access to see pipelines, endpoints, pipeline executions, and dashboards, but cannot create, update, or delete them. A user who also has the Service viewer role can see all the information that is available to the administrator. They cannot take any action unless you make them a project administrator or a project member. If the user is affiliated with a project, they have the permissions related to the role. The project viewer would not extend their permissions the way that the administrator or member role does.

In addition to the service roles, Automation Pipelines has project roles. Any project is available in all the services.

The project roles are defined in Automation Pipelines and can vary between projects.

In the following tables, which tell you what the different service and project roles can see and do, remember that the service administrators have full permission on all areas of the user interface.

Use the following descriptions of project roles to help you decide what permissions to give your users.

- Project administrators leverage the infrastructure that is created by the service administrator to ensure that their project members have the resources they need for their development work. The project administrator can add members.
- Project members who have a service role can use services.
- Project viewers can see projects but cannot create, update, or delete them.

All actions except restricted means this role has permission to perform create, read, update, and delete actions on entities except for restricted variables and endpoints.

Assembler Migration Assistant Service Roles

The Migration Assistant service roles determine what you can see and do in Migration Assistant and Assembler. These service roles are defined in the console by an organization owner.

Table 10: Assembler Migration Assistant Service Roles Descriptions

Role	Description
Migration Assistant Administrator	A user who has full view, update, and delete privileges in the Migration Assistant and Assembler. This role must also have at least the Assembler Viewer role.
Migration Assistant Viewer	A user who has read access to see information but cannot create, update, or delete values in Migration Assistant or in Assembler. This role must also have at least the Assembler Viewer role.

Orchestrator Service Roles

The Automation Orchestrator service roles determine what you can see and do in Automation Orchestrator. These service roles are defined in the console by an organization owner.

Table 11: Automation Orchestrator Service Roles Descriptions

Role	Description
Orchestrator Administrator	A user who has full view, update, and delete privileges in Automation Orchestrator. An administrator can also access the content created by specific groups.
Orchestrator Viewer	A user who has read access to see features and content, including all groups and group content, but cannot create, update, run, delete values, or export content. This is a read-only role across all projects in all the services.
Orchestrator Workflow Designer	A user who can create, run, edit, and delete their own Automation

Table continued on next page

Continued from previous page

Role	Description
	Orchestrator content. They can add their own content to their assigned group. The workflow designer does not have access to the administration and troubleshooting features of the Automation Orchestrator.

Automation users without an assigned Orchestrator service role can still access all Automation Orchestrator instances in the organization but have limited permissions. They can view and run their own content and respond to user interaction requests that are assigned to them.

Users without an assigned Orchestrator service role in Automation who have an assigned role in an individual Automation Orchestrator instance can only access that Automation Orchestrator instance.

Automation Config Service Role

The Automation Config service role determines what you can see and do in Automation. This service role is defined in the console by an organization owner.

Table 12: Automation Config Service Role Description

Role	Description
Config Administrator	A user who can access the Automation Config tile on the console when the integration with Assembler is configured. To log in on the Automation Config instance, the user must have Automation Config administrator permissions that are defined in Automation Config. The user must also have the Assembler Administrator role.
Config User	A user who does not have the Config Administrator role.
Salt Master	
Config Superuser	

Custom user roles in VMware Aria Automation

Custom user roles

As an Automation Assembler administrator, you can create custom roles that define what users can see and do in VMware Aria Automation. You can then assign users to those roles.

Custom user role permissions

Using Automation Assembler, you can define more granular user roles and then assign users to those roles. The custom roles have two categories, view and manage.

- View. A user assigned to a role with this permission can see all the items for all projects in the selected sections of the user interface. This role is useful for users who need to see accounts, configurations, or assigned values.
- Manage. A user assigned to a role with this permission can see all the items and has full add, edit, and delete permissions for all projects in the selected sections of the user interface.

These permissions extend the privileges that are granted by the other roles and are not restricted by project membership. For example, you can expand a project administrator's permissions to manage parts of the infrastructure or give a service viewer an ability to review and respond to approvals requests.

How do I create custom user roles

To define the user roles and assign users, open Automation Assembler or Automation Service Broker as a service administrator. You cannot configure the custom roles in Automation Pipelines, however the roles apply to all the services.

1. Select **Infrastructure > Administration > Custom Roles**.
2. Click **New Custom Role** and enter a unique **Name** that you can identify when you assign users to the role.
3. Select the check boxes that correspond to the permissions you want the users to have over the resources.
4. Click **Create**.
5. In the list, click the custom role name and click **Assign**.
6. Add the users or groups that you want to have this role and click **Add**.

How do I determine what custom roles the users have

To manage the users with the custom roles, you can review the users and groups.

1. Select **Infrastructure > Administration > Users and Groups**.
2. Review the Custom Roles column to locate users with the role.
3. To add or remove roles for a user, click the user's name and then modify the custom role assignments.

Custom Role Descriptions

In most cases the role description is provided in the user interface. However, there are some extended descriptions provided in the following table.

Table 13: Custom Roles

User Interface	Permission	Description
Infrastructure		
	View Cloud Accounts.	View cloud accounts.
	Manage Cloud Accounts	Create, update, or delete cloud accounts.
	View Image Mappings	View image mappings.
	Manage Image Mappings	Create, update, or delete image mappings.
	View Flavor Mappings	View flavor mappings.
	Manage Flavor Mappings	Create, update, or delete flavor mappings.
	View Cloud Zones	View cloud zones, Insights, and alerts.
	Manage Cloud Zones	Create, update, or delete cloud zones. Manage alerts.
	View Requests	View activity requests.
	Manage Requests	Delete requests from the list.
	View Integrations	View integrations.
	Manage Integrations	Create, update, or delete integrations.
	View Projects	View projects.
	Manage Projects	Create projects. Add users and assign roles in projects. Update, or delete

Table continued on next page

Continued from previous page

User Interface	Permission	Description
		values from project summary, users, provisioning, Kubernetes, integrations, and test project configurations.
	View Onboarding Plans	View onboarding plans
	Manage Onboarding Plans	Create, update, run, or delete onboarding plans
Catalog		
	View Content	
	Manage Content	Add, update, delete content sources. Customize the content, including the catalog icons and request forms.
Policies		
	View Policies	View policy definitions.
	Manage Policies	Create, update, or delete policy definitions.
Deployments		
	View Deployments	View all deployments, including deployment details, deployment history, alerts, and troubleshooting information.
	Manage Deployments	View all deployments, respond to alerts, and run all day 2 actions that the day 2 policies allow an administrator to run on deployments and deployment components.
Cloud Templates		
	View Cloud Templates	View cloud templates.
	Manage Cloud Templates	Create, update, test, delete, version, share cloud templates, and release/unrelease a cloud template version.
	Edit Cloud Templates	Create, update, test, version, share cloud templates, and release/unrelease a cloud template version. The role does not have permission to delete cloud templates.
	Deploy Cloud Templates	Test and deploy any cloud template in any project.
	Deploy In-line Cloud Template Content	Deploy any cloud template in the projects that the assignees are associated with. The project roles can be administrator, member, or viewer.
	View property groups	View all property groups for all projects.
	Manage property groups	Create, update, and delete property groups in any project.
XaaS

Use cases: How can user roles help me control access in VMware Aria Automation

Use cases: How can user roles help me control access

As a cloud administrator, you want to control the tasks that your users can perform in VMware Aria Automation.

Depending on your management goals and application development team responsibilities, there are different ways that you can configure the user roles to support those goals.

- Verify that you have the Organization Owner role. You must see the **Identity and Access Management** tab with you log in to the console. If not, contact the organization owner.
- Verify that you have the service administrator role for the various services. If you are not certain about your role, contact the organization owner.
- Verify that your users are added to VMware Aria Automation.
When you install VMware Aria Automation, your Active Directory users are added as part of the process.
- For a more detailed task and role list for various roles, see [Organization and service user roles in VMware Aria Automation](#).

The following Automation Assembler and Automation Service Broker examples are based on three use cases. These examples provide only enough instruction to illustrate the application of users roles.

The target audience for these use cases is the cloud administrator, who is also considered the cloud administrator, and the service administrators.

The use cases build on each other. If you are ready to go directly to use case 3, you might need to review use cases 1 and 2 to better understand why you configure the roles in the ways specified.

The purpose of the use cases is to demonstrate user roles, not to provide detailed information about configuring your infrastructure, managing projects, creating cloud templates, and working with deployments.

Before you begin, you must understand the levels of user roles that are configured by a cloud administrator in the VMware Aria Automation Console.

- Organization Roles

The organization roles control who can access the console.

As an organization owner, you must ensure that all users of any of the services are assigned at least an organization member role.

Role	Description
Organization Owner	An administrator can add users, change the role of users, and remove users from the organization. The owner manages which services users have access to.
Organization Member	A general user can log in to the organization console. To access the services, an organization owner must assign the users service roles.

- Service Roles

The service roles control who can access their assigned services.

As an organization owner, you must ensure that the users who need access to the services are assigned the appropriate role. You use the roles to control how much the user can do in each service.

Table 14: Automation Assembler Service Role Descriptions

Role	Description
Assembler Administrator	A user who has read and write access to the entire user interface and API resources. This is the only user role that can see and do everything, including add cloud accounts, create new projects, and assign a project administrator.
Assembler User	A user who does not have the Assembler Administrator role. In an Automation Assembler project, the administrator adds users to projects as project members, administrators, or viewers. The administrator can also add a project administrator.
Assembler Viewer	A user who has read access to see information but cannot create, update, or delete values. This is a read-only role across all projects in all the services. Users with the viewer role can see all the information that is available to the administrator. They cannot take any action unless you make them a project administrator or a project member. If the user is affiliated with a project, they have the permissions related to the role. The project viewer would not extend their permissions the way that the administrator or member role does.

Table 15: Service Broker Service Role Descriptions

Role	Description
Service Broker Administrator	Must have read and write access to the entire user interface and API resources. This is the only user role that can perform all tasks, including creating a new project and assigning a project administrator.
Service Broker User	Any user who does not have the Automation Service Broker Administrator role. In an Automation Service Broker project, the administrator adds users to projects as project members, administrators, or viewers. The administrator can also add a project administrator.
Service Broker Viewer	A user who has read access to see information but cannot create, update, or delete values. This is a read-only role across all projects in all the services. Users with the viewer role can see all the information that is available to the administrator. They cannot take any action unless you make them a project administrator or a project member. If the user is affiliated with a project, they have the permissions related to the role. The project viewer would not extend their permissions the way that the administrator or member role does.

Table 16: Pipelines Service Role Descriptions

Role	Description
Pipelines Administrator	A user who has read and write access to the entire user interface and API resources. This is the only user role that can see and do everything, including create projects, integrate endpoints, add triggers, create pipelines and custom dashboards, mark endpoints and variables as restricted resources, run pipelines that use restricted resources, and request that pipelines be published in Automation Service Broker.
Pipelines Developer	A user who can work with pipelines, but cannot work with restricted endpoints or variables. If a pipeline includes a restricted endpoint or variable, this user must obtain approval on the pipeline task that uses the restricted endpoint or variable.
Pipelines Executor	A user who can run pipelines and approve or reject user operation tasks. This user can resume, pause, and cancel pipeline executions, but cannot modify pipelines.
Pipelines User	A user who can access Automation Pipelines, but does not have any other privileges in Automation Pipelines.
Pipelines Viewer	A user who has read access to see pipelines, endpoints, pipeline executions, and dashboards, but cannot create, update, or delete them. A user who also has the Service viewer role can see all the information that is available to the administrator. They cannot take any action unless you make them a project administrator or a project member. If the user is affiliated with a project, they have the permissions related to the role. The project viewer would not extend their permissions the way that the administrator or member role does.

- Project membership roles

The project membership determines what infrastructure resources and cloud templates are available.

Project membership is defined in the service by a user with a service administrator role. The service administrator must ensure that the users who need access to one or more projects are assigned the appropriate project role in each project.

Table 17: Project Roles

Role	Description
Project Administrator	A project administrator can manage their own projects, create and deploy cloud templates associated with their projects, and manage project deployments for all project members.
Project Member	A project member can create and deploy cloud templates associated with their projects, manage their own deployments, and manage any shared deployments.
Project Viewer	A project viewer is a member of the project with read-only access to their project resources, cloud templates, and deployments.

- Custom roles

The custom roles are created by the Automation Assembler to refine the member and viewer roles.

The procedures provided in these use cases are meant to highlight the user roles. They are not detailed or definitive procedures for setting up VMware Aria Automation.

As you configure roles, remember that users who are running API operations are subject to the roles that you assign here.

User role use case 1: Set up the VMware Aria Automation user roles to support a small application development team

Set up user roles to support a small application development team

As an VMware Aria Automation cloud administrator, you are responsible for managing the access and the budget for your infrastructure resources. You add yourself and two others as administrators. This small team can create the infrastructure and develop the cloud templates that match the business goals of the teams that consume the cloud templates. You and your small team of administrators then deploy the cloud templates for your non-administrator consumers. You don't allow non-administrators to access VMware Aria Automation.

- Verify that you meet all the prerequisites stipulated in the use case introduction. See [Use cases: How can user roles help me control access in .](#)

In this use case, you are the organization owner and you have a small team where they all have the service administrator role.

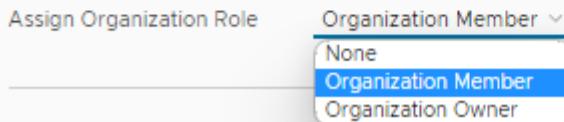

The following procedure follows one user all the way through the process. You can do each step for multiple users.

- Assign organization roles. Click **Identity and Access Management**.

- Log in to the VMware Aria Automation console.
- Click **Identity and Access Management**.
- Select the user name and click **Edit Roles**.
- In the **Assign Organization Roles** drop-down menu, select **Organization Member**.

Edit Roles

You are editing the roles of the user Ezio Enzo (ezio@coke.sqa-horizon.local)

The organization member role ensures that the user can access the console and any services that you add them to. They cannot manage organization users.

Leave the Edit Role page open for this user and continue to the next step.

- Assign Assembler Administrator role to yourself and to the one or two other administrators in this scenario.

The service administrator role has full privileges to add, edit, and delete infrastructure, projects, cloud templates, and deployments. Defining an administrator role for one person and the user role for a different person is covered in Scenario 2. This example uses Sylvia.

- Click **Add Service Access**.
- Configure the user with the following value.

Service	Role
VMware Aria Automation	Assembler Administrator

IDENTITY & ACCESS MANAGEMENT

Edit Roles

You are editing the roles of the user **Sylvia Adams** (`sylvia@coke.sqa-horizon.local`)

Assign Organization Role Organization Member

Assign Service Roles [\(i\)](#)

Assembler [▼](#) with roles Assembler Administrator [▼](#) [X](#)

[+ ADD SERVICE ACCESS](#)

SAVE **CANCEL**

3. Create a project in Automation Assembler that you use to group resources and manage resource billing for different business groups.
 - a) In the console, click **Services**, and then click **Assembler**.
 - b) Select **Infrastructure > Projects > New Project**.
This user role use case is focused on providing examples of how you can implement user roles, not on creating the fully defined system.
For information about configuring the infrastructure, see [Building your resource infrastructure](#). For more about projects, see [Adding and managing projects](#).
 - c) Enter **WebAppTeam** as the project name.
 - d) Click **Users**, and then click **Add Users**.
 - e) Enter email addresses for the individuals who can help you build and manage the infrastructure and cloud templates.
For example, `tony@mycompany.com,sylvia@mycompany.com`.
 - f) In the **Assign role** drop-down menu, select **Administrator**.
As Automation Assembler administrators, these two users already have administrator access to the cloud accounts, infrastructure, and all projects. This step helps you understand the roles used in the later scenarios. In the later scenarios, you define project administrator and project member roles, which have different permissions.
 - g) Click the **Provisioning** tab and add one or more cloud zones.
Another reminder. This use case is about user roles.
4. Develop a simple cloud template so that you can test the WebAppTeam project.

This cloud template section is abbreviated. The focus is users and user roles as defined by projects, not how to create a cloud template.

- a) Select **Cloud Templates** > **New**.
- b) For the new cloud template name, enter WebApp.
- c) For **Project**, select WebAppTeam.

New Cloud Template

X

Name *	WebApp
Description	<div style="border: 1px solid #ccc; height: 100px; width: 100%;"></div>
Project *	<input type="text" value="WebAppTeam"/>
Cloud template sharing in	<input checked="" type="radio"/> Share only with this project
Service Broker	<input type="radio"/> Allow an administrator to share with any project in this organization
CANCEL CREATE	

- d) Select **Share only with the project**.

This setting ensures that the cloud template is only available to project members. When you are ready to provide the cloud templates to other teams, you can select Allow an administrator to share with any project in this organization. Sharing the cloud template with other projects means that you do not have to maintain duplicate instances of the same base templates. You can move cloud templates from development projects to production projects so that catalog consumers can deploy to production infrastructure resources.

- e) Click **Create**.
 - f) In the cloud template designer, drag the **Cloud Agnostic** > **Machine** component to the canvas.
- For more about configuring cloud templates, see [Designing your deployments](#).
- g) Click **Deploy**.
 - h) Continue iterating on the cloud template until you are ready to provide it to your consumers.
 - i) Click **Version** and release and version the cloud template.

- Send the users the log in information using your most common method.

In this use case, you made your two colleagues organization members. You then made Sylvia a Automation Assembler administrator. You made Tony a WebApp project administrator. This user role configuration only works for small teams where you deliver deployed applications to your consumers rather than providing them with self-service access or a catalog.

User role use case 2: Set up VMware Aria Automation user roles to support larger development teams and the catalog

Set up user roles to support large teams and the catalog

As a VMware Aria Automation organization owner, you are responsible for managing the access and the budget for your infrastructure resources. You have a team of cloud template developers who iteratively create and deploy templates for different projects until they are ready to deliver to their consumers. You then deliver the deployable resources to the consumers in a catalog.

- Review first use case. See [User role use case 1: Set up the user roles to support a small application development team](#).
- Identify the following users based on what permissions you want them to have:
 - cloud template developers who will be Automation Assembler users and viewers
 - An Automation Service Broker administrator
 - Non-developer users who will be catalog consumers as Automation Service Broker users

This use case assumes that you understand that use case 1 is an administrator-only use case. You now want to expand your system to support more teams and larger goals.

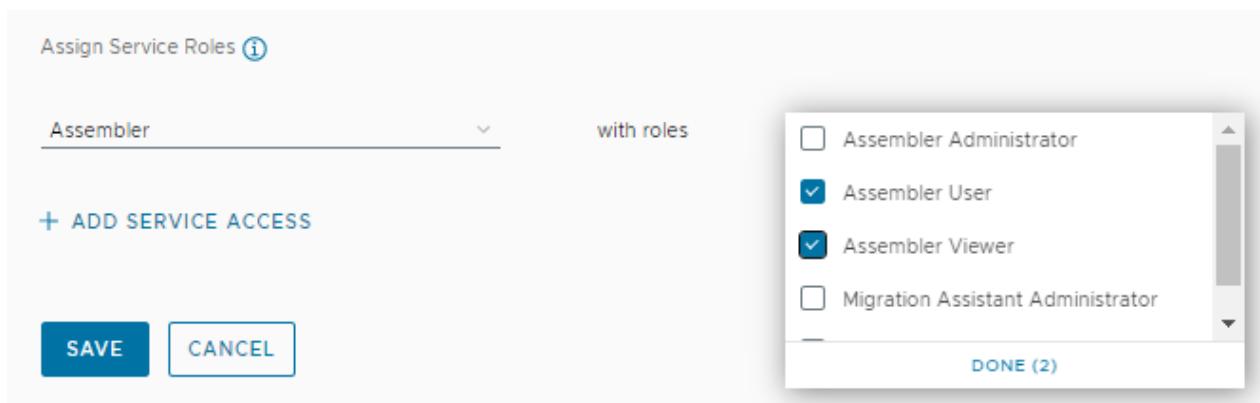

- Let developers create and deploy their own application cloud templates during development. You add yourself as administrator, then add additional users with both the service user and the service viewer role. Next, you add the users as project members. The project members can develop and deploy their own cloud templates.
- Publish cloud templates to a catalog where you make them available for non-developers to deploy. Now you are assigning user roles for Automation Service Broker. Automation Service Broker provides a catalog for the cloud template consumers. You can also use it to create policies, including leases and entitlements, but that functionality is not part of this user role use case.

- Assign organization member roles to your cloud template developer users.

If you need instructions, see the [previous use case](#).

- Assign the Automation Assembler service member role to your cloud template developers.

- Click **Add Service Access**.

- Configure the user with the following value.

Service	Role
Assembler	Assembler User
Assembler	Assembler Viewer

In this use case, your developers need to see the infrastructure to ensure that they are building deployable cloud templates. As users that you will assign as project administrators and project members in the next step, they cannot see the infrastructure. As service viewers they can see how the infrastructure is configured, but cannot make any changes. As the cloud administrator, you remain in control, but give them access to the information they need to develop cloud templates.

3. Create projects in Automation Assembler that you use to group resources users.

In this use case, you create two projects. The first project is PersonnelAppDev and the second is PayrollAppDev.

- a) In the console, click **Services**, and then click **VMware Aria Automation**.
- b) In VMware Aria Automation, click **Assembler**.
- c) Select **Infrastructure > Projects > New Project**.
- d) Enter **PersonnelAppDev** as the name.
- e) Click **Users**, and then click **Add Users**.
- f) Add project members and assign a project administrator.

Project Role	Description
Project User	A project member is the primary developer user role in a project. Projects determine what cloud resources are available when you are ready to test your development work by deploying a cloud template.
Project Administrator	A project administrator supports their developers by adding and removing users for your projects. You can also delete your projects. To create a project, you must have service administrator privileges.

- g) For the users that you are adding as project members, enter the email address of each user, separated by a comma, and select **User** in the **Assign role** drop-down menu.

For example, tony@mycompany.com,sylvia@mycompany.com.

The screenshot shows the 'Users' tab for the 'PersonnelAppDev' project. The 'Deployment sharing' toggle is turned on. The 'User roles' section lists three users with their accounts and roles:

	Name	Account	Role
<input type="checkbox"/>	Sylvia Adams	sylvia	Administrator
<input type="checkbox"/>	Gloria Martinez	gloria	Member
<input type="checkbox"/>	Tony Anteater	tony	Member

At the bottom, there are 'SAVE' and 'CANCEL' buttons.

- h) For the designated administrators, select **Administrator** in the **Assign role** drop-down menu and provide the necessary email address.

- i) Click the **Provisioning** tab and add one or more cloud zones.

When the cloud template developers who are part of this project deploy a template, it is deployed to the resources available in the cloud zones. You must ensure that the cloud zone resources match the needs of the project development team templates.

- j) Repeat the process to add the PayrollAppDev project with the necessary users and an administrator.

4. Provide the service user with the necessary login information and verify that the members of each project can do the following tasks.

- Open Automation Assembler.
- See the infrastructure across all projects.
- Create a cloud template for the project that they are a member of.
- Deploy the cloud template to the cloud zone resources defined in the project.
- Manage their deployments.

5. Assign organization member roles to your cloud template developer users.

If you need instructions, see the [first use case](#).

6. Assign roles to a catalog administrator, catalog consumers, and cloud template developers based on their job.

- Click **Add Service Access**.
- Configure the catalog administrator with the following value.

This role might be you, the cloud administrator, or it might be someone else on your application development team.

Service	Role
Service Broker	Service Broker Administrator

- c) Configure the cloud template consumers with the following value.

Service	Role
Service Broker	Service Broker User

Edit Roles

You are editing the roles of the user **Sylvia Adams** (sylvia@coke.sqa-horizon.local)

Assign Organization Role [Organization Member](#) ▾

Assign Service Roles [\(i\)](#)

Service Broker
with roles

[+ ADD SERVICE ACCESS](#)

Service Broker Administrator

Service Broker User

CANCEL

- d) Configure the cloud template developers with the following value.

Service	Role
Assembler	Assembler User

7. Create projects in Automation Assembler that you use to group resources and users.

In this use case, you create two projects. The first project is PersonnelAppDev and the second is PayrollAppDev.

If you need instructions, see the [previous use case](#).

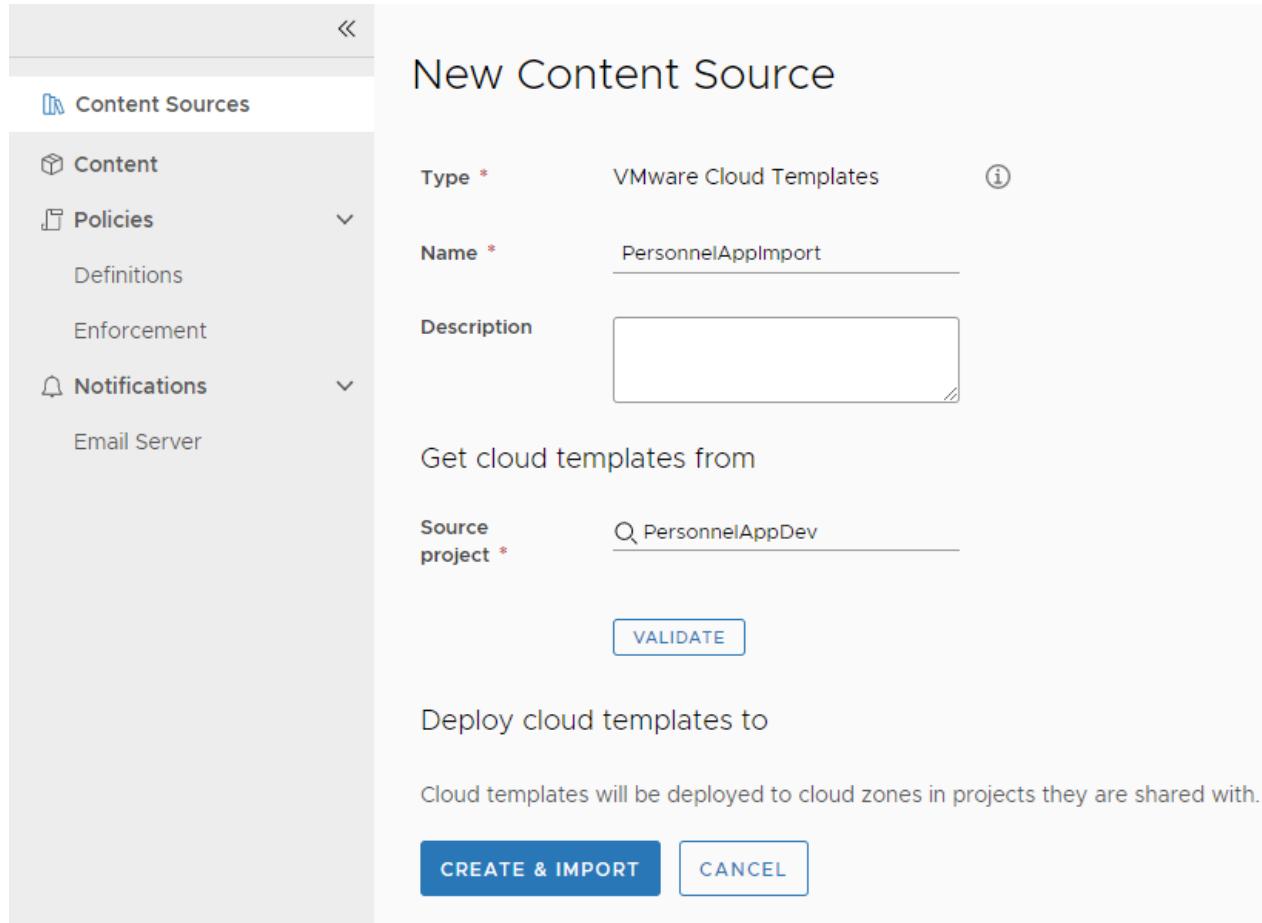

8. Create and release cloud templates for each project team.

If you need instructions, see the [first scenario](#).

9. Import an Automation Assembler cloud template into Automation Service Broker.

You must log in as a user with the Automation Service Broker Administrator role.

- Log in as a user with the Automation Service Broker Administrator role.
- In the console, click **Services**, and then click **Service Broker**.
- Select **Content and Policies** > **Content Sources**, and click **New**.

- Select **VMware Cloud Templates**.
 - Enter PersonnelAppImport as the name.
 - In the **Source project** drop-down menu, select PersonnelAppDev and click **Validate**.
 - When the source is validated, click **Create and Import**.
 - Repeat for PayrollAppDev using PayrollAppImport as the content source name.
- Share an imported cloud template with a project.

Although the cloud template is already associated with a project, you create a sharing policy in Automation Service Broker to make it available in the catalog.

- Continue as a user with the Automation Service Broker administrator role.
- In Automation Service Broker, select **Content and Policies** > **Policies** > **Definitions**.
- Click **New Policy**, and then click **Content Sharing Policy**.
- Enter a **Name**.
- On the **Scope** list, select the PersonnelAppDev project.
- In the **Content sharing** section, click **Add Items**.

Share Items with PersonnelAppDev X

Select the templates to share with the project members. [\(1\)](#)

CONTENT SOURCES C

	Items Shared with this Project	Description
<input checked="" type="checkbox"/>	PersonnelAppImport	
<input checked="" type="checkbox"/>	WebApp for Personnel	

1 1 item(s)

CANCEL SAVE

- g) In the **Share Items** dialog box, select the PersonnelApp cloud template and click **Save**.
 - h) In the **Users** section, select the project users and groups that you want to see the item in the catalog.
 - i) Click **Create**.
11. Verify that the cloud template is available in the Automation Service Broker catalog to the project members.
- a) Request that a project member log in and select **Consume > Catalog**.

Catalog Items 1 item Filter

Search

WebApp for Perso... VMware Cloud Templates

Projects: PersonnelAppDev

REQUEST

- b) Click Request on the PersonnelApp cloud template card.
 - c) Complete the form and click **Submit**.
12. Verify that the project member can monitor the deployment process.

- a) Request that the project member select **Consume > Deployments** and locate their provisioning request.

Deployments 2 items Filter

Search deployments ① | Sort: Created on (descending) ▼

	Web App for Pers...	1 Resource	Created 11 min...	Never expires	ACTIONS
Cloud	No description	Cloud_Machine_1-mc...	On		Actions
Project	PersonnelAp...				
Requestor	gloria@coke.s...				

- b) When the cloud template is deployed, verify that the requesting user access the application.
13. Repeat the process for the additional projects.

In this use case, recognizing that need to delegate the cloud template development to the developers, you add more organization members. You made them Automation Assembler users. You then made them members of relevant projects so that they can create and deploy cloud templates. As project members, they cannot see or alter the infrastructure that you continue to manage, but you gave them full service viewer permissions so that they could understand the constraints of infrastructure that they are designing for.

In this use case, you configure users with various roles, including the Automation Service Broker administrator and users. You then provide the non-developer users with the Automation Service Broker catalog.

To learn how to define and assign custom roles to user, see [User role use case 3: Set up custom user roles to refine system roles](#).

User role use case 3: Set up VMware Aria Automation custom user roles to refine system roles

Set up custom user roles to refine standard roles

As a VMware Aria Automation organization owner or service administrator, you manage user access using the organization and service system roles. However, you also want to create custom roles to that selected users and perform tasks or see content that is outside of their system roles.

- Review the Automation Assembler and Automation Service Broker service roles and project roles tables in [What are the VMware Aria Automation user roles](#). You must understand what each service user role can see and do in those services.
- Review the [Custom Roles](#) descriptions so that you know more about how you can refine the permissions for your users.
- Review the first use case so that you understand organization roles and the service administrator roles. See [User role use case 1: Set up the user roles to support a small application development team](#).
- Review the second use case so that you understand the service user and project member roles. See [User role use case 2: Set up user roles to support larger development teams and the catalog](#).
- Familiarize yourself with Automation Service Broker. See [Adding content to the catalog](#).

This scenario assumes that you understand the service user and viewer, and the project member and viewer roles that are defined in use case 2. You can see that they are more restrictive than the service and project administrator roles used in use case 1. Now you have identified some local use cases where you want some users to have full management permissions to on some features, view permissions on others, and you do not want them to even view yet another set of features. You use custom roles define those permission.

This use case is based on three possible local use cases. This procedure shows you how to create permissions for the following custom roles.

- Restricted Infrastructure Administrator. You want some service users, who are not service administrators, to have broader infrastructure permissions. As the administrator, you want them to help set up cloud zones, images, and flavors. You also want them to be able on-board and manage discovered resources. Notice they cannot add cloud accounts or integrations, they can only define the infrastructure for those endpoints.
- Extensibility Developer. You want some service users to have full permissions to use the extensibility actions and subscriptions as part of cloud template development for their project team and for other projects. They will also develop custom resource types and custom actions for multiple projects.
- XaaS Developer. You want some service users to have full permissions to develop custom resource types and custom actions for multiple projects.
- Deployment Troubleshooter. You want your project administrators to have permissions they need to troubleshoot and perform root cause analysis on failed deployments. You give them manage permissions on non-destructive or less expensive categories such as image and flavor mappings. You also want the project administrators to have permission to set approvals and day 2 policies as part of the failed deployment troubleshooting role.

1. Assign organization member roles to your cloud template developer users.

If you need instructions, see the [first use case](#).

2. Assign Automation Assembler and Automation Service Broker service roles for your cloud template developers and catalog consumers.

If you need instructions, see the [second use case](#).

3. Create projects in Automation Assembler that you use to group resources and users.

The steps below for the custom roles also includes project roles.

If you need instructions for creating projects, see the [second use case](#).

4. Create and release cloud templates for each project team.

If you need instructions, see the [first use case](#).

5. Log in to Automation Assembler as a service administrator and select **Infrastructure > Administration > Custom Roles**.

6. Create a Restricted Infrastructure Administrator role.

In this example, you have a user, Tony, who is expert at setting up the infrastructure for various projects, but you don't want to give him full service permissions. Instead, Tony builds the core infrastructure the supports the work of all the projects. You give him limited infrastructure management permissions. Tony, or an outside contractor, might also have similar permissions for onboarding discovered machines and bringing them under VMware Aria Automation management.

- a) Add Tony to Automation Assembler as a service user and viewer.

With his viewer permissions, he can see the underlying cloud accounts and integrations if he needs to troubleshoot his work, but he cannot make changes.

- b) Create a project and add Tony as project member.

- c) To create the custom role, select **Infrastructure > Administration > Custom Roles**, and click **New Custom Role**.

- d) Enter the name **Restricted Infrastructure Administrator** and select the following permissions.

Select this permission ...	So that the users can ...
Infrastructure > Manage Cloud Zones	Create, update, and delete cloud zones.
Infrastructure > Manage Flavor Mappings	Create, update, and delete flavor mappings.
Infrastructure > Manage Image Mappings	Create, update, and delete image mappings.
Infrastructure > Manage Network Profiles	Create, update, or delete network profiles.
Infrastructure > Manage Storage Profiles	Create, update, or delete storage profiles.
Infrastructure > Onboarding	Create, update, or delete onboarding plans.

- e) Click **Create**.

- f) On the Custom Roles page, select the Restricted Infrastructure Administrator role and click **Assign**.

- g) Enter Tony's email account and click **Add**.

For example, enter Tony@yourcompany.com.

You can also enter any defined Active Directory user groups.

- h) Have Tony verify that when he logs in, he can add, edit, and delete values in the areas defined by the custom role.

7. Create an Extensibility Developer role.

In this example, you have several cloud template developers, Sylvia and Igor, who are knowledgeable about how to use extensibility actions and subscriptions to manage daily development tasks. They are also experienced with VMware Aria Automation Orchestrator, so you task them with providing custom resources and actions for various projects. You give them additional permissions manage extensibility by managing custom resources and actions, and by managing extensibility actions and subscriptions.

- a) Add Sylvia and Igor as Automation Assembler users.

- b) Add them as members of the projects that they are contributing their extensibility skills to.

- c) Create a custom user role that you name **Extensibility Developer** and select the following permissions.

Select this permission ...	So that the users can ...
XaaS > Manage Custom Resources	Create, update, or delete custom resources.
XaaS > Manage Resource Actions	Create, update, or delete custom actions.
Extensibility > Manage Extensibility Resources	Create, update, or delete extensibility actions and subscriptions. Deactivate subscriptions. Cancel and delete action runs.

- d) Click **Create**.
 - e) Assign Sylvia and Igor to the Extensibility Developer role.
 - f) Verify that Sylvia and Igor can manage the custom resources and actions, and that they can manage the various options on the Extensibility tab.
8. Create a Deployment Troubleshooter role.

In this example, you give your project administrators more manage permission so that they can remedy deployment failures for their teams.

- a) Add your project administrators, Shauna, Pratap, and Wei, as Automation Assembler and Automation Service Broker service users.
- b) In their projects, add them as project administrators.
- c) Create a custom user role that you name **Deployment Troubleshooter** and select the following permissions.

Select this permission ...	So that the users can ...
Infrastructure > Manage Flavor Mappings	Create, update, and delete flavor mappings.
Infrastructure > Manage Image Mappings	Create, update, and delete image mappings.
Infrastructure > View Network Profiles	View network profiles.
Infrastructure > View Storage Profiles	View storage profiles.
Deployments > Manage Deployments	View all deployments, across projects, and run all day 2 actions on deployments and deployment components.
Policy > Manage Policies	Create, update, or delete policy definitions.

- d) Click **Create**.
- e) Assign Shauna, Pratap, and Wei to the Deployment Troubleshooter role.
- f) Verify that they can manage flavor mappings, image mappings, and policies in Automation Service Broker.

In this use case, you configure different users with various roles, including custom roles that expand their service and project roles.

Create custom roles that address your local use cases.

How do I assign the Automation Assembler Infrastructure Administrator built-in role to a user

Infrastructure Administrator built-in role

The infrastructure administrator role is a built-in role that you can assign to selected users. You cannot assign the role in the user interface.

When should I assign this user role

You can duplicate the permissions using the custom user role options. However, you can give this built-in role to users who are limited administrators.

Infrastructure administrator role permissions

The following table provides the list of management permissions and other permissions the an infrastructure administrators needs. These permissions cannot be modified. If you want a user to have more limited permissions, use the custom roles to create a user role that meets your particular needs.

Table 18: Provided permissions for the Infrastructure Administrator built-in role

Permission to create, edit, update, or delete	Other permissions
<ul style="list-style-type: none"> • Cloud accounts • Integrations • Cloud zones • Flavor mappings • Image mappings • Onboarding plans 	<ul style="list-style-type: none"> • Create and view projects • Add users and assign roles to users in projects • Edit cloud zones in projects • View and delete request status • View event logs • View request details

How do I assign the Infrastructure Administrator role

This built-in role is assigned using the RBAC API. You first get the role and then assign the role to a user.

Before you begin:

- Familiarize yourself with the VMware Aria Automation APIs and CLI.
 - Within an API Programming Guide, find the instructions to get an API token at [Get Your Access Token](#).
 - at
1. Go to \$vra/project/api/swagger/swagger-ui.html?urls.primaryName=rba where \$vra is the base URL for your instance.
 2. In the upper right corner of the page, in the **Select a definition** drop-down list, select **rbac: 2020-08-10**.
 3. To retrieve the user role, open the **Role** section, run GET /rbac-service/api/roles.
- The results should look similar to the following example.

```
"content": [
  {
    "description": "Infrastructure Administrator",
    "hidden": false,
    "id": "infrastructure_administrator",
    "name": "Infrastructure Administrator",
    "orgId": "string",
    "permissions": [
      "string"
    ],
  },
]
```

```

    "projectScope": true
}

```

- To add a user to the role, open the **Role Assignment** section, open and edit the `PUT /rbac-service/api/role-assignments` command with the user name included.

For example,

```

{
  "orgId": "string",
  "principalId": "Username@domain",
  "principalType": "user",
  "projectId": "string",
  "rolesToAdd": [
    "infrastructure_administrator"
  ],
  "rolesToRemove": [
    "string"
  ]
}

```

- Run the modified PUT command.
- To verify the results, instruct the assigned user to log in and ensure that they have the permissions defined above.

Adding cloud accounts to Automation Assembler

Adding cloud accounts

Cloud accounts are the configured permissions that Automation Assembler uses to collect data from the regions or data centers, and to deploy cloud templates to those regions.

The collected data includes the regions that you later associate with cloud zones.

When you later configure cloud zones, mappings, and profiles, you select the cloud account to which they are associated.

As a cloud administrator, you create cloud accounts for the projects in which team members work. Resource information such as network and security, compute, storage, and tags content is data-collected from your cloud accounts.

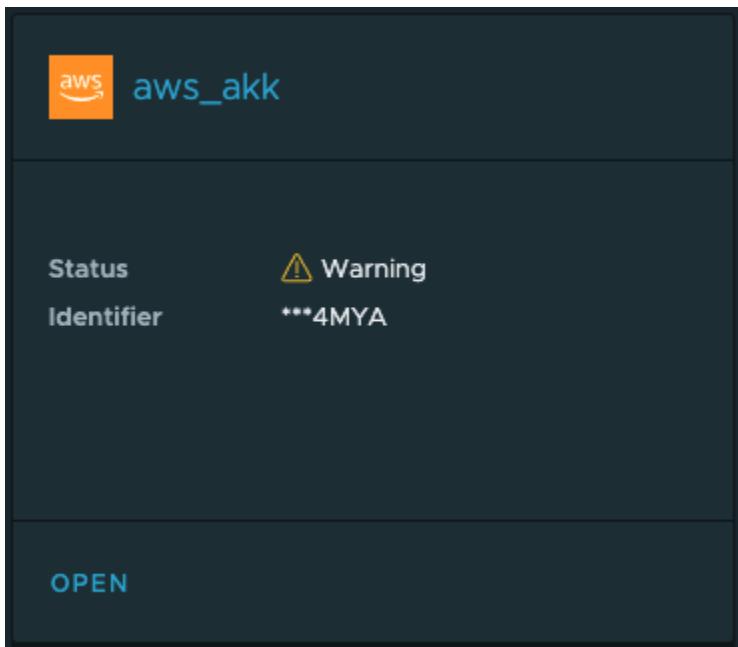

NOTE

If the cloud account has associated machines that have already been deployed in the region, you can bring those machines into Automation Assembler management by using an onboarding plan. See [What are onboarding plans in Automation Assembler](#).

If you remove a cloud account that is used in a deployment, resources that are part of that deployment become unmanaged.

Monitoring the cloud account health

To ensure that your cloud accounts are communicating with the target system, the status of the account appears on the card based on periodic health checks.

Warnings indicate that there might be a problem that needs your attention.

Status	① Data collection failed. See details.. ⓘ
	② Image synchronization completed 5 hours ago. ⓘ SYNC IMAGES
	③ Available for deployment. ⓘ UPDATE

Name * aws_akk

Description

In some cases, the details can help you resolve the issue. In other cases, you can run the **Update** option. It might be that the connection has been, in which case **Update** does not resolve the problem. One possible scenario is that the credentials have expired. To troubleshoot, first re-establish a connection with the updated credentials.

Credentials required for working with cloud accounts in VMware Aria Automation

Credentials required for working with cloud accounts

To configure and work with cloud accounts in VMware Aria Automation, verify that you have the following credentials.

Required overall credentials

To...	You need...
Sign up for and log in to Automation Assembler	A VMware ID. <ul style="list-style-type: none"> • Set up a My VMware account by using your corporate email address at VMware Customer Connect.
Connect to VMware Aria Automation services	HTTPS port 443 open to outgoing traffic with access through the firewall to: <ul style="list-style-type: none"> • *.vmwareidentity.com • gaz.csp-vidm-prod.com • *.vmware.com For more information about ports and protocols, see VMware Ports and Protocols . For more information about ports and protocols, see <i>Port Requirements in the Reference Architecture</i> help.

vCenter cloud account credentials

This section describes the credentials that are required to add a vCenter cloud account.

Privileges are required for the vSphere agent to manage the vCenter instance. Provide an account with the following read and write privileges:

- vCenter IP address or FQDN

The permissions needed to manage VMware Cloud on AWS and vCenter cloud accounts are listed. Permissions must be enabled for all clusters in the vCenter, not just clusters that host endpoints.

To support control of VMware's Virtual Trusted Platform Module (vTPM) when deploying Windows 11 VMs, you must have the cryptographic operations -> direct access privilege in vCenter. Without this privilege, console access from VMware Aria Automation to Windows 11 VMs is not possible. For related information, see [Virtual Trusted Platform Module Overview](#).

For all vCenter-based cloud accounts - including NSX-V, NSX-T, vCenter, and VMware Cloud on AWS - the administrator must have vSphere endpoint credentials, or the credentials under which the agent service runs in vCenter, that provide administrative access to the host vCenter.

For more information about agent requirements, see [VMware vSphere product documentation](#).

Setting	Selection
Content library To assign a privilege on a content library, an administrator must grant the privilege to the user as a global privilege. For related information, see Hierarchical Inheritance of Permissions for Content Libraries in <i>vSphere Virtual Machine Administration</i> at VMware vSphere Documentation .	<ul style="list-style-type: none"> • Add library item • Create local library • Create subscribed library • Delete library item • Delete local library • Delete subscribed library • Download files • Evict library item • Probe subscription information • Read storage • Sync library item

Amazon Web Services (AWS) cloud account credentials

This section describes the credentials that are required to add a Amazon Web Services cloud account. See the above *vCenter cloud account credentials* section for addition credential requirements.

Provide a power user account with read and write privileges. The user account must be a member of the power access policy (PowerUserAccess) in the AWS Identity and Access Management (IAM) system.

Enable the 20-digit Access Key ID and corresponding Secret Access Key access.

If you are using an external HTTP Internet proxy, it must be configured for IPv4.

VMware Aria Automation actions-based extensibility (ABX) and external IPAM integration may require additional permissions.

Setting	Selection
Autoscaling actions	<p>The following AWS permissions are suggested to allow autoscaling functions:</p> <ul style="list-style-type: none"> • autoscaling:DescribeAutoScalingInstances • autoscaling:AttachInstances • autoscaling>DeleteLaunchConfiguration • autoscaling:DescribeAutoScalingGroups • autoscaling>CreateAutoScalingGroup • autoscaling:UpdateAutoScalingGroup • autoscaling>DeleteAutoScalingGroup • autoscaling:DescribeLoadBalancers

Microsoft Azure cloud account credentials

This section describes the credentials that are required to add a Microsoft Azure cloud account.

Configure a Microsoft Azure instance and obtain a valid Microsoft Azure subscription from which you can use the subscription ID.

Create an Active Directory application as described in [How to: Use the portal to create an Azure AD application and service principal that can access resources](#) in Microsoft Azure product documentation.

If you are using an external HTTP Internet proxy, it must be configured for IPv4.

- General settings

The following overall settings are required.

Setting	Description
Subscription ID	Allows you to access to your Microsoft Azure subscriptions.
Tenant ID	The authorization endpoint for the Active Directory applications you create in your Microsoft Azure account.
Client application ID	Provides access to Microsoft Active Directory in your Microsoft Azure individual account.
Client application secret key	The unique secret key generated to pair with your client application ID.

- Settings for creating and validating cloud accounts

The following permissions are needed for creating and validating Microsoft Azure cloud accounts.

Setting	Selection
Microsoft Compute	<ul style="list-style-type: none"> Microsoft.Compute/virtualMachines/extensions/write Microsoft.Compute/virtualMachines/extensions/read Microsoft.Compute/virtualMachines/extensions/delete Microsoft.Compute/virtualMachines/deallocate/action Microsoft.Compute/virtualMachines/delete Microsoft.Compute/virtualMachines/powerOff/action Microsoft.Compute/virtualMachines/read Microsoft.Compute/virtualMachines/restart/action Microsoft.Compute/virtualMachines/start/action Microsoft.Compute/virtualMachines/write Microsoft.Compute/availabilitySets/write Microsoft.Compute/availabilitySets/read Microsoft.Compute/availabilitySets/delete Microsoft.Compute/disks/delete Microsoft.Compute/disks/read Microsoft.Compute/disks/write

- Settings for action-based extensibility with extensions

If you are using Microsoft Azure with action-based extensibility with extensions, the following permissions are also required.

Setting	Selection
Microsoft.Compute	<ul style="list-style-type: none"> Microsoft.Compute/virtualMachines/extensions/write Microsoft.Compute/virtualMachines/extensions/read Microsoft.Compute/virtualMachines/extensions/delete

Google Cloud Platform (GCP) cloud account credentials

This section describes the credentials that are required to add a Google Cloud Platform cloud account.

The Google Cloud Platform cloud account interacts with the Google Cloud Platform compute engine.

The Project Admin and Owner credentials are required for creating and validating Google Cloud Platform cloud accounts.

If you are using an external HTTP Internet proxy, it must be configured for IPv4.

The compute engine service must be enabled. When creating the cloud account in VMware Aria Automation, use the service account that was created when the compute engine was initialized.

The following compute engine permissions are also needed, depending on the actions that the user can take.

Setting	Selection
roles/compute.admin	Provides full control of all compute engine resources.
roles/iam.serviceAccountUser	<p>Provides access to users who manage virtual machine instances that are configured to run as a service account. Grant access to the following resources and services:</p> <ul style="list-style-type: none"> • compute.* • resourcemanager.projects.get • resourcemanager.projects.list • serviceusage.quotas.get • serviceusage.services.get • serviceusage.services.list
roles/compute.imageUser	<p>Provides permission to list and read images without having other permissions on the image. Granting the compute.imageUser role at the project level gives users the ability to list all images in the project. It also allows users to create resources, such as instances and persistent disks, based on images in the project.</p> <ul style="list-style-type: none"> • compute.images.get • compute.images.getFromFamily • compute.images.list • compute.images.useReadOnly • resourcemanager.projects.get • resourcemanager.projects.list • serviceusage.quotas.get • serviceusage.services.get • serviceusage.services.list
roles/compute.instanceAdmin	<p>Provides permissions to create, modify, and delete virtual machine instances. This includes permissions to create, modify, and delete disks, and also to configure shielded VMBETA settings.</p> <p>For users that manage virtual machine instances (but not network or security settings or instances that run as service accounts), grant this role to the organization, folder, or project that contains the instances, or to the individual instances.</p> <p>Users that manage virtual machine instances that are configured to run as a service account also need the roles/iam.serviceAccountUser role.</p> <ul style="list-style-type: none"> • compute.acceleratorTypes • compute.addresses.get • compute.addresses.list • compute.addresses.use • compute.autoscalers • compute.diskTypes

Table continued on next page

	<ul style="list-style-type: none"> • compute.targetHttpsProxies.list • compute.targetInstances.get • compute.targetInstances.list • compute.targetPools.get • compute.targetPools.list • compute.targetSslProxies.get • compute.targetSslProxies.list • compute.targetTcpProxies.get • compute.targetTcpProxies.list • compute.targetVpnGateways.get • compute.targetVpnGateways.list • compute.urlMaps.get • compute.urlMaps.list • compute.vpnTunnels.get • compute.vpnTunnels.list • compute.zoneOperations.get • compute.zoneOperations.list • compute.zones • resourcemanager.projects.get • resourcemanager.projects.list • serviceusage.quotas.get • serviceusage.services.get • serviceusage.services.list

NSX-T cloud account credentials

This section describes the credentials that are required to add an NSX-T cloud account.

As of NSX-T Data Center 3.1, custom roles are supported.

Provide an account with the following read and write privileges.

- NSX-T IP address or FQDN
- NSX-T user name and password

Associate the user with both the **Audit** role and the custom role, which has the specified privileges outlined below. Add this user to VMware Aria Automation as a cloud account for seamless authentication with NSX-T.

The following lists the minimum privileges required for the custom role.

Category/Subcategory	Permission
Networking - Tier-0 Gateways	Read-only
Networking - Tier-0 Gateways -> OSPF	None
Networking - Tier-1 Gateways	Full Access
Networking - Segments	Full Access
Networking - VPN	None

Table continued on next page

Continued from previous page

Category/Subcategory	Permission
Networking - NAT	Full Access
Networking - Load Balancing	Full Access
Networking - Forwarding Policy	None
Networking - Statistics	None
Networking - DNS	None
Networking - DHCP	Full Access
Networking - IP Address Pools	None
Networking - Profiles	Read-only
Security - Threat Detection & Response	None
Security - Distributed Firewall	Full Access
Security - IDS/IPS & Malware Prevention	None
Security - TLS Inspection	None
Security - Identity Firewall	None
Security - Gateway Firewall	None
Security - Service Chain Management	None
Security - Firewall Time Window	None
Security - Profiles	None
Security - Service Profiles	None
Security - Firewall Settings	Full Access
Security - Gateway Security Settings	None
Inventory	Full Access
Troubleshooting	None
System	None

Administrators also require access to the vCenter as described in the *vCenter cloud account credentials* section of this topic.

NSX-V cloud account credentials

This section describes the credentials that are required to add an NSX-V cloud account.

Provide an account with the following read and write privileges:

- NSX-V Enterprise Administrator role and access credentials
- NSX-V IP address or FQDN

Administrators also require access to the vCenter as described in the *Add a vCenter cloud account* section of this table.

VMware Cloud on AWS (VMC on AWS) cloud account credentials

This section describes the credentials that are required to add an VMware Cloud on AWS (VMC on AWS) cloud account.

Provide an account with the following read and write privileges:

- The `cloudadmin@vmc.local` account or any user account in the CloudAdmin group
- NSX Enterprise Administrator role and access credentials
- NSX Cloud Admin access to your organization's VMware Cloud on AWS SDDC environment
- Administrator access to your organization's VMware Cloud on AWS SDDC environment

- The VMware Cloud on AWS API token for your VMware Cloud on AWS environment in your organization's VMware Cloud on AWS service
- vCenter IP address or FQDN

Administrators *also* require access to the vCenter as described in the *Add a vCenter cloud account* section of this table.

For more information about the permissions needed to create and use VMware Cloud on AWS cloud accounts, see *Managing the VMware Cloud on AWS Data Center* in [VMware Cloud on AWS product documentation](#).

VMware Cloud Director (vCD) cloud account credentials

This section describes the credentials that are required to add a VMware Cloud Director (vCD) cloud account.

Creating a VMware Cloud Director cloud account in VMware Aria Automation requires that you provide account credentials for a VMware Cloud Director user with the Organization Administrator role. Specifically, the following subset of the Organization Administrator role, available in VMware Cloud Director, is needed for creating and validating VMware Cloud Director cloud accounts in VMware Aria Automation:

Setting	Selection
Access All Organization vDCs	All
Catalog	<ul style="list-style-type: none"> • Add vApp from My Cloud • View Private and Shared Catalogs • View Published Catalogs
General	<ul style="list-style-type: none"> • Administrator Control • Administrator View
Metadata File Entry	Create/Modify
Organization Network	<ul style="list-style-type: none"> • Edit Properties • View
Organization vDC Gateway	<ul style="list-style-type: none"> • View • Edit Properties • View Properties
Organization vDC	<ul style="list-style-type: none"> • View • View CPU and Memory Reservation
Organization	<ul style="list-style-type: none"> • Edit Properties • View
Quota Policy Capabilities	View
VDC Template	<ul style="list-style-type: none"> • Instantiate • View
vApp Template / Media	<ul style="list-style-type: none"> • Copy • Create/Upload • Edit • View • VAPP_VM_METADATA_TO_VCENTER
vApp Template	<ul style="list-style-type: none"> • Change Owner • Checkout • Download

Table continued on next page

Continued from previous page

Setting	Selection

vDC Group	<ul style="list-style-type: none"> • Configure • Configure Logging • View

Creating and using a VMware Cloud Director cloud account in VMware Aria Automation is not supported if VMware Aria Automation has FIPS enabled.

VMware Aria Operations integration credentials

This section describes the credentials that are required to integrate with VMware Aria Operations. Note that these credentials are established and configured in VMware Aria Operations, not in VMware Aria Automation.

Provide a local or non-local login account to VMware Aria Operations with the following read privileges.

- Adapter Instance vCenter Adapter > VC Adapter Instance for *vCenter-FQDN*
- A non-local account might need to be imported first, before you can assign its read-only role.

NSX integration with Microsoft Azure VMware Solution (AVS) for VMware Aria Automation

For information about connecting NSX running on Microsoft Azure VMware Solution (AVS) to VMware Aria Automation, including configuring custom roles, see [NSX-T Data Center clouadmin user permissions](#) in the Microsoft product documentation.

Configure Microsoft Azure for use with VMware Aria Automation Assembler

You must gather some information and complete an appropriate configuration in order to use a Microsoft Azure instance with a Automation Assembler cloud account.

This task describes the process of configuring Microsoft Azure at a high level. Because Microsoft Azure is a third party product, the interface can be changed or updated at any time independently of VMware Aria Automation Assembler, the accuracy of specific steps might vary. You should regard this procedure as representative rather than definitive.

You will need the following to complete this procedure:

- Subscription ID - Click the Subscriptions icon on the left toolbar in your Azure portal to view the subscription ID.
- Tenant ID - Click the Help icon and select Show Diagnostics in your Azure portal. Search for tenant and record the ID when you have located it.
- Client Application ID - You can locate this under App registrations on the Manage menu.
- Client Application Secret Key - The Client Application Secret Key functions like a password that Automation will use to authenticate with Azure. You must generate a secret key when you set up Azure. See Step 7 below for specific instructions.

1. Locate and record your Microsoft Azure subscription and tenant IDs as well as the Client Application ID and appropriate Client Application Secret Key.

Note that the location and configuration procedures related to these components may change with different versions of Azure. See the Microsoft Azure documentation for the latest information.

2. Now you can add permissions to the account. Select API permissions in the Azure interface and add a permission. Then you can use the Select an API page, select Azure Service Management under Commonly used Microsoft APIs. Select Delegated permissions to select Delegated permissions and add the `user_impersonation` permission.
3. After you create an account to connect to Azure, you must give it the required permissions to the subscription. Navigate back to Subscriptions, select the subscription you are adding to Automation Assembler and on the menu, select Access control (IAM).
4. You can create a new storage account and a resource group at this point. Alternatively, you can create these in blueprints later.

- Storage Account - Use the following procedure to configure an account.

1. In your Microsoft Azure portal, locate the Storage Accounts icon, currently located on the sidebar. Make sure the correct subscription is selected and click **Add**. You can also, search for storage account in the Azure search field.
2. Enter the required information for the storage account. You will need your subscription ID.
3. Select whether to use an existing resource group or create a new one. Make note of your resource group name, as you will need it later.

NOTE

Save the location of your storage account as you will need it later.

5. Create a virtual network. Alternatively, if you have a suitable existing network, you can select that one.

If you are creating a network, you must select Use an Existing Resource Group and specify the group that you created in the preceding step. Also, select the same location that you specified previously. Microsoft Azure will not deploy virtual machines or other objects if the location doesn't match between all applicable components that the object will consume.

- a) Locate the Virtual Network icon on the left panel and click it, or search for virtual network. Make sure to select the correct subscription and click **Add**.
- b) Enter a unique name for your new virtual network and record it for later.
- c) Enter the appropriate IP address for your virtual network in the **Address space** field.
- d) Ensure that the correct subscription is selected and click **Add**.
- e) Enter the remaining basic configuration information.
- f) You can modify the other options as necessary. For most configurations, you can leave the defaults.
- g) Click **Create**.

6. Set up an Azure Active Directory application so that VMware Aria Automation can authenticate.
 - a) Locate the Active Directory icon on the Azure left menu and click it.
 - b) Click **App Registrations** and select **Add**.
 - c) Type a name for your application that complies with Azure name validation.
 - d) Leave Web app/API as the Application Type.
 - e) The Sign-on URL can be anything that is appropriate for your usage.
 - f) Click **Create**.
7. Create a secret key to authenticate the application in Automation Assembler.
 - a) Click the name of your application in Azure.

Make note of your Application ID for later use.

 - b) Click **All Settings** in the next pane and select Keys from the settings list.
 - c) Enter a description for the new key and choose a duration.
 - d) Click **Save** and make sure to copy the key value to a safe location as you will be unable to retrieve it later.
 - e) On the left menu, select **API Permissions** for the application and click **Add a Permission** to create a new permission.
 - f) Select Azure Service Management on the Select an API page.
 - g) Click **Delegated Permissions**.
 - h) Under Select permissions select user_impersonation and then click **Add Permissions**.
8. Authorize your Active Directory application to connect to your Azure subscription so that you can deploy and manage virtual machines.
 - a) In the left menu, click the Subscriptions icon, and select your new subscription.

You may need to click on the text of the name to get the panel to slide over.

 - b) Select the Access control (IAM) option to see the permissions to your subscription.
 - c) Click **Add** under the Add a Role Assignment heading.
 - d) Choose Contributor from the Role drop down.
 - e) Leave the default selection in the Assign Access to drop down.
 - f) Type the name of your application in the Select box.
 - g) Click **Save**.
 - h) Add additional roles so that your new application has Owner, Contributor, and Reader roles.
 - i) Click the **Save**.

It is highly recommended that you install the Microsoft Azure command line interface tools. These tools are freely available for both Windows and Mac operating systems. See the Microsoft documentation for more information about downloading and installing these tools.

When you have the command line interface installed, you can use it to authenticate your new subscription.

1. Open a terminal window and type your Microsoft Azure login. You will receive a URL and a shortcode that will allow you to authenticate.
2. In a browser, enter the code that you received from the application on your device.
3. Enter your Auth Code and click **Continue**.
4. Select your Azure account and login.
If you have multiple subscriptions, ensure that the correct one is selected using the `azure account set --subscription <subscription-name>` command.
5. Before you proceed, you must register the `Microsoft.Compute` provider to your new Azure subscription using the `azure provider register --namespace "Microsoft.Compute"` command.

If the command times out and generates an error the first time you run it, run it again.

When you have completed configuration, you can use the `az vm image list` command to retrieve available Azure virtual machine marketplace image names. You can choose the desired image and record the URN provided for it and later use it in blueprints.

You must manually accept the agreement terms of the image using the Azure command line interface as shown:

```
"az vm image terms accept --urn jetware-srl:postgresql:postgresql96-ubuntu-1604:1.0.170503"
```

The following example shows how you might sign in a specific subscription using the Azure command line.

```
az account list
```

```
az login --identity --username <client_id|object_id|resource_id>
```

Automation Assembler allows any subscription user to map a marketplace image. This does not indicate that the user has access to the image. The user account used to accept all Azure image term agreements must be the same one that was used to create the Automation Assembler cloud account.

Create a Microsoft Azure cloud account in VMware Aria Automation

Create a Microsoft Azure cloud account

As a cloud administrator, you can create a Microsoft Azure cloud account for account regions to which your team will deploy VMware Aria Automation cloud templates.

- Verify that you have the required administrator credentials and have enabled HTTPS access on port 443. See [Credentials required for working with cloud accounts in VMware Aria Automation](#).
- Verify that you have the required user role. See [What are the user roles](#).
- Configure a Microsoft Azure account for use with VMware Aria Automation. See [Configure Microsoft Azure for use with VMware Aria Automation Assembler](#).
- If you do not have external Internet access, configure an Internet server proxy. See [How do I configure an Internet proxy server for VMware Aria Automation](#).

VMware Aria AutomationMicrosoft Azure integrations support Azure Marketplace images. Users can specify an Azure Marketplace when they set up image mapping in Automation Assembler. Automation Assembler automatically picks up the plan information in any specified Marketplace image. When using Marketplace images, users must accept legal terms for plans in their Azure portal or an exception will occur when they try to deployment the cloud template and the deployment will fail.

To view an example use case of how Microsoft Azure cloud account works in VMware Aria Automation see [WordPress end-to-end use case](#).

1. Select **Infrastructure > Connections > Cloud Accounts** and click **Add Cloud Account**.
2. Select the Microsoft Azure account type and enter credentials and other values.
3. Select the appropriate **Azure environment**. The selection can be Azure Public Cloud, which is appropriate for most users, or it can be Azure US Government Cloud, which is valid for authorized government users.
4. Click **Validate**.
The account regions associated with the account are collected.
5. Select the regions to which you want to provision this resource.
6. For efficiency, click **Create a Cloud zone for the selected regions**.
7. If you need to add tags to support a tagging strategy, enter capability tags. See [maphead-how-to-use-tags.dita#GUID-1F1FD968-2EA1-404E-B081-E13383392061-en](#) and [Creating a tagging strategy](#).

For more information about how capability tags and constraint tags help control deployment placements, see the [Constraint Tags and Placement](#) video tutorial.

8. Click **Save**.

The account is added to VMware Aria Automation, and the selected regions are available for the specified cloud zone.

Create infrastructure resources for this cloud account.

When you create a cloud template using the Azure cloud account, you can use constraints to deploy a resource group to a selected region.

The cloud template type:cloud.Azure.ResourceGroup option is visible in the auto-suggestion list and the properties pop-ups in the cloud template as seen in the following samples.

```
1  formatVersion: 1
2  inputs:
3    strProp0:
4      type: string
5      default: hh
6    objProp0:
7      type: object
8      default:
9        domain: hello
10   resources:
11     Cloud_Azure_ResourceGroup_1:
12       type: Cloud.Azure.ResourceGroup
13       properties:
14         name: ''
15
16     Clo
17     t:
18     p:
19       constraints: array
20       count: integer
21       tags: array
22       useExisting: boolean
23       constraints:
24         - tag: null
25
```

When you add an Azure cloud account to a cloud template, you can choose to reuse availability sets if you want. Subscriptions have a limit of 2000 availability sets and 25,000 virtual machines, so it makes sense to reuse availability sets when possible. There are two YAML properties that you can use to control how deployments use availability sets. The `availabilitySetName` property enables you to specify an availability set to use. The second property is `doNotAttachAvailabilitySet` which is set to false by default. If this property is set to true, VMware Aria Automation will create the deployment with no availability set.

You can use availability sets or availability zones with an Azure cloud account, but not both.

You cannot create a deployment without an availability set if you use a load balancer attached to the virtual machine.

The following table describes how VMware Aria Automation behaves depending on whether a resource group and an availability set are specified in the cloud template.

An availability set cannot exist without being part of a resource group. The availability sets in a given resource group must have unique names. Availability sets can have the same name only if they are part of different resource groups.

If you do not specify a resource group name, then VMware Aria Automation will create a new resource group, which means that a new availability set must also be created even if a name is passed. The new set will use the name that is passed.

Table 19:

Resource Group Specified	Availability Set Specified	Result
No	No	VMware Aria Automation creates a new resource group and a new availability set for the virtual machine.
Yes	No	VMware Aria Automation reuses the existing resource group and creates a new availability set for the virtual machine.
No	Yes	VMware Aria Automation creates a new resource group and a new availability set with the specified name.

Table continued on next page

Continued from previous page

Resource Group Specified	Availability Set Specified	Result
Yes	Yes	VMware Aria Automation reuses the existing resource group. If an availability set with the specified name already exists in that group, it will also be reused. If there is no availability set with the specified name in the group, a new one is created with that name.

As an alternative, you can use availability zones with deployed Azure virtual machines rather than availability sets. If you use availability zones, you can specify an Azure availability zone for a provisioned machine, either by tagging compute resources or by using restrictions expressed through flavor mapping.

This feature enables users to provision a machine in an Azure availability zone by tagging the computes, or selecting the flavor mapping that contains the desired availability zone.

If you want to use availability zones for an Azure virtual machine, you must explicitly pass the `attachAvailabilityZone` boolean property set to `true` in the cloud template for the cloud account as shown in the following cloud template snippet.

```
formatVersion: 1
inputs: {}
resources:
  Cloud_Azure_Machine_1:
    type: Cloud Azure Machine
    properties:
      image: ubuntu
      flavor: small
      attachAvailabilityZone: true
```

If this property is not present, no availability zone are used for the provisioned machine; instead, an availability set is created. If this property is present and set to true, you can select the desired availability zone on the Compute tab of the cloud zone.

If availability zones are used in a cloud account, the IP SKU type and IP allocation method will be Static and the `PublicIPAddress` sku type is limited to Standard. Also, not all availability zones are supported for every flavor in every region. The following table outlines the regions that support selection of availability zones. Note that each of the supported regions has three zones. Each region in the table should support Azure availability zones, but depending on the selected size in the flavor mapping, it can be restricted to only one zone.

Region	Zones Supported
Brazil South	3
Canada Central	3
Central US	3
East US	3
East US 2	3

Table continued on next page

Continued from previous page

Region	Zones Supported
South Central US	3
West US 2	3
West US 3	3
US Gov Virginia	3
East Asia	3
Southeast Asia	3
Australia East	3
China North 3	3
Central India	3
Japan East	3
Korea Central	3
North Europe	3
West Europe	3
France Central	3
Germany West Central	3
Norway East	3
Sweden Central	3
Switzerland North	3
UK South	3
South Africa North	3

If you want to use machine provisioning in an availability zone and later have a working ssh to the machine, you must first have a correctly configured network security group, with enabled ssh, in the Azure portal. In addition, you must create a network profile with the enumerated data for the network and security groups and then use this network profile on provisioning.

Automation Assembler supports Azure disk snapshots for deployed virtual machines. See [Working with snapshots for Microsoft Azure virtual machine disks](#) in for more information.

Automation Assembler supports several boot diagnostics options for Azure deployments. Boot diagnostics supports debugging of Azure virtual machines and includes collection of log information and relevant screen shots. See [Using boot diagnostics and log analytics with a Microsoft Azure virtual machine](#) for more information.

In addition to standard disk options, Azure integrations supports selection of Azure performance disk types for users of Azure SSD Premium managed disks. This feature enables users to maximize performance as needs demand. Not all performance disk configurations are supported. See <https://learn.microsoft.com/en-us/azure/virtual-machines/disks-change-performance> for more information about supported configurations.

You can configure the performance disk type during deployment configuration using the `performanceTierType` property in your cloud template. The following example demonstrates a potential implementation.

```

formatVersion: 1
inputs: {}
resources:
  Cloud_Azure_Disk_1:
    type: Cloud.Azure.Disk

```

```

properties:
  capacityGb: 2
  managedDiskType: Premium SSD
  performanceTier: P1

```

Using boot diagnostics and log analytics with a Microsoft Azure virtual machine

You can invoke and configure Microsoft Azure boot diagnostics from an Azure instance in a cloud template. In addition you can also configure log analytics for an Azure virtual machine instance. Boot diagnostics is a debugging feature for Azure virtual machines that facilitates diagnostics for virtual machine boot failures. Using boot diagnostics, a user can monitor the state of a virtual machine as it is booting up by collecting serial log information and screenshots.

Boot Diagnostics

Boot diagnostics captures serial log information and screenshots and these needs to be saved to the disk. The disk can be of two types, Azure Managed Disk or Unmanaged Disk.

The `bootDiagnostics` YAML property is supported in Azure cloud templates. When this property is set to `true`, boot diagnostics are enabled on the applicable Azure virtual machine deployment.

The following YAML snippet shows an example of how the `bootDiagnostics` property is used.

```

formatVersion: 1
inputs: {}
resources:
  Cloud_Azure_Machine_1:
    type: Cloud.Azure.Machine
    metadata:
      layoutPosition:
        - 0
        - 0
    properties:
      image: ubuntu
      flavor: small
      bootDiagnostics: true

```

Boot diagnostics can also be invoked on a deployed Azure virtual machine as a day 2 operation. Navigate to the Deployments page in Automation Assembler and select the Azure deployment. The Actions menu on this page enables you to toggle between Enable Boot Diagnostics and Disable Boot Diagnostics.

After you have deployed a cloud template with boot diagnostics enabled, the Automation Assembler Deployments page for the deployment will indicate that boot diagnostics are enabled. If you want to disable boot diagnostics, click the Actions menu on the Deployments page and select Disable Boot Diagnostics.

Log Analytics

Log Analytics enables you to edit and run log queries on data collected by Azure Monitor Logs, and then interactively analyze the results. You can use Log Analytics queries to retrieve records that match specific criteria to help identify trends and patterns and provide a variety of data insights. By enabling Log Analytics on a Azure virtual machine, that machine will act as a data source.

Before you can configure log analytics in an Automation Assembler cloud template, you must create and configure an Azure Log Analytics workspace. You can do this using the Virtual Machines option in the Azure Monitor menu. See the Microsoft Azure documentation for more information.

To configure log analytics, you must have the Azure Workspace ID and Workspace Key. You can find these on the Agent Management tab in Azure under the Log Analytics Workspace.

The following cloud template example shows how log analytics can be configured using extensions.

```
formatVersion: 1
inputs: {}
resources:
  Cloud_Azure_Machine_1:
    type: Cloud.Azure.Machine
    properties:
      image: ubuntu
      flavor: small
    extensions:
      - autoUpgradeMinorVersion: true
        name: test-loga
    protectedSettings:
      workspaceKey: xxxxxxxxx
    publisher: Microsoft.EnterpriseCloud.Monitoring
    settings:
      workspaceId: aaaaaaaaa
      type: OmsAgentForLinux
      typeHandlerVersion: '1.0'
```

After you have deployed a cloud template with Log Analytics enabled, you can enable or disable it using the Actions menu options on the Automation Assembler Deployments page for the deployment.

Working with snapshots for Microsoft Azure virtual machine disks in VMware Aria Operations

Working with snapshots for Microsoft Azure virtual machine disks

You can create full or incremental snapshots of Microsoft Azure managed disks.

The Automation Assembler Deployments page for an Azure deployment contains an Actions menu that provides several options for creating and deleting snapshots from Azure deployments on virtual machine managed disks and on independent managed disks. The following list outlines the specific snapshot functionality that is supported.

- Create a disk snapshot - Supported for both external and compute disks. You can also create snapshots for a disk in a different resource group.
- Delete a disk snapshot - Supported for external disks only
- Encrypt snapshots using an Azure disk encryption set.
- You can provide key-value pairs as tags during snapshot creation.

Snapshots on unmanaged disks are currently not supported.

If you use encryption, the current snapshot implementation supports platform-managed key encryption. By default, the network policy allows access from everywhere, so restricting access to snapshots by using the network policy is not possible.

For more information about using the Automation Assembler Actions and the Deployments page, see [What actions can I run on deployments or supported resources](#).

For more information about Microsoft Azure snapshot support, see [Create a snapshot of a virtual hard disk](#) in Microsoft product documentation.

Create an Amazon Web Services cloud account in VMware Aria Automation

Create an Amazon Web Services cloud account

As a cloud administrator, you can create a VMware Aria Automation cloud account for Amazon Web Services (AWS) for account regions to which your team will deploy VMware Aria Automation cloud templates.

- Verify that you have the required administrator credentials and have enabled HTTPS access on port 443. See [Credentials required for working with cloud accounts in VMware Aria Automation](#).
- Verify that you have the required user role. See [What are the user roles](#).
- Verify that you have required AWS administrator credentials.
- If you do not have external Internet access, configure an Internet server proxy. See [How do I configure an Internet proxy server for VMware Aria Automation](#).

For authorized users, AWS cloud accounts support access to the AWS GovCloud configuration. This configuration supports most of the standard VMware Aria Automation cloud account functionality with regard to project configuration, tags, and infrastructure. In Automation Assembler templates, it does support use of AWS Platform as a Service (PaaS) properties.

The following procedure describes how to configure an AWS cloud account.

1. Select **Infrastructure > Connections > Cloud Accounts** and click **Add Cloud Account**.
2. Select the AWS account type, and enter credentials and other values.
3. Click **Validate**.
The account regions associated with the account are collected.
4. Select the regions to which you want to provision this resource.

NOTE

AWS China regions are not supported.

5. For efficiency, click **Create a Cloud zone for the selected regions**.

6. If you need to add tags to support a tagging strategy, enter capability tags. See [maphead-how-to-use-tags.dita#GUID-1F1FD968-2EA1-404E-B081-E13383392061-en](#) and [Creating a tagging strategy](#).

For more information about how capability tags and constraint tags help control deployment placements, see the [Constraint Tags and Placement](#) video tutorial.

7. Click **Add**.

The account is added to VMware Aria Automation, and the selected regions are available for the specified cloud zone.

Configure infrastructure resources for this cloud account.

AWS integration supports use of GP3 and IO2 VolumeType disk options. There are some constraints on volume size and I/Os values for specific volume types. The follow page explains the supported configurations: <https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/ebs-volume-types.html>.

GP3 and IO2 VolumeType selections must be configured in a storage profile before they can be used in deployments. Then, users can add them when setting up a cloud template using the `volumeType` property to specify the volume configuration. The following cloud template snippet shows an example of how the `volumeType` property is used.

```
formatVersion: 1
inputs: {}
resources:
  Cloud_AWS_Volume_1:
    type: Cloud.AWS.Volume
    properties:
      capacityGb: 1
      volumeType: gp3
      iops: 3000
```

You can also add a valid GP3 or IO2 volume to an existing deployment as a day 2 action using the Actions menu on the Automation Assembler Deployments page. In addition, resize, update and delete operations are supported as day 2 actions.

AWS configuration options

There are several AWS configuration options that facilitate particular customer configurations, such as role based authentication.

[Configure a role based cloud account for use with AWS](#)

You can configure role-based access to an AWS cloud account using the following procedure. VMware provides a helper JSON to facilitate this procedure that is displayed when you click Create IAM Role on the AWS create cloud account page. The JSON helper includes instructions to create and configure an IAM role for VMware Aria Automation.

NOTE

The helper JSON helps you to configure access to basic functionality such as machine creation. If you want to run more complex tasks using ABX extensibility actions, you must assign more permissions to the AWS role in the AWS portal.

To set up role based permissions for AWS when using the on-premise version of VMware Aria Automation, you must create a master cloud account for trusted identity authentication. When you create a new role-based cloud account, the external ID -- which is the same as the orgId for the organization – will be populated and you can copy it and use it when you set up the role in the AWS portal. After the role is configured, you can create the AWS cloud account using the ARN ID from the AWS role that you created.

1. Create a user account in the AWS portal with `sts:AssumeRole` permissions.
2. Create the master cloud account in Automation Assembler using `accessKey/secretKey`, For the Authentication Method, you must select the radio button for Trusted Identity for role-based authentication.
3. In the AWS portal, create a policy and paste in the snippet from the helper JSON.
4. In VMware Aria Automation, open the cloud account wizard to create a role-based AWS cloud account. The External ID field is populated, and you can copy the ID.
5. In the AWS portal, create the AWS role with trust on the AWS master cloud account that you created in VMware Aria Automation. You can get the externalId from the role-based cloud account that you created in Automation Assembler, and then paste it into the External ID field in the AWS portal.
6. Search for the vRA Access Policy in the AWS portal, then create the role that you want to use for AWS cloud account access on this policy.
7. Then copy the ARN ID that you will need when you create the cloud account.
8. Create the AWS cloud account in Automation Assembler using the ARN ID.

Create a Google Cloud Platform cloud account in VMware Aria Automation

Create a Google Cloud Platform cloud account

As a cloud administrator, you can create a Google Cloud Platform (GCP) cloud account for account regions to which your team deploys VMware Aria Automation cloud templates.

- Verify that you have the required administrator credentials and have enabled HTTPS access on port 443. See [Credentials required for working with cloud accounts in VMware Aria Automation](#).
- Verify that you have the required user role. See [What are the user roles](#).
- Verify that you can access to the Google Cloud Platform JSON security key.
- Verify that you have the needed security information for your Google Cloud Platform instance. You can obtain most of this information from your instance or from the Google documentation.
- If you do not have the external Internet access, configure an Internet server proxy. See [How do I configure an Internet proxy server for](#) .

1. In Automation Assembler, select **Infrastructure > Connections > Cloud Accounts** and then click **Add Cloud Account**.
2. Select the Google Cloud Platform account type and enter the appropriate credentials and related information. Use the service account that was created when the source GCP account compute engine was initialized.

As noted in the **Prerequisites** section above, credential requirements are available at [Credentials required for working with cloud accounts in VMware Aria Automation](#). To successfully create the cloud account in VMware Aria Automation, the source GCP account must have the compute engine service enabled.

In VMware Aria Automation, the project ID is part of the Google Cloud Platform endpoint. You specify it when you create the cloud account. During data collection of project-specific private images, the VMware Aria Automation GCP adapter queries the Google Cloud Platform API.

3. Click **Validate**.

- The account regions associated with the account are collected.
4. Select the regions to which you want to provision this resource.
 5. For efficiency, click **Create a Cloud zone for the selected regions**.
 6. If you need tags to support a tagging strategy, enter capability tags. See [maphead-how-to-use-tags.dita#GUID-1F1FD968-2EA1-404E-B081-E13383392061-en](#) and [Creating a tagging strategy](#).

For more information about how capability tags and constraint tags help control deployment placements, see the [Constraint Tags and Placement](#) video tutorial.

7. Click **Add**.

The account is added to VMware Aria Automation, and the selected regions are available for the specified cloud zone.

When you configure a Google Cloud Platform cloud account and specify a GCP project, users with appropriate privileges can use GCP Virtual Private Cloud (VPC) network functionality. These users have access to local networks for that project as well as to all of the shared networks and sub networks for that host project. You can select one of these local or shared networks on the Automation Assembler**Networks** page and add it to a network profile so that you can use it in a GCP deployment. Users with the following roles can use VPC networks.

- Compute Instance Administrators
- Compute Network Administrators
- Owners
- Editors

Create infrastructure resources for this cloud account.

The following paragraphs provide some information on deploying a Google Cloud Platform virtual machine from Automation Assembler.

When you add a Google Cloud Platform cloud account to an Automation Assembler cloud template, you can use the `useSoleTenant` YAML property to indicate that you want to deploy a virtual machine to a sole tenant node. This configuration enables you to isolate virtual machines for security, privacy or others issues.

To facilitate this functionality, Google Cloud Platform node affinity labels are converted to tags in Automation Assembler, and these tags are applied on relevant VMware Aria Automation availability zones where node groups reside. When the `useSoleTenant` property is set to true, constraint tags must be one of the node affinity labels. Also, to deploy a machine in sole tenant mode, you must include the `useSoleTenant` property in the cloud template as well as the constraint tags.

Before using this feature, you must create the appropriate node template and node affinity labels in Google Cloud Platform and then create a node group.

The following YAML example shows how the `useSoleTenant` property can be used in Automation Assembler cloud templates. The constraint tags are the node affinity labels that were auto-collected from your Google Cloud Platform server.

```
resources:
  Cloud_GCP_Machine_1:
    type: Cloud.GCP.Machine
    properties:
      image: ubuntu
```

```

flavor: c2-family
name: demo-vm
useSoleTenant: true
constraints:
  -tag: 'env:prod'
  -tag: 'region:asia-east1'

```

The Google Cloud Platform cloud account supports several administrator day 2 actions on deployed virtual machines. These day 2 actions for Google Cloud Platform virtual machines include create, delete, and revert actions for snapshots and attached disks. These actions are available from the **Actions** menu on the Automation Assembler**Deployments** page.

Setting up storage bucket resources for Google Cloud Platform (Classic)

VMware Aria Automation supports Google Cloud Platform (GCP) storage buckets allowing users to quickly and easily create and manage their storage resources. VMware Aria Automation storage bucket support includes the creation of multi-regional/dual-regional storage buckets, restricted public access, and encryption.

NOTE

This topic describes how to create classic storage bucket resources. If you would like to create plug-in based storage bucket resources, see [Configuring plug-in based storage bucket resources](#).

You create storage buckets using Automation Assembler cloud templates and you deploy these cloud templates in the typical manner using the Automation Assembler**Design** tab functionality. After you deploy a cloud template you can check the GCP portal to confirm that the storage bucket was provisioned successfully.

The following are required properties for storage bucket cloud templates.

- Storage bucket name - There are some limitations on the storage bucket name construction. See the following page for detailed information: <https://cloud.google.com/storage/docs/buckets>
- locationType - one of {SINGLE_REGION, DUAL_REGION, MULTI_REGION"} If the locationType is either DUAL_REGION or MULTI_REGION - regionID property is also MANDATORY There are different values of the regionId, depending on the locationType. See the following page for detailed information: <https://cloud.google.com/storage/docs/locations>
- storageClass - one of {STANDARD, NEARLINE, COLDLINE, ARCHIVE, REGIONAL, MULTI_REGIONAL, DURABLE_REDUCED_AVAILABILITY}

If you want to create storage buckets with restricted public access and that are encrypted by CMEK, there are some prerequisites described in the following link: <https://cloud.google.com/storage/docs/encryption/using-customer-managed-keys>

NOTE

The customer-managed encryption key must be located in the same region as the storage bucket.

Storage bucket cloud template examples

The following cloud template examples demonstrate some typical approaches to creating storage buckets using Automation Assembler cloud templates.

The following cloud template example shows how you might create a simple single region storage bucket.

```
formatVersion: 1
inputs: {}
resources:
  Cloud_GCP_StorageBucket_1:
    type: Cloud.GCP.StorageBucket
    properties:
      name: simple-storage-bucket
      locationType: SINGLE_REGION
      storageClass: STANDARD
```

The following cloud template example demonstrates restricted public access using an encryption key.

```
formatVersion: 1
inputs: {}
resources:
  Cloud_GCP_StorageBucket_1:
    type: Cloud.GCP.StorageBucket
    properties:
      name: encrypted-storage-bucket
      storageClass: STANDARD
      locationType: SINGLE_REGION
    kmsKey:
      kmsProjectId: gcp
      keyRingRegion: asia-east1
      keyRing: asia-key
      keyName: asia-east-key
```

The following cloud template example demonstrates how you might create a multi-region storage bucket.

```
formatVersion: 1
inputs: {}
resources:
  Cloud_GCP_StorageBucket_1:
    type: Cloud.GCP.StorageBucket
    properties:
      name: multi-regional-sb
```

```

locationType: MULTI_REGION
storageClass: STANDARD
regionId: EU

```

The following cloud template shows an example of dual-regional storage bucket implementation.

```

formatVersion: 1
inputs: {}
resources:
Cloud_GCP_StorageBucket_1:
  type: Cloud.GCP.StorageBucket
  properties:
    name: dual-regional-sb
    storageClass: NEARLINE
    locationType: DUAL_REGION
    regionId: ASIA
    locations:
      - ASIA-EAST1
      - ASIA-SOUTHEAST1

```

Configuring load balancers with Google Cloud Platform cloud accounts (Classic)

VMware Aria Automation Google Cloud Platform (GCP) cloud account users can configure load balancers to support custom solutions, including high availability.

VMware Aria Automation GCP cloud account users can configure several aspects of load balancer configuration to support specific requirements. These features can support provisioning infrastructure for SAP NetWeaver and SAP Hana, for example.

NOTE

This topic describes how to create classic load balancer resources. If you would like to create plug-in based load balancers, see [Configuring plug-in based load balancers](#).

Setting up a high availability load balancer configuration with a GCP cloud account

VMware Aria Automation users with a GCP cloud account can configure several aspects of load balancer configuration to support specific requirements, such as high availability. These features can support provisioning infrastructure for SAP NetWeaver and SAP Hana.

This configuration enables you to deploy different load balancer instances in different availability zones. To set this up, you need to configure the following components in GCP:

- Reserve virtual IP addresses

- Provision health checks
- Create a firewall rule to support the health checks

The following page describes how to set up and configure these components in GCP: https://cloud.google.com/solutions/sap/docs/netweaver-ha-config-rhel#configure_the_failover_support In addition, see the following pages for information about NetWeaver and Hana configurations:

- NetWeaver: https://cloud.google.com/solutions/sap/docs/netweaver-ha-config-rhel#configure_the_failover_support
- SAP Hana: https://cloud.google.com/solutions/sap/docs/sap-hana-ha-config-rhel#configure_the_failover_support

After you set up the GCP side, you must set up the appropriate components in VMware Aria Automation as described below:

- Create a GCP cloud account if you don't already have one.
- Set up flavor and image mapping as appropriate for your environment.
- Create a default network profile and tag it so that you can invoke it from a cloud template.
- Create compute availability zones and tag them appropriately. These enable you to tell VMware Aria Automation to provision instances and instance groups to specific availability zones in a cloud template.

When you have configured all of these components, you can navigate to the Automation Assembler**Design** tab and create a cloud template. This template should model the appropriate load balancer configuration with specifications for health check and instances and instance groups as appropriate. For high availability purposes, you must configure multiple load balancers. The cloud template should also specify the appropriate virtual machines and the availability zones in which they should be deployed.

The following cloud template example demonstrates how one might set up a high availability load balancer configuration for NetWeaver.

```
formatVersion: 1
inputs: {}
resources:
  Cloud_LoadBalancer_1:
    type: Cloud.LoadBalancer
    properties:
      routes:
        - healthCheckConfiguration:
            healthyThreshold: 2
            unhealthyThreshold: 2
            timeoutSeconds: 10
            intervalSeconds: 10
            port: 65000
            protocol: TCP
            protocol: TCP
            port: 1000
            instancePort: 1000
      network: ${resource.Cloud_Network_1.id}
```

```
instances:
  - ${resource.Cloud_GCP_Machine_1.id}
  - ${resource.Cloud_GCP_Machine_2.id}

internetFacing: false

fallbackInstanceGroupsByInstanceNames:
  - ${resource.Cloud_GCP_Machine_2.resourceName}

Cloud_LoadBalancer_2:
  type: Cloud.LoadBalancer
  properties:
    routes:
      - healthCheckConfiguration:
          healthyThreshold: 2
          unhealthyThreshold: 2
          timeoutSeconds: 10
          intervalSeconds: 10
          port: 65000
          protocol: TCP
          protocol: TCP
          port: 1000
          instancePort: 1000
    network: ${resource.Cloud_Network_1.id}

  instances:
    - ${resource.Cloud_GCP_Machine_1.id}
    - ${resource.Cloud_GCP_Machine_2.id}

  internetFacing: false

  useInstanceGroupsFrom: ${resource.Cloud_LoadBalancer_1.resourceName}

  fallbackInstanceGroupsByInstanceNames:
    - ${resource.Cloud_GCP_Machine_1.resourceName}

Cloud_GCP_Machine_2:
  type: Cloud.GCP.Machine
  properties:
    image: image
```

```

flavor: flavor

networks:
  - network: ${resource.Cloud_Network_1.id}

constraints:
  - tag: zone-b

Cloud_Network_1:
  type: Cloud.Network

  properties:
    networkType: existing

  constraints:
    - tag: default

Cloud_GCP_Machine_1:
  type: Cloud.GCP.Machine

  properties:
    image: image

    flavor: flavor

    networks:
      - network: ${resource.Cloud_Network_1.id}

    constraints:
      - tag: zone-a

```

Additional load balancer configuration options

Using cloud template configurations, VMware Aria Automation users can configure the following additional aspects of load balancer configuration.

- Share instance groups between load balancers
- Configure failover instance groups
- Configure your load balancers to accept traffic on all ports

Share instance groups

To share instance groups between the load balancers the users must explicitly declare it in the blueprint. Because there isn't direct access to the instance groups in the cloud template, the customers must use the `useInstanceGroupsFrom` property. In this way VMware Aria Automation will provision the first load balancer and will reuse the instance groups in the other load balancers.

The following example illustrates how you can use a cloud template to configure two load balancers where the second one uses the instance groups from the first one:

```
Cloud_LoadBalancer_1:
  type: Cloud.LoadBalancer
  properties:
    routes:
      - healthCheckConfiguration:
          healthyThreshold: 2
          unhealthyThreshold: 2
          timeoutSeconds: 10
          intervalSeconds: 10
          port: 65000
          protocol: TCP
        protocol: TCP
  network: ${resource.Cloud_Network_1.id}
  instances:
    - ${resource.Cloud_GCP_Machine_1.id}
    - ${resource.Cloud_GCP_Machine_2.id}
  internetFacing: false

Cloud_LoadBalancer_2:
  type: Cloud.LoadBalancer
  properties:
    routes:
      - healthCheckConfiguration:
          healthyThreshold: 2
          unhealthyThreshold: 2
          timeoutSeconds: 10
          intervalSeconds: 10
          port: 65000
          protocol: TCP
        protocol: TCP
  network: ${resource.Cloud_Network_1.id}
  instances:
    - ${resource.Cloud_GCP_Machine_1.id}
```

```

- ${resource.Cloud_GCP_Machine_2.id}

internetFacing: false

useInstanceGroupsFrom: ${resource.Cloud_LoadBalancer_1.resourceName}

```

Configure failover instance groups

To configure failover instance groups for each GCP load balancer, you must explicitly declare it in the cloud template. Because there isn't direct access to the instance groups in the template, you must use the `failoverInstanceGroupsByInstanceNames` property which tells VMware Aria Automation to find the instance group by a machine that is contained in that instance group.

The following example illustrates configuration of a load balancer which has one primary and one failover instance group:

`Cloud_LoadBalancer_1:`

```

type: Cloud.LoadBalancer

properties:

routes:
  - healthCheckConfiguration:
      healthyThreshold: 2
      unhealthyThreshold: 2
      timeoutSeconds: 10
      intervalSeconds: 10
      port: 65000
      protocol: TCP
      protocol: TCP

network: ${resource.Cloud_Network_1.id}

instances:
  - ${resource.Cloud_GCP_Machine_1.id}
  - ${resource.Cloud_GCP_Machine_2.id}

internetFacing: false

failoverInstanceGroupsByInstanceNames:
  - ${resource.Cloud_GCP_Machine_2.resourceName}

```

Configure for traffic on all ports

To configure a load balancer to accept traffic on all ports, you can omit the `port` property of the route configuration. You can view a sample cloud template that uses the three newly created features and provisions the infrastructure for this setup. For related information, see [Configure the Cloud Load Balancing failover support](#).

```
formatVersion: 1
inputs: {}
resources:
  Cloud_LoadBalancer_1:
    type: Cloud.LoadBalancer
    properties:
      routes:
        - healthCheckConfiguration:
            healthyThreshold: 2
            unhealthyThreshold: 2
            timeoutSeconds: 10
            intervalSeconds: 10
            port: 65000
            protocol: TCP
            protocol: TCP
      network: ${resource.Cloud_Network_1.id}
      instances:
        - ${resource.Cloud_GCP_Machine_1.id}
        - ${resource.Cloud_GCP_Machine_2.id}
      internetFacing: false
      failoverInstanceGroupsByInstanceNames:
        - ${resource.Cloud_GCP_Machine_2.resourceName}
      address: 10.132.0.72
  Cloud_LoadBalancer_2:
    type: Cloud.LoadBalancer
    properties:
      routes:
        - healthCheckConfiguration:
            healthyThreshold: 2
            unhealthyThreshold: 2
            timeoutSeconds: 10
            intervalSeconds: 10
```

```
port: 65000
protocol: TCP
protocol: TCP
network: ${resource.Cloud_Network_1.id}
instances:
- ${resource.Cloud_GCP_Machine_1.id}
- ${resource.Cloud_GCP_Machine_2.id}
internetFacing: false
useInstanceGroupsFrom: ${resource.Cloud_LoadBalancer_1.resourceName}
failoverInstanceGroupsByInstanceNames:
- ${resource.Cloud_GCP_Machine_1.resourceName}
address: 10.132.0.64
Cloud_GCP_Machine_2:
type: Cloud.GCP.Machine
properties:
image: image
flavor: flavor
networks:
- network: ${resource.Cloud_Network_1.id}
constraints:

Cloud_GCP_Machine_1:
type: Cloud.GCP.Machine
properties:
image: image
flavor: flavor
```

```

networks:
  - network: ${resource.Cloud_Network_1.id}

constraints:
  - tag: zone-b

```

Create a basic vCenter cloud account in VMware Aria Automation

Create a vCenter cloud account

You can add a basic vCenter cloud account for the account regions to which you want to deploy VMware Aria Automation cloud templates.

- Verify that you have the required service account credentials and have enabled HTTPS access on port 443. See [Credentials required for working with cloud accounts in VMware Aria Automation](#).
- Verify that you have the cloud administrator user role. See [What are the user roles](#).
- If you are creating the cloud account for use with a remote vSphere agent (which is possible by using the **Forward all traffic through proxy** option), verify that you have deployed and configured a VMware Aria Automation extensibility (vREx) proxy on the target remote vCenter server. See [How can I configure and use a Extensibility proxy with a cloud account for improved performance across datacenters](#).
- Verify that you have properly configured your ports and protocols to support the cloud account. See the *System Requirements* topic in [Installing VMware Aria](#)

Automation with Easy Installer and the *Port Requirements* topic in *Reference Architecture Guide*. Both publications are available on the [VMware Aria Automation product documentation page](#).

For network and security purposes, you can associate a vCenter cloud account with an NSX-T or NSX-V cloud account. An NSX-T cloud account can be associated to one or more vCenter cloud accounts. However, an NSX-V cloud account can only be associated to one vCenter cloud account.

1. Select **Infrastructure > Connections > Cloud Accounts** and click **Add Cloud Account**.
2. Select the vCenter cloud account type.
3. Enter the vCenter server host IP address.
4. If you want to use a remote vSphere agent, select the **Forward all traffic through proxy** option and select the VMware Aria Automation extensibility (vREx) proxy from the drop-down menu.

After you select a vREx proxy, you must revalidate and save your user name and password credentials.

5. Enter your vCenter server administrator credentials and click **Validate**.

All data centers that are associated with the vCenter account are data-collected.

The following elements are data-collected, as are all vSphere tags for the following elements:

- Machines
- Clusters and hosts
- Port groups
- Data stores

Remote vSphere agents (proxies) are also collected if they have been configured on the vCenter, see [How can I configure and use a Extensibility proxy with a cloud account for improved performance across datacenters](#).

You might consider using the VMware Aria Automation extensibility proxy option to gain a more reliable connection to a distant server, to get better processing throughput, or for network isolation reasons. To use a remote vSphere agent, where you have already met the required prerequisites for deploying and configuring a VMware Aria Automation extensibility (vREx) proxy, select the Forward all traffic through proxy check box and select the configured VMware Aria Automation extensibility (vREx) proxy from the drop-down menu of available VMware Aria

Automation extensibility (vREx) proxies. After you select a vREx proxy, you must revalidate and save your user name and password credentials.

6. Select at least one of the available data centers on the specified vCenter server to allow provisioning for this cloud account.

7. For efficiency, create a cloud zone for provisioning to the selected data centers.

You can also create cloud zones as a separate step according to your organization's cloud strategy.

For information about cloud zones, see [Learn more about Automation Assembler cloud zones](#).

8. Select an existing NSX cloud account.

You can select the NSX account now, or later when you edit the cloud account.

For information about NSX-T cloud accounts, see [Create an NSX-T cloud account in VMware Aria Automation](#).

For information about making network association changes after you have deployed a cloud template, see [What happens if I remove an NSX cloud account association in VMware Aria Automation](#).

9. If you want to add tags to support a tagging strategy, enter capability tags.

You can add tags now, or later when you edit the cloud account. For information about tagging, see [maphead-how-to-use-tags.dita](#).

For more information about how capability tags and constraint tags help control deployment placements, see the [Constraint Tags and Placement](#) video tutorial.

10. Click **Save**.

The cloud account is added and the selected data centers are available for the specified cloud zone. Collected data such as machines, networks, storage, and volumes is listed in the **Resources** section of the **Infrastructure** tab.

Configure remaining infrastructure resources for this cloud account. See [Building your Automation Assembler resource infrastructure](#).

For information about converting an existing cloud account, see [Convert a traditional cloud account to one based on a extensibility \(vREx\) proxy](#).

Convert a traditional vCenter cloud account to one based on a VMware Aria Automation extensibility (vREx) proxy

Convert a traditional vCenter cloud account to one based on a VMware Aria Automation extensibility (vREx) proxy. You can convert an existing vCenter cloud account in VMware Aria Automation from one that connects to a vCenter server directly to one that connects through a VMware Aria Automation extensibility (vREx) proxy.

Regardless of whether you use the **Forward all traffic through proxy** option, VMware Aria Automation manages the associated vCenter instance with the cloud account. The difference is whether VMware Aria Automation manages it directly or through an intermediary VMware Aria Automation extensibility (vREx) proxy.

Reasons you might want to toggle to a remote proxy method include the following:

- A better throughput for highly loaded VMware Aria Automation instances.
- A more reliable connection to distant vCenter servers.
- The opportunity to manage vCenter servers in network isolation.

You can toggle and test the connection mode.

To change the association of an existing vCenter cloud account from a direct vCenter connection to an indirect, intermediary VMware Aria Automation extensibility (vREx) proxy, use the following procedure:

1. Verify that you have the needed prerequisites for managing vCenter cloud account through a vREx proxy. See [How can I configure and use a Extensibility proxy with a cloud account for improved performance across datacenters](#).
2. Log in to VMware Aria Automation and open the Automation Assembler service.
3. Click **Infrastructure > Connections > Cloud Accounts** and select the existing vCenter cloud account.
4. In the **Credentials** area of the cloud account page, select the **Forward all traffic through proxy** option and select the configured VMware Aria Automation extensibility (vREx) proxy from the drop-down menu of available VMware Aria Automation extensibility (vREx) proxies.
After you select a vREx proxy, you must revalidate your user name and password credentials.
5. Revalidate your vCenter credentials as prompted.
6. Save the changes.

For related information about creating a vCenter cloud account, see [Create a basic cloud account in .](#)

Create an NSX-V cloud account in VMware Aria Automation

Create an NSX-V cloud account

For network and security purposes, you can create and associate an NSX-V cloud account with a vCenter cloud account.

- Verify that you have the required administrator credentials and have enabled HTTPS access on port 443. See [Credentials required for working with cloud accounts in VMware Aria Automation](#).
Also verify that you have properly configured your ports and protocols to support the cloud account. See the *System Requirements* topic in *Installing VMware Aria Automation with Easy Installer* and the *Port Requirements* topic in *Reference Architecture Guide*. Both publications are available on the VMware Aria Automation product documentation page.
- Verify that you have the cloud administrator user role. See [What are the user roles](#).
- Verify that you have a vCenter cloud account to use with this NSX cloud account. See [Create a basic cloud account in .](#)

For related information, see [VMware NSX Documentation](#).

An NSX-V cloud account can only be associated to one vCenter cloud account.

The association between NSX-V and a vCenter cloud account must be configured outside of VMware Aria Automation, specifically in your NSX application. VMware Aria Automation doesn't create the association between NSX and vCenter. In VMware Aria Automation, you specify an association that already exists in NSX.

1. Select **Infrastructure > Connections > Cloud Accounts** and click **Add Cloud Account**.
2. Select the NSX-V account type and enter the NSX-V host IP address.
3. Enter your NSX administrator credentials and click **Validate**.

The assets associated with the account are collected.

If the NSX host IP address is not available, validation fails.

4. If available, select the vCenter endpoint that represents the vCenter cloud account that you are associating with this NSX-V account.

Only vCenter cloud accounts that are not currently associated to an NSX-T or NSX-V cloud account are available for selection.

For information about making association changes after you have deployed a cloud template, see [What happens if I remove an NSX cloud account association in VMware Aria Automation](#).

5. If you want to add tags to support a tagging strategy, enter capability tags.

You can add or remove capability tags later. See [maphead-how-to-use-tags.dita](#).

For information about how capability tags and constraint tags help control deployment placements, see the [Constraint Tags and Placement](#) video tutorial.

6. Click **Save**.

You can create or edit a vCenter cloud account to associate with this NSX cloud account. See [Create a basic vCenter cloud account in VMware Aria Automation](#).

Create and configure one or more cloud zones for use with the data centers that are used by this cloud account. See [Learn more about cloud zones](#).

Configure infrastructure resources for this cloud account. See [Building your Automation Assembler resource infrastructure](#).

Create an NSX-T cloud account in VMware Aria Automation

Create an NSX-T cloud account

For network and security purposes, you can create an NSX-T cloud account and associate it with one or more vCenter cloud accounts.

- Verify that you have the required administrator credentials and have enabled HTTPS access on port 443. See [Credentials required for working with cloud accounts in VMware Aria Automation](#).

Also Verify that you have properly configured your ports and protocols to support the cloud account. See the *System Requirements* topic in *Installing VMware Aria*

Automation with Easy Installer and the *Port Requirements* topic in *Reference Architecture Guide*. Both publications are available on the VMware Aria Automation [product documentation page](#).

- Verify that you have the cloud administrator user role. See [What are the user roles](#).
- Verify that you have a vCenter cloud account to use with this NSX cloud account. See [Create a basic vCenter cloud account in VMware Aria Automation](#).

For related information, see [VMware NSX Documentation](#).

An NSX-T cloud account can be associated to one or more vCenter cloud accounts. However, an NSX-V cloud account can only be associated to one vCenter cloud account.

The association between NSX-T and one or more vCenter cloud accounts must be configured outside of VMware Aria Automation, specifically in your NSX application. VMware Aria Automation doesn't create the association between NSX and vCenter. In VMware Aria Automation, you specify one or more configuration associations that already exists in NSX. When you create an NSX cloud account in VMware Aria Automation, you specify a manager type and an NSX mode. These selections cannot be changed after you create the cloud account.

You can connect to an NSX Global Manager and configure an association between an NSX Global Manager and local managers in the context of the NSX federation.

For related information about NSX options and capabilities in general, see [VMware NSX Documentation](#).

To facilitate fault tolerance and high availability in deployments, each NSX endpoint represents a cluster of three NSX Managers.

- VMware Aria Automation can point to one of the NSX Managers. Using this option, one NSX Manager receives the API calls from VMware Aria Automation.
- VMware Aria Automation can point to the Virtual IP of the cluster. Using this option, one NSX Manager assumes control of the VIP. That NSX Manager receives the API calls from VMware Aria Automation. In case of failure, another node in the cluster assumes control of the VIP and receives the API calls from VMware Aria Automation.
For more information about VIP configuration for NSX, see *Configure a Virtual IP (VIP) Address for a Cluster* in the *NSX Installation Guide* at [VMware NSX Documentation](#).
- VMware Aria Automation can point to a load balancer VIP to load-balance the calls to the three NSX Managers. Using this option, all three NSX Managers receive API calls from VMware Aria Automation.
You can configure the VIP on a third-party load balancer or on an NSX-T load balancer.

For large scale environments, consider using this option to split the VMware Aria Automation API calls among the three NSX Managers.

1. Select **Infrastructure > Connections > Cloud Accounts** and click **Add Cloud Account**.
2. Select the NSX-T account type and specify a cloud account name and description.
3. Enter the host IP address for the NSX-T Manager instance or VIP (see above for information about the expected behavior that pertains to the NSX Manager and VIP options).
4. Enter your NSX user name and password administrator credentials.
5. For **Manager type**, select either **Global** or **Local** (default).

- Global Manager
The Global Manager setting is only available for use with the Policy **NSX mode** setting. It is not available when using the Manager **NSX mode** setting.

The Global setting refers to the NSX-T federation capabilities, including global network segments. Only NSX-T cloud accounts with the Global setting support NSX-T federation.

When using the Global Manager setting, you are prompted to identify a Local Manager NSX-T cloud account and an associated vCenter cloud account.

You cannot associate a Global Manager NSX-T cloud account with vCenter cloud account, as you can with a Local Manager NSX-T cloud account. Similar to how a Local Manager NSX-T cloud account can be associated to multiple vCenter cloud accounts, a Global Manager NSX-T cloud account can be associated to multiple Local Manager NSX-T cloud accounts.

- Local Manager
Use the Local setting to define a traditional NSX-T cloud account, which can be associated to one or more vSphere cloud accounts. You can associate a Global manager NSX-T cloud account with a Local NSX-T cloud accounts. Note that this is also the setting to use if you are creating a new and empty target NSX-T cloud account for the purposes of NSX-V to NSX-T migration.

You cannot change the **Manager type** setting after you create the cloud account.

6. For **NSX mode**, select either **Policy** or **Manager**.

- Policy mode (default)
The Policy mode is available for NSX-T 3.0 and NSX-T 3.1 forward. This option enables VMware Aria Automation to use the additional capabilities available in the NSX-T Policy API.

If you are using NSX-T with a VMware Cloud on AWS cloud account in a cloud template, the NSX-T cloud account must use the Policy **NSX mode**.

The Policy setting refers to the NSX-T Policy API form of NSX-T.

- Manager mode

Existing NSX-T endpoints or cloud accounts that are upgraded from an earlier version of VMware Aria Automation that did not provide a Policy option are treated as Manager mode NSX-T cloud accounts.

The Manager mode is supported for NSX-T 2.4, NSX-T 3.0, and NSX-T 3.1 forward.

If you specify Manager mode, use the Manager mode option for other NSX-T cloud accounts until VMware Aria Automation introduces a Manager mode to Policy mode migration path.

Some VMware Aria Automation options for NSX-T require NSX-T 3.0 or greater, including adding tags to virtual machine NIC components in the cloud template.

The Manager setting refers to the NSX-T Manager API form of NSX-T.

If you have existing NSX-T cloud accounts that were created prior to the introduction of the Policy mode in VMware Aria Automation 8.2, they use the Manager API method. It is recommended that you replace your existing NSX-T cloud accounts with new NSX-T cloud accounts that specify the Policy API method.

You cannot change the **NSX mode** value after you create the cloud account.

7. Click **Validate** to confirm the credentials in relation to the selected NSX Manager type and NSX mode.

The assets associated with the account are collected.

If the NSX host IP address is not available, validation fails.

8. In **Associations**, add one or more vCenter cloud accounts to associate with this NSX-T cloud account. You can also remove existing vCenter cloud account associations.

Only vCenter cloud accounts that are not currently associated in VMware Aria Automation to an NSX-T or NSX-V cloud account are available for selection.

See [What can I do with NSX-T mapping to multiple vCenters in VMware Aria Automation](#).

For information about making association changes after you have deployed a cloud template, or about deleting the cloud account after you have deployed a cloud template, see [What happens if I remove an NSX cloud account association in VMware Aria Automation](#).

9. If you want to add tags to support a tagging strategy, enter capability tags.

You can add or remove capability tags later. See [maphead-how-to-use-tags.dita](#).

For more information about how capability tags and constraint tags help control deployment placements, see the [Constraint Tags and Placement](#) video tutorial.

10. Click **Save**.

You can create or edit a vCenter cloud account to associate with this NSX cloud account. See [Create a basic vCenter cloud account in VMware Aria Automation](#).

Create and configure one or more cloud zones for use with the data centers that are used by this cloud account. See [Learn more about cloud zones](#).

Configure infrastructure resources for this cloud account. See [Building your Automation Assembler resource infrastructure](#).

For samples of using NSX-T options in VMware Aria Automation cloud templates, see [Network, security group, and load balancer resource examples in Automation Assembler](#).

Create a VMware Cloud on AWS cloud account in VMware Aria Automation

Create a VMware Cloud on AWS cloud account

As a cloud administrator, you can create a VMware Cloud on AWS cloud account for account regions to which your team will deploy VMware Aria Automation cloud templates.

For information about creating a VMware Cloud on AWS cloud account within a sample workflow that includes satisfying needed prerequisite tasks, see [Create a cloud account in in the workflow](#).

For related information about VMware Cloud on AWS outside of VMware Aria Automation, see [VMware Cloud on AWS documentation](#).

Create a VMware Cloud Foundation cloud account

You can configure a VMware Cloud Foundation (VCF) as a cloud account within Automation Assembler to use workload domains.

You must have an instance of VMware SDDC Manager 4.1 or higher configured as an Automation Assembler integration for use with this cloud account. For more information, see [configure-a-vmware-sddc-integration.dita](#).

A VCF cloud account enables you to incorporate a VCF workload into Automation Assembler to facilitate a comprehensive hybrid cloud management solution. Automation Assembler offers several entry points from which you can activate the VCF cloud account configuration page. If you access this page using the **Add Cloud Account** button on the SDDC integration Workload Domain tab, the workload is pre-selected, including the basic information for the vCenter and NSX Manager.

1. Select **Infrastructure > Connections > Cloud Accounts** and click **Add Cloud Account**.
2. Select the VCF Cloud Account type, and enter a **Name** and **Description**.
3. Enter the FQDN and credentials for the SDDC manager instance that you are using with this cloud account.

You can skip this step if you have already configured the SDDC manager instance that you will use with this account.
4. Select one or more workload domains that you want to use with this VCF cloud account.
5. If you want to have Automation Assembler use Cloud Foundation managed service credentials for vCenter and NSX, select **Automatically create service credentials**. Later, if you want to change these credentials, you must use the VCF mechanism for password management.

If you select this option, you can skip steps 7 and 8.
6. Enter the credentials required to access the vCenter associated with this cloud account.
7. Under the NSX Manager heading, enter NSX credentials if you want to manually enter credentials for the VCF cloud account, or click Create and Validate Service Credentials if you want Automation Assembler to create and validate NSX credentials.
8. Enter the credentials required to access the NSX-T network associated with this cloud account.
9. If applicable, select the NSX mode.
10. Click **Validate** to confirm a connection to the SDDC manager.
11. If applicable, select the data centers that you want to provision to under the Configuration heading. Click the check box if you want to create a cloud zone for the selected data centers.
12. If you use tags to support a tagging strategy, enter capability tags. See [maphead-how-to-use-tags.dita#GUID-1F1FD968-2EA1-404E-B081-E13383392061-en](#) and [Creating a tagging strategy](#).

NOTE

When capability tags are applied to a VMware Cloud Foundation cloud account, these tags are not inherited by deployments for the underlying vCenter Server and NSX-T components. As a workaround, you can apply tags at the next level, such as on the cloud zones.

13. Click **Save**.

This cloud account brings the selected workload domain associated with the specified SDDC manager into Automation Assembler for use.

If you want to manage additional workload domains using VMware Aria Automation, you must repeat this processs for each domain.

After you configure the VCF cloud account, you can select the account on the main cloud account page and click **Setup Cloud** to initiate the VMware Cloud Foundation Quickstart wizard that will configure your cloud.

For more information about the Quick Start wizard, see [How do I get started with VMware Aria Automation using the VMware Cloud Foundation Quickstart](#).

Create a VMware Cloud Director cloud account in VMware Aria Automation

Create a VMware Cloud Director cloud account in VMware Aria Automation

You can create a VMware Cloud Director cloud account in VMware Aria Automation to deploy Cloud Director virtual machines using cloud agnostic objects. Cloud Director supports flexible provisioning of network, storage and compute resources, and provides a portal-based experience to manage vCenters and their NSX-T and NSX-V network appliances and associated virtual data centers via a catalog.

- Set up a VMware Cloud Director deployment with one or more appropriate organizations. See <https://interopmatrix.vmware.com/Interoperability> for information about what specific Cloud Director versions are supported.
- Users specified for this integration must have Organization Administrator privileges to read applicable templates and to create virtual machines as well as to view other resources such as compute policies, disks, virtual data centers, etc. The VCD cloud account for VMware Aria Automation works within a tenant context in Cloud Director, so you connect to an individual organization in Cloud Director with your tenant credentials. For more information about required credentials, see [Credentials required for working with cloud accounts in VMware Aria Automation](#).
- You must configure the appropriate storage, network, image, and flavors, or sizing policy, within your VMware Cloud Director instance and map these objects into VMware Aria AutomationAssembler either before or after you configure your integration. The following list explains how VMware Cloud Director virtual objects should be mapped to VMware Aria Automation objects in Automation Assembler.
 - VMware Cloud Director organization networks (isolated, direct, routed) - map to VMware Aria Automation networks. No static IP pool can be set for the network adapter.
 - VMware Cloud Director virtual machine sizing policies - map to VMware Aria Automation flavors.
 - VMware Cloud Director storage policies - map to VMware Aria Automation storage profiles.
 - VMware Cloud Director images (OVF, ISO boot media) - map to VMware Aria Automation images. Images can be vApp template or media such as ISO files. If you use ISO then an "empty" virtual machine is created and media is attached as boot media.
 - VMware Cloud Director virtual machines - map to VMware Aria Automation computes.
 - VMware Cloud Director virtual machines disks - map to VMware Aria Automation cloud volumes.

You map these VMware Cloud Director objects to VMware Aria Automation objects using the options under the **Infrastructure > Configure >** pages in Automation Assembler. See the relevant topics under [Building your Automation Assembler resource infrastructure](#) for detailed information about mapping objects in VMware Aria Automation.

The VMware Cloud Director cloud account supports creation of standalone Cloud Director virtual machines with no vApp. Three scenarios for provisioning Cloud Director virtual machines by using Automation Assembler cloud templates are supported:

- Virtual machines
- Virtual machine attached networks that are discovered from networks dedicated to virtual data centers within a tenant. Networks shared across virtual data centers are not supported for discovery or attachment to virtual machines provisioned by VMware Aria Automation. See [Managing Data Center Group Networking with NSX in the VMware Cloud Director Tenant Portal](#) for more information.

- Virtual machines with additional disk/s

For more information about working with VMware Cloud Director, including information about setting up multiple servers for high availability, see the official documentation at <https://docs.vmware.com/en/VMware-Cloud-Director/index.html>.

NOTE

A VMware Cloud Director cloud account will not function in an environment with FIPs enabled. Also, once enabled, FIPs can't be disabled for VMware Aria Automation 8.x.

The VMware Cloud Director cloud account supports up to 1000 virtual machines with VMware Aria Automation in sustain mode.

The following procedure describes how to set up a VMware Cloud Director cloud account within VMware Aria Automation Assembler.

1. Select **Infrastructure > Connections > Cloud Accounts** and click **Add Cloud Account**.
2. Select the VMware Cloud Director cloud account type, and enter a **Name** and **Description**.
3. Enter the appropriate account information required to access the VMware Cloud Director server.
4. Enter the base URL to use to connect with the VMware Cloud Director server.
5. Enter an appropriate **Username** and **Password** for a valid account that can access the specified Cloud Director instance.
6. Enter the desired **Organization** name to use with this integration.

In VMware Cloud Director, an organization contains users, the vApps that they create, and the resources the vApps use.

7. Click **Validate**.

During validation, you might be asked to accept a certificate. When the connection is validated, you can select additional settings.

8. If you use tags to support a tagging strategy, enter capability tags. See [maphead-how-to-use-tags.dita#GUID-1F1FD968-2EA1-404E-B081-E13383392061-en](#) and [Creating a tagging strategy](#).
9. After you validate, the page displays a list of Cloud Director virtual data centers from which you can select. Select the appropriate data center. This selection determines the Director regions to which you can deploy.
10. Click **Add** to add the VMware Cloud Director cloud account to VMware Aria Automation.

The VMware Cloud Director cloud account is available for configuration in VMware Aria Automation. The networks associated with the Cloud Director instance are available for configuration on the Automation Assembler **Resources > Networks** page.

NOTE

Only networks that are dedicated to vCloud Director are discovered.

You can set up the appropriate storage profiles and then use the cloud account to create deployments in cloud templates. In addition, ensure that an appropriate project is configured in Automation Assembler for use with the Cloud Director instance.

The VMware Cloud Director cloud account is ready for use in Automation Assembler cloud templates.

The following is an example cloud template for a basic VMware Cloud Director deployment.

```
formatVersion: 1
inputs: {}
resources:
Cloud_Network_1:
```

```

type: Cloud.Network
properties:
  networkType: existing
constraints:
  - tag: net1:isolated

Cloud_Volume_1:
type: Cloud.Volume
properties:
  capacityGb: 2

Cloud_Machine_1:
type: Cloud.Machine
properties:
  image: image1
  flavor: small
  storage:
    constraints:
      - tag: storage:development
attachedDisks:
  - source: '${resource.Cloud_Volume_1.id}'
networks:
  - network: '${resource.Cloud_Network_1.id}'

```

The following day 2 actions are supported on deployed VMware Cloud Director virtual machines:

- Power on
- Power off
- Suspend
- Create snapshot
- Revert to snapshot
- Remove snapshot
- Add disk
- Remove disk
- Resize disk (note: only increasing disk size is supported)
- Resize boot disk

After a cloud template is deployed, you can apply tags on newly provisioned machines in VMware Aria Automation. These VMware Aria Automation tags are mapped to VMware Cloud Director metadata which can be retrieved using the VMware Cloud Director API. You can also tag other VMware Aria Automation resources, but only machines on the VMware Cloud Director side are updated as it's the only supported type of resource of this feature.

In addition, you can resize a virtual machine's boot disk. Also regular disks are supported; in this case, users only need to attach a disk resource to a machine resource. When everything is deployed, you can use the option to "update boot disk" or "update disk" to increase, but not decrease, the size of the desired disk.

You can change a virtual machine sizing policy using the VMware Aria Automation flavor configuration Resize option. Once selected, the VMware Cloud Director virtual machine will use the provided sizing policy.

This feature requires that the **Default Rights Bundle** assigned to the Organization Administrator role contains the "Change compute policies" right, for which internal code is VAPP_EDIT_VM_COMPUTE_POLICY. Then, this right must be activated for the Organization Administrator. Otherwise, the resize operation will fail with an error 403: Either you need some or all of the following rights [VAPP_EDIT_VM_COMPUTE_POLICY] to perform operations.

You can resize the boot disk of a VMware Cloud Director virtual machine as a day 2 operation, by selecting the virtual machine on the Automation Assembler Deployments page. However, you must disable Fast provisioning before attempting to resize the boot disk or the following error may occur:

Request timed out after 120 minutes. Please configure project request timeout parameter for long running resource requests.

Note that this requirement applies only to virtual machines created from vApp Template disks. It does not apply to virtual machines created from ISO files.

The following procedure describes how to disable fast provisioning.

1. Log in to VMware Cloud Director as a system administrator: https://vcd_url/provider with the system user
2. Click on Organization VDCs.
3. Select the target organization.
4. Click on Storage (under Policies).
5. Disable **Fast Provisioning**.

Use logs and other resources to troubleshoot VMware Cloud Director cloud accounts in VMware Aria Automation

If you encounter issues when configuring or using a VMware Cloud Director cloud account in VMware Aria Automation you can consult logs and other resources as described below.

Troubleshooting VMware Cloud Director cloud account connection issues

If the VMware Cloud Director adapter is not listed on the cloud account creation screen or is not responding, you can use the following command to verify the status by logging in to the VMware Aria Automation Kubernetes host and checking the adapter pod status:

```
root@host [ ~ ]# kubectl -n prelude get pods | grep adapter-host-service-app
adapter-host-service-app-65f5c945bb-p6hpn      1/1      Running     0          4d1h
```

If the VMware Cloud Director adapter cannot communicate with the Cloud Director physical machine, an error is displayed in the cloud account screen with statements about connection and processing exceptions. The error also appears in the logs.

Working with VMware Cloud Director logs

The VMware Cloud Director adapter main log file resides under the local (pod) dir `/var/log/adapter-host-service-app.log` and in the case of the adapter running inside the VMware Aria Automation appliance host, this log is also copied to `/services-logs/prelude/adapter-host-service-app/file-logs/`. By default most of the logging is restricted to DEBUG or INFO levels. You can alter the configuration for the following loggers to enable more verbose logging for debugging purposes:

- `org.apache.cxf.services=INFO` - this logger provides verbose info for communication between the adapter and VMware Cloud Director.
- `com.vmware.vra.vcloud.director.adapter=TRACE` - this logger provides verbose info for communication between the adapter and VMware Aria Automation.

There are three ways you can access the logs:

- access log by login to the adapter pod

```
root@host [ ~ ]# kubectl -n prelude exec -ti adapter-host-service-app-65f5c945bb-p6hp -- bash
```

```
root [ / ]# less /var/log/adapter-host-service-app.log
```

- access log using kubectl

```
root@host [ ~ ]# kubectl -n prelude get logs adapter-host-service-app-65f5c945bb-p6hp
```

- access log using the adapter kubernetes host local copy

```
root@host [ ~ ]# less /services-logs/prelude/adapter-host-service-app/file-logs/adapter-host-service-app.log
```

You can query or change the loggers configuration via `/actuator/loggers` REST API endpoint.

- Example of enabling VMware Cloud Director client communication tracing via curl :

```
curl -i -X POST -H 'Content-Type: application/json' -d '{"configuredLevel": "INFO"}'  
http://{adapter-url}/actuator/loggers/org.apache.cxf.services
```

- Example of disabling VMware Cloud Director client communication tracing via curl :

```
curl -i -X POST -H 'Content-Type: application/json' -d '{"configuredLevel": "OFF"}'  
http://{adapter-url}/actuator/loggers/org.apache.cxf.services
```

- Example of obtaining current configuration for VMware Cloud Director client communication via curl :

```
curl http://{adapter-url}/actuator/loggers/org.apache.cxf.services
```

```
...
```

```
{"configuredLevel": "OFF", "effectiveLevel": "INFO"}
```

There are other parameters that can be adjusted to alter performance of VMware Cloud Director.

- `vcd.max.thread.count` - this parameter determines the maximum degree of parallelism when performing VMware Cloud Director API calls. The default is 128.

NOTE

Decreasing the value for this parameter will reduce the stress on the VMware Cloud Director backend when performing enumeration but may decrease the enumeration performance.

- `VCD_ADAPTER_PAGINATION_SIZE_IMAGES` - this parameter determines the page size when performing image enumeration. The default is 50.

NOTE

Decrease this parameter if adapter timeout errors occur during image enumeration.

Create a VMware Avi Load Balancer cloud account

VMware Aria Automation supports automating VMware Avi Load Balancer to deliver a Load Balancer as a Service (LBaaS) offering on VMware clouds. You can configure Avi Load Balancer as a cloud account to establish a connection to the Avi Load Balancer Controller and provision Avi Load Balancer resources in Automation Assembler.

Prerequisites

- For VMware Aria Automation, verify that you have the following permissions:
 - Verify that you have the required administrator credentials and have enabled HTTPS access on port 443. See [Credentials required for working with cloud accounts in VMware Aria Automation](#).
 - Verify that you have the cloud administrator user role. See [What are the VMware Aria Automation user roles](#).
- For VMware Avi Load Balancer, verify that you have the following **Write** privileges:
 - Application Profile
 - Health Monitor
 - Persistence Profile
 - Pool
 - TCP/UDP Profile
 - Virtual Service

You can leave all other permissions as **Read**.

For more information about Avi Load Balancer roles, see [User Roles](#) in the *VMware NSX Advanced Load Balancer Administration* guide.

Step 1: Add a cloud account

1. Select **Infrastructure > Connections > Cloud Accounts** and click **Add Cloud Account**.
2. Select the VMware Avi Load Balancer account type and enter name and credentials.
3. Click **Validate**.
4. Add a default Avi Load Balancer tenant and cloud connector.
Defaults are used in case you don't specify an Avi Load Balancer tenant and a cloud connector reference when designing a template.
5. If you need to add tags to support a tagging strategy, enter capability tags.
You can use tags to distinguish between multiple Avi Load Balancer cloud accounts when designing a template. You can use Avi Load Balancer tags in combination with tags for vCenter cloud accounts.
6. You can add or remove capability tags later. See [../../using-automation-assembler/topics/maphead-how-to-use-tags.dita](#) and [Creating a tagging strategy](#).
6. Click **Add**.

Once the cloud account is added to VMware Aria Automation, a cloud zone is automatically created. To verify, select **Infrastructure > Configure > Cloud Zones**.

Step 2: Add the cloud zone to a project

Each Avi Load Balancer cloud account is associated with one cloud zone. You must assign the cloud zone to a project so you can control access to the Avi Load Balancer Controller. If you don't add the cloud zone to a project, you must specify the cloud account in the resource, otherwise your deployments will fail. You also need the cloud zone if you want to use allocation helpers with your Avi Load Balancer resources, like the cloud zone allocation helper.

Multiple cloud zones can be assigned to a project to support deploying to multiple Avi Load Balancer Controllers. Multiple projects can be allowed to provision to the same cloud zone.

Note that cloud zones for compute resources are separate. You must add a cloud zone for compute and a cloud zone for Avi Load Balancer to provision to both.

1. Select **Infrastructure > Administration > Projects** and create a new project.

You can also use an existing project.

2. On the **Provisioning** tab, select **Add Zone > Cloud Zone**.

- a. Search for the cloud zone that was automatically created for you when you added the Avi Load Balancer cloud account.
- b. Configure the cloud zone parameters.
- c. Click **Add**.

3. Click **Create**.

What to do next

Provision Avi Load Balancer resources. See [Using VMware Avi Load Balancer resources](#).

Integrating VMware Aria Automation with other applications

Integrating with other applications

Integrations enable you to add external systems to VMware Aria Automation.

Integrations include VMware Aria Automation Orchestrator, configuration management and other external systems such as GitHub, Ansible, Puppet, and external IPAM providers such as Infoblox.

NOTE

If you do not have external Internet access and your integration requires it, you can configure an Internet server proxy. See [How do I configure an Internet proxy server for VMware Aria Automation](#).

How do I use Git integration in Automation Assembler

How do I use GitLab and GitHub integration

Automation Assembler supports integration with various flavors of Git repositories so that you can manage VMware cloud templates and action scripts under source control. This functionality facilitates auditing and accountability of processes around deployment.

Automation Assembler supports different flavors of Git integration as described in the following list. Each of these options is a separate integration.

- GitHub cloud, GitHub Enterprise on-premises
- GitLab cloud GitLab Enterprise on-premises
- BitBucket on-premises

You must have an appropriate local Git repository configured with access for all designated users in order to set up Git integration with Automation Assembler. Also, you must save your cloud templates in a specific structure in order for them to be detected by Git. To create an integration with GitLab or GitHub, select **Infrastructure > Connections > Integrations** in Automation Assembler and then make the appropriate selection. You will need the url and token for the target repository.

When Git integration is configured with an existing repository, all cloud templates associated with selected projects become available to qualified users. You can use these templates with an existing deployment or as the basis of a new deployment. When you add a project, you must select some properties regarding where and how it is stored in Git.

You can save actions to a Git repository directly from Automation Assembler. You can version action scripts either directly to Git, or you can create versions in Automation Assembler. If you create a version of an action in Automation Assembler, then it is automatically saved to Git as a version. Cloud templates are a bit more complicated, because you cannot directly add them to a Git integration from Automation Assembler. You must save them directly to a Git instance, and then you can retrieve them from Git when working with the cloud template management page in Automation Assembler.

Before you Begin

You must create and save your cloud templates in a specific structure in order for them to be detected by GitLab or GitHub.

- Configure and store cloud templates to be integrated with GitLab correctly. Only valid templates are imported into GitLab.
 - Create one or more designated folders for the cloud templates.
 - All cloud templates must be stored within `blueprint.yaml` files.
 - Ensure that the top of your templates include the `name:` and `version:` properties.
- Extract an API key for the applicable repository. In your Git account, select your login in the upper right corner, and click **Developer Settings**. Navigate to **Personal Access Tokens**, and then name your token and set an expiration date. Then, select API and create the token. Copy the resulting value and save it.

The following guidelines must be observed for all cloud templates used with Git integration.

- Each cloud template must reside in a separate folder.
- All cloud templates must be named `blueprint.yaml`.
- All cloud template YAML files must use `name` and `version` fields.
- Only valid cloud templates are imported.
- If you update a draft cloud template imported from Git, and its content differs from that in the top version, the draft will not be updated in subsequent syncs and a new version is created. If you want to update a template and also allow further sync's from Git, then you must create a new version after final changes.

How to upgrade to a newer external IPAM integration package in VMware Aria Automation

How to upgrade to a newer external IPAM integration package

You can upgrade an existing external IPAM integration point to source a more recent version of the vendor-specific IPAM integration package.

This procedure assumes that you have already created an external IPAM integration point and want to upgrade that integration point to use a more recent version of the vendor's IPAM integration package.

For information about how to create an external IPAM integration point, see [Add an external IPAM integration for Infoblox in VMware Aria Automation](#).

- Verify that you have cloud administrator credentials. See [Credentials required for working with cloud accounts in VMware Aria Automation](#).
- Verify that you have the cloud administrator user role. See [What are the user roles](#).
- Verify that you have an account with the external IPAM provider and that you have the correct access credentials to your organization's account with that IPAM provider.

- Verify that you have access to a deployed integration package for your IPAM provider. The deployed package is initially obtained as a .zip download from your IPAM provider website or from the [VMware Marketplace](#) and then deployed to VMware Aria Automation.
For information about how to download and deploy the provider package .zip file and make it available as a **Provider** value on the IPAM Integration page, see [Download and deploy an external IPAM provider package for use in VMware Aria Automation](#).
- Verify that you have access to a configured running environment for the IPAM provider. The running environment is typically an actions-based extensibility (ABX) On-Prem Embedded integration point.
For information about running environment characteristics, see [Create a running environment for an IPAM integration point in VMware Aria Automation](#).

An external IPAM provider or VMware may upgrade a source IPAM integration package for a particular vendor. For example, the external IPAM integration package for Infoblox has been upgraded several times. To preserve any existing VMware Aria Automation infrastructure settings that use a named IPAM integration point, you can edit an IPAM integration point to source the updated IPAM integration package, rather than create a new IPAM integration point.

1. Select **Infrastructure > Connections > Integrations > IPAM** and open the existing IPAM integration point.
2. Click **Manage Providers**.
3. Navigate to and import the updated IPAM integration package.
4. Click **Validate** and click **Save**.

Configure an Automation Orchestrator integration in Automation Assembler

You can configure one or more VMware Aria Automation Orchestrator integrations, so that you can use workflows as part of extensibility and cloud templates.

- Verify that you have cloud administrator credentials. See [Credentials required for working with cloud accounts in VMware Aria Automation](#).
- Upgrade or migrate to this latest Automation Orchestrator release. See [Upgrading and Migrating Automation Orchestrator](#).

VMware Aria Automation includes a preconfigured embedded Automation Orchestrator instance. You can access the client of the embedded Automation Orchestrator from the VMware Aria Automation Cloud Services Console.

NOTE

You can access the Control Center of the embedded Automation Orchestrator by navigating to https://your_Vmware-Aria-Automation_FQDN/vco-controlcenter and logging in as **root**.

You can also integrate an external Automation Orchestrator instance for use in your VMware Aria Automation extensibility subscriptions and XaaS (Anything as a Service) operations used for cloud templates.

1. Select **Infrastructure > Connections > Integrations**.
2. Click **Add integration**.
3. Select **Orchestrator**.
4. Enter a name for the Automation Orchestrator integration.
5. Enter a description for the Automation Orchestrator integration.
6. Under **VMware Aria Automation Orchestrator URL**, enter the fully qualified domain name (FQDN) of your external Automation Orchestrator instance.
For example, https://my_Orechestrator_FQDN.com:443.
7. To validate the integration, click **Validate**.
8. If prompted to do so, review the certificate information, and click **Accept**.
9. Add capability tags. For more information on capability tags, see [Using capability tags in](#).

NOTE

Capability tags can be used to manage multiple Automation Orchestrator integrations. See [Managing multiple integrations with project constraints](#).

10. Click **Add**.

The Automation Orchestrator integration is saved.

11. To verify that the integration is configured and that the workflows are added, select **Extensibility > Library > Workflows**.

Activate or deactivate Automation Orchestrator integrations

You can manually activate or deactivate your Automation Orchestrator integration so you can perform maintenance while the integration is still running.

Configure one or more Automation Orchestrator integrations in Automation Assembler. See [Configure an integration in](#).

You can deactivate your Automation Orchestrator integration to perform maintenance. While deactivated, your Automation Orchestrator integration is still in a **RUNNING** state so you can continue to perform tasks such as resource monitoring and data collection.

NOTE

In addition to manual disabling, the Automation Orchestrator Gateway service performs periodic health status checks to verify if your Automation Orchestrator integrations are active or not. Any inactive Automation Orchestrator integrations are deactivated automatically and are set to the **DISCONNECTED** state. You will be unable to perform tasks such as data collection or resource monitoring on disconnected integrations.

After disabling a Automation Orchestrator integration, or having the integration be disconnected by the health status checker, workflows will only run on remaining integrations that are activated. If your environment includes multiple activated Automation Orchestrator integrations which are not managed through project constraints or capability tags, a random Automation Orchestrator integration will be selected to run your workflow.

NOTE

Since the Automation Orchestrator integration is selected randomly, you must ensure that information required to run a given operation is available on all integrations. For content entities such as workflows, this means that they should be synchronized across all integrations. For inventory objects there is no guarantee that they will have the same object identifier on all integrations, so trying to run a workflow that includes such an inventory object as a input parameter might fail.

For information on managing multiple Automation Orchestrator integrations with project constraints and capability tags, see [Managing multiple integrations with project constraints](#) and [Managing multiple integrations with cloud account capability tags](#).

1. Deactivate your Automation Orchestrator integration.
 - a) Navigate to **Infrastructure > Connections > Integrations**.
 - b) Select the Automation Orchestrator integration you want to deactivate.
 - c) Under **Orchestrator Server Credentials**, toggle off the **Enable endpoint** option.
 - d) Click **Validate**.
 - e) After successful validation, click **Save**.
2. Perform the necessary maintenance tasks on the deactivated Automation Orchestrator integration.
3. Activate your Automation Orchestrator integration.
 - a) Navigate to **Infrastructure > Connections > Integrations**.
 - b) Select the previously deactivated Automation Orchestrator integration.
 - c) Under **Server Credentials**, toggle on the **Enable endpoint** option.
 - d) Click **Validate**.
 - e) After successful validation, click **Save**.

Managing multiple Automation Orchestrator integrations with project constraints

You can use project constraints to manage what Automation Orchestrator integrations are used in workflow subscriptions.

- Verify that you have cloud administrator credentials. See [What are the user roles](#).
- Configure two or more Automation Orchestrator integrations in Automation Assembler. See [Configure an integration in](#).
- Add capability tags to your Automation Orchestrator integrations. See [Using capability tags in](#).

Automation Assembler supports the integration of multiple Automation Orchestrator servers that can be used in workflow subscriptions. You can manage what Automation Orchestrator integrations are used in cloud templates provisioned by your project with soft or hard project constraints. For more information on project constraints, see [Using project tags and custom properties](#).

1. Navigate to **Infrastructure > Administration > Projects** and select your project.
2. Select the **Provisioning** tab.
3. Enter the capability tags of your Automation Orchestrator integrations in the **Extensibility constraints** text box and set them as soft or hard project constraints.
4. Click **Save**.

When you deploy a cloud template, Automation Assembler uses the project constraints to manage what Automation Orchestrator integrations are used in workflow subscriptions.

Alternatively, you can use capability tags to manage multiple Automation Orchestrator integrations on a cloud account level. For more information, see [Managing multiple integrations with cloud account capability tags](#).

Managing multiple Automation Orchestrator integrations with cloud account capability tags

You can use capability tags to manage what Automation Orchestrator integrations are used in workflow subscriptions.

- Verify that you have cloud administrator credentials. See [What are the user roles](#).
- Configure two or more Automation Orchestrator integrations in Automation Assembler. For more information, see [Configure an integration in](#).
- Add capability tags to your Automation Orchestrator integrations. See [Using capability tags in](#).

Automation Assembler supports the integration of multiple Automation Orchestrator servers that can be used in workflow subscriptions. You can manage what Automation Orchestrator integrations are used in workflow subscriptions by adding capability tags to your cloud account.

1. Navigate to **Infrastructure > Connections > Cloud Accounts**.
2. Select your cloud account.
3. Enter the capability tags of the Automation Orchestrator integrations you want to use.
The capability tags are automatically converted into soft constraints. To use hard constraints in managing your integrations, you must use project constraints. For more information, see [Managing multiple integrations with project constraints](#).
4. Click **Save**.

When you deploy a cloud template, Automation Assembler uses the tagging in the associated cloud account to manage what Automation Orchestrator integrations are used in workflow subscriptions.

Data collection for Automation Orchestrator integrations

VMware Aria Automation performs periodic data collection for your Automation Orchestrator integrations.

Data collection events for Automation Orchestrator integrations are triggered every 10 minutes. The data collection gathers data about the workflows included in the library of each Automation Orchestrator integration.

IMPORTANT

Verify that you version up a workflow when you are finished editing it. Changes to non-versioned up workflows are not picked up by the data collector.

You can find information about the last data collection performed on a Automation Orchestrator integration by navigating **Infrastructure > Connections > Integrations** and selecting the specific integration. You can also trigger a manual data collection event by clicking **Start Data Collection**.

For more information on VMware Aria Automation data collection, see [How does data collection work in](#) .

How do I work with Kubernetes in Automation Assembler

Automation Assembler offers several options for configuring, managing and deploying Kubernetes virtual workloads.

The following use cases cover working with Tanzu Kubernetes resources in Automation Assembler.

- You can create a vSphere with Tanzu Kubernetes configuration, which requires only a suitable vCenter cloud account and a cluster plan to access the native vSphere Tanzu Kubernetes capabilities. This use case allows you to leverage a vCenter cloud account to access supervisor namespaces to deploy vSphere Kubernetes-based workloads. You can also integrate external Kubernetes resources in Automation Assembler
- You can integrate VMware Tanzu Kubernetes Grid Integrated Edition (TKGI), formerly PKS. This type of Kubernetes implementation requires a PKS integration in Automation Assembler. It does not require an Automation Assembler cluster plan.
- You can create a Red Hat OpenShift integration with Automation Assembler to configure, manage and deploy Kubernetes resources.

NOTE

Many of the Kubernetes integration capabilities listed in this section including TKG integration and TMC integration will be deprecated and removed from Automation Assembler. All users should plan to stop using this functionality and start leveraging the Cloud Consumption Interface. This change will require the manual migration of existing cloud templates. See [Automating Kubernetes-based workloads in Automation Assembler](#).

Working with vSphere with Tanzu Kubernetes Clusters

vSphere 7.x contains significant enhancements that enable you to work with Kubernetes natively to manage both virtual machines and containers from one interface. Automation Assembler enables users to leverage the vSphere with Tanzu Kubernetes capabilities embedded within vSphere. You can access vSphere with Tanzu Kubernetes functionality via a vCenter cloud account with a vSphere implementation that contains supervisor clusters. This implementation enables you to manage both conventional virtual machines and Kubernetes clusters from vCenter.

For Tanzu Kubernetes supervisor namespaces, users must have access to an applicable vSphere SSO so that they can log in to a provided link to the supervisor namespace details. Then, they can download a customized Kubectl with vSphere authentication so they can use their supervisor namespace.

To use this functionality, you must have a vCenter with vSphere cloud account that has supervisor namespaces configured. After a user has logged in they can begin working with applicable namespaces.

Working with VMware Tanzu Kubernetes Grid Integrated Edition (TKGI) or Openshift Integrations

For TKGI, external clusters, or Openshift configurations, Automation Assembler provides access to a Kubeconfig that enables users to access applicable Kubernetes clusters.

After you create a TKGI or OpenShift integration, applicable Kubernetes clusters become available in Automation Assembler and you can add and create Kubernetes components to Automation Assembler to support management of cluster and container applications. These applications form the basis of self-service deployments that are available from the Service Broker catalog.

Provision a vSphere with Tanzu Kubernetes deployment in VMware Aria Automation

VMware Aria Automation enables you to provision a vSphere with Tanzu Kubernetes deployment from Automation Assembler to leverage the vSphere 7.x or later native capabilities to deploy and manage Tanzu Kubernetes clusters, providing an infrastructure-agnostic layer for provisioning and management of virtual infrastructure.

- To provision a vSphere with Tanzu Kubernetes deployment with Automation Assembler, you must have access to vSphere 7.x or later. In VMware Aria Automation, vSphere is available as part of a vCenter cloud account. See [Create a basic vCenter cloud account in VMware Aria Automation](#).
- Tanzu must be enabled on the vSphere cloud account, and it must contain appropriate supervisor namespaces.
- You must have an appropriate cluster plan to use with the integration. See [Create a cluster plan in for use with a vSphere with Tanzu Kubernetes deployment](#).

The Tanzu with vSphere Kubernetes functionality leverages the native Kubernetes capability of vSphere 7.x. It does not require a VMware Aria Automation PKS integration to function.

1. If a suitable vCenter cloud account does not already exist in Automation Assembler, create one.
See [Create a basic vCenter cloud account in VMware Aria Automation](#).
2. Select **Infrastructure > Configure > Kubernetes Zone** to create or select a Kubernetes zone in Automation Assembler.
You can use an existing Kubernetes zone if you have an appropriate one already configured, but an administrator must add one or more supervisor namespaces to the zone. These namespaces serve as the compute resources on which provisioned Tanzu Kubernetes clusters are created within the zone. See [Configure a Kubernetes Zone in](#) for more information about Kubernetes zones.
3. Navigate to the Kubernetes Provisioning tab on the **Infrastructure > Administration > Projects** page in Automation Assembler and associate the Kubernetes Zone with the appropriate project.
4. Create or select a cluster plan for an appropriate vSphere 7.x cloud account.
See [Create a cluster plan in for use with a vSphere with Tanzu Kubernetes deployment](#) for more information.
5. Select **Design > Templates** and create a cloud template for a project which has access to an appropriate Kubernetes zone. Then, drag a K8s Cluster component on the cloud template scheme and specify its name and cluster plan.
You have the option of also specifying the number of worker nodes.
6. Run the cloud template and then, when it completes, find the address of the provisioned Tanzu cluster on the deployment on the Automation Assembler Deployments page resource properties.
7. Find and explore the Tanzu cluster on the Automation Assembler **Infrastructure > Configure > Kubernetes** page.

The Tanzu Kubernetes cluster is provisioned as specified in the cloud template.

After you deploy the Tanzu cluster, you have several option for working with it.

- Navigate to the **Resources > Deployments** page in Automation Assembler, and locate and download the related Kubeconfig file to access the provisioned Tanzu cluster. You can use the Kubeconfig file to manage the deployed Tanzu Kubernetes cluster as any other compliant Kubernetes cluster.
- You can find and explore the Tanzu cluster on the Automation Assembler**Infrastructure > Resources > Kubernetes** page.
- To create a new namespace, navigate to the Namespaces tab on the Automation Assembler**Infrastructure > Resources > Kubernetes** page and click **New Namespace** to create a namespace on the applicable Tanzu cluster. You can verify that the namespace was created by verifying that it is listed on the Namespaces tab on the Kubernetes page.

Configure a Kubernetes Zone in Automation Assembler

Kubernetes zones enable cloud administrators to define policy-based placement of Kubernetes clusters and namespaces and supervisor namespaces used in Automation Assembler deployments. An administrator can use this page to specify what clusters are available for provisioning of Kubernetes namespaces and what properties are acceptable for clusters.

Configure integration with a suitable VMware Tanzu Kubernetes Grid Integrated Edition (TKGI) deployment. See [configure-tanzu-grid-integrated-edition-tkgi-integration-in-cloud-assembly.dita](#)

Cloud administrators can associate Kubernetes zones with TKGI cloud accounts configured for Automation Assembler or with external Kubernetes clusters that are not associated with a project.

When you create a Kubernetes zone, you can assign multiple provider-specific resources to the zone, and these resources will dictate what properties can be set for the newly provisioned clusters in terms of the number of workers, masters, available CPU, memory, and other configuration settings. For TKGI providers, these correspond to TKGI plans. An administrator can also assign multiple clusters to a Kubernetes zone that will be used for placement of newly provisioned Kubernetes namespaces. The administrator can only assign clusters that are not onboarded, or not managed by CMX, and are provisioned via the preselected cluster provider. The administrator can assign multiple Kubernetes zones to a single project, thus making them all available for placement operations that happen within this project. A cloud administrator can assign priorities on multiple levels.

- Kubernetes zone priority within a project.
- Resource priority within a Kubernetes zone.
- Cluster priority within a Kubernetes zone.

The cloud administrator can also assign tags on multiple levels:

- Capability tags per Kubernetes zone.
- Tags per resource assignment.
- Tags per cluster assignment.

You can create Kubernetes zones with supervisor namespaces on vSphere in the same way that you work with generic Kubernetes namespaces. To add a supervisor namespace to a Kubernetes zone, you must associate the zone with a vSphere 7 endpoint that contains the desired Pacific namespace resources.

Automation Service Broker contains a version of the Kubernetes Zone page to enable Automation Service Broker administrators to access existing Kubernetes zones so they can create placement policies for Kubernetes namespaces and clusters provisioned from the catalog.

1. Select **Infrastructure > Configure > Kubernetes Zone** and click **New Kubernetes Zone**.
2. Enter the TKGI integration **Account** name to which you want this zone to apply.

This defines the cloud account or endpoint that is associated with the zone. You can assign only one endpoint to each zone. If you are working with Supervisor Namespace on vSphere, you can only select vSphere instances here that contain Supervisor namespaces.

3. Add a **Name** and **Description** for the Kubernetes Zone.
4. Add capability tags if appropriate. See [Using capability tags in](#) for more information.

5. Click **Save**.
6. Click the On-demand tab and add TKGI plans as appropriate for the zone to use for cluster provisioning.
You can select one or more plans and assign priorities to them. Lower numbers equal higher priority. Priority assignments are secondary to tag based selection.
7. Click the Cluster tab and then click the **Add Compute** button to add Kubernetes or supervisor clusters to the zone. If you are working with an external cluster, it is automatically onboarded to Automation Assembler when you select it.
You can add Kubernetes namespaces to the cluster on the Kubernetes Clusters page in Automation Assembler.

Kubernetes zones are configured for use with Automation Assembler deployments.

Assign the Kubernetes zone to a project.

1. Select **Infrastructure > Administration > Projects** and then select the project that you want to associate with your Kubernetes zone.
2. Click the Kubernetes Provisioning tab on the Project page.
3. Click **Add Kubernetes Zone** and add the zone that you just created. You can multiple zones if applicable, and you also set the priority on the zones.
4. Click **Save**.

The Kubernetes Provisioning tab of the Automation Assembler Project page enables you to set limits on the type and number of namespaces users can provision to a kubernetes zone. You can also select the type of namespaces that can be provisioned to a zone, either regular namespaces or supervisor namespaces. The Kubernetes Zones table on the Kubernetes Provisioning tab contains columns that show the current limit settings. To set limits, click the applicable zone on the table to open a dialog that enables you to choose namespace and supervisor namespace limits.

Click within the Supports column on the Kubernetes Zones table to select what type of namespace can be provisioned to the zone.

After you assign a Kubernetes zone to a project, you can use the Cloud Templates page under the Automation Assembler Design tab to provision a deployment based on the Kubernetes zone and project configuration. This Cloud Templates page includes options to add a K8S Cluster, K8S Namespace and Supervisor Namespace. Select the appropriate option for the Kubernetes resource you are working with.

Create a cluster plan in VMware Aria Automation Assembler for use with a vSphere with Tanzu Kubernetes deployment

You must create a cluster plan for use with vSphere with Tanzu Kubernetes deployments in VMware Aria Automation. A cluster plan functions as a configuration template for provisioning Tanzu Kubernetes cluster instances on a particular vSphere cloud account instance.

- To create a vSphere with Tanzu Kubernetes deployment in Automation Assembler, you must have access to vSphere 7.x which is available as part of a vCenter cloud account. See [Create a basic vCenter cloud account in VMware Aria Automation](#).
- Tanzu must be enabled on the vSphere cloud account with one or more supervisor namespaces.
- All supervisor clusters on the registered vSphere cloud account that are eligible for provisioning of Tanzu Clusters must be added as managed entities on the Automation Assembler **Infrastructure > Kubernetes > Supervisor Clusters** page using the **Add Supervisor Cluster** option.

A cluster plan defines a configuration mapping, similar to a flavor-mapping, for a set of vSphere cloud account instances. Generally, the cluster plan encodes a meaningful set of configuration properties, such as virtual machine classes, storage classes, and so on, that are used when provisioning Tanzu Kubernetes clusters on a particular vSphere server cloud account.

Note that a single cluster plan might have a particular configuration property mapping in one vSphere cloud account and another configuration mapping in another vSphere instance. For example, if you have two eligible vSphere cloud accounts, one with high resource and another with limited resources, the `large` cluster plan might specify `guaranteed-xlarge` for the high-profile vSphere server and `best-effort-medium` for the limited vSphere instance. In general, the `large` specification maps a different configuration property set to each eligible vSphere server instance. After a cluster plan is created for one or more vSphere instance, all eligible supervisor namespaces, that an administrator assigns to host a Tanzu Kubernetes cluster using a Kubernetes zone assignment, should be aligned with respect to the configuration defined in the cluster plan specification. For example, the storage policy specified in the cluster plan should be added as a storage class to all vSphere supervisor namespaces dedicated for provisioning of Tanzu clusters.

1. In Automation Assembler, select **Infrastructure > Configure > Cluster Plan** and click **New Cluster Plan**.
2. Enter an **Account**, **Name**, and **Description** for the cluster plan. The account defines the cloud account to which this cluster plan applies.
3. Enter cluster information details including **Kubernetes versions** and **Control plane**. This information includes allocations for nodes, machine class and storage class.
 - Enter the version of Kubernetes that is applicable to this cluster plan. This is the Kubernetes version of the provisioned Tanzu Kubernetes clusters: for example, 1.19 or 1.20.
 - The control plane count defines the specification for Kubernetes API server nodes.
 - A virtual machine class is a request for reservations on the virtual machine for processing power. There are numerous predefined machine classes, which represent different levels of compute power. See [Virtual Machine Classes for Tanzu Kubernetes Clusters](#) for more information.
 - Workers specify the Tanzu Kubernetes worker nodes to be deployed with this plan.
4. Enter and select Additional Settings for the cluster plan.
 - Enter the **Default PVC storage class** to use with this cluster.
 - Use the radio buttons to indicate behavior in regards to usage of storage classes and network settings.
5. Click **Create**.

The cluster plan is created and is available for use within Automation Assembler cloud templates.

After you create a cluster plan, you can use it to create a vSphere with Tanzu Kubernetes deployment in Automation Assembler. See [Provision a vSphere with Tanzu Kubernetes deployment in](#) .

Working with Kubernetes clusters and namespaces in Automation Assembler

Cloud administrators can add, view, and manage the configuration of deployed Kubernetes clusters and namespaces, both generic and Pacific-based, in Automation Assembler.

Users with cloud administrator privileges can view, add, and manage Kubernetes clusters and namespaces to which you are entitled access on the **Infrastructure > Resources > Kubernetes** page. This page contains tabs for Clusters, Namespaces, Supervisor Clusters and Supervisor Namespaces. You can select one of these tabs to view and manage the analogous resources. Most typically, this page facilitates management of deployed clusters and namespaces.

- **Cluster:** A cluster is a group of Kubernetes nodes distributed across one or more physical machines. This page shows provisioned and undeployed clusters that have been configured for use on your Automation Assembler instance. You can click on a cluster to view information about its current status. When you deploy a cluster, it includes a link to a Kubconfig file that is accessible only for cloud administrators. This file grants full admin privileges over the cluster including a list of namespaces.
- Supervisor clusters are unique to vSphere instances and use ESXI as their worker nodes instead of Linux.
- **Namespaces:** Namespaces are virtual clusters that provide administrators with a way to group or separate cluster resources. They facilitate management of resources among large groups of users and organizations. As a form of

role-based access control, a cloud administrator can allow users to add namespaces to a project when they request a deployment and then later manage those namespaces from the Kubernetes Clusters page. When you deploy a namespace, it includes a link to a kubeconfig file that allows valid users, such as developers, to view and manage some aspects of that namespace.

Supervisor clusters and supervisor namespaces exist only on vSphere instances and provide Kubernetes-like access to vSphere objects.

A cloud administrator can change the project associated with a Kubernetes namespace or cluster on this page so that the administrator can provision Kubernetes resources from cloud templates and Automation Service Broker and then assign them to specific projects for consumption. The administrator can change the scope of a cluster to make it global or project specific. Global clusters appear Clusters tab for all Kubernetes zones and are available for selection and provisioning. If a cluster is global, it can be added to a Kubernetes zone and then used to provision namespaces from the catalog.

If you are configuring new or existing cluster, you must select whether to connect with a primary IP address or a primary hostname.

Working with generic Kubernetes Clusters in Automation Assembler

You can add new, existing, or external clusters to Automation Assembler using the options on this page.

1. Select **Infrastructure > Resources > Kubernetes** and confirm that the Clusters tab is active.
If there are any clusters currently configured for your Automation Assembler instance, they appear on this page.
2. If you are adding a new or existing cluster, or deploying a cluster, select the appropriate option according to the following table.

Option	Description	Details
Deploy	Add new clusters to Automation Assembler	You must specify the TKGI cloud account that to which this cluster will be deployed as well as the desired plan and the number of nodes.
Add Existing	Configure an existing cluster to work with your project.	You must specify the TKGI cloud account, the cluster to use, and the appropriate project for the targeted developer. Also, you need to specify the sharing scope. If you want to share globally, you must configure your Kubernetes zones and namespaces appropriately.
Add External	Add a vanilla Kubernetes cluster, that might not be associated with TKGI, to Automation Assembler.	You must designate a project to which the cluster is associated, enter the IP address for the desired cluster and select a cloud proxy and certificate information required to connect to this cluster.

3. Click **Add** to make the cluster available within Automation Assembler.

Working with Kubernetes Namespaces in Automation Assembler

If you are a cloud administrator, namespaces help you group and manage Kubernetes cluster resources. If you are a user, namespaces are the area in Kubernetes clusters for your deployments. Administrators and users can access namespaces using the Namespaces tab located on the **Infrastructure > Resources > Kubernetes** page.

There are several ways to add Kubernetes namespaces to resources in Automation Assembler. The following procedure outlines one typical method.

1. Select **Infrastructure > Resources > Kubernetes** and click the Namespaces tab.
2. To add a new namespace, click **New Namespace**. To add an existing namespace click **Add Namespace**.
3. Enter a **Name** and **Description** for the namespace.
At this point you have added a namespace for use with Kubernetes resources, but it is not associated with anything in particular.
4. Specify the **Cluster** that you want to associate with this namespace.
5. Click **Create** to add the namespace to Automation Assembler.

You can add custom properties on Kubernetes namespaces to support extensibility in several different ways. You add custom properties when you provision a namespace by creating an Automation Assembler template. When you specify a Kubernetes namespace in a cloud template you can add properties to the namespace. First, you can right click on the properties in the template to access the default properties that are part of the cloud template schema. As a second option, you can add user-defined properties in the properties section of the namespace in the cloud template.

After deployment, these custom properties appear on the Deployments page in Automation Assembler for the applicable deployment.

Finally, you can also add custom properties to a namespace using actions configured on the **Extensibility > Actions** page in Automation Assembler.

Working with Supervisor clusters and Supervisor namespaces

Cloud administrators can view and change the configuration of supervisor clusters and namespaces on the Kubernetes page in Automation Assembler.

1. Select **Infrastructure > Resources > Kubernetes** in Automation Assembler.
2. Select **Add Supervisor Cluster**.
3. Specify the Account details for the target vSphere cloud account.
4. Click the Search icon in the Supervisor cluster text box to either view all supervisor clusters or search for a cluster by name.
5. Select the desired cluster and click **Add**.
6. Select the Supervisor Namespaces tab and click the **New Supervisor Namespace** button to add a new namespace.
7. Select the Supervisor Namespaces tab and click the **New Supervisor Namespace** button to add a new namespace.
 - a. If you are creating a new namespace, add a **Name** and **Description**.
 - b. Select the appropriate cloud **Account** to associate with the namespace.
 - c. Select the **Supervisor cluster** to associate with this namespace.
 - d. Select the **Project** to associate with the namespace.
 - e. Use the **Available storage policies** selection to add storage policies for use with the namespace.
You can add all available storage policies or select specific policies for use with the supervisor namespace.
Also, you can optionally set a limit on the storage size available with each available storage policy.
 - f. Click **Create**.
8. Review the relevant details for the new namespace. You can change the storage policy configuration if needed.
Users and groups that currently have access to the namespace in vSphere are listed on the Users tab. If new users or groups are added to the project, click the **Update Users** button on this tab to update the list. The list is not updated automatically, so you must use the button to update.

NOTE

Synchronization of users makes sense only if Automation Assembler and vCenter are configured with a common Active Directory/LDAP service.

After a cluster or namespace is configured, the **Infrastructure > Resources > Kubernetes** page in Automation Assembler displays the clusters and namespaces available to the user. You can click an individual namespace or cluster to open a page that contains a number of tabs that show statistics and other information for the resource, and allows you to configure various options.

The Summary tab for clusters on the Kubernetes page allows administrators to view and, in some cases, update configuration of a cluster including changing the scope. The Sharing radio buttons allow you to select either Global (shareable within the Kubernetes Zone) or Project (access limited to a single project). If you select Project, you must also specify the applicable project in the following Project selection.

NOTE

Changing the sharing configuration can affect the namespaces that are available on the cluster.

Users can click the Address link on the Summary tab to open the vSphere Kubernetes CLI Tools to manage the namespace. Users must be a cloud administrator or a member of the namespace for the designated project to access a link to the Supervisor namespace details. Also users can download a customized Kubectl to use the Supervisor namespace. Users can log in to the supervisor namespace and use it as they would any other namespace, and then create cloud templates and deploy applications.

Adding Kubernetes components to cloud templates in Automation Assembler

When adding Kubernetes components to an Automation Assembler cloud template, you can choose to add clusters or enable users to create namespaces in various configurations. Typically, this choice depends on your access control requirements, how you have configured your Kubernetes components, and your deployment requirements.

To add a Kubernetes component to a cloud template in Automation Assembler, select **Design > Templates**, click **New from > Blank canvas**, and then locate and expand the Kubernetes option on the left menu. Then, make the desired selection, either K8S Cluster or K8S Namespace by dragging it to the canvas.

Adding a Kubernetes cluster that is associated with a project to a cloud template is the most straightforward method of making Kubernetes resources available to valid users. You can use tags on clusters to control where they are deployed just as you do with other Automation Assembler resources. You can use tags to select a zone and a VMware Tanzu Kubernetes Grid Integrated Edition (TKGi) plan during the allocation phase of cluster deployment.

Once you add a cluster in this way, it is automatically available to all valid users.

Cloud template examples

The first cloud template example shows a template for a simple Kubernetes deployment that is controlled by tagging. A Kubernetes zone was created with two deployment plans, configured on the New Kubernetes Zone page. In this case, a tag called `placement:tag` was added as a capability on the zone, and it was used to match the analogous constraint on the cloud template. If there were more than one zone configured with the tag, the one with the lowest priority number would be selected.

```
formatVersion: 1
inputs: {}
resources:
  Cluster_provisioned_from_tag:
    type: Cloud.K8S.Cluster
    properties:
      hostname: 109.129.209.125
```

```

constraints:
  -tag: 'placement tag'
  port: 7003
  workers: 1
  connectBy: hostname

```

The second cloud template examples shows how to set up a template with a variable called `$(input.hostname)` so that users can input the desired cluster hostname when requesting a deployment. Tags can also be used to select a zone and a TKGI plan during the resource allocation phase of cluster deployment.

```

formatVersion: 1
inputs:
  hostname:
    type: string
    title: Cluster hostname
resources:
  Cloud_K8S_Cluster_1:
    type: Cloud.K8S.Cluster
    properties:
      hostname: ${input.hostname}
      port: 8443
      connectBy: hostname
      workers: 1

```

If you want to use namespaces to mange cluster usage, you can set up a variable in the cloud template called `name: ${input.name}` to substitute for the namespace name which a user enters when requesting a deployment. For this sort of deployment, you would create a template something like the following example:

```

1 formatVersion: 1
2 inputs:
3   name:
4     type: string
5     title: "Namespace name"
6 resources:
7   Cloud_KBS_Namespace_1:
8     type: Cloud.K8S.Namespace

```

```

9     properties:
10        name: ${input.name}

```

Users can manage deployed clusters via kubeconfig files that are accessible from the **Infrastructure > Resources > Kubernetes** page. Locate the card on the page for the desired cluster and click **Kubeconfig**.

Supervisor Namespaces in VMware Cloud Templates

The following is the schema for a basic Supervisor namespace in an Automation Assembler cloud template.

```

{
  "title": "Supervisor namespace schema",
  "description": "Request schema for provisioning of Supervisor namespace resource",
  "type": "object",
  "properties": {
    "name": {
      "title": "Name",
      "description": "Alphabetic (a-z and 0-9) string with maximum length of 63 characters. The character '-' is allowed anywhere except the first or last position of the identifier.",
      "type": "string",
      "pattern": "^.*\$\{\.\*\}\.*$|^((?!-)[a-zA-Z0-9-]{1,63}(?!-))$",
      "ignoreOnUpdate": true
    },
    "description": {
      "title": "Description",
      "description": "An optional description of this Supervisor namespace.",
      "type": "string",
      "ignoreOnUpdate": true
    },
    "content": {
      "title": "Content",
      "description": "Kubernetes Yaml Content",
      "type": "string",
      "maxLength": 65000
    },
    "constraints": {

```

```

"title": "Constraints",
  "description": "To target the correct resources, blueprint constraints are matched against infrastructure capability tags. Constraints must include the key name. Options include value, negative [!], and hard or soft requirement.",
  "type": "array",
  "recreateOnUpdate": true,
  "items": {
    "type": "object",
    "properties": {
      "tag": {
        "title": "Tag",

```

Cloud templates support the use of limits with supervisor namespaces. Limits enable you to control resource usage for CPUs and memory as well as the maximum number of pods allowed in the namespace by deployed machines.

```

formatVersion: 1
inputs: {}
resources:
    Cloud_SV_Namespace_1:
        type: Cloud.SV.Namespace
        properties:
            name: '${env.deploymentName}'
        limits:
            - cpu_limit: 1000
            cpu_request_default: 800

```

```

memory_limit: 2000
memory_limit_default: 1500
pod_count: 200

```

The following example shows how you could specify a storage policy using tags.

```

formatVersion: 1
inputs: {}
resources:
  Cloud_SV_Namespace_1:
    type: Cloud.SV.Namespace
    properties:
      name: 'ns-with-storage-policy'
      description: 'sample'
    storage:
      - profile:
          limitMb: 1000
        constraints:
          - tag: 'storage:fast'
      - profile:
          constraints:
            - tag: 'storage:cheap'

```

Using arbitrary YAMLs with self-service namespace or cluster VCTs

As part of a cluster or namespace creation, you may want to run additional customizations. For example, you may want to add users (role/role binding) or create a pod security policy, or install agents. By using the YAML content property, you can define customized packages to provision on that cluster/namespace/supervisor namespace.

Each YAML content package associated with the content property must be separated with a triple dash (---). Also the content information must be a multi-line string. Refer to the following YAML example to see how content packages can be configured.

```

formatVersion: 1
inputs: {}
resources:
  Cloud_Tanzu_Cluster_1:

```

```
type: Cloud.Tanzu.Cluster
properties:
  name: ddonchev-tkc
  plan: small
  content: |-  

    apiVersion: rbac.authorization.k8s.io/v1
    kind: ClusterRoleBinding
    metadata:
      name: psp:authenticated-from-yaml
    subjects:
      - apiGroup: rbac.authorization.k8s.io
        kind: Group
        name: system:authenticated
    roleRef:
      apiGroup: rbac.authorization.k8s.io
      kind: ClusterRole
      name: psp:vmware-system-privileged
    ---  

    apiVersion: apiextensions.k8s.io/v1
    kind: CustomResourceDefinition
    metadata:
      # name must match the spec fields below, and be in the form: <plural>.<group>
      name: crontabs.stable.example.com
    spec:
      # group name to use for REST API: /apis/<group>/<version>
      group: stable.example.com
      # list of versions supported by this CustomResourceDefinition
      versions:
        - name: v1
          # Each version can be enabled/disabled by Served flag.
          served: true
          # One and only one version must be marked as the storage version.
```

```

storage: true

schema:

openAPIV3Schema:

  type: object

  properties:

    spec:

      type: object

      properties:

        cronSpec:

          type: string

        image:

          type: string

        replicas:

          type: integer

# either Namespaced or Cluster

scope: Namespaced

names:

  # plural name to be used in the URL: /apis/<group>/<version>/<plural>

  plural: crontabs

  # singular name to be used as an alias on the CLI and for display

  singular: crontab

  # kind is normally the CamelCased singular type. Your resource manifests use
this.

kind: CronTab

# shortNames allow shorter string to match your resource on the CLI

shortNames:

- ct

```

The YAML defined in the `content` property also appears on the Properties tab for the deployment.

Automation Assembler can only create content resources in the scope of the resource being deployed. For example, if you provision a Kubernetes namespace, Automation Assembler cannot create a deployment inside a different namespace. Users have the same rights as if they were using the `kubectl`.

After the virtual machine is provisioned, an installation of the Kubernetes objects inside the `content` property begins. If one of the resources referenced in the YAML `content` property fails to provision, Automation Assembler rolls back and

delete all the previous Kubernetes objects from the resource and the deployment will have a Failed status. The resource is still provisioned and visible. Also, you can still use Day 2 actions, including trying to apply the content again.

You can enhance the `content` property with inputs from the cloud template as shown in the following example.

```
formatVersion: 1
inputs: {}
resources:
  Cloud_SV_Namespace_1:
    type: Cloud.SV.Namespace
    properties:
      name: sv-namespace-with-vm-classes
      vm_classes:
        - name: best-effort-2xlarge
        - name: best-effort-4xlarge
        - name: best-effort-8xlarge
```

In addition, you can provision custom resources such as the `TanzuKubernetesCluster`. This would fail as a day 1 operation, because the supervisor namespace will not contain the required virtual machine classes and storage classes. When the virtual machine classes and storage classes are bound to the supervisor namespace you can create the `TanzuKubernetesCluster` (or another resource) using the day 2 action.

NOTE

You can provision a resource without content, and you will still be able to add Kubernetes objects as YAML with the day 2 action.

The content that appears in the `YAML` property defines what is provisioned on the resource. When you edit this content, the following table shows the possible results:

Action	Result
If you add a Kubernetes object and submit.	The specified object is created on the resource.
If you remove a Kubernetes object and submit.	The specified object is deleted from the resource.
If you modify a Kubernetes object and submit.	The specified object is patched on the resource.

It is important to clarify what actions are considered as a modification to the current object. For example, if you modify the `namespace` field of an object, then a new object is created instead of the old one being patched.

The uniqueness of a resource is defined by the following fields: `apiVersion`, `kind`, `metadata.name`, `metadata.namespace`

Using Automation Assembler extensibility with Kubernetes

Automation Assembler provides a set of event topics that correspond to typical actions related to Kubernetes cluster and namespace deployment. Users can subscribe to these topics as desired, and they will run at the appropriate time. Users receive notification when the event related to the subscribed topic occurs. You can also configure vRO workflows to run based on event notifications.

The following topics are available for subscription on the **Extensibility > Library > Event Topics** page in Automation Assembler. To view these topics, search for Kubernetes in the Event Topics Search text box.

- Kubernetes cluster allocation
- Kubernetes cluster post provision
- Kubernetes cluster post removal
- Kubernetes cluster provision
- Kubernetes cluster removal
- Kubernetes namespace allocation
- Kubernetes namespace post provision
- Kubernetes namespace post removal
- Kubernetes namespace removal
- Kubernetes namespace allocation
- Kubernetes supervisor namespace allocation
- Kubernetes supervisor namespace post provision
- Kubernetes supervisor namespace post removal
- Kubernetes supervisor namespace removal
- Kubernetes supervisor namespace allocation

Click one of the topics to view the schema for that topic which shows all the information that is collected and transmitted. There are namespace topics for both Kubernetes namespaces and supervisor namespaces. You can use any of this schema information to set up various notifications and management and reporting tasks.

You can set up action scripts for CMX-related actions on the **Extensibility > Library > Actions** page. Action scripts can be used for various purposes: for example, to create a DNS record of Kubernetes cluster provisioning. If you are creating a DNS record, you can use the `masternodeips` field from the Kubernetes cluster post provision topic with a REST command in an Action script to create a DNS record.

The Subscriptions page defines the relationship between the event topics and action scripts. You can view and manage these components on the Subscriptions page in Automation Assembler

See the Automation Assembler extensibility documentation at [Extending and automating application life cycles with extensibility](#) for more information.

Automating Kubernetes-based workloads in Automation Assembler

As an Automation Assembler administrator, you can use Automation Assembler to configure, manage and deploy Kubernetes-based workloads using the Cloud Consumption Interface.

After you set up and configure the Cloud Consumption Interface service in VMware Aria Automation, you can drag, drop, and configure the CCI elements in VMware Aria Automation templates to provision Kubernetes-based workloads.

You can then version and release your template to Automation Service Broker, so that users can use the template to deploy CCI resources within a Supervisor Namespace, such as virtual machines that use the VM Service or TKG Clusters that use the Tanzu Kubernetes Grid service.

Cloud Consumption Interface setup and configuration

CCI is available to VMware Aria Automation on-premises users who want to manage and consume all the Kubernetes-based, desired state IaaS APIs that are available in the vSphere platform using a single, unified consumption interface.

With a cloud-intuitive user interface, a Kubernetes command-line kubectl plugin, and APIs, CCI provides multiple ways for enterprises to develop modern applications with increased agility, flexibility, and to develop modern techniques on vSphere while maintaining infrastructure control.

Enabling the Cloud Consumption Interface

Before a user can use CCI to consume vSphere Kubernetes resources, a VMware Aria Automation administrator must configure access to CCI. The following summary describes the main configuration steps. Cross references provide the details for each step.

- Enable one or more Supervisor clusters by configuring applicable Supervisor clusters. See [Configuring and Managing a Supervisor](#).
For information about Supervisor clusters and Namespaces and how they work with vSphere and Tanzu, see [VMware vSphere with Tanzu Documentation](#).
- Configure CCI Supervisor Service Single Sign-On (SSO). See [Setting Up Single Sign-On for CCI](#).
- Set up the CCI command line interface (CLI) by downloading the kubectl plug-in. See [Preparing to use the Command Line Interface to perform CCI tasks](#).
- Add a vCenter Server cloud account in Automation Assembler.
See [Create a basic vCenter cloud account in VMware Aria Automation](#).
- Use the kubectl CCI CLI to set up CCI components so that they are available to project users. See [Setting up the Cloud Consumption Interface infrastructure using kubectl](#).

Setting Up Single Sign-On for CCI

As a VMware Aria Automation administrator, you must configure CCI Supervisor Service Single Sign-On (SSO) authentication before enabling CCI for your users.

CCI single sign-on requires users to use a local Active Directory that has been federated to vCenters and VMware Aria Automation. Federating the Active Directory domain supports maintaining user identity during Supervisor Namespace and IaaS services, UI or command line operations.

Users access CCI services and resources through a dedicated Kubernetes proxy to allow a single sign-on flow that maintains user identity as the proxy accesses the vCenter Kubernetes APIs. The Automation Service Broker user service role and project member role would then include the necessary privileges to access the provisioned Supervisor namespaces as an SSO user.

Before configuring SSO:

- Verify that your infrastructure includes the following:
 - VMware Cloud Foundation (VCF) SDDC Manager 5.1.1 or later
 - vCenter 8.0U2 or later
- Download the following files needed to set up CCI Supervisor Single Sign-On (SSO) on a Supervisor Cluster:
 - Service definition YAML file `cci-supervisor-service.yml` available from <https://tinyurl.com/ycy4b8yw>.
 - Python script: `service_config_from_automation.py` available from <https://tinyurl.com/389xawm3>.

Registering the Consumption Interface Service with Supervisors in vCenter

Consumption Interface Service 1.0.0 is a supervisor service that contains the following components:

- Cloud Consumption Interface SSO Component. Required to support CCI end-to-end SSO communication in Aria Automation.
- Local Consumption Interface Component. UI Interface in the vSphere Client that requires vSphere 8.0 U3 or higher. See <https://vsphere-tmm.github.io/Supervisor-Services/#consumption-interface>.

To install the Consumption Interface service on Supervisors, you must add the Consumption Interface service as a Supervisor Service by uploading its service definition YAML file, then registering the Consumption Interface service on the supervisor as described in the following steps:

1. Log in to the vCenter.
2. Under **Workload Management**, select the **Services** tab.
3. For the vCenter, select the vCenter that is managing the Supervisor Cluster where you are installing the CCI single sign-on service that you are planning to integrate with VMware Aria Automation.
4. On the **Add New Service** tile, click the **Add** button.

Workload Management

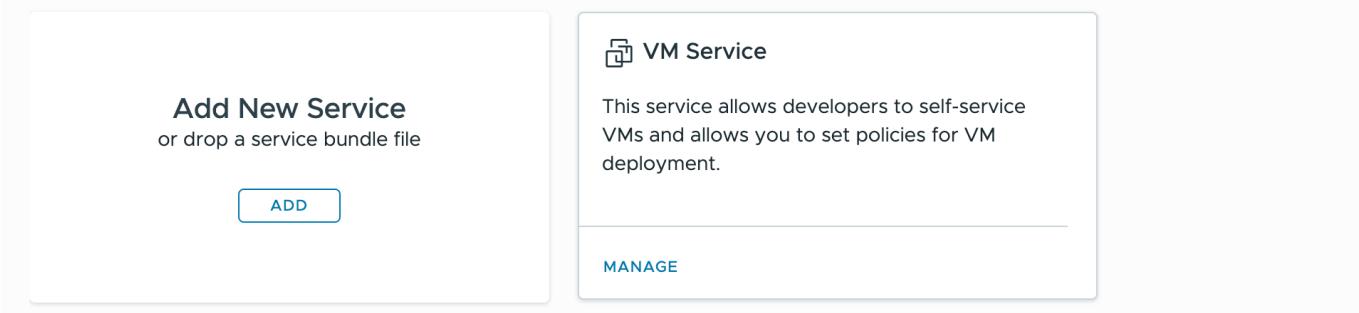

Namespaces Supervisors **Services** Updates

Supervisor Services | SC2-10-186-192-88.ENG.VMWARE.COM ▾

Supervisor Services is a platform for managing core infrastructure components, such as virtual machines. Application teams are able to deploy instances of Supervisor Services within their own Namespaces using industry standard tools and practices. [Discover and download available Supervisor Services here.](#) 

Sort By: Recently added ▾ ↑

Below are the services registered to this vCenter Server system. You can manage services with multiple versions from the same service card.

Add New Service
or drop a service bundle file

ADD

 **VM Service**

This service allows developers to self-service VMs and allows you to set policies for VM deployment.

MANAGE

5. On the Register Service page that appears, click the **Upload** button and specify the YAML file.

6. When the YAML file details appear, verify the Service Details and click **Finish**.

The screenshot shows the 'Register Service' dialog box. On the left, a sidebar says 'New Service' with '1 Register Service'. The main area has a title 'Register Service' with a close button 'X'. It contains two message boxes: an orange one warning about running 3rd party services on user workloads, and a blue one confirming successful YAML upload. Below these is a note to upload a service definition. The 'YAML File details' section shows a file named 'cci-supervisor-service.yml'. The 'Service Details' section lists the following information:

vCenter Server	sc2-10-186-192-88.eng.vmware.com
Service Name	Consumption Interface
Service ID	cci-service.flng.vsphere.vmware.com
Service Description	Provides the Local Consumption Interface (LCI) for Namespaces within vSphere Client. This also includes the Single Sign On (SSO) component required by the Cloud Consumption Interface (CCI) in Aria Automation within VMware Cloud Foundation.
Version	1.0.0

At the bottom right are 'CANCEL' and 'FINISH' buttons.

After a few minutes, a new tile for the Supervisor Service named **Consumption Interface** appears. You can select actions on the tile to edit the service or install the service on supervisors.

The screenshot shows the VMware Aria Automation interface under the Workload Management section. The Services tab is selected. The Supervisor Services page displays a list of registered services. The Consumption Interface service is highlighted with a green banner stating: "Service 'Consumption Interface' is successfully registered. You can now install the service on Supervisors." Below this, there are cards for VM Service, Consumption Interface, Kubernetes Service, and Velero vSphere Operator. The Consumption Interface card shows its status as Active, with 1 active version and 0 supervisors. It also provides a link to "Provides the Local Consumption Interface (LCI) f...".

Installing the Consumption Interface service on Supervisor

You must install the Consumption Interface service on all supervisors that are part of the vCenter cloud accounts that you will add to VMware Aria Automation, which includes every supervisor added to a CCI region. Perform the following steps to install the Consumption Interface service on Supervisors:

1. To extract the idpConfig YAML payload from the VMware Aria Automation appliance, run the `service_config_from_automation.py` Python script against the VMware Aria Automation FQDN. The following code sample shows the command and output from the run.

```
$ service_config_from_automation.py cava-6-001-163.eng.vmware.com
```

```
idpConfig: |
```

```
{"issuer_url": "http://identity-service.prelude.svc.cluster.local:8000", "keyset": {"keys": [{"kty": "RSA", "kid": "231057088464251322", "use": "sig", "n": "wra13Nca99mlsUtf0IeEEB7fsnMGZOiWEgalfySBCon89wM_dwlrxTmvPMFGBMUB83kp0h3e9qhs3Dc7F6UnwaGVN1cg4utZ5UtTG8paa-unWFOD8vSuYIBFonv7M5nCDH_qkURdEGkcc9TCrMSittUU117yL37z395fP5DDzvjjkGifJpAX9e1WopnKLtiAN8NT4K1GkfQu8Pv9GKvNii0732AXVkJujGGq7gpwXY8hVM1QnJ4OYvqrFpiJ5vRTQ608ouPYCj4g6vcV5jk3i5_ShXQORJuIy3MRVkpJGRIZzLYsLqNe5oH7yHm830ERnq97nOy_juo_kuGcliay-8lw", "e": "AQAB"}]}}
```

This YAML serves as input when installing Consumption Interface. Copy and save the output from the script to use later.

2. On the Consumption Interface tile, click **Actions > Manage Service**.

6. To check if the CCI service is running by logging into the vCenter, perform the following steps:

- From the list of namespaces, select the namespace with `svc-cci...domain...` in the name.
- Click the **Compute** tab, and under Core Kubernetes, select **vSphere Pods**.
- Under vSphere Pods, check to see if the CCI service is running.

Name	YAML	Phase
cci-service-5fddc986ff-ntjzq	View YAML	Running

Preparing to use the Command Line Interface to perform CCI tasks

Preparing to use the CLI to perform CCI tasks

The Cloud Consumption Interface includes a command line interface that administrators and developers can use to perform CCI tasks programmatically.

As a VMware Aria Automation administrator, you use the command line interface to create cloud accounts, create and configure projects, regions, and Supervisor namespace classes. Users have some limited access to the CCI kubectl CLI commands.

Download the CCI kubectl plug-in

To use the Kubernetes command line tool (kubectl), download the CCI plug-in. The plug-in provides a way for kubectl to interact with CCI, for example when you log in to CCI.

NOTE

Before downloading the CCI kubectl plug-in, you must have the Kubernetes tool installed. For information about the Kubernetes tool, see <https://kubernetes.io/docs/tasks/tools/>.

To download the CCI kubectl plug-in:

1. Log in to VMware Aria Automation.
2. Click to launch **Service Broker**.
3. If you are a user and the **Overview** page appears, click :**DOWNLOAD CLI PLUGIN**.

The screenshot shows the VMware Aria Automation Service Broker interface. On the left, there's a sidebar with 'Service Broker' and 'CHANGE' buttons, followed by tabs for 'Consume' (which is selected) and 'Inbox'. Below these are sections for 'Overview', 'Projects' (showing all), 'Search projects', 'Catalog', 'Deployments' (with a dropdown menu for 'Deployments', 'Resources', 'Virtual Machines', and 'Volumes'), and a 'View definitions' link. The main content area has a heading 'Getting started with key concepts.' and a list of concepts: Projects, Catalog, Deployments and Applications, Resources, Cloud zones and Kubernetes zones, Governance, Supervisor regions, and Supervisor namespaces. It also includes a link 'How do they all work together?'. To the right, there's a graphic of a person interacting with floating circles, and text about accessing Aria Automation through APIs or CLI, a 'LEARN MORE' link, and a 'DOWNLOAD CLI PLUGIN' button.

4. If you are an administrator or a user who did not download from the **Overview** page, click the **Consume** tab, and click **Supervisor Namespace**.
5. The download method depends on your environment.
 - If you see the **Getting Started with supervisor namespaces** page, click **DOWNLOAD PLUGIN**.

The screenshot shows the 'Supervisor Namespaces' page. On the left, there's a sidebar with a 'Supervisor Namespaces' link. The main area has a 'Download CLI plugin' button and a list of instructions: 'Click "Open" on the card to provision a resource.', 'You can use the familiar syntax of KubeCtl CLI to perform all supervisor namespace tasks.', 'Download & extract our kubectl plugin to your \$PATH.', 'Login using your company SSO credentials by performing kubectl cci login.', and 'Try accessing your resources: kubectl cci get namespace.' Below the list is another 'DOWNLOAD PLUGIN' button.

- If you see the **Supervisor Namespaces** page:

1. Click **New Supervisor Namespace**.
2. On the **Create a namespace** page, click **DOWNLOAD PLUGIN** > **DOWNLOAD CLI PLUGIN** > .

In a Mac, Linux, or Windows environment, you set the `kubectl-cci` plug-in as an executable then copy it to your execution path along with the `kubectl` executable file. For example, in a Mac or Linux environment, use the following command:

```
chmod +x kubectl-cci && mv kubectl-cci /usr/local/bin
```

Log in to CCI

To log in to CCI, choose one of the following methods:

- Log in with your username.

Logging in with your username is the simplest option. The login will prompt you for a password or you can define a variable to store your password, for example:

```
export KUBECTL_CCI_PASSWORD=<User_Password>
```

If a variable for the password is assigned, the CCI login command checks the value and you are not prompted for a password each time you log in with:

```
kubectl cci login -u <your_username> --server appliance.domain.com --insecure-skip-tls-verify
```

- Log in with an API token (optional).

You can also use an API token to authenticate your session. To obtain the API refresh token, perform the following steps:

1. Secure a channel between the web browser and the VMware Aria Automation server. Open a browser and enter the URL such as: `https://appliance.domain.com`.
2. Use the VMware Aria Automation Identity Service API to obtain the API token.

NOTE

The API token is also known as the refresh token. It is valid for 90 days. You cannot revoke the refresh token.

```
curl --insecure --location --request POST \
  'https://<Your_Aria_Automation_FQDN>/csp/gateway/am/api/login?access_token' \
  --header 'Content-Type: application/json' \
  --data-raw '{
    "username": "<Your_Username>",
    "password": "<Your_Password>",
    "domain": "<Your_Domain>" }'
echo
```

3. The output is a compact string of characters as in the following example:

```
{"refresh_token":"ZhZVZnoLEsg7OK4WMef9rUzfsZnWNm6a"}
```

After obtaining your API token, use it to log in to the CCI server.

```
kubectl cci login -t <YOUR_API_Token> --server appliance.domain.com --insecure-skip-tls-verify
```

Create Kubeconfig Context

After you log in to CCI, you set your context to `cci` for management operations such as creating supervisor namespaces, regions, or supervisor namespace classes.

```
kubectl config use-context cci
```

Set your context to `cci:project_name:supervisor_namespace` to interact with a supervisor namespace.

```
kubectl config use-context cci:project_name:supervisor_namespace
```

NOTE

If your CCI login command is configured with the Automation Service Broker admin role, you can choose to use the `--skip-set-context` argument. In this way, you will avoid creating kubeconfig contexts for all existing supervisor namespaces managed by VMware Aria Automation.

The following example shows how to create a kubeconfig context manually for a specific Supervisor Namespace from a specific project.

```
kubectl cci set-context --project cci-explore --supervisor-namespace elastic-sky
```

To view additional information about a command, use `kubectl cci [command] --help`.

Setting up the Cloud Consumption Interface infrastructure using kubectl

Setting up the CCI infrastructure using kubectl

As a VMware Aria Automation cloud administrator, you can use a command line interface to set up Cloud Consumption Interface (CCI) access and configure governance constructs. The command line interface uses the Kubernetes command-line tool, or `kubectl`.

For a complete list of actions that you can perform using the CLI, see [Kubernetes API Reference for the Cloud Consumption Interface](#).

NOTE

You can also use the UI to perform some of the following steps. Links to documentation for the UI are provided with those steps.

Prerequisites

- Verify that a Supervisor Cluster is enabled on a vCenter instance and is registered with VMware Aria Automation.
- Verify that you are at least an organization member in VMware Aria Automation with the Administrator service role for Automation Assembler or Automation Service Broker.
- Verify that you have:
 - Downloaded the CCI `kubectl` plug-in.
 - Obtained an API token for the admin user or defined a variable to store your user password.
 - Used your token with the `-t` option or used your admin credentials with the `-u` option to log in to the CCI server and changed the default context to CCI.
- Verify that you have added a vCenter cloud account in Automation Assembler.
- Verify that the vCenter cloud account name does not include any spaces or upper case letters. For example, `my-vcenter-cloud-account`.

For more information about any of these prerequisites, see [Cloud Consumption Interface setup and configuration](#)

Step 1: Create a project and project role bindings

To group Automation users and set access to infrastructure resources, you create a project and project role bindings.

To create project and project role bindings using the UI, see [How do I add a project for my Automation Assembler development team..](#)

1. Create a project.

```
kubectl create -f project.yaml
```

```
Example project.yaml file.
apiVersion: project.cci.vmware.com/v1alpha1
kind: Project
metadata:
  name: <project_name>
spec:
  description: <description_of_project>
  sharedResources: true
```

2. Create a project role binding to assign roles to users or groups within a created project.

```
kubectl create -f projectrolebinding.yaml
```

The following example projectrolebinding.yaml file adds a user with the admin project role. Project role values are: admin, view, or edit.

```
apiVersion: authorization.cci.vmware.com/v1alpha1
kind: ProjectRoleBinding
metadata:
  name: cci:user:vmware.com:<user_alias>
  namespace: <project_name>
roleRef:
  apiGroup: authorization.cci.vmware.com
  kind: ProjectRole
  name: admin
subjects:
  - kind: User
    name: <username@company.com>
```

Step 2: Create a region

You create a region so that you can assign Supervisors to that region.

```
kubectl create -f region.yaml
```

Example region.yaml file.

```
apiVersion: topology.cci.vmware.com/v1alpha1
kind: Region
metadata:
  name: <region_name>
spec:
```

```
description: <description_of_region>
```

Step 3: Associate a Supervisor with a region

To associate a Supervisor with a region, you find the Supervisor that you want to update then add the region and labels that will be used for namespace placement.

1. To find the Supervisor that you want to update, list the supervisors. Supervisor resources are visible after vCenter data-collection.

```
kubectl -n cci-config get supervisors
```

The following is an example result.

NAME	AGE
demo-self-service:domain-c50	75d
adminannie-vcenter:domain-c8	5d18h
scale-test-vc-01:domain-c8	56d

2. Update the Supervisor named adminannie-vcenter:domain-c8.

```
kubectl -n cci-config edit supervisor adminannie-vc:domain-c8
```

The following example includes `metadata.labels` key-value pairs and regions `spec.regionNames`. The labels `environment: testing` and `fipsMode: strict` can be used to help with supervisor placement decisions.
`apiVersion: infrastructure.cci.vmware.com/v1alpha1`

```
kind: Supervisor
metadata:
  labels:
    environment: testing
  name: adminannie-vc:domain-c8
  namespace: cci-config
  uid: ccd3d154-6404-47b7-8786-bb2d49ad9f5d
spec:
  cloudAccountName: adminannie-vc
  externalId: domain-c8
  externalName: wcp-test-dc-cluster
  regionNames:
    - <region_name>
```

To view a list of Supervisor regions in the Automation Assembler or Automation Service Broker UI, go to:

- **Infrastructure > Configure > Supervisor Regions**
- Or click the **Supervisor Regions** tab for a project located at **Infrastructure > Administration > Projects**

See [Viewing Administrator Constructs](#).

Step 4: Create a region binding and region binding config

You create a region binding and region binding config so that users in a project can create Supervisor Namespaces on Supervisors in a region.

1. Create a region binding.

```
kubectl create -f regionbinding.yaml
```

Example `regionbinding.yaml` file.

```
apiVersion: topology.cci.vmware.com/v1alpha1
kind: RegionBinding
metadata:
  name: <region_name>
  namespace: <project_name>
```

A region binding does not include any Supervisor placement settings, so you must also create a Region Binding Config.

2. Create a Region Binding Config for every region binding created. You can include match expressions that are used for additional filtering of Supervisors. Supervisor labels are used to allow Supervisor Namespace placement on a subset of the Supervisors in a region.

```
kubectl create -f regionbindingconfig.yaml
```

In the following example `regionbindingconfig.yaml` file, any supervisors that match the `testing` environment label can host the Supervisor Namespaces created in that project and region.

```
apiVersion: topology.cci.vmware.com/v1alpha1
kind: RegionBindingConfig
metadata:
  name: <region_name>
  namespace: <project_name>
spec:
  supervisorSelector:
    matchExpressions:
      - key: environment
        operator: In
        values:
          - testing
```

[Step 5: Create a Supervisor Namespace Class and add a Supervisor Namespace Class config](#)

To define namespace templates with optional parameters that can be used to customize the namespace settings during creation, you create a Supervisor Namespace Class. Then you can create a Supervisor Namespace Class Config with match expressions that are used for additional filtering of Supervisors that are used for Supervisor Namespace placement.

To create a Supervisor Namespace Class with a Supervisor Namespace Class config using the UI, see [How do I create and configure namespace classes, namespace class config, and namespaces class binding using the UI](#).

1. Create a Supervisor Namespace Class.

```
kubectl create -f supervisornamespaceclass.yaml
```

In the following example `supervisornamespaceclass.yaml` file, the optional input under parameters reflect Namespace Class parameters that users provide when creating the namespace. All input must have default values.

The values are used to customize the storage classes, limits, and additional constraints. The `name` value must be all lowercase and without spaces.

```
apiVersion: infrastructure.cci.vmware.com/v1alpha1
kind: SupervisorNamespaceClass
metadata:
  name: <class_name>
spec:
  description: supervisor namespace class
  parameters:
    - name: podcountlimit
      type: Integer
      minimum: 100
      maximum: 1000
      default: 500
```

The Supervisor Namespace Class does not contain any Supervisor placement settings, so you must also create a Supervisor Namespace Class Config.

2. Create a Supervisor Namespace Class Config.

```
kubectl create -f supervisornamespaceclassconfig.yaml
```

The YAML is configured with all the supervisor namespace configurations that you want the supervisor namespace to inherit and can include:

- Content libraries that contain the images the VM Service uses when provisioning Virtual Machines.
- Virtual Machine Classes such as T-Shirt Sizes.
- CPU, Memory and Storage enforced Resource Limits.
- Storage Classes to use.
- SupervisorSelector to decide which supervisor to use for supervisor namespace creation.

In the following example `supervisornamespaceclassconfig.yaml` file, the `supervisorSelector` is used to match supervisor labels.

```
apiVersion: infrastructure.cci.vmware.com/v1alpha1
kind: SupervisorNamespaceClassConfig
metadata:
  name: <class_name>
spec:
  storageClasses:
    - name: management-storage-policy-thin
  vmClasses:
    - name: big-vm-class
```

```

- name: small-vm-class

contentSources:
  - name: global-content-library
    type: ContentLibrary

# Below limits are an EXAMPLE! Setting them may cause unexpected behavior in your
namespace

# Either set reasonable limits, or remove the below section to get unlimited
resources

limits:
  - name: pod_count
    limit: "((parameters.podCountLimit))"

supervisorSelector:
  matchExpressions:
    - key: environment
      operator: In
      values:
        - testing

```

Step 6: Associate a Namespace Class with a project

To allow the creation of a Supervisor Namespace using the Supervisor Namespace Class in a project, you create a Supervisor Namespace Class Binding.

To associate a namespace class with a project using the UI, see [How do I create and configure namespace classes, namespace class config, and namespaces class binding using the UI](#).

```
kubectl create -f supervisornamespaceclassbinding.yaml
```

Example supervisornamespaceclassbinding.yaml file.

- **namespace** specifies the name of the project name that you want to associate with the Supervisor Namespace Class.
- **overrideParameters** are optional. They are used to force a parameter value while ignoring the user provided parameter values when the Supervisor Namespace is created. Valid types are Integer, String, or Boolean. The name value must be all lowercase and without spaces.

```

apiVersion: infrastructure.cci.vmware.com/v1alpha1
kind: SupervisorNamespaceClassBinding
metadata:
  name: <class_name>
  namespace: <project_name>
spec:
```

```

overrideParameters:
  - name: podcountlimit
    type: Integer
    const: 1000
  
```

How do I create and configure namespace classes, namespace class config, and namespaces class binding using the UI

As a VMware Aria Automation administrator, you can create, update, or delete Supervisor Namespace Class objects from the **Infrastructure** tab in the UI.

Create a Supervisor Namespace Class with a Supervisor Namespace Class config

Before creating a namespace class, verify that you have created a project and project role bindings. To create project and project role bindings using the UI, see [How do I add a project for my Automation Assembler development team](#).

To create a supervisor namespace class, select **Configure > Supervisor Namespace Classes**, and click **New Class**

1. On the **Summary** tab, enter a name, such as sample-namespace-class. Click **Create**.
2. On the **Parameter** tab, click **New Parameter**. Add parameter values such as:
 - Name: podcountlimit.
 - Type: Integer
 - Default value: 500
 - Minimum: 100
 - Maximum: 1000
 Click **Add**.
3. To add a config, click the **Config** tab. Add configuration values such as:
 - Storage Classes: management-storage-policy-thin.
 - VM Classes: big-vm-class, small-vm-class.
 - Content Libraries: global-content-library.
 - Limits. pod_count with a limit value of 2.
 - Supervisor selector. Match expression with environment select operator in enter the value testing.
4. Click **Create**.

The list of Supervisor Namespace Classes reappears with sample-namespace-class listed.

NOTE

When the supervisor namespace class is created, a default project named **vmware-system-cci** is automatically created and should not be deleted.

Associate a Namespace Class with a project to create a namespace class binding

To associate the supervisor namespace class with a project, select **Administration > Projects**, and open the project that you want to use.

1. Click the **Supervisor Provisioning** tab.
2. Click **Add Namespace Class**
3. Select the namespace class, for example sample-namespace-class.
4. Click **Add**.
5. Click **Save**.

To verify that the Namespace class and project are associated, select **Configure > Supervisor Namespace Classes**. In the list of Supervisor Namespace Classes, the namespace and its associated project appear on the same row.

Edit a Namespace Class

To edit a supervisor namespace class, select **Configure > Supervisor Namespace Classes**, and click the name of the Supervisor Namespace Class that you want to edit.

1. Click the **Parameters** tab or **Configuration** tab to make updates.
2. After making updates, click **Save**.

Delete a Namespace Class

The following procedure shows how to delete a supervisor namespace class with one associated project. If a supervisor namespace class is associated with multiple projects, repeat step 1 to remove it from all associated projects before deleting the supervisor namespace class.

1. Select **Administration > Projects**, and open the associated project.
 - a. Click the **Supervisor Provisioning** tab.
 - b. Select the check box for the namespace class and click **Remove**.
 - c. Click **Save**.
2. Select **Configure > Supervisor Namespace Classes**. In the list of Supervisor Namespace Classes, verify that the namespace appears without an associated project.
3. Select the check box for the Supervisor Namespace Class that you want to remove. Click **Delete** and click to verify the deletion.

How do I onboard vSphere namespaces

How do I onboard vSphere namespaces

As an administrator, you can add a namespace created in the vSphere client into VMware Aria Automation. Then you can open the Supervisor Namespace to manage the resources and services in the namespace.

Add a vSphere namespace

Before you begin:

- Verify you know the name of the vCenter cloud account with the namespace that you want to add.
- Verify the namespace was created using vCenter version 8.0.2 or later.

To add a vSphere namespace, start on the **Infrastructure** tab.

1. Under **Resources**, click **Supervisors**.
2. Click the **Supervisor Namespaces** tab, and click **Add**.
3. On the **Summary** tab, enter the following:
 - Account. Select the vCenter server cloud account where the namespace that you want to onboard is running.
 - Supervisor cluster. Select from the list of discovered clusters.
 - Supervisor namespace. Select the namespace that you want to add.
 - Project. Select the project that you want to associate with the namespace.

After the namespace is added, VMware Aria Automation synchronizes project users and groups permissions with the namespace permissions in vCenter.

 - Toggle on Service Broker access. This enables project users to see and interact with the supervisor namespace. The setting can be changed at any time, but if toggled off, the namespace is not accessible from the **Consume** tab in the Automation Service Broker UI or from the CCI command line.

NOTE

Namespaces created in Automation Service Broker using the **Consume** tab are enabled by default and the setting cannot be changed.

- Click **Add**.

The screenshot shows the 'Add' dialog for creating a new supervisor namespace in the Service Broker interface. The 'Infrastructure' tab is selected. The form fields are as follows:

- Account ***: vc-802
- Supervisor cluster ***: test-vpx-1719508622-24844-wcp.wcp-sanity-cluster
- Supervisor namespace ***: my-vc-created
- Project ***: demo1
- Description**: (empty)
- Service Broker access**: A toggle switch is turned on, with a tooltip: "Allow access for project users from Service Broker and kubectl".
- Available storage policies**: A table showing two policies:

Policy Name	Description	Limit (GB)
VM Encryption Policy	Sample storage policy for VMware's VM and virtual disk encryption	Unlimited
wcpglobal_storage_profile	wcp global profile	Unlimited

 A note at the bottom right of the table says "1 - 2 of 2 storage policies".

At the bottom are 'ADD' and 'CANCEL' buttons.

Managing resources in the vSphere namespace

After you add the vSphere namespace and toggle on Service Broker access, it appears on the **Consume** tab in Automation Service Broker.

The screenshot shows the 'Supervisor Namespaces' page in the Service Broker interface. The 'Consume' tab is selected. The main area displays the following information:

Supervisor Namespaces

- Resources based on supervisor infrastructure are deployed in supervisor namespaces.
- You can also deploy namespaces via the kubectl CLI. ⓘ

A search bar at the top right is labeled "Search supervisor namespaces".

+ NEW SUPERVISOR NAMESPACE X DELETE						
	Name	Status	Namespace Class	Region	Project	Created On
<input type="checkbox"/>	my-cci-created	<input checked="" type="checkbox"/> Active	gold	us-east	demo1	7/1/24, 5:07 PM
<input checked="" type="checkbox"/>	my-vc-created	<input checked="" type="checkbox"/> Active		us-east	demo1	7/1/24, 2:51 PM
<input type="checkbox"/>	ns-rscm	<input checked="" type="checkbox"/> Active	junwei-class3	junwei-region3	demo2	6/28/24, 9:09 AM
<input type="checkbox"/>	svc-tkg-domain-c52	<input checked="" type="checkbox"/> Active			demo2	6/27/24, 3:29 PM

The left sidebar includes sections for Catalog, Deployments (with 'Deployments' expanded), Resources, Virtual Machines, Volumes, Networking & Security, and Supervisor Namespaces (which is currently selected).

When Service Broker access is toggled on for the onboarded vSphere namespace, it is associated with the region of the supervisor that you used to add it. If the project used to onboard the namespace does not have a region binding, the the namespace is listed without an associated region. Unlike supervisor namespaces created in CCI, you cannot delete an onboarded vSphere namespace.

Resources that existed in the vSphere namespace are visible in Automation Service Broker. To create and manage resources within the namespace, select the namespace and click the service that you want to work with.

The screenshot shows the Service Broker interface with the 'my-vc-created' namespace selected. The namespace details are as follows:

- Region:** us-east
- Project:** demo1
- Last updated:** 7/1/2024, 2:51:12 PM

Available storage classes: 1
Available VM classes: 10
Resource limits: N/A

The Services section lists four options:

- Virtual Machine:** Deploy and manage Virtual Machines using Kubernetes APIs. Status: 1 Virtual Machine. Action: OPEN.
- Tanzu Kubernetes Grid:** Deploy and manage fully upstream compliant Kubernetes clusters. Action: OPEN.
- Volume:** Deploy and manage your Kubernetes storage objects. Status: 0 Volumes.
- Network:** Deploy and manage your Kubernetes network services. Status: 0 Network Services.

The left sidebar shows navigation categories: Projects, Catalog, Deployments (selected), Resources, Virtual Machines, Volumes, Networking & Security, and Supervisor Namespaces.

For information about working with services, see:

- [Working with the Virtual Machine service](#)
- [Working with the Tanzu Kubernetes Grid service](#)
- [Working with the Volume service](#)

Viewing Administrator Constructs

As a VMware Aria Automation administrator, you can view information about administrator constructs under the **Infrastructure** tab in Automation Assembler and Automation Service Broker.

[Viewing Supervisor Namespace Classes](#)

To view Supervisor Namespace Classes, navigate to **Infrastructure** > **Configure** > **Supervisor Namespace Classes**.

The screenshot shows the Service Broker interface with the 'Infrastructure' tab selected. A modal window titled 'Supervisor Namespace Classes' is open, containing information about supervisor namespace classes and a table listing existing classes.

Using Supervisor Namespace Classes

- A supervisor namespace class is a template that users can request to get their own namespace on a supervisor.
- Supervisor namespace classes govern the usage limits of resources and access to storage, content libraries, and VM classes.
- A supervisor namespace class should be associated with a project so that the project members can request it.
- To create a supervisor namespace class and associate it with a project, see [Setting up the Cloud Consumption Interface infrastructure using kubectl](#).

Don't show this again

Supervisor Namespace Classes

Name	Projects	Description	Created On
vpaif-ns-class-vpaif	vpaif	Automatically generated via VPAIF quickstart workflow	Mar 1, 2024, 1:07:10 PM
moad-default	moad	MOAD default supervisor namespace class	Feb 24, 2024, 7:50:00 AM

2 supervisor namespace classes

Click on a Namespace Class to view more details about it.

- The Summary shows configuration information for the Namespace Class. This information is derived from SupervisorNamespaceClassConfigs in Kubernetes.
- Click the **Parameters** tab to see the parameters configured on the SupervisorNamespaceClass object in Kubernetes.

[View Supervisor Regions](#)

To list all Supervisor Regions with the name, description, and bound projects for each region., navigate to **Infrastructure > Configure > Supervisor Regions**.

The screenshot shows the Service Broker interface with the Infrastructure tab selected. On the left, a sidebar lists various configuration options under 'Configure' and 'Resources'. The main content area is titled 'Supervisor Regions' and contains a 'Using Supervisor Regions' help box with instructions about creating regions and a 'Don't show this again' checkbox. Below the help box is a search bar and a table listing two supervisor regions:

Name	Description	Projects
private-ai-foundation	Automatically generated via VPAIF quickstart workflow	vpaif
tmm-us-west	The TMM US West region	moad

At the bottom right of the table, it says '2 supervisor regions'.

View Projects

To view Projects, navigate to **Infrastructure > Administration > Projects** and click a project name.

- Badges on the Summary page display the count of all entities that are bound to the project. To list the Supervisor regions or Supervisor namespace classes that are associated with the project, click a badge.
- Click the **Supervisor Provisioning** tab to list all Supervisor regions and Namespace Classes that are bound to the project. Click the name of a Supervisor region to see its region binding configuration.

Using the CCI elements in VMware Aria Automation templates

You can add Cloud Consumption Interface (CCI) elements to use the CCI service within a VMware Aria Automation template so that your users can request Kubernetes-based workloads using the Virtual Machine service and Tanzu Kubernetes Grid service within a supervisor namespace.

To see the CCI elements, expand the **Cloud Consumption Interface** section within the resource library in your cloud template or type `cci` in the **Search resource types** field.

Resource Type	Description
Supervisor Namespace	Create a new Supervisor Namespace, that provides a Kubernetes-based workspace with resource limits, user access, and available Supervisor services, so that users can provision VM and TKG resources based on application needs.
Supervisor Resource	Create any supported Supervisor Kubernetes resource within a Supervisor Namespace, such as virtualmachines, virtualmachineservices, tanzukubernetesclusters, persistentvolumeclaims, secrets, and so on, depending on the Kubernetes manifest passed to the Supervisor resource that is being configured.
TKG Resource	Create any supported Kubernetes resource within a TKG cluster.

The table below shows the three types of CCI resources that are available in the template.

Supervisor Namespace resource CCI.Supervisor.Namespace	Create a new Supervisor Namespace, that provides a Kubernetes-based workspace with resource limits, user access, and available Supervisor services, so that users can provision VM and TKG resources based on application needs.
Supervisor resource CCI.Supervisor.Resource	Create any supported Supervisor Kubernetes resource within a Supervisor Namespace, such as virtualmachines, virtualmachineservices, tanzukubernetesclusters, persistentvolumeclaims, secrets, and so on, depending on the Kubernetes manifest passed to the Supervisor resource that is being configured.
TKG resource CCI.TKG.Resource	Create any supported Kubernetes resource within a TKG cluster.

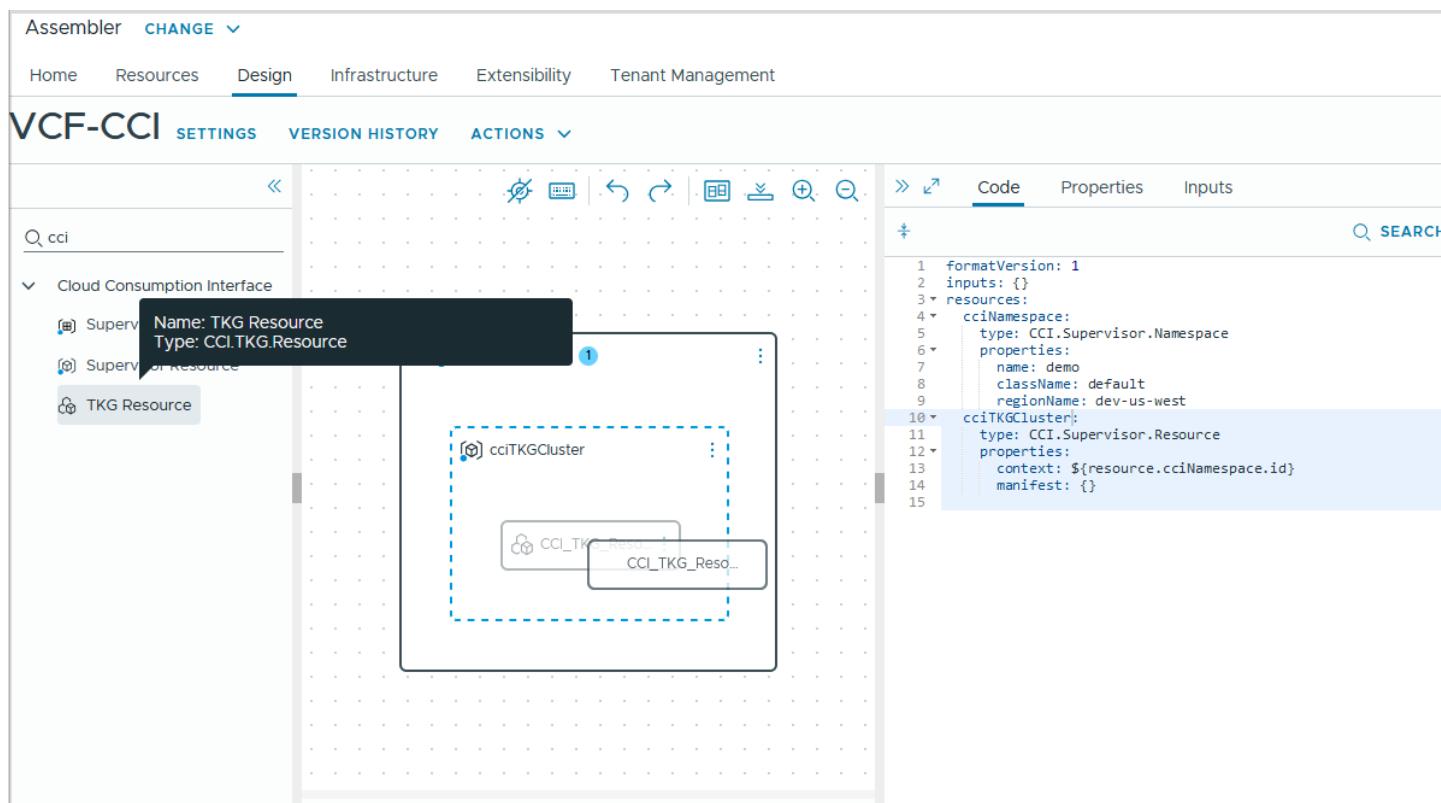

NOTE

Before you can add CCI elements to your cloud template, a VMware Aria Automation administrator must set up CCI first. See [Cloud Consumption Interface setup and configuration](#).

To add elements to your template, you drag and drop them onto the canvas. If your resources have a context driven relationship, you can drop them in a nested configuration with the following rules:

- **CCI.Supervisor.Namespace** Drop directly onto canvas.
- **CCI.Supervisor.Resource** Drop onto a Supervisor Namespace resource or directly on canvas.
- **CCI.TKG.Resource** Drop onto another TKG Resource, a Supervisor Resource, or directly on canvas. CCI resources are limited to five levels of nesting.

In the canvas view below, you see a TKG resource being dragged into a supervisor resource named `cciTKGCluster`. A supervisor namespace that contains a supervisor resource that contains a TKG resource, shows three levels of nesting.

The following examples show how the CCI resources such as `cciNamespace` and `cciTKGCluster` appear in the YAML code of your cloud template. Each example is pruned to show only the important lines.

Supervisor Namespace Resource example

`CCI.Supervisor.Namespace` represents the Supervisor Kubernetes-based workspace where the user-managed vSphere Supervisor IaaS resources for the application are created.

This example defines a CCI supervisor namespace resource named `cciNamespace` to provision a Supervisor Namespace called `demo`.

NOTE

When dragging and dropping a CCI supervisor namespace resource on the canvas, you must enter a value for the `name` property in the YAML code.

To ensure that the namespace is provisioned on a targeted Supervisor, you must configure the Supervisor Namespace with a project-defined `className` and `regionName`.

```
formatVersion: 1
inputs: {}
resources:
  cciNamespace:
    type: CCI.Supervisor.Namespace
    properties:
      name: demo
      className: default
      regionName: dev-us-west
```

Supervisor Resource example

You use `CCI.Supervisor.Resource` to pass the Kubernetes manifest for Kubernetes objects supported to run within a supervisor namespace context.

- To provision the supervisor resource within a particular supervisor namespace, you configure the supervisor resource context property by mapping it to the Supervisor Namespace ID using a template bind expression, for example `context: ${resource.cciNamespace.id}`.
- To specify the objects to provision, you configure the manifest property of the Supervisor Resource by passing the Kubernetes manifest to the Kubernetes object that you are creating.

This example creates a supervisor resource named `cciTKGCluster` in the supervisor namespace `cciNamespace` by providing a Kubernetes manifest for a TKG cluster that specifies the network, topology, control plane size, and worker node count among other settings.

```
formatVersion: 1
inputs: {}
resources:
  cciTKGCluster:
    type: CCI.Supervisor.Resource
    properties:
      context: ${resource.cciNamespace.id}
      manifest:
        apiVersion: cluster.x-k8s.io/v1beta1
        kind: Cluster
        metadata:
          name: ${input.tkg_Name}
```

```
labels:
  tkg-cluster-selector: ${input.tkg_Name}
spec:
  clusterNetwork:
    cni:
      name: antrea
    pods:
      cidrBlocks:
        - 192.168.156.0/20
    services:
      cidrBlocks:
        - 10.96.0.0/12
    serviceDomain: cluster.local
  topology:
    class: tanzukubernetescluster
    version: v1.24.9---vmware.1-tkg.4
    variables:
      - name: storageClasses
        value:
          - tmm-kubernetes-storage-policy
      - name: defaultStorageClass
        value: tmm-kubernetes-storage-policy
      - name: vmClass
        value: ${input.controlPlaneVmClassName}
      - name: storageClass
        value: tmm-kubernetes-storage-policy
  controlPlane:
    replicas: ${input.controlPlaneCount}
    metadata:
      annotations:
        run.tanzu.vmware.com/resolve-os-image: os-name=photon
  workers:
```

```

machineDeployments:
  - class: node-pool
    name: ${input.tkg_Name}-nodepool
    replicas: ${input.workerCount}
    metadata:
      annotations:
        run.tanzu.vmware.com/resolve-os-image: os-name=photon
    variables:
      overrides:
        - name: vmClass
          value: ${input.workerVmClassName}

```

This example defines a supervisor resource named `vm` in the supervisor namespace `cciNamespace` by providing a Kubernetes manifest that defines the VM configuration and includes a wait based condition.

```

formatVersion: 1

inputs: {}

resources:
  vm:
    type: CCI.Supervisor.Resource
    properties:
      context: ${resource.cciNamespace.id}
    manifest:
      apiVersion: vmoperator.vmware.com/v1alpha1
      kind: VirtualMachine
      metadata:
        finalizers:
          - virtualmachine.vmoperator.vmware.com
      generation: 1
      labels:
        vm-selector: vm-2rfx
      name: vm-2rfx
    spec:
      className: best-effort-xsmall

```

```

imageName: vmi-c3d184be88e1af1cd

suspendMode: hard

wait:

conditions:
  - type: VirtualMachinePrereqReady
    status: "False"
    reason: VirtualMachineImageNotReady
    indicatesFailure: true

```

On the canvas, the supervisor namespace `cciNamespace` contains two supervisor resources `cciTKGCluster` and `vm`.

TKG Resource example

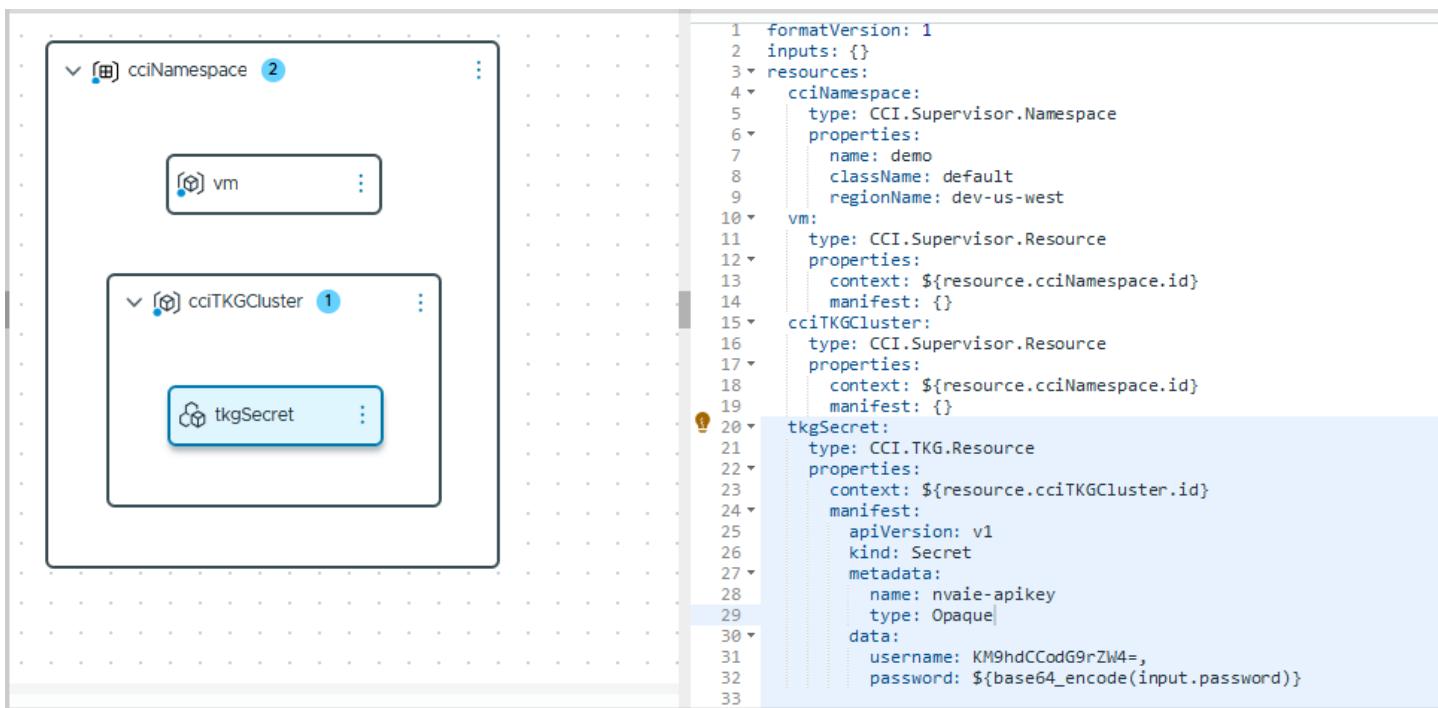

You use `CCI.TKG.Resource` to create supported Kubernetes resources within a TKG cluster or within a namespace running on the TKG cluster.

- To bind a TKG resource to a TKG cluster, you map the ID of the supervisor TKG Cluster resource with the context property, for example `context: ${resource.cciTKGCluster.id}`.
- If you are creating a namespace within a TKG resource named `cciTkgNamespace` for example, you can bind a TKG resource to the namespace by inserting the name of the TKG resource in the context property or `context: ${resource.cciTKGNamespace.id}`.
- The Kubernetes manifest that is passed within the resource properties specifies the type of the Kubernetes object to provision.

This example shows a secret as a TKG resource bound to a TKG cluster named `cciTkgCluster`.

```
...
tkgSecret:
  type: CCI.TKG.Resource
  properties:
    context: ${resource.cciTKGCluster.id}
  manifest:
    apiVersion: v1
    kind: Secret
    metadata:
      name: nvaie-apikey
    type: Opaque
    data:
      username: KM9hdCCodG9rZW4=
      password: ${base64_encode(input.password)}
...
...
```

On the canvas, the TKG resource `tkgSecret` appears nested within the TKG resource `cciTkgCluster`.

Adding a wait property

Both the supervisor resource and the TKG resource support a wait property that will wait for specific conditions or field values within a resource, before considering the resource creation to be completed. Wait property types are:

- Field Wait: List of fields where each field can be configured with a property path and a value. The value must be matched before the resource is considered completed.
- Condition Wait: List of conditions that indicate success or failure of resource creation.

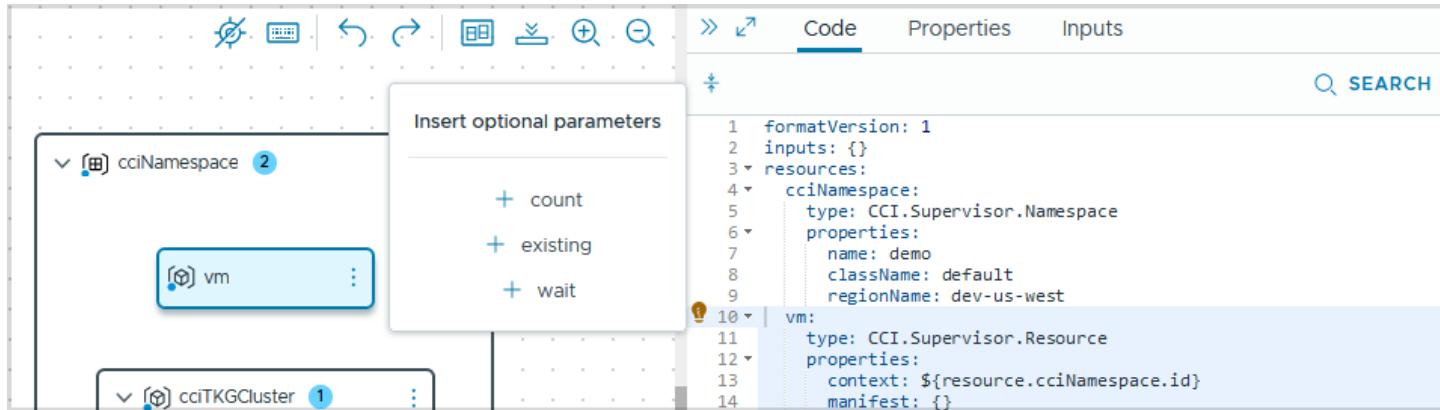

This example shows a wait condition added to a supervisor resource. The condition must be met before the supervisor resource can be flagged as completed.

```

...
wait:
  conditions:
    - type: VirtualMachinePrereqReady
      status: "False"
      reason: VirtualMachineImageNotReady
      indicatesFailure: true
...

```

To add optional parameters using the UI, click the lightbulb next to the resource name in the Code panel.

What Is configuration management in Automation Assembler

Automation Assembler supports integration with Puppet Enterprise, Ansible Open Source, and Ansible Tower so that you can manage deployments for configuration and drift.

Puppet Integration

To integrate Puppet-based configuration management, you must have a valid instance of Puppet Enterprise installed on a public or private cloud with a vSphere workload. You must establish a connection between this external system and your Automation Assembler instance. Then you can make Puppet configuration management available to Automation Assembler by adding it to appropriate blueprints.

The Automation Assembler blueprint service Puppet provider installs, configures, and runs the Puppet agent on a deployed compute resource. The Puppet provider supports both SSH and WinRM connections with the following prerequisites:

- SSH connections:
 - The user name must be either a super user or a user with sudo permissions to run commands with **NOPASSWD**.
 - Deactivate **requiretty** for the given user.
 - cURL must be available on the deployment compute resource.
- WinRM connections:
 - PowerShell 2.0 must be available on the deployment compute resource.
 - Configure the Windows template as described in the VMware Aria Automation Orchestrator documentation.

The DevOps administrator is responsible for managing the connections to a Puppet master and for applying Puppets roles, or configuration rules, to specific deployments. Following deployment, virtual machines configured to support configuration management are registered with the designated Puppet Master.

When virtual machines are deployed, users can add or delete a Puppet Master as an external system or update projects assigned to the Puppet Master. Finally, appropriate users can de-register deployed virtual machines from the Puppet Master when the machines are decommissioned.

Ansible Open Source Integration

When setting up an Ansible integration, install Ansible Open Source in accordance with the Ansible installation instructions. See the Ansible documentation for more information about installation.

Ansible enables host key checking by default. If a host is reinstalled with a different key in the `known_hosts` file, an error message appear. If a host is not listed in the `known_hosts` file, you must supply the key on start-up. You can deactivate host key checking with the following setting in the `/etc/ansible/ansible.cfg` or `~/.ansible.cfg` file:

```
[defaults]
host_key_checking = False
localhost_warning = False

[paramiko_connection]
record_host_keys = False

[ssh_connection]
#ssh_args = -C -o ControlMaster=auto -o ControlPersist=60s
ssh_args = -o UserKnownHostsFile=/dev/null
```

To avoid the host key checking errors, set `host_key_checking` and `record_host_keys` to `False` including adding an extra option `UserKnownHostsFile=/dev/null` set in `ssh_args`. In addition, if the inventory is empty initially, Ansible warns that the host list is empty. This causes the playbook syntax check to fail.

Ansible vault enables you to store sensitive information, such as passwords or keys, in encrypted files rather than as plain text. Vault is encrypted with a password. In Automation Assembler, Ansible uses Vault to encrypt data such as ssh passwords for host machines. It assumes that the path to the Vault password has been set.

You can modify the `ansible.cfg` file to specify the location of the password file using the following format.

```
vault_password_file = /path/to/file.txt
```

You can also set the `ANSIBLE_VAULT_PASSWORD_FILE` environment variable so that Ansible automatically searches for the password. For example, `ANSIBLE_VAULT_PASSWORD_FILE=~/vault_pass.txt`

Automation Assembler manages the Ansible inventory file, so you must ensure that the Automation Assembler user has `rwx` access on the inventory file.

```
cat ~/var/tmp/vmware/provider/user_defined_script/$(ls -t ~/var/tmp/vmware/provider/user_defined_script/ | head -1)/log.txt
```

If you want to use a non-root user with Automation Assembler open-source integration, the users require a set of permissions to run the commands used by the Automation Assembler open-source provider. The following commands must be set in the user's sudoers file.

```
Defaults:myuser !requiretty
```

If the user is not part of an admin group that has no askpass application specified, set the following command in the user's sudoers file.

```
myuser ALL=(ALL) NOPASSWD: ALL
```

If you encounter errors or other problems when setting up Ansible integration, refer to the `log.txt` file at '`cat~/var/tmp/vmware/provider/user_defined_script/$(ls -t ~/var/tmp/vmware/provider/user_defined_script/ | head -1)/'` on the Ansible Control Machine.

Ansible Tower Integration

Supported Operating System Types

- Red Hat Enterprise Linux 8.0 or later 64-bit (x86), supports only Ansible Tower 3.5 and greater.
- Red Hat Enterprise Linux 7.4 or later 64-bit (x86).

- CentOS 7.4 or later 64-bit (x86).

The following is a sample inventory file, which is generated during an Ansible Tower installation. You may need to modify it for Automation Assembler integration uses.

```
[root@cava-env8-dev-001359 ansible-tower-setup-bundle-3.5.2-1.el8]# pwd
```

```
/root/ansible-tower-install/ansible-tower-setup-bundle-3.5.2-1.el8
```

```
[root@cava-env8-dev-001359 ansible-tower-setup-bundle-3.5.2-1.el8]# cat inventory
```

```
[tower]
```

```
localhost ansible_connection=local
```

```
[database]
```

```
[all:vars]
```

```
admin_password='Vmware1!'
```

```
pg_host=''
```

```
pg_port=''
```

```
pg_database='awx'

pg_username='awx'

pg_password='VMware1!'

rabbitmq_port=5672

rabbitmq_vhost=tower

rabbitmq_username=tower

rabbitmq_password='VMware1!'

rabbitmq_cookie=cookiemonster

# Needs to be true for fqdns and ip addresses

rabbitmq_use_long_name=false

# Isolated Tower nodes automatically generate an RSA key for authentication;
```

```
# To deactivate this behavior, set this value to false

# isolated_key_generation=true
```

Integrating with vRealize Operations Manager

Advanced workload placement using VMware Aria Operations

VMware Aria Automation and VMware Aria Operations can work together to optimally place deployment workloads.

You enable workload placement at the vSphere based cloud zone level. Only Distributed Resource Scheduler (DRS) enabled clusters of a cloud zone are eligible for advanced placement using VMware Aria Operations.

- VMware Aria Automation placement—The VMware Aria Automation placement engine is application intent based. It considers tag-based constraints, project membership and the associated cloud zones, and affinity filters related to network, storage, and compute. Resource placement depends on all of these factors plus the presence of other, related target resources in the same deployment.
- VMware Aria Operations placement—VMware Aria Operations considers operational intent for optimal placement. Operational intent can take past workloads and future, what-if predictions into account.

When using advanced workload placement, you must apply VMware Aria Automation tagging in order to implement business intent decisions, instead of using the VMware Aria Operations business intent options.

When integrating with VMware Aria Operations, VMware Aria Automation continues to follow its application intent model and its related constraints to filter for target placement. Then, from within those results, it uses the VMware Aria Operations recommendation to further refine placement.

In the absence of a recommendation

If you enable advanced workload placement, and VMware Aria Operations analysis returns no recommendations, you may configure VMware Aria Automation to fall back to its default, application intent placement.

Limitations on workload placement

Certain limitations apply when using VMware Aria Operations to place workloads.

- VMware Aria Operations does not support workload placement on resource pools in vCenter Server.
- If VMware Aria Operations is down, the timeout used for workload placement to call VMware Aria Operations might expire.
- Placement doesn't cross multiple cloud zones. VMware Aria Automation sends one cloud zone to VMware Aria Operations for placement recommendations within that single cloud zone.

How to enable workload placement

To enable workload placement, there are steps to take for vSphere, VMware Aria Operations, and VMware Aria Automation.

1. In Automation Assembler, connect to your vCenter cloud account.
The options are under **Infrastructure > Connections > Cloud Accounts**.
2. In vCenter, verify that DRS enabled clusters exist and are set to fully automated.
3. In VMware Aria Operations, verify that the same vCenter is being managed.
You need VMware Aria Operations 8 or later.
4. In Automation Assembler, add the VMware Aria Operations integration.
The options are under **Infrastructure > Connections > Integrations**.

To add the integration, you need the VMware Aria Operations primary node URL below, plus the login username and password.

`https://operations-manager-IP-address-or-FQDN/suite-api`

After entering the values, click VALIDATE.

5. Synchronize the integration to the vCenter by clicking SYNC.
Also synchronize any time that Automation Assembler and VMware Aria Operations begin managing a new vCenter.
6. In Automation Assembler, create a cloud zone for the vCenter account.
The options are under **Infrastructure > Configure > Cloud Zones**.
7. Under the cloud zone Summary tab, set the Placement Policy to ADVANCED.
8. Under the Placement Policy, select whether to have VMware Aria Automation fall back to its default placement if VMware Aria Operations returns no recommendations.

Troubleshooting workload placement

If VMware Aria Operations isn't recommending workload placements the way that you expect, review the deployment request details in Automation Assembler or VMware Aria Automation Service Broker.

1. Go to **Infrastructure > Activity > Requests**, and click the request.
2. In Request Details, look at the allocation phases.
Look for targets that were successfully or unsuccessfully identified.
3. In Request Details, at the upper right, enable Dev Mode.
4. Follow the request path to locate filter blocks.
5. Click a filter block, and review the following section.

```
filterName: ComputePlacementPolicyAffinityHostFilter
  ✓ computeLinksBefore
  ✓ computeLinksAfter
  ✓ filteredOutHostsReasons
```

Entry	Description
computeLinksBefore	List of potential placement hosts based on VMware Aria Automation algorithms.
computeLinksAfter	Selected placement host.
filteredOutHostsReasons	<p>Messages describing why a host was selected or rejected. When VMware Aria Operations selects the host, the following message appears.</p> <p>advance policy filter: Filtered hosts based on recommendation from vROPS.</p>

Learn more about workload placement

To find the best infrastructure on which to place a deployment, VMware Aria Automation makes several filtering decisions. VMware Aria Automation integration with VMware Aria Operations may further refine the placement decision.

VMware Aria Operations can help to optimally place workloads provided that you have enabled the Advanced placement policy option in your vSphere based cloud zones.

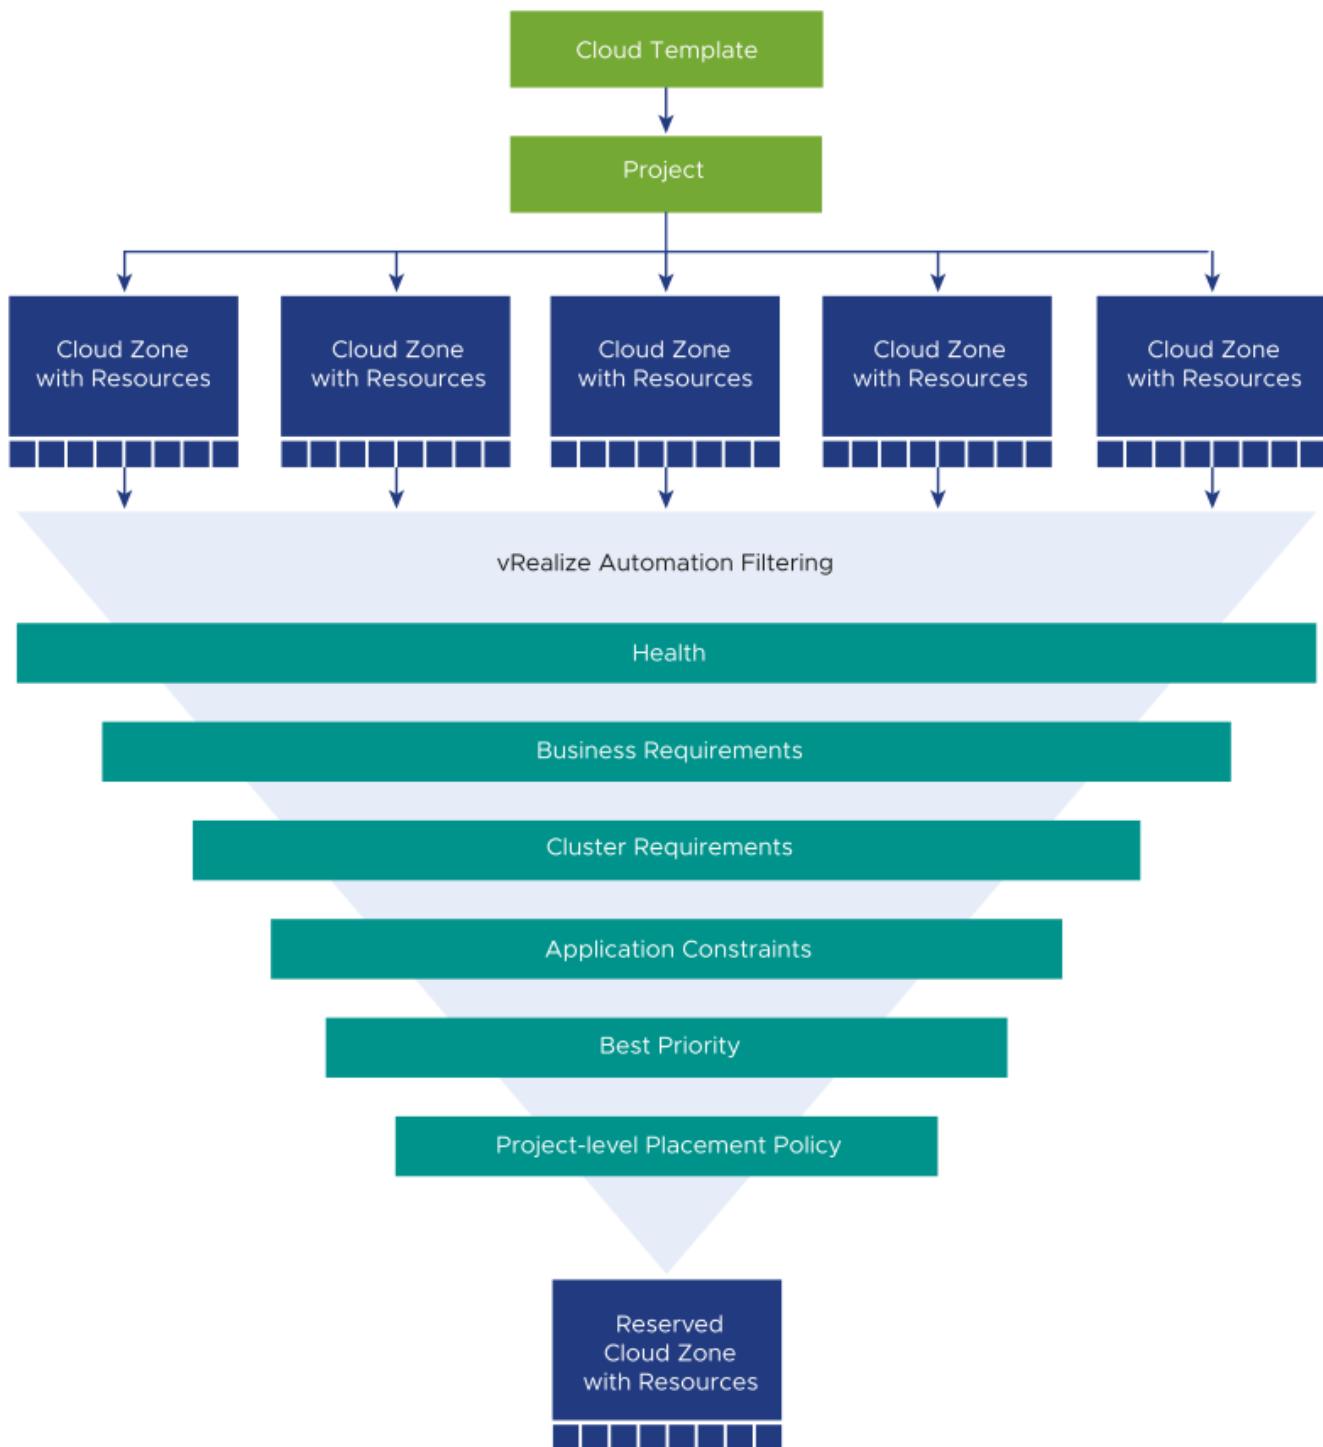

In addition, the vSphere cloud accounts for the cloud zones must be monitored by VMware Aria Operations.

Phase 1: Reservation

NOTE

Although the name is the same, reservation isn't related to the vRealize Automation 7 reservation feature.

The VMware Aria Automation reservation phase is the same whether or not you enable Advanced placement with VMware Aria Operations.

1. Reservation starts with a cloud template linked to a project. That project is in turn linked to cloud zones.
2. The cloud zones consist of compute resource hosts, pools, and clusters, and attached storage.
Initially, any cloud zone in the project may be a potential placement target.
3. VMware Aria Automation filters out cloud zones that don't have enough healthy resources for the deployment.
For example, if too many resources are powered off or in maintenance, that cloud zone is filtered out.
4. VMware Aria Automation filters out cloud zones that can't meet business requirements.
For example, the deployment might exceed a pricing or budget limit for the zone.

5. VMware Aria Automation filters out cloud zones that can't meet cluster requirements.
For example, the cloud zone resources might have CPU or memory usage limits that are too low for the deployment.
6. VMware Aria Automation filters out cloud zones that have no affinity with application constraints.
Affinity requires that cloud template or project-level constraint tags match capability tags found somewhere in the cloud zone resources.

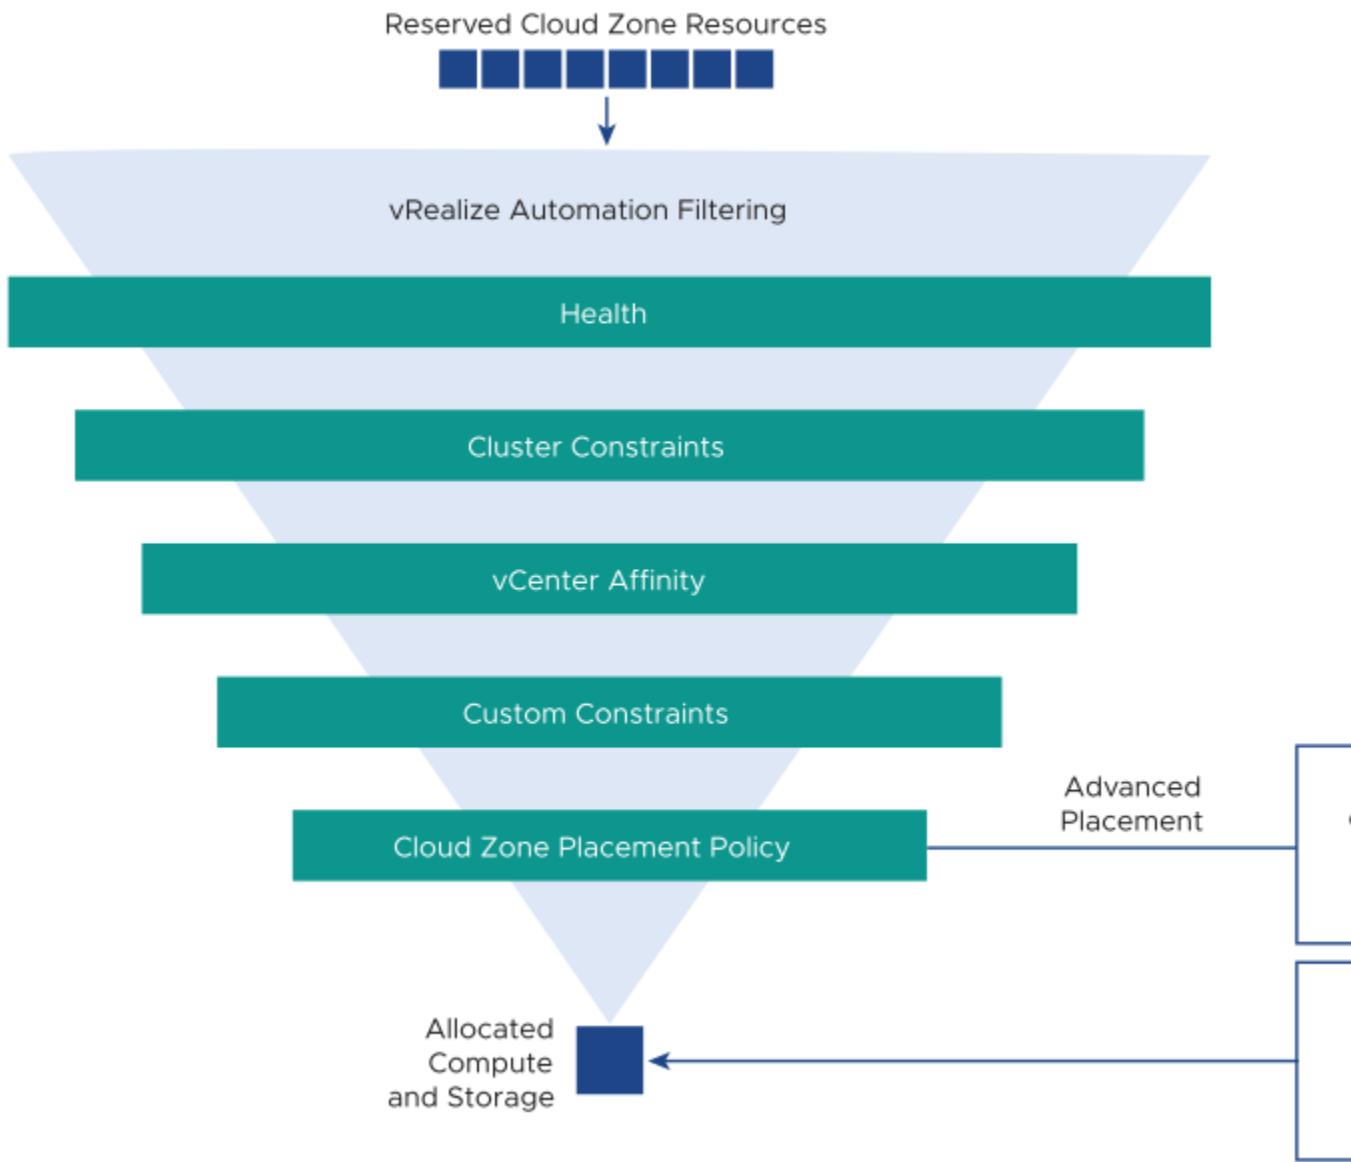

For example, if the cloud template or project includes a storage constraint to use storage tagged `pci`, a cloud zone where none of the storage resources have that capability tag would be filtered out.
7. VMware Aria Automation selects cloud zones with the best provisioning priority.
8. If the project-level placement policy is something other than Default, VMware Aria Automation selects a cloud zone that supports the non-default placement policy.
In this release, Spread is the only non-default. Spread distributes the load by selecting the cloud zone with the lower ratio of virtual machines to hosts. Default simply deploys to the first available zone.

The project placement policy is only a factor during the cloud zone reservation phase. It has no effect on, nor relation to, the cloud zone placement policy in the allocation phase.

When finished, the reservation phase selects one cloud zone and its resources. VMware Aria Automation reserves the first available zone that remains qualified after passing the preceding filters.

Phase 2: Allocation

VMware Aria Automation inspects the reserved cloud zone compute resources and linked storage.

1. Within the cloud zone, VMware Aria Automation filters out resources that are in a maintenance or powered-off state. Note that there are still enough healthy resources for the deployment. Otherwise, the entire cloud zone would have been filtered out during the reservation phase.
2. VMware Aria Automation filters out resources that don't match cluster-level constraints found in the cloud template or project.
For example, a resource in the cloud zone might be tagged `test` under **Infrastructure > Resources > Compute**.

If the cloud template or project includes a constraint tag to use a `dev` resource, the `test` resource is filtered out.

In addition, storage or network profiles in the cloud zone might be tagged in ways that don't match cluster-level storage or network constraints in the cloud template or project.

3. VMware Aria Automation filters out resources based on affinity settings that are defined in vCenter.
For example, there might be a rule in vCenter where the presence of a virtual machine in one cluster might block another cluster from being used.

4. VMware Aria Automation filters out resources that don't match any remaining custom constraints found in the cloud template or project.

For example, if the cloud template includes a constraint to use a `ubuntu` tagged image, a cloud zone where none of the image mappings are tagged `ubuntu` would be filtered out.

5. VMware Aria Automation looks for the best possible compute and storage according to the cloud zone placement policy.

VMware Aria Automation engages VMware Aria Operations only when the following two conditions are true:

- The cloud zone placement policy is set to Advanced.
- After filtering through step 4, at least one DRS enabled cluster and the storage linked to it remain qualified.

Otherwise, VMware Aria Automation proceeds with its own placement algorithm without input from VMware Aria Operations.

VMware Aria Operations placement recommendation

If qualified for input from VMware Aria Operations, VMware Aria Automation contacts VMware Aria Operations for a recommendation of the best possible compute and storage for the deployment. VMware Aria Automation sends the following data to VMware Aria Operations:

- The qualified target DRS enabled clusters and their attached datastores or datastore cluster
- The resource count or cluster size of the deployment
- CPU and memory requirements for the virtual machines in the deployment
- Disk requirements for the virtual machines in the deployment

From the qualified targets, if VMware Aria Operations can return an optimal placement for each of the virtual machines, VMware Aria Automation allocates compute and storage according to the VMware Aria Operations recommendation.

For more about how VMware Aria Operations handles workloads, see the [vRealize Operations documentation](#).

If VMware Aria Operations couldn't find a recommendation, or VMware Aria Automation couldn't find any DRS enabled cluster and storage, VMware Aria Automation checks the fallback setting of the cloud zone:

- With Fallback
VMware Aria Automation allocates compute and storage that remains qualified even without a VMware Aria Operations recommendation.
- Without Fallback
VMware Aria Automation cancels the request and does not proceed with provisioning.

Phase 3: Provisioning

VMware Aria Automation deploys the requested virtual machines, storage, and network through the adapter for the placement target selected at the end of the allocation phase.

The placement target consists of compute hosts, clusters, or resource pools, and attached storage datastore or datastore cluster.

Continuous optimization using VMware Aria Operations

When you add the VMware Aria Automation adapter in VMware Aria Operations, VMware Aria Operations automatically creates a new custom datacenter (CDC) for VMware Aria Automation based workloads.

With continuous optimization, you take advantage of workload rebalancing and relocation, and use VMware Aria Automation with VMware Aria Operations beyond initial workload placement. As virtualization resources move or come under heavier or lighter load, VMware Aria Automation provisioned workloads can move as needed.

- Continuous optimization automatically creates a new CDC in VMware Aria Operations.
There is one new CDC for each VMware Aria Automation vSphere cloud zone.
- The newly created CDC contains every VMware Aria Automation managed cluster associated with the cloud zone.

NOTE

Do not manually create a mixed CDC of VMware Aria Automation and non- VMware Aria Automation clusters.

- You use VMware Aria Operations to run continuous optimization for the newly created VMware Aria Automation based CDC.
 - Workloads can only be rebalanced or relocated within the same cloud zone or CDC.
 - Optimization never creates a new VMware Aria Automation or VMware Aria Operations placement violation.
 - If you have existing placement violations, optimization can fix VMware Aria Operations operational intent issues.
 - If you have existing placement violations, optimization cannot fix VMware Aria Operations business intent issues.

For example, if you used VMware Aria Operations to manually move a virtual machine to a cluster that doesn't support your constraints, VMware Aria Operations doesn't detect a violation nor try to resolve it.
 - This release obeys operational intent at the CDC level. All member VMware Aria Automation clusters are optimized to the same settings.
- To set a different operational intent for clusters, you must configure them in separate VMware Aria Automation CDCs, associated with separate vSphere cloud zones. Having different test and production clusters might be one example situation.
- VMware Aria Automation application intent and the constraints defined in VMware Aria Automation are honored during any optimization rebalance or relocation operations.
 - VMware Aria Operations placement tags cannot be applied to VMware Aria Automation provisioned workloads.

In addition, scheduled optimization involving multiple machines is supported. Regularly scheduled optimizations are not all-or-nothing processes. If conditions interrupt machine movement, successfully relocated machines stay relocated, and the next VMware Aria Operations cycle attempts to relocate the remainder as is usual for VMware Aria Operations. Such a partially completed optimization causes no negative effect in VMware Aria Automation.

How to enable continuous optimization

When you add the VMware Aria Automation adapter in VMware Aria Operations, VMware Aria Operations automatically creates a new, dedicated datacenter for VMware Aria Automation based workloads.

Other than adding the integration within Automation Assembler, there are no separate installation steps for continuous optimization. You may begin configuring and using VMware Aria Operations for workload relocation in the new datacenter. See the [Continuous optimization example](#).

Continuous optimization example

The following example shows a rebalancing workflow for VMware Aria Automation continuous optimization with VMware Aria Operations.

1. From the VMware Aria Operations home page, click **Workload Optimization**.
2. Select the automatically created VMware Aria Automation datacenter.
3. Under **Operational Intent**, click **Edit**, and select **Balance**.

You cannot select or edit Business Intent, which is disabled when the datacenter is for VMware Aria Automation optimization.

10.160.148.47-Custom DataCenter

Optimization Status History

Optimization Recommendation

Status: Not Optimized

You can optimize your datacenter by moving workloads to avoid performance issues.

OPTIMIZE NOW SCHEDULE AUTOMATE

Operational Intent

Utilization Objective: Balance

✓ Avoid Performance Issues
✓ Balance Workloads

EDIT

4. Under **Optimization Recommendation**, click **Optimize Now**.
VMware Aria Operations displays a before-and-after diagram of the proposed operation.
5. Click **Next**.
6. Click **Begin Action**.
7. In VMware Aria Automation, monitor the operation in progress by clicking **Resources > Deployments** and looking at event status.

Tasks	Component	Status	Depends On
Submitted	Deployment	<input checked="" type="checkbox"/> Successful	
Pre-approval	Deployment	<input checked="" type="checkbox"/> Approved	
Relocate	Deployment	<input type="radio"/> In Progress	
Post-approval	Deployment		
Completed	Deployment		

When rebalancing finishes, VMware Aria Automation refreshes. The Compute Resources page shows that machines have moved.

In VMware Aria Operations, the next data collection refreshes the display to show that optimization is complete.

The screenshot shows the VMware Aria Operations interface. At the top, it displays the IP address "10.160.148.47-Custom DataCenter". Below this, there are two main sections: "Optimization Status" and "History". The "Optimization Status" section is active, showing "Status: Optimized" with a smiling face icon. It also includes a message: "Your workloads are optimized according to your settings." with a thumbs-up icon. Below this are three buttons: "OPTIMIZE NOW", "SCHEDULE", and "AUTOMATE". The "History" section is shown as a small preview. To the right, there is a "Operational Intent" section titled "Utilization Objective: Balance" with three bar charts showing load levels. Below the charts, it says "✓ Avoid Performance Issues" and "✓ Balance Workloads". There is also an "EDIT" button.

In VMware Aria Operations, you can review the operation by clicking **Administration > History > Recent Tasks**.

Locate VMware Aria Automation managed datacenters

You can use VMware Aria Operations to display only the VMware Aria Automation managed datacenters.

1. From the VMware Aria Operations home page, click **Workload Optimization**.
2. Near the top right, click the **View** drop-down.
3. Select only the VMware Aria Automation managed datacenters.

The screenshot shows the "View" dropdown menu in VMware Aria Operations. It includes options for "Filter" and "Group By: Criticality". Below these, there is a list of datacenter types with checkboxes: "Datacenters" (unchecked), "Custom Datacenters" (unchecked), and "vRA Managed" (checked). A hand cursor is hovering over the "vRA Managed" checkbox.

Deployment monitoring based on VMware Aria Operations

VMware Aria Automation can show VMware Aria Operations data about your deployments.

Reviewing the filtered set of metrics directly in VMware Aria Automation saves you the task of accessing or searching VMware Aria Operations. Although you cannot launch in context to VMware Aria Operations, you are of course free to log in and use VMware Aria Operations for additional data as needed.

Enable VMware Aria Operations data

For VMware Aria Automation to show VMware Aria Operations data, specific integrations must be present. The integrations require you to supply the address and login credentials for VMware Aria Automation, VMware Aria Operations, and vCenter.

1. In VMware Aria Operations, go to **Data Sources > Integrations**, and verify or add your vCenter account integration.

2. In Automation Assembler, go to **Infrastructure > Connections > Cloud Accounts**, and verify or add your vCenter account.

VMware Aria Operations and VMware Aria Automation must be connected to the same vCenter.

3. In VMware Aria Operations, go to **Data Sources > Integrations**, and add the VMware Aria Automation 8.x adapter account integration.
4. In Automation Assembler, go to **Infrastructure > Connections > Integrations**, and add the VMware Aria Operations integration.

Enter the VMware Aria Operations address in the following form:

`https://operations-manager-IP-address-or-FQDN/suite-api`

For additional background, see [maphead-vrops-integrations.dita#GUID-0C20F25F-EB98-4335-9D8C-4C16BB847C37-en](#).

In Automation Assembler, click **Resources > Deployments**, select a deployment on your vCenter, and verify that the Monitor tab appears.

Health and alerts provided by VMware Aria Operations

When monitoring is enabled, VMware Aria Automation retrieves VMware Aria Operations Health and associated alerts about your deployments.

To access monitoring, click a deployment and select the **Monitor** tab. If the tab is missing, see [Enable data](#).

To see alerts, highlight the deployment name at the top of the component tree in the left panel.

- You can review the severity and text of the alerts.
- To focus on areas of concern, filter and sort on data in the columns.
- Only Health badges and Health alerts appear. Other alert types such as Efficiency or Risk are not supported.

Metrics provided by VMware Aria Operations

When monitoring is enabled, VMware Aria Automation retrieves VMware Aria Operations metrics about your deployments.

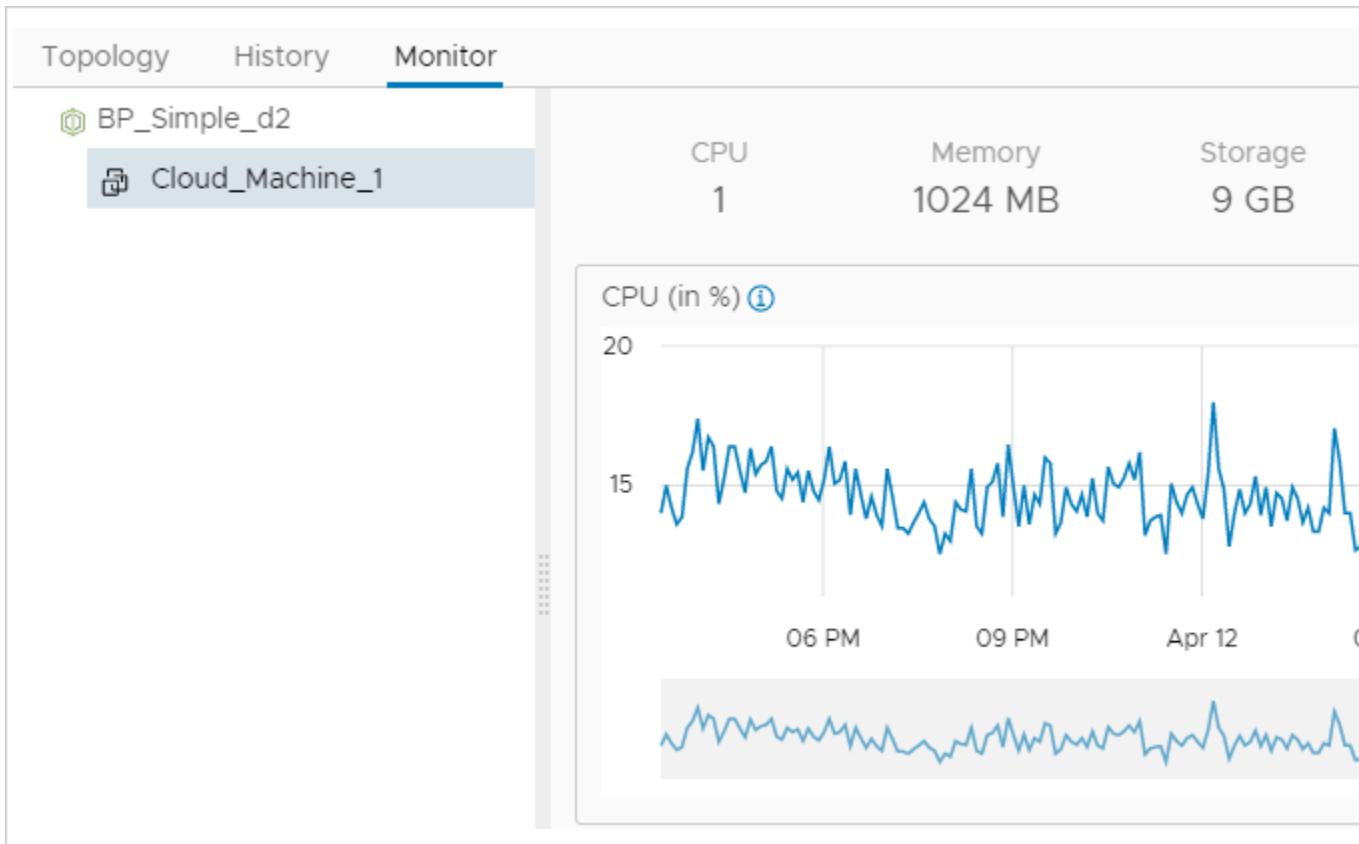

To access monitoring, click a deployment and select the **Monitor** tab. If the tab is missing, see [Enable data](#).

To see metrics, expand the component tree on the left, and highlight a virtual machine.

- Metrics are not cached. They come directly from VMware Aria Operations and might take a few moments to load.
 - Only virtual machine metrics appear. Metrics from other components such as vCloud Director, Software, or XaaS are not supported.
 - Only vSphere virtual machine metrics appear. Other cloud providers such as AWS or Azure are not supported.
- Metrics appear as timeline graphs that show highs and lows for the following measures.

- CPU
- Memory
- Storage IOPS
- Network MBPS

To reveal the specific metric name, click the blue information icon at the upper left corner of the timeline.

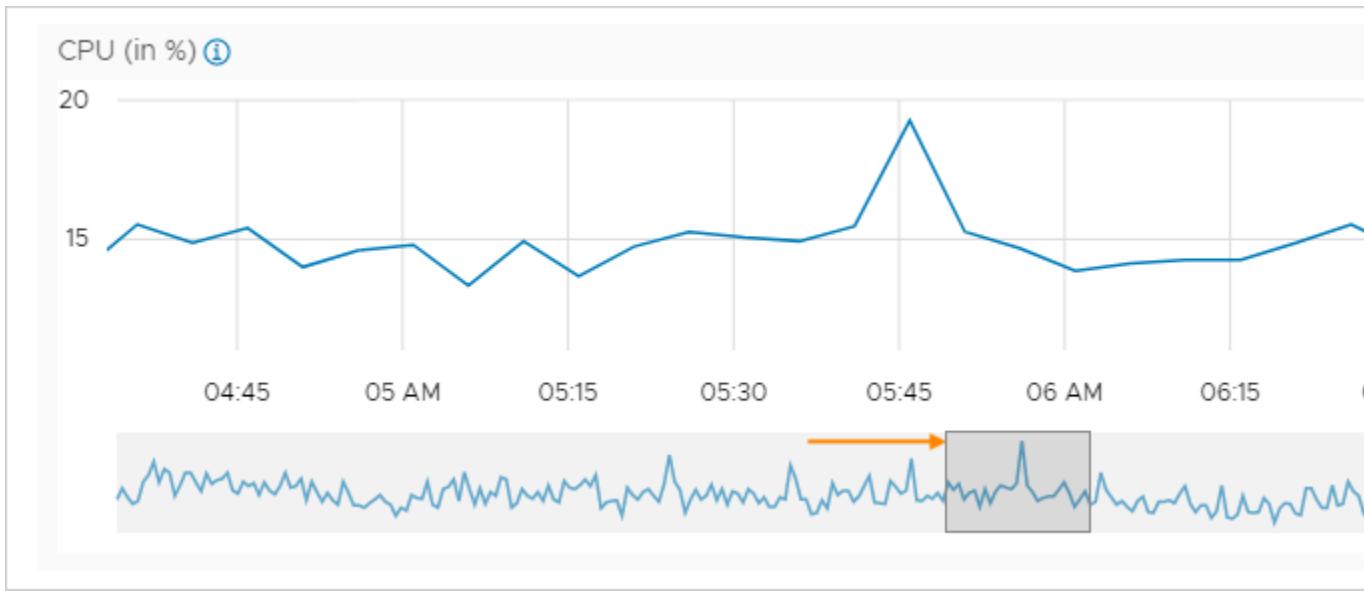

Acting on data provided by VMware Aria Operations

When metrics provided by VMware Aria Operations expose a problem, you can identify trouble areas directly in VMware Aria Automation.

To see metrics provided by VMware Aria Operations, click a deployment and select the **Monitor** tab. If the tab is missing, see [Enable data](#).

Metrics for the past day, week, or month are available. To zoom in on an area of concern, select a small area in the lower, shaded part under any metric timeline:

Resource management and deployment optimization using VMware Aria Operations metrics in VMware Aria Automation

Resource management and deployment optimization using VMware Aria Operations metrics

In an integrated VMware Aria Automation and VMware Aria Operations environment, you can access insights and alerts for VMware Aria Automation objects that are monitored by VMware Aria Operations.

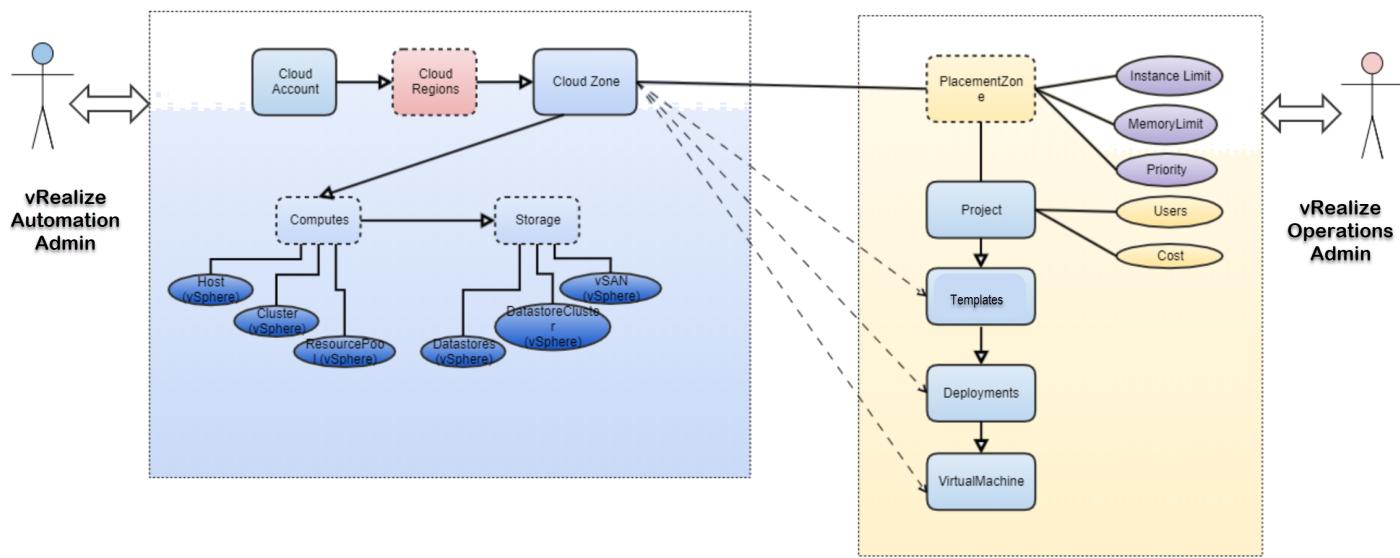

The **Insights** dashboard and **Alerts** tab pages provide the real-time capacity and related awareness information that you need to make management decisions in VMware Aria Automation without needing to open VMware Aria Operations. The information is supplied by the associated VMware Aria Operations application.

Working with the insights dashboard and with resource alerts

The **Insights** dashboard conveys information about capacity consumption across all computes within the cloud zone and grouped by projects. It can also show project deployments that are in need of optimization.

The **Alerts** pages displays potential capacity and performance concerns for objects such as cloud zones, projects, deployments, and virtual machines. They also contain information for project owners as to which of their deployments can be optimized. Each deployment link opens the **Optimize** tab in the deployment, where specific guidance is provided.

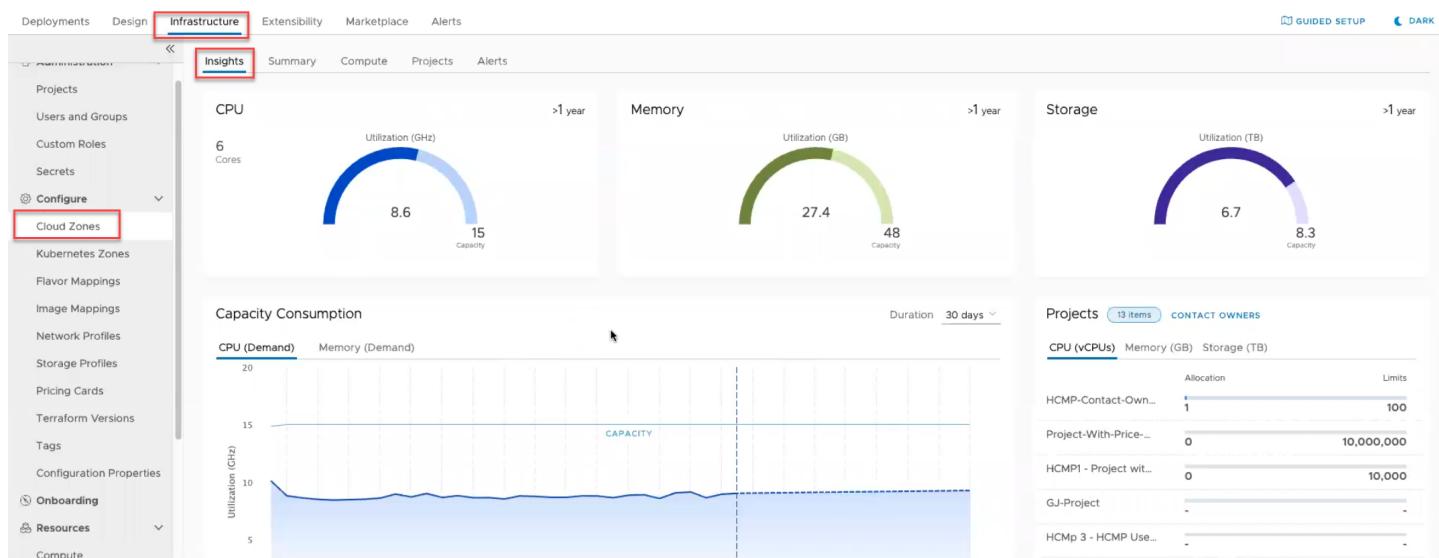

The following diagram illustrates the relationship between VMware Aria Automation resources and deployments, and the data that the associated VMware Aria Operations application provides in VMware Aria Automation.

Working with the insights dashboard

The **Insights** dashboard, which is available on each cloud zone page, provides the following VMware Aria Operations metrics:

- CPU, memory, and storage utilization usage as a percentage of capacity
- Capability consumption summary
- CPU and memory demand and usage history
- Consumption across projects
- Reclaimable resource capacity, with cost savings, for deployments and projects in a cloud zone

It also provides an option to alert project owners of deployments that can be optimized.

The **Insights** dashboard is available for vSphere and VMware Cloud on AWS cloud zones, provided that the cloud accounts are configured in both VMware Aria Automation and VMware Aria Operations and are being monitored in VMware Aria Operations.

For details, see: [Use the Insights dashboard to monitor resource capacity and notify project owners in VMware Aria Automation](#).

Working with alerts

The **Alerts** pages provide the following filtering categories. Filtering categories are supplied by the associated VMware Aria Operations application.

- Severity
- Status
- Impact
- Type
- Subtype
- Resource

Each filter can be further refined using quick filters. For example, the resource filter can be further refined by its quick filter types of cloud zone, virtual machine, deployment, and project resource.

You use combinations of filters and quick filters to control which alerts are available for display.

The screenshot shows the VMware Aria Automation interface with the 'Alerts' tab selected. At the top, there are several filtering options: 'Resource Type' dropdown (set to 'Virtual Machine, Project, Cloud Zone'), 'Status' dropdown ('Active'), and 'Impact' dropdown ('Health'). Below these are 'Quick filters' for 'Resource Type': 'Cloud Zone' (checked), 'Virtual Machine' (checked), 'Deployment' (unchecked), and 'Project' (checked). The main area displays a list of alerts:

- Virtual machine is powered off for more than 5 days** (Severity: Warning, Status: Active, Impact: Health, Type: Infrastructure, Subtype: Performance)
 - Created: Dec 13, 2020, 4:40:46 PM | Updated: Dec 14, 2020, 7:04:47 PM

Investigating

ADD NOTE

Alerts are available for vSphere and VMware Cloud on AWS resource objects.

For details about how to configure and use integrated alerts, see [How to use Alerts to manage resource capacity, performance, and availability in VMware Aria Automation](#) and [How to use Alerts to optimize deployments in VMware Aria Automation](#).

What are onboarding plans in Automation Assembler

What are onboarding plans

You use a workload onboarding plan to identify machines that have been data-collected from a cloud account type in a target region or data center but that are not yet managed by an Automation Assembler project.

When you add a cloud account that contains machines that were deployed outside of Automation Assembler, the machines are not managed by Automation Assembler until you onboard them. Use an onboarding plan to bring unmanaged machines into Automation Assembler management. You create a plan, populate it with machines, and then run the plan to import the machines. Using the onboarding plan, you can create a cloud template and can also create one or many deployments with or without existing cloud templates.

You can use resource placement in your onboarding plan to enforce resource limits that are defined in the cloud zones or the resource quota policies associated with the project. When you use resource placement, users can only select eligible discovered machines from the cloud zones associated with the project. Once you create the onboarding plan, the **Use Placement** option is read only.

You can onboard one or many unmanaged machines in a single plan by selecting machines manually.

- You can onboard up to 3,500 unmanaged machines within a single onboarding plan per hour.
- You can onboard up to 17,000 unmanaged machines concurrently within multiple onboarding plans per hour.

Machines that are available for workload onboarding are listed on the **Discovered** tab on the **Resources > Virtual Machines** page. Only machines that have been data-collected are listed. After you onboard the machines, they appear on

the **Managed** tab as Onboarded. You can filter for onboarded machines by clicking the filter icon.

The person who runs the workload onboarding plan is automatically assigned as the machine owner.

Onboarding also supports onboarding custom properties, attached disks, changing deployment owners, and vSphere networks.

- Resource Limits. You can enable onboarded workloads to respect and count against established resource limits.
- Custom properties. You can set custom properties at the plan and at the individual machine levels. A custom property set at the machine level overrides the same property on the plan level.
- Attached disks. If a machine has any non-bootable disks, they are automatically onboarded with the parent machine. To view non-bootable disks, click the machine name in the plan, and then navigate to the **Storage** tab.
- Deployment ownership. Onboarding allows you to change the default deployment owner. To change the owner, select a deployment from the **Deployment** tab, click **Actions > Change Owner**, and select the desired user associated with the project.

For additional information on bulk VMware Aria Automation onboarding, see [VMware Aria Automation bulk onboarding](#).

Onboarding examples

During onboarding, each added machine is placed in its own Automation Assembler deployment.

NOTE

As of VMware Aria Automation 8.18, onboarding no longer supports automatic generation of templates.

Administrators must onboard either with or without a template. Onboarding to existing deployments is no longer supported.

You can deploy onboarded machines in three different ways:

- Onboard a machine or a set of machines that are not associated with a cloud template and create a deployment out of them in Automation Assembler.
- Once the machines are onboarded, deployment owners can run most day 2 actions on the deployment, except the Update day 2 action.

For an example of this onboarding technique, see [Example: Onboard selected machines as a single deployment in](#).

- Onboard machines and associate them with an existing template.

If user input is provided in the cloud template, the Update day 2 action is available for such deployments. However, the Update action might provide a plan that original resources are deleted and then re-created based on the cloud template details.

NOTE

The Update day 2 action might delete the original resources and recreate them based on the template.

- Onboard machines with a cloud template and mapping.

Use this option to create a deployment where the VM is mapped to the resources in the selected template. The deployment must have the same number of machines as the selected cloud template and you must map the template resources to the respective machines.

NOTE

Mapping is supported only for plans with vSphere accounts. Only the Cloud.Machine and Cloud.vSphere.Machine resource types and their associated disks and networks are supported. Clustered machines are not supported.

Running the Update day 2 action on the onboarded deployments applies the new changes to the existing resources. The original resources are only recreated if there are major changes between the current version of cloud template and deployment.

For an example of this onboarding technique, see [Example: Onboard machines with template and mapping](#).

Onboarding event subscriptions

A Deployment Onboarded event is created when you run the plan. Using **Extensibility** tab options, you can subscribe to these deployment events and perform actions on them.

After onboarding, you can update a project as a day 2 action for onboarded deployments. To use the change project action, the target project must use the same cloud zone resources as the deployment. You cannot run the change project action on any onboarded deployments where you made changes after onboarding.

IP allocation during onboarding

When you onboard VMs, their associated networks get onboarded and IP addresses get allocated. You can verify that networks are onboarded correctly at **Infrastructure > Resources > Networks > IP Addresses**.

To ensure IP allocation during onboarding, verify the following:

1. The IP address of the VM must be data collected.
2. IP ranges must be created for the network associated with the VM.
If the VM belongs to a vSphereNSX network, the IP ranges for the NSX network must be created.
3. A record for the IP address must already exist on the **IP Addresses** page in Automation Assembler.
 - If a record exists, the IP address is available. Only available addresses get allocated.
 - If a record does not exist under IP Addresses, the IP is Available by default and is available for allocation.
4. In case of external IPAM onboarding, the `__Infoblox.IPAM.Migration.ExtensibilityKey` and `__IPAM.Migration.ExtensibilityKey` custom properties must be added to the VM before running the onboarding plan.

The values are the resourceIDs of the VM. The resourceIDs can be retrieved from Infoblox under the extensible attributes. This helps to deallocate the IP from Infoblox in case the VM is deleted in Automation Assembler.

Troubleshooting

If you encounter problems with onboarding plans in Automation Assembler, you can refer to this troubleshooting section to understand the problem or solve it, if there is a workaround.

Template is not available

Problem: You want to use a particular template, but the template is not available for selection during onboarding.

Solution:

- Verify that the onboarding plan is created in the same project as the template you want to use.
- Verify that the template is in a valid state with no errors.

Update day 2 action is not enabled

Problem: The Update day 2 action is not available for the deployment.

Solution:

- Verify that the underlying template expects inputs. If it doesn't, then the Update day 2 action is not enabled for both provisioned and onboarded deployments with assigned templates.
- Verify that there is a Day 2 policy created that applies to the deployment.

Update day 2 action shows updates to onboarded resources

Problem: The Update day 2 action/iterative deployment shows updates to onboarded resources.

Solution:

- Verify that the machines were correctly mapped to the template resources.
- Unregister the machines and then onboard them again with the correct mapping.

Example: Onboard selected machines as a single deployment in Automation Assembler

Onboard selected machines as a single deployment

In this example, you onboard two unmanaged machines as a single Automation Assembler deployment and create a single cloud template for all machines in the plan.

- Verify that you have the required user role. See [What are the user roles](#).

- Review [What are onboarding plans in Automation Assembler](#).

- Create and prepare an Automation Assembler project.

This procedure involves some of the steps from the basic Wordpress use case. See [Tutorial: Setting up and testing multi-cloud infrastructure and deployments in Automation Assembler](#).

- Create a project, add users, and assign user roles in the project. See [Part 2: Create the example project](#).

- Create an Amazon Web Services cloud account for the project. See the cloud account section of the [WordPress infrastructure example](#).

The Amazon Web Services cloud account in this procedure contains machines that were deployed before the cloud account was added to Automation Assembler and by an application other than Automation Assembler.

- Verify that the **Resources > Virtual Machines** page contains machines to onboard. See [Managing resources in Cloud Assembly](#) for more information.

When you create a cloud account, all machines that are associated to it are data-collected and then displayed on the **Resources > Virtual Machines** page. If the cloud account has machines that were deployed outside of Automation Assembler, you can use an onboarding plan to allow Automation Assembler to manage the machine deployments.

NOTE

You can only rename deployments before they are onboarded. After onboarding, the **Rename** option is deactivated.

Once the machines are onboarded, you can run most Day 2 actions on the deployment, except the Update day 2 action.

1. Go to **Infrastructure > Onboarding**.

2. Click **New** and enter sample values.

Setting	Sample Value
Plan name	VC-sqa-deployments
Description	Sample onboarding plan for AWS machine for OurCo-AWS cloud account
Cloud account	OurCo-AWS
Default project	WordPress
Use placements	No

3. Click **Create**.

4. On the plan's **Deployments** tab, click **New > Without Cloud Template**.

5. On the **Create Deployments** page, select **Create a single deployment for a group of selected machines**.

6. Select one or more machines and click **Create**.

Create Deployments

X

Create Deployments that are not associated with a cloud template. Such deployments will not support update actions.

10. Click the deployment name check box, click **Run**, and then click **Run** again on the **Run plan** page. The selected machines are onboarded as a single deployment, with an accompanying cloud template.
11. To open and examine the template, click the **Design > Templates** page and then click the template name.
12. To open and examine the deployment, click the **Resources > Deployments** page and then click the deployment name.

Example: Onboard machines with template and mapping

Onboard machines with template and mapping

In this example, you onboard two vSphere machines in Automation Assembler that you associate with an existing template and map the machines to the resources in the template.

- Verify that you have the required user role. See [What are the user roles](#).
- Review [What are onboarding plans in Automation Assembler](#).
- Create an Automation Assembler project, add users, and assign user roles in the project. See [Part 2: Create the example project](#).
- Create a vCenter cloud account for the project. See [Create a basic vCenter cloud account in VMware Aria Automation](#).

The vCenter cloud account in this procedure contains machines that were deployed before the cloud account was added to Automation Assembler and by an application other than Automation Assembler.

- Verify that the **Resources > Virtual Machines** page contains machines to onboard. See [Managing resources in Cloud Assembly](#).
- Verify that you have a template where the number of machines that you onboard matches the template resources. During onboarding, you can't have resources that are not assigned to a machine.

When you create a cloud account, all machines that are associated to it are data-collected and then displayed on the **Resources > Virtual Machines** page. If the cloud account has machines that were deployed outside of Automation Assembler, you can use an onboarding plan to allow Automation Assembler to manage the machine deployments. After onboarding, running the Update day 2 action on the onboarded deployments applies the new changes to the existing resources.

- Go to **Infrastructure > Onboarding**.
- Click **New** and enter sample values.

Setting	Sample Value
Plan name	VC-sqa-deployments-mapped
Description	Sample onboarding plan for vSphere machine with mapping
Cloud account	OurCo-vCenter
Default project	Onboarding Project
Use placements	No

- Click **Create**.
- On the plan's **Deployments** tab, click **New > With Cloud Template**.
- On the **Create Deployments** page, select the cloud template that you want to associate with the deployment.
- Select to map the discovered VMs to the resources in the template.

NOTE

Mapping is supported only for onboarding plans with vSphere accounts.

- Click **Next**.
- Assign a virtual machine to each resource from the template.
 - Next to the resource name, click **Select VM**.
 - Select a discovered virtual machine and then click **Select**.

To preview the machine within the template, click **View Template**. To go back to the onboarding plan, click the **Infrastructure** tab.
- Click **Create**.
- Click the deployment name check box, click **Run**, and then click **Run** again on the **Run plan** page. The selected machines are onboarded and mapped to an accompanying cloud template.
- To open and examine the template, click the **Design > Templates** page and then click the template name.
- To open and examine the deployment, click the **Resources > Deployments** page and then click the deployment name.

Advanced configuration for the Automation Assembler environment

Advanced configuration

You can configure your Automation Assembler environment to further support project configuration, integration, and deployment.

For related and additional information about administration methods, such as working with users and logs and joining or leaving the Customer Experience program, see [Administering VMware Aria Automation](#) on the VMware Aria Automation documentation landing page.

How do I set my preferences for VMware Aria Automation

How do I set my display language and theme

You can specify your VMware Aria Automation language and appearance theme on your account preference page.

How do I set my language preference for VMware Aria Automation

You can specify your VMware Aria Automation language on your account preference page. Your language preference settings apply to all services in your account.

1. Log in to your VMware Aria Automation.
2. From the **User/Organization settings** panel, click **My Account** in the **User Settings** section.
3. Click the **Preferences** tab and then click **Edit** in the **Language Format** section of the page.

My Account

Profile Preferences

Language Format EDIT

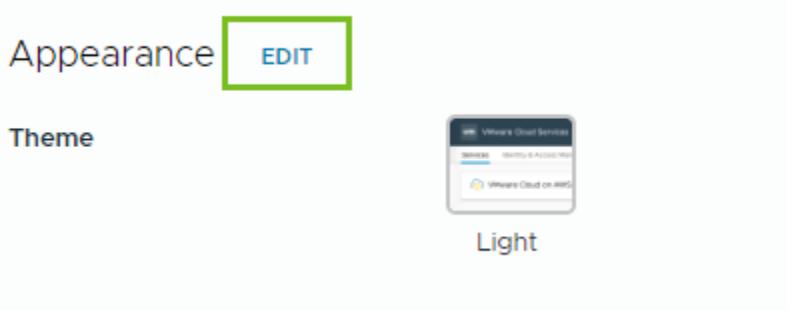

Language English

4. To specify your language choice, make selections from the **Language** drop-down menu.
5. Click **Save**.

How do I set the theme for VMware Aria Automation

You can specify your VMware Aria Automation theme on your account preference page. Your theme is applied to all services in your account that support the theme.

1. Log in to your VMware Aria Automation.
2. From the **User/Organization settings** panel, click **My Account** in the **User Settings** section.
3. Click the **Preferences** tab and then click **Edit** in the **Appearance** section of the page.

4. Select your preferred theme.

NOTE

The Dark theme is a Beta offering.

5. Click **Save**.

How do I configure an Internet proxy server for VMware Aria Automation

How do I configure an Internet proxy server

For VMware Aria Automation installations on isolated networks with no direct Internet access, you can use an Internet proxy server to allow Internet by proxy functionality. The Internet proxy server supports HTTP and HTTPS.

- Verify that you have an existing HTTP or HTTPS server, that you can use as the Internet proxy server, in the VMware Aria Automation network that is able to pass outgoing traffic to external sites. The connection must be configured for IPv4.
- Verify that the target Internet proxy server is configured to support IPv4 as its default IP format.
- If the Internet proxy server uses TLS and requires an HTTPS connection with its clients, you must import the server certificate by using one of the following commands prior to setting the proxy configuration.
 - `vracli certificate proxy --set path_to_proxy_certificate.pem`
 - `vracli certificate proxy --set stdin`
Use the `stdin` parameter for interactive input.

To configure and use public cloud providers such as Amazon Web Services (AWS), Microsoft Azure, and Google Cloud Platform (GCP) and also external integration points such as IPAM, Ansible, and Puppet, with VMware Aria Automation, you must configure an Internet proxy server.

VMware Aria Automation contains an internal proxy server that communicates with your Internet proxy server. This server communicates with your proxy server if it has been configured with the `vracli proxy set ...` command. If you have not configured an Internet proxy server for your organization, then the VMware Aria Automation internal proxy server attempts to connect directly to the Internet.

You can set up VMware Aria Automation to use an Internet proxy server by using the supplied `vracli` command line utility. Information about how to use the `vracli` API is available by using the `--help` argument in the `vracli` command line, for example `vracli proxy --help`.

NOTE

Access to Workspace ONE Access is not supported by the Internet proxy. You cannot use the `vracli set vidm` command to access Workspace ONE Access through the Internet proxy server.

The internal proxy server requires IPv4 as its default IP format. It doesn't require Internet protocol restrictions, authentication or man-in-the-middle actions on TLS (HTTPS) certificate traffic.

All external network traffic traverses the Internet proxy server. Internal network traffic bypasses the proxy.

1. Create a proxy configuration for the pods or containers that are used by Kubernetes. In this example, the proxy server is accessed by using the HTTP scheme.

```
vracli proxy set --host http://proxy.vmware.com:3128
```

2. Show the proxy configuration.

```
vracli proxy show
```

The result will be similar to the following:

```
{
  "config_timestamp": "1709214693",
  "enabled": true,
  "generation": "1709214693",
  "host": "proxy-service.prelude.svc.cluster.local",

}
```

```

all\nread_timeout 15 minutes\nmax_filedescriptors 16384\n# End autogen
configuration\n# http configuration of remote peer follows\ncache_peer
proxy.vmware.com parent 3128 0 no-query default \nnever_direct allow all\n",
"internal.proxy.config.type": "non-default"
}

```

NOTE

If you have configured an Internet proxy server for your organization, then "internal.proxy.config.type": "non-default" appears in the above example instead of 'default'. For security, the password is not shown.

- Exclude DNS domains, FQDNs, and IP addresses from being accessed by the Internet proxy server.

You can specify addresses that cannot be accessed through the Internet proxy server by specifying the --proxy-exclude parameter when running the **vracli proxy set** command. For example, if you want to add .acme.com as a domain that cannot be accessed by using the Internet proxy server, run the following command:

```
vracli proxy set .... --proxy-exclude .acme.com
```

NOTE

This command resets your previous proxy exclude settings and adds .acme.com to the list of domains that must be accessed directly rather than through the Internet proxy server. If you wish to preserve any previous settings, you must pass the previously existing proxy exclude list, extended with .acme.com, as a value for the --proxy-exclude parameter. You can check the currently set proxy exclude list by running the **vracli proxy show** command and inspecting the value of the user-proxy-exclude property. For example, if you have previously added exclude.vmware.com to the proxy exclude list, the **vracli proxy show** command will have output similar to the following:

```
{
...
"user-proxy-exclude": "exclude.vmware.com",
...
}
```

To add .acme.com to the list of exclusions, without losing exclude.vmware.com as a exclusion, you must run the following command:

```
vracli proxy set .... --proxy-exclude exclude.vmware.com,.acme.com
```

- After you set the Internet proxy server with **vracli proxy set ...** command, you can use the **vracli proxy apply** command to update the Internet proxy server configuration and make the latest proxy settings active.

- If needed, configure the proxy server to support external access on port 22.

To support integrations such as Puppet and Ansible, the proxy server must allow port 22 to access the relevant hosts.

Sample Squid configuration

Relative to step 1, if you are setting up a Squid proxy, you can tune your configuration in /etc/squid/squid.conf by adapting it to the following sample:

```
acl localnet src 192.168.11.0/24

acl SSL_ports port 443

acl Safe_ports port 80 # http
acl Safe_ports port 21 # ftp
acl Safe_ports port 443 # https

Configure workload mobility in VMware Aria Automation

Configure workload mobility

If you are using Site Recovery Manager as a business continuity and disaster recovery solution for your vSphere resources, you can configure VMware Aria Automation to continue to manage the resources even if they are moved by SRM to a secondary location.

Workload mobility is currently supported for resources deployed on vSphere. The workload resources include virtual machines, disks, and VM network. Due to Site Recovery Manager limitations, first class disks are not included.

Workload mobility only works with SRM. If you relocate workloads using a non-SRM tool, VMware Aria Automation loses the ability to manage the resources regardless of the account site association and project workload mobility settings.

After resources fail over from the primary to the secondary site, the information about the resources on the secondary site are reconciled during data collection. The complete reconciliation process might take several collection cycles to complete.

Before you begin

- Ensure that the primary and secondary sites belong to the same project.
- To understand how you can manage the resources after a failover, review the following considerations.

Considerations	Solutions
After resources fail over from the primary to the secondary site, the information about the resources on the secondary site are reconciled during data collection. The complete reconciliation process might take several collection cycles to complete.	If you encounter errors, you can review the SRM logs to identify the problem.
Storage resources do not belong to a cloud zone after reconciliation on the new site. After failover, storage quotas might be inaccurate and the allocation of new disks might fail, depending on the new vCenter topology.	None
Some actions might not work on the secondary site if the policies are different from the primary site.	<p>For example, some tags might not exist on the new vCenter datastore and they are not reconciled when the resources are moved. If the resources are staying on the datastore on the secondary site, you must update the tags on the new vCenter to ensure ongoing compliance with your policies.</p> <p>An alternative solution is to mirror the sites, including the policies and tags.</p>
<p>Most day 2 actions related to machines, disks, and VM networks are supported.</p> <p>The following day 2 actions are not supported on the secondary site.</p> <ul style="list-style-type: none"> • Changing networks when you use the Update deployment action. 	<p>Any action that consumes more resources, such as adding or resizing disks, are constrained by the available resources.</p>

Table continued on next page

Continued from previous page

Considerations	Solutions
First class disks are not supported due to Site Recovery Manager limitations.	None
If you do not reprotect the resources on the secondary site before you modify a resource as part of iterative development or general resource management, SRM generates an error and the resource is not moved when you fail back to the primary site.	After failover, reprotect the resources on the secondary site to ensure that SRM is aware of the changes. Re-protecting ensures that your resources can fail back to the primary site with minimal disruption. An alternative solution is to use an VMware Aria Automation Orchestrator plug-in that adds newly provisioned machines in Site Recovery Manager protection groups. The plug-in guide is available on the SRM documentation page .
If iterative development continues on the secondary site, any destroyed resources are not recoverable.	If the move to the secondary site is temporary, consider halting any destructive actions until you fail back to the primary site.

Configure VMware Site Recovery Manager

Ensure that the resources managed by VMware Aria Automation are configured to support workload mobility. See the [Site Recovery Manager](#) documentation for more information.

1. Identify your primary and secondary vCenter instances.
2. Create a protection group for the resources.
3. Create a recovery plan for the resources.

Associate the primary and secondary accounts in VMware Aria Automation

VMware Aria Automation must be aware of the alternative cloud accounts used by SRM for the protection group and recovery plan.

The alternative accounts must belong to the same project as primary account.

1. In Automation Assembler, select **Infrastructure > Connections > Cloud Accounts** and ensure that the primary and the secondary cloud accounts are configured.
2. Open the primary account and locate the **Site Association** section.
3. Click **Add** and select the secondary cloud account.
4. To support migrating back to the primary site, turn on the **Bidirectional** toggle.
5. Click **Save**.

How can I configure and use a VMware Aria Automation Extensibility proxy with a vCenter cloud account for improved VMware Aria Automation performance across datacenters

Configure and use a VMware Aria Automation Extensibility (vREx) proxy for improved performance across datacenters. You can use a VMware Aria Automation Extensibility (vREx) proxy to manage datacenters from a single VMware Aria Automation instance.

Use a VMware Aria Automation Extensibility proxy when vCenter servers are in geographically dispersed datacenters, or in datacenters that are not networked together. You can manage datacenters from a single VMware Aria Automation instance instead of deploying a dedicated VMware Aria Automation instance for each vCenter server. The VMware Aria Automation Extensibility proxy is also referred to as the vREX proxy.

You can create or convert a vCenter cloud account in VMware Aria Automation to access the remote vSphere agent, for example in separate datacenters that are not directly networked together. Instead of deploying an entire independent VMware Aria Automation deployment to a remote datacenter, you can use a vSphere agent within a specified VMware Aria Automation Extensibility proxy to act as a vCenter server proxy. In this scenario, using a VMware Aria Automation Extensibility proxy can improve network reliability and optimize vSphere provisioning and enumeration across datacenters that may not be otherwise connected.

The remote vSphere agent is a software component that resides within the VMware Aria Automation Extensibility proxy. The VMware Aria Automation Extensibility proxy is the virtual appliance that you deploy and configure. The vSphere agent running in the properly configured VMware Aria Automation Extensibility proxy acts as a communications intermediary between VMware Aria Automation and vSphere. When you deploy the VMware Aria Automation Extensibility proxy virtual appliance, the vSphere agent is configured automatically.

Note that the VMware Aria Automation Extensibility proxy must be able to connect to port 443 of the remote VMware Aria Automation machine over HTTPS. You can enable this access by configuring and maintaining an HTTP proxy. That proxy must allow HTTPS traffic on port 443 to and from the FQDN of the remote VMware Aria Automation machine or the corresponding load balancer in case of an HA setup. If working in a multi-tenant environment, traffic must be allowed to and from the FQDN of the tenant that the VMware Aria Automation Extensibility proxy VA should access.

To set up and use the VMware Aria Automation Extensibility proxy, perform the following sequential steps.

1. Deploy a VMware Aria Automation Extensibility proxy to one or more vCenter servers in one or more datacenters.
2. Configure VMware Aria Automation settings that support remote vSphere servers by using an VMware Aria Automation Extensibility proxy.
3. Join the VMware Aria Automation Extensibility proxy to the remote VMware Aria Automation instance.
4. Create or edit a vCenter cloud account in VMware Aria Automation and associate it to the VMware Aria Automation Extensibility proxy in the specified datacenter to access the remote site vCenter server.

Step 1 - Deploy a VMware Aria Automation Extensibility proxy to one or more vCenter servers in one or more datacenters.

To deploy the needed VMware Aria Automation Extensibility proxy OVA, use the following procedure.

1. Open the VMware Aria Automation [Download Product page in Customer Connect](#), select your VMware Aria Automation product and version, and then open the downloads page.
Alternatively, you can open the VMware Aria Suite downloads page and then access the VMware Aria Automation downloads from there.
2. Download the version-specific VMware Aria Automation Extensibility proxy OVA to the target vCenter server in the remote datacenter.
The OVA appears as **VMware Aria Extensibility *version* virtual appliance** on the VMware Aria Automation downloads page.
3. To deploy the OVA as a VMware Aria Automation Extensibility proxy, select **Extend VMware Aria Automation on premises**.
4. To facilitate network isolation between VMware Aria Automation and the target datacenter, configure an HTTP proxy.
The HTTP proxy allows services that are running in the remote datacenter to contact VMware Aria Automation. For example, this is important in network isolation scenarios where you have configured a single HTTP proxy as the only way to reach remote network locations (such as the VMware Aria Automation instance), from within the datacenter.

Step 2 - Configure VMware Aria Automation to support remote vSphere servers by using a VMware Aria Automation Extensibility proxy

As a cloud admin user, enable the remote vSphere agent capability in VMware Aria Automation by using the `vracli` command line.

This step involves opening the vCenter server where the VMware Aria Automation instance is deployed and using the vSphere client user interface to power down all nodes of the VMware Aria Automation cluster.

Once the nodes are powered down, you can open each node in the cluster and add an additional 6 GB of memory. The default memory is typically 42 GB. Add at least 6 GB more memory to each node to accommodate the extra services needed to support the remote vSphere agent.

After you add the additional memory to each node in the cluster, you again use the vSphere client user interface to power all of the nodes that are associated to the VMware Aria Automation instance back on.

The overall procedure is as follows.

1. Power down the nodes. Use SSH to open the host environment and stop the VMware Aria Automation services by using the following command:

```
/opt/scripts/deploy.sh --shutdown
```

2. Add memory, at least 6 GB, to each VMware Aria Automation node in the vCenter server by using the vSphere host client.

For information about working in the vSphere client to add memory to a node, see topics such as *Virtual Memory Configuration* in the vSphere product documentation.

3. Power on the nodes.

4. Wait for the VMware Aria Automation VA to recover after the restart. Use the following command to wait for up to 10 minutes (600 seconds) for the restart check to pass:

```
vracli status first-boot --wait 600
```

If the command returns a `First boot complete` message, you can then proceed to the configuration step.

5. In the host environment command line, run the following `vracli` command to enable remote agent (proxy) support:

```
vracli capabilities remote-proxy --enable
```

This feature toggle is not enabled by default.

6. Restart VMware Aria Automation services by using the following command:

```
/opt/scripts/deploy.sh
```

Step 3 - Join the VMware Aria Automation Extensibility proxy to the remote VMware Aria Automation instance

As a cloud admin user, configure the VMware Aria Automation Extensibility proxy on the target vCenter in the designated datacenter by using the following procedure.

1. Open the host environment command line by using SSH and use a `vracli join` command to connect the VMware Aria Automation instance with a particular organization, namely the organization for which the specified cloud administrator user is an administrator.

NOTE

This is the command line of the VMware Aria Automation Extensibility proxy, not the VMware Aria Automation command line that we used in the Step 1 procedure above.

With this action, the VMware Aria Automation Extensibility proxy (from where you run the `join` command) is joined to the VMware Aria Automation instance. The VMware Aria Automation Extensibility proxy is thus connected to VMware Aria Automation and associated with a specific VMware Aria Automation organization.

A command line example for both a default tenant and a named tenant are provided below:

- Default tenant (single tenant environment)

In this example, the FQDN of the VMware Aria Automation load balancer is passed to associate the VMware Aria Automation Extensibility proxy with the default tenant of VMware Aria Automation.

```
vracli vra joinvra.my-company.com -uadmin_user@org_domain
```

- Named tenant (multi-tenant environment)

In this example, the FQDN of specific tenant (organization) is passed to associate the VMware Aria Automation Extensibility proxy with the named organization.

```
vracli vra joinmy-tenant.vra.my-company.com-uadmin_user@org_domain
```

If you are using a multi-tenant environment, you must create an integration for each tenant. Specifically, you must deploy a separate VMware Aria Automation Extensibility proxy for each tenant (organization). A VMware Aria Automation Extensibility proxy can only be associated with one VMware Aria Automation organization at a time.

2. The above `join` command returns a certificate for the remote VMware Aria Automation instance. If you are prompted to trust the certificate, enter `yes` as prompted.
3. Allow 5 minutes or so for the VMware Aria Automation Extensibility proxy to deploy the necessary software components before proceeding.

Step 4 - Create or edit a vCenter cloud account in VMware Aria Automation to connect to a remote vCenter server account by using a VMware Aria Automation Extensibility proxy

To create a vCenter cloud account in VMware Aria Automation, see [Create a basic vCenter cloud account in VMware Aria Automation](#).

To convert an existing vCenter cloud account, see [Convert a traditional cloud account to one based on a extensibility \(vREx\) proxy](#).

Upgrading a VMware Aria Automation Extensibility (vREx) proxy virtual appliance

Upgrade binaries are available for download at [VMware Customer Connect](#). Search for and open your specific VMware Aria Automation product version. The upgrade binaries appear as *VMware Aria Automation Extensibility Appliance* on the product version page. The download may be specific to a particular VMware Aria Automation version.

Prerequisites

1. Navigate to [VMware Customer Connect Downloads](#) page and search on your product name and version. Click **Download Now** in the *VMware Aria Automation Extensibility Appliance* section to download the needed *VMware Aria Automation <version> virtual appliance* OVA. For related information, see [KB 80305](#).
2. Connect the CD-ROM drive of the VMware Aria Automation Extensibility proxy virtual machine in vSphere. See the vSphere Virtual Machine Administration product documentation.

NOTE

After connecting the CD-ROM drive, navigate to your VMware Aria Automation Extensibility proxy VM settings page and verify that the **Connect At Power On** option is enabled.

3. Mount the ISO image to the CD-ROM drive of the VMware Aria Automation Extensibility proxy virtual machine in vSphere. See the vSphere Virtual Machine Administration product documentation.

Procedure

1. Log in to the VMware Aria Automation Extensibility proxy command line as **root**.
2. Run the `blkid` command, and note the device name for the VMware Aria Automation Extensibility proxy CD-ROM drive.
3. Mount the CD-ROM drive by using the following procedure.
`mount /dev/xxx /mnt/cdrom`
4. Back up your VMware Aria Automation Extensibility proxy by taking a virtual machine (VM) snapshot. See [Take a Snapshot of a Virtual Machine](#).
The VMware Aria Automation Extensibility proxy does not support memory snapshots. Before taking the snapshot, verify that the **Snapshot the virtual machine's memory** option is deactivated.
5. To initiate the upgrade, run the following command, based on which version you are upgrading from.
If you are upgrading from vRealize Automation (the precursor to VMware Aria Automation 8.8.1 or 8.8.2, run the following command.

```
vracli upgrade exec -y --repo cdrom://
```

If you are upgrading from vRealize Automation (the precursor to VMware Aria Automation) 8.9 or later, run the following command.

```
vracli upgrade exec -y --profile lcm --repo cdrom://
```

During the upgrade process, you are automatically logged out because the VMware Aria Automation Extensibility proxy reboots.

6. Log in to the VMware Aria Automation Extensibility proxy command line as **root** and run the following command.

```
vracli upgrade status --follow
```

Results

You have successfully upgraded your VMware Aria Automation Extensibility proxy to the latest version.

What to do next

Validate that the VMware Aria Automation Extensibility proxy virtual appliance upgrade was successful by running the `vracli version` command in the command line of the appliance. By running this command, you can validate the product version and build number of the VMware Aria Automation Extensibility proxy virtual appliance.

What can I do with NSX-T mapping to multiple vCenters in VMware Aria Automation

What can I do with NSX-T mapping to multiple vCenters

You can associate an NSX-T cloud account to one or more vCenter cloud accounts to support various deployment objectives.

You can associate the same existing NSX-T network to network profiles for different vCenters and provision a deployment in either vCenter based on constraints. Several examples are listed below:

- Cloud templates that contain a single machine with multiple NICs that use the same network profile, where that network profile contains an NSX-T network that spans multiple vCenters.
- Cloud templates that contain a machine on a *private* network that uses a network profile with subnet-based isolation and that uses an NSX-T *existing* network that spans multiple vCenters.
- Cloud templates that contain a single machine on a *private* network that uses a network profile with security group-based isolation and that uses an NSX-T network that spans vCenters.
- Cloud templates that contain a single machine on a *routed* network that uses a network profile that contains an NSX-T network that spans multiple vCenters.
- Cloud templates that contain an on-demand load balancer that is defined in a network profile where the load balancer is applied to all the vCenter machines on the network.
- Cloud templates that contain an on-demand network that is defined in a network profile where the on-demand network is used by all the vCenters that use the network profile.
- Cloud templates that contain an on-demand security group that optionally contains firewall rules and where the security group is associated to all the vCenters on the network.

You can configure VMware Aria Automation internal or external IPAM on the NSX-T network and share the same IP address for machines that are provisioned in different vCenters.

If no network profile is defined in your system, you can provision a cloud template that contains multiple machines on different vCenters that share a single *existing*NSX-T network.

What happens if I remove an NSX cloud account association in VMware Aria Automation

What happens if I remove an NSX cloud account association

If you remove an association between an NSX cloud account and a vCenter cloud account, you also need to update the related network profiles to remove the associated NSX objects.

If you remove an association between an NSX cloud account and a vCenter cloud account, the infrastructure elements are not updated automatically by VMware Aria Automation. You must update your existing network profiles to remove the associated NSX objects.

The user interface provides information to help highlight the impacted network profile elements as follows:

- If the network profile has an NSX existing network selected:
 - The object is marked as *invalid* and the message *Some network objects are missing or invalid.* is displayed.
 - The objects are removed when you save the network profile.
- If the network profile has app isolation configured, you must update the Isolation policy settings before the network profile can be saved.
- If the network profile has security groups or load balancers selected, the objects are removed when you save the network profile.

Existing deployments continue to work as designed for existing components, but will fail when creating new components, for example in a scale-out operation.

If you re-establish the association, the network profile is repopulated and existing deployments work as designed.

If you remove the NSX cloud account, the above behavior is the same, but network objects are marked as *missing* rather than *invalid*.

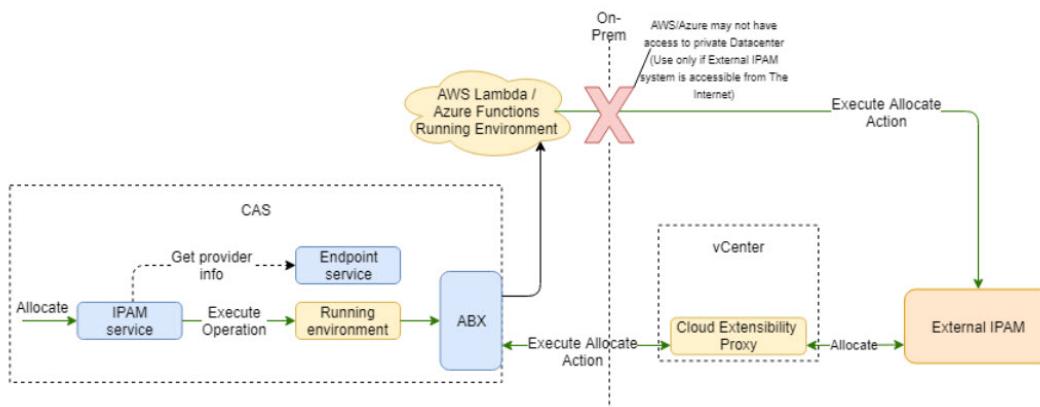

How do I use the IPAM SDK to create a provider-specific external IPAM integration package for VMware Aria Automation

How do I use the IPAM SDK to create a provider-specific external IPAM integration package

External IPAM vendors and partners can download and use the IPAM SDK to create an IPAM integration package that enables VMware Aria Automation to support their provider-specific IPAM solution.

The process for building and deploying a custom IPAM integration package for VMware Aria Automation by using the supplied IPAM SDK is described in the [Creating and Deploying a Provider-specific IPAM Integration Package for VMware Aria Automation](#) document. As described in the document, you can download the most recent [VMware Aria Automation Third-Party IPAM SDK](#) from the [VMware Developer](#) site. The following IPAM SDK packages are available:

- [VMware Aria Automation Third-Party IPAM SDK 1.1.0](#)
- [VMware Aria Automation Third-Party IPAM SDK 1.0.0](#)

Before taking the time to create a vendor-specific IPAM integration package by using the IPAM SDK, check to see if one already exists for VMware Aria Automation. You can check for a provider-specific IPAM integration package on the IPAM provider's website or the [VMware Marketplace](#).

While the [Tutorial: Configuring a provider-specific external IPAM integration for VMware Aria Automation](#) example is vendor-specific, it also contains helpful reference information.

Using VMware Aria Automation with Azure VMware Solution

This procedure describes how to set up VMware Aria Automation to work with a Microsoft Azure VMware Solution self-service hybrid cloud environment so that they can use VMware Aria Automation workloads within this environment.

VMware Aria Automation supports connections with Azure VMware Solution (AVS) to move and run VMware workloads on an Azure cloud environment. AVS was created by Microsoft to support interface with VMware environments.

Use of AVS is well documented by Microsoft. You can find the documentation here:

- Azure VMware Solution -<https://docs.microsoft.com/en-us/azure/azure-vmware/>

To use AVS in VMware Aria Automation, you must set up both vCenter and NSX-T cloud accounts. See the following documentation for setting up these cloud accounts:

- Set up vCenter cloud account - [Create a basic vCenter cloud account in VMware Aria Automation](#)
- Create an NSX-T cloud account - [Create an NSX-T cloud account in VMware Aria Automation](#)

The following procedure outlines the high level steps to configure your environment so that you can deploy VMware Aria Automation workloads on AVS.

1. Install and configure Azure VMware Solution based on the vendor instructions as appropriate for your environment.
2. Create vCenter and NSX-T cloud accounts within your VMware Aria Automation deployment.

Using VMware Aria Automation with Google Cloud VMware Engine

This procedure describes how to set up VMware Aria Automation to work with a Google Cloud VMware Solution self-service hybrid cloud environment so that you can use VMware Aria Automation workloads within this environment.

VMware Aria Automation supports connections with Google Cloud VMware Engine (GCVE) to move and run VMware workloads on Google Cloud. GCVE was created by Google to support interface with VMware environments.

Use of GCVE is well documented by Google. You can find the documentation here:

- Google Cloud VMware Engine - <https://cloud.google.com/vmware-engine/docs>

To use GCVE with VMware Aria Automation, you must set up both vCenter and NSX-T cloud accounts in VMware Aria Automation. See the following documentation for setting up these cloud accounts:

- Set up vCenter cloud account - [Create a basic vCenter cloud account in VMware Aria Automation](#)
- Create an NSX-T cloud account - [Create an NSX-T cloud account in VMware Aria Automation](#)

The following procedure outlines the high level steps to configure your environment so that you can deploy VMware Aria Automation workloads on GCVE.

1. Install and configure Google Cloud VMware Engine based on the vendor instructions as appropriate for your environment.
2. Create vCenter and NSX-T cloud accounts within your VMware Aria Automation deployment.

Using VMware Aria Automation with Oracle Cloud VMware Solution

This procedure describes how to set up VMware Aria Automation to work with an Oracle Cloud VMware Solution self-service hybrid cloud environment so that you can use VMware Aria Automation workloads within this environment.

VMware Aria Automation supports connection with Oracle Cloud VMware Solution (OCVS) to move and run VMware workloads on Oracle Cloud. OCVS was created by Oracle to support interface with VMware environments.

Use of OCVS is well documented by Oracle. You can find the documentation here:

- Oracle Cloud VMware Solution - <https://docs.oracle.com/en-us/iaas/Content/VMware/Concepts/ocvsoverview.htm>
- To use OCVS, you must set up both vCenter and NSX-T cloud accounts. See the following documentation for setting up these cloud accounts:

- Set up vCenter cloud account - [Create a basic vCenter cloud account in VMware Aria Automation](#)
- Create an NSX-T cloud account - [Create an NSX-T cloud account in VMware Aria Automation](#)

The following procedure outlines the high level steps to configure your environment so that you can deploy VMware Aria Automation workloads on OCVS.

1. Install and configure Oracle Cloud VMware Solution based on the vendor instructions as appropriate for your environment.
2. Create vCenter and NSX-T cloud accounts within your VMware Aria Automation deployment.

Using VMware Aria Automation with VMware Cloud on Dell EMC

This procedure describes how to set up VMware Aria Automation to work with a VMware Cloud on Dell EMC self-service hybrid cloud environment so that you can use VMware Aria Automation workloads within this environment.

VMware Aria Automation supports connection with VMware Cloud on Dell EMC to move and run VMware workloads.

See the VMware Cloud on Dell EMC documentation at <https://docs.vmware.com/en/VMware-Cloud-on-Dell-EMC/index.html> for more information.

To use VMware Aria Automation with VMware Cloud on Dell EMC, you must set up a vCenter cloud account. See the following documentation for setting up this cloud account:

- Set up vCenter cloud account - [Create a basic vCenter cloud account in VMware Aria Automation](#)

The following procedure outlines the high level steps to configure your environment so that you can deploy VMware Aria Automation workloads on VMware Cloud on Dell EMC.

1. Install and configure VMware Cloud on Dell EMC based on the vendor instructions as appropriate for your environment.
2. Create a vCenter cloud account within your VMware Aria Automation deployment.

Building your Automation Assembler resource infrastructure

Building your resource infrastructure

Automation Assembler resource infrastructure is where you define cloud account regions as zones into which cloud templates and their workloads can be deployed.

In addition, resource infrastructure involves creation of common mappings of images and machine sizes, and profiles that define network and storage capabilities across cloud account regions or data centers.

How to add cloud zones that define Automation Assembler target placement regions or data centers

How to add cloud zones

An Automation Assembler cloud zone is a set of resources within a cloud account type such as AWS or vSphere.

Cloud zones in a specific account region are where your cloud templates deploy workloads. Each cloud zone is associated with an Automation Assembler project.

Select **Infrastructure > Configure > Cloud Zones** and click **Add New Zone**.

Learn more about Automation Assembler cloud zones

Learn more about cloud zones

Automation Assembler cloud zones are sections of compute resources that are specific to your cloud account type such as AWS or vSphere.

Cloud zones are specific to a region, you must assign them to a project. There is a many-to-many relationship between cloud zones and projects. Automation Assembler supports deployment to the most popular public clouds including Azure, AWS, and GCP as well as to vSphere. See [Adding cloud accounts to Automation Assembler](#).

Additional placement controls include placement policy options, capability tags, and compute tags.

You can add up to 3000 cloud zones to a project. However, the maximum amount of cloud zones that can be part of a cloud template deployment can be no more than 100. At the deployment stage, the cloud zones are filtered based on assigned constraint tags or cloud account. If there are more than 100 applicable cloud zones left, the deployment fails.

Placement policy

Placement policy drives host selection for deployments within the specified cloud zone.

- default - Distributes compute resources across clusters and hosts machines based on availability. For example, all machines in a particular deployment are provisioned on the first applicable host.
- binpack - Places compute resources on the most loaded host that has enough available resources to run the given compute.
- spread - Provisions compute resources, at a deployment level, to the cluster or host with the least number of virtual machines. For vSphere, Distributed Resource Scheduler (DRS) distributes the virtual machines across the hosts. For example, all requested machines in a deployment are placed on the same cluster, but the next deployment may choose another vSphere cluster depending on the current load.

For example, let's assume you have the following configuration:

- DRS cluster 1 with 5 virtual machines
- DRS cluster 2 with 9 virtual machines
- DRS cluster 3 with 6 virtual machines

If you request a cluster of 3 virtual machines and you select a Spread policy, they should all be placed on cluster 1. The updated loads become 8 virtual machines for cluster 1, while the loads for clusters 2 and 3 remain the same at 9 and 6.

Then, if you request an additional 2 virtual machines, they are placed on DRS cluster 3, which will now have 8 virtual machines. The load for clusters 1 and 2 remain the same at 8 and 9.

- spread by memory - Provisions compute resources, at a deployment level, to the cluster or host with the greatest amount of free memory. However, the free memory calculation for private cloud zones is different from public cloud zones.
 - Private cloud zones - Total memory of the hosts or clusters is retrieved for the zone. The amount of allocated memory for all the managed machines is retrieved. The allocated memory is divided by the total memory to determine the ratio, which is inversely proportional to the size of the zone or cluster. The zone or cluster with the smallest ratio is considered to have the most available memory because it has the largest amount of free memory proportional to its size.
 - Public cloud zones - Total memory cannot be retrieved from the hosts or clusters. Therefore, the amount of memory allocated to all the managed virtual machines is retrieved. The cloud zones are ordered by the amount of allocated memory so that the zone with the least amount of allocated memory is prioritized.

If two cloud zones both match all the criteria needed for provisioning, then the placement logic selects the one with the highest defined project provisioning priority.

For more information about how the selected cloud zone placement policy interacts with a project placement policy, see [How do project-level placement policies affect resource allocation](#).

Capability tags

Cloud template contain constraint tags to help determine deployment placement. During deployment, cloud template constraint tags are mapped to matching capability tags in cloud zones and compute resources to determine which cloud zones are available for virtual machine resource placement.

Compute resources

You can view and manage the compute resources that are available to provision workloads, such as AWS availability zones and vCenter clusters, to this cloud zone.

NOTE

Beginning with the VMware Aria Automation 8.3 release, cloud zones can no longer share compute resources. Legacy cloud zones that use shared compute resources are still supported, but users are prompted to update them to conform with current standards.

Cloud zones that are auto-generated during cloud account creation are associated with the underlying compute resources after data collection.

If a vCenter compute cluster is DRS-enabled, the cloud zone only displays the cluster in the list of computes and it does not display the child hosts. If a vCenter compute cluster is not DRS-enabled, the cloud zone only displays standalone ESXi hosts, if present.

Add compute resources as appropriate for the cloud zone. The Compute tab contains a filter mechanism that enables you to control how compute resources are included with cloud zones. Initially, the filter selection is Include all Compute and the list below shows available compute resources, and they are all available for use in deployments. You have two additional options for adding compute resources to a cloud zone.

- Manually select compute - Select this option if you want to manually select compute resources from the list below. After you select them, click Add Compute to add the resources to the zone. The selected resources are available for use in deployments.
- Dynamically include compute by tags - Select this option if you want to include or exclude compute resources for the zone based on tags. All compute resources are shown until you add appropriate tags that match existing tags on compute resources. After you add one or more tags, compute resources with tags that match the filter are included in the zone and are available for use in deployments, while those that don't match are excluded.
- Include all unassigned compute - If you select this option, the cloud zone is not updated dynamically when new computes become available. Only the computes that were available when it was created are present in the zone.

For either compute option, you can remove one or more of the compute resources shown on the page by selecting the box to the right and clicking Remove.

Compute tags help to further control placement. You can use tags to filter available compute resources to only those that match one or more tags, as shown in the following examples.

- Computes contain no tags and no filtering is used.

New Cloud Zone

Summary **Compute** Projects

All compute resources listed apply to this cloud zone. Use the filter to add or remove resources from the list.

The screenshot shows a table of compute resources. The columns are: Name, Account / region, Type, and Tags. There are 6 rows, each representing an Availability Zone named us-east-1a through us-east-1f. The 'Tags' column is empty for all rows. A yellow box highlights the 'Tags' section at the top left and the 'Tags' column header.

<input type="checkbox"/>	Name	Account / region	Type	Tags
<input type="checkbox"/>	us-east-1a	Amazon / us-east-1	Availability Zone	
<input type="checkbox"/>	us-east-1b	Amazon / us-east-1	Availability Zone	
<input type="checkbox"/>	us-east-1c	Amazon / us-east-1	Availability Zone	
<input type="checkbox"/>	us-east-1d	Amazon / us-east-1	Availability Zone	
<input type="checkbox"/>	us-east-1e	Amazon / us-east-1	Availability Zone	
<input type="checkbox"/>	us-east-1f	Amazon / us-east-1	Availability Zone	

6 computes

- Two computes contain the same tag but no filtering is used.

New Cloud Zone

Summary Compute Projects

All compute resources listed apply to this cloud zone. Use the filter to add or remove resources from the list.

<input type="checkbox"/>	Name	Account / region	Type	Tags
<input type="checkbox"/>	us-east-1a	Amazon / us-east-1	Availability Zone	test:case42
<input type="checkbox"/>	us-east-1b	Amazon / us-east-1	Availability Zone	
<input type="checkbox"/>	us-east-1c	Amazon / us-east-1	Availability Zone	
<input type="checkbox"/>	us-east-1d	Amazon / us-east-1	Availability Zone	test:case42
<input type="checkbox"/>	us-east-1e	Amazon / us-east-1	Availability Zone	
<input type="checkbox"/>	us-east-1f	Amazon / us-east-1	Availability Zone	

6 computes

- Two computes contain the same tag and the tag filter matches the tag used on the two computes.

You can view which projects have been configured to support workload provisioning to this cloud zone.

Insights dashboard

If you have an associated VMware Aria Operations application that you have configured to work with VMware Aria Automation, you can access an **Insights** dashboard in the cloud zone. The dashboard displays capacity-related information about resources and deployments for the vSphere or VMware Cloud on AWS cloud zone, provided that the cloud accounts are configured in both VMware Aria Automation and VMware Aria Operations and are being monitored in VMware Aria Operations. To learn more about the **Insights** dashboard, see [Resource management and deployment optimization using VMware Aria Operations metrics in VMware Aria Automation](#).

How to add flavor mappings in VMware Aria Automation to specify common machine sizings

How to add flavor mappings

A VMware Aria Automation flavor map is where you use natural language to define target deployment sizes for a specific cloud account/region.

Flavor maps express the deployment sizes that make sense for your environment. One example might be `small` for 1 CPU and 2 GB memory and `large` for 2 CPUs and 8 GB memory for a vCenter account in a named datacenter and `t2.nano` for an Amazon Web Services account in a named region.

1. Open the Automation Assembler service in VMware Aria Automation.
2. Select either **Tenant Management > Flavor Mappings** or **Infrastructure > Flavor Mappings** and click **New Flavor Mapping**.
3. Respond to onscreen prompts to create the flavor mapping.

Learn more about flavor mappings in VMware Aria Automation

Learn more about flavor mappings

A flavor mapping groups a set of target deployment sizings for a specific cloud account/region in VMware Aria Automation using natural language naming.

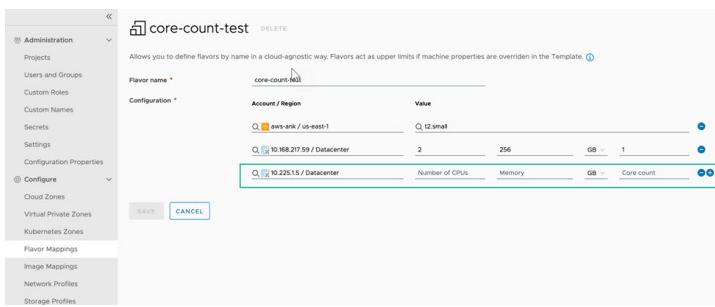

Flavor mapping lets you create a named mapping that contains similar flavor sizings across your account regions. For example, a flavor map named `standard_small` might contain a similar flavor sizing (such as 1 CPU, 2 GB RAM) for some or all available account/regions in your project. When you build a cloud template, you pick an available flavor that fits your needs.

Organize flavor mappings for your project by deployment intent.

To simplify cloud template creation, you can select a pre-configuration option when you add a new cloud account. When you select the pre-configuration option, your organization's most popular flavor mapping and image mapping for the specified region are selected.

With regard to image mapping in cloud templates that contain vSphere resources, if there are no flavor mappings defined for a vSphere cloud zone, you can configure unlimited memory and CPU by using vSphere-specific settings in the cloud template. If there are flavor mappings defined for a vSphere cloud zone, the flavor mapping serves as a limit for vSphere-specific configurations in the cloud template.

You can specify a maximum number of vCPUs per socket in your flavor mappings. During compute allocation, this specification addresses the `coreCount` property in a VMware Aria Automation cloud template and when provisioning the deployment.

How to add image mapping in VMware Aria Automation to access common operating systems

How to add image mappings

A VMware Aria Automation image map is where you use natural language to define target deployment operating systems for a specific cloud account/region.

1. Open the Automation Assembler service in VMware Aria Automation.
2. Select **Infrastructure > Image Mappings** and click **New Image Mapping**.
3. Respond to onscreen prompts to create the image mapping.

NOTE

You can create an image mapping in multiple regions by activating the **Create the same mapping in multiple regions** toggle and selecting **Add account/region**. You can also perform this operation by cloning an image mapping. To do this, select **View ungrouped** in the grid view and click **Clone**.

Learn more about image mappings in VMware Aria Automation

Learn more about image mappings

An image mapping groups a set of predefined target operating system specifications for a specific cloud account/region in VMware Aria Automation by using natural language naming.

Cloud vendor accounts such as Microsoft Azure and Amazon Web Services use images to group a set of target deployment conditions together, including OS and related configuration settings. vCenter and NSX-based environments, including VMware Cloud on AWS, use a similar grouping mechanism to define a set of OS deployment conditions. When you build and eventually deploy and iterate a template, you pick an available image that best fits your needs.

Organize image mappings for a project by similar operating system settings, tagging strategy, and functional deployment intent.

To simplify template creation, you can select a pre-configuration option when you add a new cloud account. When you select the pre-configuration option, your organization's most popular flavor mapping and image mapping for the specified region are selected.

When you add image information to a template, you use either the `image` or `imageRef` entry in the `properties` section of a machine component. For example, if you want to clone from a snapshot, use the `imageRef` property.

For examples of `image` and `imageRef` entries in template code, see [Designing your Automation Assembler deployments](#).

To assign a permission on a content library, an administrator must grant the permission to the user as a global permission. For related information, see [Hierarchical Inheritance of Permissions for Content Libraries](#) in the VMware vSphere documentation.

Applying an image mapping to multiple regions

You can apply an image mapping to cloud accounts in multiple regions. Use the image mapping UI to filter and search your cloud accounts by account type (for example, AWS or Azure), and then select an image to apply to that cloud account type in multiple regions at the same time. For example, you can specify that all ubuntu20 images be available for all AWS cloud accounts in one or more specific AWS AMI regions. This capability also allows you to display, edit, and delete images mappings for one or more regions at a time.

- Search and filter configurable cloud accounts and regions across properties (for example account type, region name, and so on).
- Select and deselect which regions to apply an image mapping to based on the search filter results.
- Apply an updated image mapping to multiple regions at the same time.

To display ungrouped image mappings, select **View ungrouped** in the **Filter** drop-down menu.

Name	Account / Regions
alpine	2
asddas	1
aws-encryption-test	1
awsImage	1
az_image	8
cent-os	2
debian-demo	1
dimage	1
dsafasd + ddased	1
GCP_shieldedVM	1

20

1 - 20 of 24 image mappings 1 / 2

Selected image mappings can be edited or deleted. A sample **Edit Mapping** menu is shown.

Note that some edit options are not available for certain selection scenarios. For example, a scenario in which you have selected multiple cloud account types would not allow you to edit an image (on the **Edit Mapping** menu) because the cloud account types would not have a common image. Use the following table to determine if you can edit an image (on the **Edit Mapping** menu) for your selected items.

Synchronizing images for the cloud account/region

To ensure that the images you are adding or removing for a given cloud account/region on the Automation Assembler`Infrastructure > Configure > Image Mapping` page are current, run image synchronization.

1. Open the associated **Cloud Account/Region** by selecting **Infrastructure > Connections > Cloud accounts** in Automation Assembler.
2. Select the existing cloud account/region.
3. Click the **Sync Images** button and let the action complete.

Status

Collecting data... (i)

Image synchronization completed 23 hours ago. (i) SYNC IMAGES

Available for deployment. (i) UPDATE

4. When the action is complete, click **Infrastructure > Configure > Image Mapping**.
5. Define a new or edit an existing image mapping and select the cloud account/region from step 1.
6. Click the image synchronization icon on the **Image Mapping** page.

7. Configure image mappings settings for the specified cloud account/region on the **Image Mapping** page.

Viewing OVF details

You can include OVA/OVF specifications in Automation Assembler template objects, such as vCenter machine components and images.

If your image contains an OVF file, you can also discover its content by hovering over the *View OVF details* option to display OVF details such as name and location. For more information about the OVF file format, see [vcenter ovf: property](#). To view the OVF details, the image mapping must reside on the web server.

NOTE

You cannot use OVF properties of images in vCenter content libraries when provisioning from a VMware Aria Automation cloud template. If the OVF is hosted directly in vCenter, the *View OVF details* option is not visible or otherwise available. The *View OVF details* option is not available for images in content libraries.

For related information about viewing OVF details by using an OVF link in the mapping field, see external article [Cloud template from an OVA](#).

Using shared and latest images from a Microsoft Azure image gallery

When creating image mappings for Microsoft Azure, you can select images from a shared Azure image gallery in the subscription. The images in the drop-down menu are data-collected and made available based on your selected region.

While shared image galleries can be used across multiple subscriptions, they cannot be listed in the image mapping drop-down menu across subscriptions. Only the images of a particular subscription are data-collected and listed in the image mappings list. To use an image from an image gallery in a different subscription, provide the image ID in the image mapping and use that image mapping in the template.

Using constraints and tags to select a suitable compute for the image

You can use image constraints to select a suitable compute based on the compute's tag. For example, if you have a `tag1` constraint on a particular image and if the image is selected during allocation, then a compute with tag `tag1` is selected for placing the machine being provisioned. If such compute does not exist, the allocation of the machine fails.

Using a cloud configuration script to control deployment

You can use a cloud configuration script in an image map, template, or both to define custom OS characteristics to be used in an Automation Assembler deployment. For example, based on whether you are deploying a template to a public or private cloud, you can apply specific user permissions, OS permissions, or other conditions to the image. A cloud configuration script adheres to a `cloud-init` format for Linux-based images or a `cloudbase-init` format for Windows-based images. Automation Assembler supports the `cloud-init` tool for Linux systems and the `cloudbase-init` tool for Windows.

For Windows machines, you can use any cloud configuration script format that is supported by `cloudbase-init`.

The machine resource in the following sample template code uses an image that contains a cloud configuration script, the content of which is seen in the `image` entry.

`resources:`

`demo-machine:`

`type: Cloud.vSphere.Machine`

`properties:`

```

flavor: small
image: MyUbuntu16
https://cloud-images.ubuntu.com/releases/16.04/release-20170307/ami-
ubuntu-16.04-1.10.3-00-15269239.ova
cloudConfig: |
ssh_pauth: yes
chpasswd:
list: |
${input.username}:${input.password}
expire: false
users:
- default
- name: ${input.username}
lock_passwd: false
sudo: ['ALL=(ALL) NOPASSWD:ALL']
groups: [wheel, sudo, admin]
shell: '/bin/bash'
runcmd:
- echo "Defaults:${input.username} !requiretty" >> /etc/sudoers.d/${input.username}

```

Dynamic property evaluation works when using cloudConfig directly in a template, but isn't supported for cloudConfig in an image map.

In the template code, you use the `image` setting to reference an image that is defined as an image mapping. You use the `imageRef` setting to identify a template that contains a snapshot (for linked clones), an image template, or a content library template OVF.

What happens when an image mapping and a template contain a cloud configuration script

When a template that contains a cloud configuration script uses an image mapping that contains a cloud configuration script, both scripts are combined. The merge action processes the contents of the image mapping script first and the contents of the template script second, with consideration being given to whether the scripts are in `#cloud-config` format or not.

- For scripts that are in the `#cloud-config` format, the merge combines the contents of each module (for example `runcmd`, `users`, and `write_files`) as follows:
 - For modules where the contents are a list, the lists of commands from the image mapping and from the template are merged, excluding commands that are identical in both lists.
 - For modules where the contents are a dictionary, the commands are merged and the result is a combination of both dictionaries. If the same key exists in both dictionaries, the key from the image mapping script dictionary is preserved and the key from the template script dictionary is ignored.
 - For modules where the contents are a string, the content values from the image mapping script are kept and the content values from the template script are ignored.

- For scripts that are in a format other than `#cloud-config` or when one script is in `#cloud-config` format and the other is not, both scripts are combined in a way that the image mapping script is run first and the template script is run when the image mapping script is finished.

Add an image from a vCenter content library

When a local or publisher content library resides in a vCenter that is managed by your VMware Aria Automation organization, content library template images appear in the image drop-down menu. The images listed include OVF and VM template images in local or publisher vCenter content libraries. Images in subscriber content libraries do not appear in the drop-down menu. The template from which a VM has been cloned is shown in the machine details section of the machine deployments user interface.

NOTE

If the publisher content library vCenter is managed by VMware Aria Automation, then publisher information is displayed in the image mapping selection grid in the following format: `publisher_content_library_name/content_item_name`

To assign a permission on a content library, an administrator must grant the permission to the user as a global permission. For related information, see [Hierarchical Inheritance of Permissions for Content Libraries](#) in [vSphere Virtual Machine Administration](#) at [VMware vSphere Documentation](#).

If the publisher content library vCenter is not managed by VMware Aria Automation, then subscriber information is displayed in the image mapping selection grid in the following format:

`subscriber_content_library_name/content_item_name`

For example, in the following scenario only the subscriber content library items are visible in the VMware Aria Automation image mapping list:

- For a vCenter named VC-1, there is a subscriber content library in the VC and a cloud account is created in VMware Aria Automation that is associated to VC-1.
- For a vCenter named VC-2, there is a publisher content library in the VC that the subscriber content library of VC-1 is subscribed from. However, there is no cloud account in VMware Aria Automation that is associated to VC-2.

Because VC-1 is associated to a VMware Aria Automation cloud account, the subscriber content library is available in VMware Aria Automation. Its contents are collected and displayed in the VMware Aria Automation image mapping list. However, because VC-2 is not associated to a cloud account, VMware Aria Automation has no knowledge of its publisher content library. To display the publisher content library items in the image mapping list, you must associate a cloud account to the VC-2 vCenter.

When you deploy a template that contains a VM template image mapping, VMware Aria Automation attempts to access the mapped image in the content library that is closest to the datastore, and then closest to the host, of the machine to be provisioned. This can include a local content library as well as a publisher or subscriber content library.

When you deploy a template that contains an OVF template image mapping, OVF images are accessed as specified in the image mapping row if the image is in a local content library or a local subscriber of a specified remote publisher content library.

The VM template in vCenter includes multiple disks known as image disks. When deploying a VM using a VM template as an image from VMware Aria Automation, one of the image disks is selected as a boot-disk. The allocation and placement of the boot-disk can be controlled adding constraints. To add a constraint, select your cloud template and navigate to **vSphere Machine > Properties > Storage > Constraints**. Other image disks follow the allocation and placement decision made for the boot-disk. You cannot control the placement of each individual image disk.

For related information about creating and using vCenter content libraries, see [Using Content Libraries](#) in the vSphere product documentation and VMware blog posts [How to Use Content Libraries](#) and [Manage templates with vSphere content library](#).

More information about configuring and using cloud configuration scripts

For more information about working with cloud configuration scripts in templates, see [Machine initialization in .](#)

Also see VMware blog articles [vSphere Customization with Cloud-init](#) and [Customizing Deployments with Cloud-Init](#).

Batch operations for image mappings

VMware Aria Automation supports batch operations through which you can easily manage large groups of image mappings. These operations allow you to create, clone, edit, and delete multiple image mappings. To access these batch operations, select **View ungrouped** in the grid view. For example, you can perform a batch edit on multiple image mappings by selecting **Edit**.

NOTE

You cannot give the same name to multiple image mappings from the same region.

While in the image mapping editor, you can also use the **Match by name** function to create or edit multiple mappings across cloud accounts and providers based on the specified name. When performing this operation VMware Aria Automation searches for a private image first. If no private image is available, the service searches for a public image or an image shared across data centers in vSphere.

How to add network profiles in VMware Aria Automation

How to add network profiles

A VMware Aria Automation network profile describes the behavior of the network to be deployed.

For example, a network might need to be Internet-facing rather than internal-only.

Networks and network profiles are cloud-specific.

Select **Infrastructure > Configure > Network Profiles** and click **New Network Profile**.

Learn more about network profiles in VMware Aria Automation

Learn more about network profiles

A network profile defines a group of networks and network settings that are available for a cloud account in a particular region or datacenter in VMware Aria Automation.

You typically define network profiles to support a target deployment environment, for example a small test environment where an existing network has outbound access only or a large load-balanced production environment that needs a set of security policies. Think of a network profile as a collection of workload-specific network characteristics.

What's in a network profile

A network profile contains specific information for a named cloud account type and region in VMware Aria Automation, including the following settings:

- Named cloud account/region and optional capability tags for the network profile.
- Named existing networks and their settings.
- Network policies that define on-demand and other aspects of the network profile.
- Optional inclusion of existing load balancers.
- Optional inclusion of existing security groups.

You determine the network IP management functionality based on the network profile.

NOTE

VMware Aria Automation supports one network profile for any given VM or VM cluster compute resource. If a VM or VM cluster compute resource has multiple networks and separate network profiles are selected for each, allocation will fail during template deployment. A VM or VM cluster compute resource can only support one network profile, not multiple network profiles.

Network profile capability tags are matched with constraint tags in cloud templates to help control network selection. Further, all tags that are assigned to the networks that are collected by the network profile are also matched with tags in the cloud template to help control network selection when the cloud template is deployed.

Capability tags are optional. Capability tags are applied to all networks in the network profile, but only when the networks are used as part of that network profile. For network profiles that do not contain capability tags, tag matching occurs on the network tags only. The network and security settings that are defined in the matched network profile are applied when the cloud template is deployed.

When using static IP, the address range is managed by VMware Aria Automation. For DHCP, the IP start and end addresses are managed by the independent DHCP server, not by VMware Aria Automation. When using DHCP or mixed network address allocation, the network utilization value is set to zero. An on-demand network allocated range is based on the CIDR and subnet size that is specified in the network profile. To support both static and dynamic assignment in the deployment, the allocated range is divided into two ranges - one for static allocation and another for dynamic allocation.

Networks

Networks, also referred to as subnets, are logical subdivisions of an IP network. A network groups a cloud account, IP address or range, and network tags to control how and where to provision a cloud template deployment. Network parameters in the profile define how machines in the deployment can communicate with one another over IP layer 3. Networks can have tags.

You can add networks to the network profile, edit aspects of networks that are used by the network profile, and remove networks from the network profile.

When you add a network to the network profile, you can select available networks from a filtered list of vSphere and NSX networks. If the network type is supported for the cloud account type, you can add it to the network profile.

In a VCF-based deployment, NSX network segments are created locally on the NSX-T network and are not created as global networks.

- **Network domain or Transport zone**

A network domain or transport zone is the distributed virtual switch (*dvSwitch*) for the vSphere vNetwork Distributed PortGroups (*dvPortGroup*). A *transport zone* is an existing NSX concept that is similar to terms like *dvSwitch* or *dvPortGroup*.

When using an NSX cloud account, the element name on the page is **Transport zone**, otherwise it is **Network domain**.

For standard switches, the network domain or transport zone is the same as the switch itself. The network domain or transport zone defines the boundaries of the subnets within vCenter.

A transport zone controls which hosts an NSX logical switch can reach to. It can span one or more vSphere clusters. Transport zones control which clusters and which virtual machines can participate in the use of a particular network. Subnets that belong to the same NSX transport zone can be used for the same machine hosts.

- **Domain**

Represents the domain name for the machine. The domain name is passed to the vSphere machine customization spec.

- **IPv4 CIDR and IPv4 default gateway**

vSphere machine components in the cloud template support IPv4, IPv6, and dual stack IP assignment for network interfaces. For example, 192.168.100.14/24 represents the IPv4 address 192.168.100.14 and its associated routing

prefix 192.168.100.0, or equivalently, its subnet mask 255.255.255.0, which has 24 leading 1-bits. The IPv4 block 192.168.100.0/22 represents the 1024 IP addresses from 192.168.100.0 to 192.168.103.255.

- **IPv6 CIDR and IPv6 default gateway**

vSphere machine components in the cloud template support IPv4, IPv6, and dual stack IP assignment for network interfaces. For example, 2001:db8::/48 represents the block of IPv6 addresses from 2001:db8:0:0:0:0:0:0 to 2001:db8:0:ffff:ffff:ffff:ffff:ffff.

The IPv6 format is not supported for on-demand networks. For related information, see [Using network settings in network profiles and cloud templates in](#).

NOTE

You can assign an IPv6 address space to single and dual stacked workloads when an IPv6 address is requested per integration with an external IPAM system. This capability requires that the integrated external IPAM plug-in also supports IPv6.

- **DNS servers and DNS search domains**

- **Support public IP**

Select this option to flag the network as public. Network components in a cloud template that have a `networkType: public` property are matched to networks that are flagged as public. Further matching occurs during cloud template deployment to determine network selection.

- **Default for zone**

Select this option to flag the network as a default for the cloud zone. During cloud template deployment, default networks are preferred over other networks.

- **Origin**

Identifies the network source.

- **Tags**

Specifies one or more tags assigned to the network. Tags are optional. Tag matching affect which networks are available for your cloud template deployments.

Network tags exist on the network item itself, irrespective of the network profile. Network tags apply to every occurrence of the network they have been added to and to all network profiles that contain that network. Networks can be instanced into any number of network profiles. Regardless of network profile residency, a network tag is associated with that network wherever the network is used.

When you deploy a cloud template, constraint tags in a cloud template's network components are matched to network tags, including network profile capability tags. For network profiles that contain capability tags, the capability tags are applied to all the networks that are available for that network profile. The network and security settings that are defined in the matched network profile are applied when the cloud template is deployed.

Network Policies

By using network profiles, you can define subnets for existing network domains that contain static, DHCP, or a mixture of static and DHCP IP address settings. You can define subnets and specify IP address settings by using the **Network Policies** tab.

When using NSX-V, NSX-T, or VMware Cloud on AWS, network policy settings are used when a cloud template requires the `networkType: outbound` or `networkType: private` or when an NSX network requires `networkType: routed`.

Depending on the associated cloud account, you can use network policies to define settings for the `outbound`, `private`, and `routed` network types and for on-demand security groups. You can also use network policies to control existing networks when there is a load balancer associated with that network.

NOTE

For information about using a VLAN transport zone to support VLAN segment specification for private NSX networks, see [Network resources in VMware Aria Automation](#).

Outbound networks allow one way access to upstream networks. Private networks do not allow any outside access. Routed networks allow East/West traffic between the routed networks. The existing and public networks in the profile are used as the underlying or upstream networks.

Options for the following on-demand selections are described in the **Network Profiles** on-screen help and summarized below.

- **Do not create an on-demand network or on-demand security group**

You can use this option when specifying an `existing` or `public` network type. Cloud templates that require an `outbound`, `private`, or `routed` network are not matched to this profile.

- **Create an on-demand network**

You can use this option when specifying an `outbound`, `private`, or `routed` network type.

Amazon Web Services, Microsoft Azure, NSX, vSphere, and VMware Cloud on AWS support this option.

- **Create an on-demand security group**

You can use this option when specifying an `outbound` or `private` network type.

A new security group is created for matched cloud templates if the network type is `outbound` or `private`.

Amazon Web Services, Microsoft Azure, NSX, and VMware Cloud on AWS support this option.

Network policy settings can be cloud account type-specific. These settings are described in the on-screen signpost help and summarized below:

- **Network domain or Transport zone**

A network domain or transport zone is the distributed virtual switch (`dvSwitch`) for the vSphere vNetwork Distributed PortGroups (`dvPortGroup`). A `transport zone` is an existing NSX concept that is similar to terms like `dvSwitch` or `dvPortGroup`.

When using an NSX cloud account, the element name on the page is **Transport zone**, otherwise it is **Network domain**.

For standard switches, the network domain or transport zone is the same as the switch itself. The network domain or transport zone defines the boundaries of the subnets within vCenter.

A transport zone controls which hosts an NSX logical switch can reach to. It can span one or more vSphere clusters. Transport zones control which clusters and which virtual machines can participate in the use of a particular network. Subnets that belong to the same NSX transport zone can be used for the same machine hosts. Transport zone types are overlay or VLAN. For information about using a VLAN transport zone for defining VLAN segments, see [Network resources in VMware Aria Automation](#).

- **External subnet**

An on-demand network with outbound access requires an external subnet that has outbound access. The external subnet is used to provide outbound access if requested in the cloud template - it does not control network placement. For example, the external subnet does not affect the placing of a private network.

- **CIDR**

CIDR notation is a compact representation of an IP address and its associated routing prefix. The CIDR value specifies the network address range to be used during provisioning to create subnets. This CIDR setting on the **Network Policies** tab accepts IPv4 notation ending in /nn and containing values between 0 - 32.

- **Subnet size**

This option specifies the on-demand network size, using IPv4 notation, for each isolated network in a deployment that uses this network profile. The subnet size setting is available for internal or external IP address management.

The IPv6 format is not supported for on-demand networks.

- **Distributed logical router**

For an on-demand routed network, you must specify a distributed logical network when using an NSX-V cloud account.

A distributed logical router (DLR) is used to route east/west traffic between on-demand routed networks on NSX-V. This option is only visible if the account/region value for the network profile is associated to an NSX-V cloud account.

- **IP range assignment**

The option is available for cloud accounts that support NSX or VMware Cloud on AWS, including vSphere.

The IP range setting is available when using an existing network with an external IPAM integration point.

You can select one of the following three options to specify an IP range assignment type for the deployment network:

- **Static and DHCP**

Default and recommended. This mixed option uses the allocated **CIDR** and **Subnet range** settings to configure the DHCP server pool to support half of the address space allocation using the DHCP (dynamic) method and half of the IP address space allocation using the Static method. Use this option when some of the machines that are connected to an on-demand network require assigned static IP addresses and some require dynamic IP addresses. Two IP ranges are created.

This option is most effective in deployments with machines that are connected to an on-demand network, where some of the machines are assigned static IPs and other machines have IPs dynamically assigned by an NSX DHCP server and deployments where the load balancer VIP is static.

- **DHCP (dynamic)**

This option uses the allocated CIDR to configure an IP pool on a DHCP server. All the IP addresses for this network are dynamically assigned. A single IP range is created for each allocated CIDR.

- **Static**

This option uses the allocated CIDR to statically allocate IP addresses. Use this option when a DHCP server is not required to be configured for the network. A single IP range is created for each allocated CIDR.

- **IP blocks**

The IP blocks setting is available when using an on-demand network with an external IPAM integration point.

Using the IP block setting, you can add a named IP block, or range, to the network profile from your integrated external IPAM provider. You can also remove an added IP block from the network profile. For information about how to create an external IPAM integration, see [Add an external IPAM integration for Infoblox in VMware Aria Automation](#).

External IPAM is available for the following cloud account/region types:

- vSphere
- vSphere with NSX-T
- vSphere with NSX-V

- **Network Resources - External network**

External networks are also referred to as existing networks. These networks are data-collected and made available for selection.

- **Network Resources - Tier-0 logical router**

NSX-T uses the tier-0 logical router as a gateway to networks that are external to the NSX deployment. The tier-0 logical router configures outbound access for on-demand networks.

- **Network Resources - Edge cluster**

The specified edge cluster provides routing services. The edge cluster is used to configure outbound access for on-demand networks and load balancers. It identifies the edge cluster, or resource pool, where the edge appliance is to be deployed.

- **Network Resources - Edge datastore**

The specified edge datastore is used to provision the edge appliance. This setting applies to NSX-V only.

Tags can be used to specify which networks are available to the cloud template.

Load Balancers

You can add load balancers to the network profile. Listed load balancers are available based on information that is data-collected from the source cloud account.

If a tag on any of the load balancers in the network profile matches a tag in a load balancer component in the cloud template, the load balancer is considered during deployment. Load balancers in a matched network profile are used when a cloud template is deployed.

For more information, see [Using load balancer settings in network profiles in VMware Aria Automation](#) and [Network, security group, and load balancer resource examples in Automation Assembler](#).

Security Groups

When a cloud template is deployed, the security groups in its network profile are applied to the machine NICs that are provisioned. For an Amazon Web Services-specific network profile, the security groups in the network profile are available in the same network domain (VPC) as the networks that are listed on the Networks tab. If the network profile has no networks listed on its Networks tab, all available security groups are displayed.

You can use a security group to further define the isolation settings for an on-demand private or outbound network. Security groups are also applied to existing networks. You can also assign global security groups.

Listed security groups are available based on information that is data-collected from the source cloud account or added as an on-demand security group in a project cloud template. For more information, see [Security resources in VMware Aria Automation](#).

Security groups are applied to all the machines in the deployment that are connected to the network that matches the network profile. As there might be multiple networks in a cloud template, each matching a different network profile, you can use different security groups for different networks.

NOTE

In addition to specifying a security group, you can also select NSX networks (default) or vSphere networks or both. When you deploy a cloud template, VMware Aria Automation adds the allocated or specified security group to machine NICs that are connected to the allocated NSX network. Only machine NICs that are connected to an NSX network can be added to an NSX security group. If the machine NIC is connected to a vSphere network, the template deployment fails.

Adding a tag to an existing security group allows you to use the security group in a cloud template `Cloud.SecurityGroup` component. A security group must have at least one tag or it cannot be used in a cloud template. For more information, see [Security resources in VMware Aria Automation](#) and [Network, security group, and load balancer resource examples in Automation Assembler](#).

More information about network profiles, networks, cloud templates, and tags

For more information about networks, see [Network resources in VMware Aria Automation](#).

For examples of sample network component code in a cloud template, see [Network, security group, and load balancer resource examples in Automation Assembler](#).

For sample network automation workflows, see the following VMware blog posts relative to VMware Aria Automation Assembler and NSX:

- [Network Automation with NSX Part 1](#)
- [Network Automation with NSX Part 2](#)
- [Network Automation with NSX Part 3](#)
- [Network Automation with NSX Part 4](#)

For more information about tags and tag strategy, see [maphead-how-to-use-tags.dita#GUID-1F1FD968-2EA1-404E-B081-E13383392061-en](#).

For information about how to name machine NICs, see [How can I configure a network interface controller name by using extensibility actions](#).

Using network settings in network profiles and cloud templates in VMware Aria Automation

Using network settings

You use networks and network profiles in VMware Aria Automation to help define the behavior of network provisioning for your deployments.

In VMware Aria Automation, you can define cloud-specific network profiles. See [Learn more about network profiles in VMware Aria Automation](#).

Using network and network profile settings, you can control how network IP addresses are used in VMware Aria Automation cloud templates and deployments.

IPv4 and IPv6 support in VMware Aria Automation networks

VMware Aria Automation networks support single stack IPv4, single stack IPv6, or dual stack IPv4 and IPv6.

IPv6 is supported for existing vSphere networks and existing NSX networks.

IPv6 is not supported for load balancers, NSX on-demand networks, or external third-party IPAM providers such as Infoblox.

You can assign an IPv6 address space to single and dual stacked workloads when an IPv6 address is requested per integration with an external IPAM system. This capability requires that the integrated external IPAM plug-in also supports IPv6.

VLAN segments and private NSX-T networks

You can specify VLAN segments for private NSX on-demand network when the network segments are used with a Policy API-type of NSX-T cloud account. For information on supported configurations and network profile requirements, see [Network resources in VMware Aria Automation](#).

External IPAM provider support

In addition to the supplied internal IPAM support, you can use an external IPAM provider to dynamically or statically allocate IP address for networks - as IP ranges for existing networks in your cloud template designs and deployments and IP blocks for on-demand networks in your cloud template designs and deployments. You can use external IPAM derived from an external provider integration that is based on the VMware Aria Automation IPAM SDK - for example one of the Infoblox plug-ins that are available for download from the [VMware Marketplace](#).

Support for external IPAM providers, such as Infoblox, is available for vendor-specific IPAM integration points that you create by using the **Infrastructure > Connections > Add Integration > IPAM** menu sequence.

Options for defining external IPAM provider address information is available by using the **Add IPAM IP Range** option on the **Network Policies > Add IPAM IP Range** page.

For information about how to create an external IPAM integration point, see [configure-a-third-party-ipam-integration-point-single.dita](#). For an example of how to create an IPAM integration point for a specific IPAM vendor, see [Tutorial: Configuring a provider-specific external IPAM integration for VMware Aria Automation](#).

In addition to the above VMware Aria Automation external IPAM options, you can also specify a VMware Aria Automation Orchestrator extensibility action in a cloud template to use a Network Configure event topic. For more information about this related IPAM method, see [Event topics provided with](#).

Network types

A network component in a cloud template is defined as one of the following `networkType` types.

Network type	Definition
existing	<p>Selects an existing network that is configured on the underlying cloud provider, such as vCenter, Amazon Web Services, and Microsoft Azure. An existing network is required by the <code>outbound</code> on-demand network.</p> <p>You can define a range of static IP addresses on an existing network.</p>
public	<p>Machines on a public network are accessible from the Internet. An IT administrator defines these networks. The definition of a <code>public</code> network is identical to that of an <code>existing</code> network for networks that allow network traffic to occur along public networks.</p>
private	<p>An on-demand network type.</p> <p>Limits network traffic to occur only between resources on the deployed network. It prevents inbound and outbound traffic. In NSX, it can be equated to on-demand NAT one-to-many.</p>
outbound	<p>An on-demand network type.</p> <p>Limits network traffic to occur between the compute resources in the deployment but also allows one-way outbound network traffic. In NSX, it can be equated to on-demand NAT one-to-many with external IP.</p>
routed	<p>An on-demand network type.</p> <p>Routed networks contain a routable IP space divided across available subnets that are linked together. The virtual machines that are provisioned with routed networks, and that have the same routed network profile, can communicate with each other and with an existing network.</p> <p>Routed networks are an on-demand network type that is available for NSX-V and NSX-T networks. Microsoft Azure and Amazon Web Services provides this connectivity by default.</p> <p>A <code>routed</code> network is only available for cloud template specification in a <code>Cloud.NSX.Network</code> network component.</p>

For more information, see [More about network resources in VMware Aria Automation cloud templates](#).

For examples of populated cloud templates that contain network component data, see [Network, security group, and load balancer resource examples in Automation Assembler](#).

Sample network scenarios

You can expect the following behavior when you deploy a cloud template that uses the following network profile configuration.

Network type or scenario	No network profiles available for cloud zone	Network profiles available for cloud zone
No network	<p>If no network is specified in the cloud template, a random network is selected from the same provisioning region as the compute.</p> <p>Preference is given to networks that are labeled as default.</p> <p>If no networks exist in an available provisioning region, provisioning fails.</p>	<p>A network is selected from a matched network profile.</p> <p>Preference is given to networks that are labeled as default.</p> <p>If none of the network profiles meet the criteria, provisioning fails.</p>
Existing network	<p>If the network component in the cloud template contains constraint tags, those constraints are used to filter the list of available networks. Constraint tags in the cloud template's network component are matched to network tags and, if available, network profile constraint tags.</p> <p>From the filtered list of networks, a single network is selected from the same provisioning region as the compute.</p> <p>Preference is given to networks that are labeled as default.</p> <p>If after filtering based on constraints there are no networks in the provisioning region, provisioning fails.</p>	<p>A network is selected from a matching network profile.</p> <p>Preference is given to networks that are labeled as default.</p> <p>If none of the network profiles meet the criteria, provisioning fails.</p> <p>Network constraints can be used to filter existing networks in the profile based on their pre-assigned tags.</p>
Public network	<p>If the network has constraints, those constraints are used to filter the list of available networks that have the supports public IP attribute set.</p> <p>From the filtered list of networks, a random network is selected from the same provisioning region as the compute.</p> <p>Preference is given to networks that are labeled as default.</p> <p>If after filtering based on constraints there are no public networks in the provisioning region, provisioning fails.</p>	<p>A network with the supports public IP attribute is selected from a matching network profile.</p> <p>Preference is given to networks that are labeled as default.</p> <p>Network constraints can be used to filter existing public networks in the profile based on their pre-assigned tags.</p>

Table continued on next page

Continued from previous page

Network type or scenario	No network profiles available for cloud zone	Network profiles available for cloud zone
Private network	Provisioning fails because private networks require information from a network profile.	A new network or new security group is created based on settings in the matched network profile. Network constraint tags can be used to filter network profiles and networks.
Outbound network	Provisioning fails because outbound networks require information from a network profile.	A new network or new security group is created based on settings in the matched network profile. Network constraint tags can be used to filter network profiles and networks.
On-demand routed network	Provisioning fails because routed networks require information from a network profile.	For NSX-V we need DLR (Distributed Logical Router) selection. For NSX-T and VMware Cloud on AWS, we require similar on-demand settings as private and outbound.
Example Wordpress use case with existing or public networks	Provisioning occurs as described for an existing network or public network.	See above descriptions for existing network and public network behavior. See Tutorial: Setting up and testing multi-cloud infrastructure and deployments in Automation Assembler.
Example Wordpress use case with existing or public networks and private or outbound networks	Provisioning fails because the network requires information from a network profile.	See above descriptions for a private network and an outbound network. See Tutorial: Setting up and testing multi-cloud infrastructure and deployments in Automation Assembler.
Example Wordpress use case with load balancer	Provisioning fails because a load balancer requires information from a network profile. Provisioning can occur when existing load balancers are present.	A new load balancer is created based on the network profile configuration. You can specify an existing load balancer that has been enabled in the network profile. Provisioning fails if you request an existing load balancer, but none meet the constraints in the network profile. See Tutorial: Setting up and testing multi-cloud infrastructure and deployments in Automation Assembler.

Using security group settings in network profiles and cloud template designs in VMware Aria Automation

Using security group settings

You can define and change security group settings in network profiles and cloud templates.

You can use security group capabilities in the following ways:

- Existing security group specified in a network profile.

You can add an existing security group to a network profile. When a cloud template uses that network profile, its machines are members of the security group. This method does not require that you add a security group resource to a cloud template. You can also use a load balancer in this configuration. For related information, see [More about load balancer resources in VMware Aria Automation cloud templates](#).

- Security group component associated to machine resource in a cloud template

You can drag and drop a security group resource onto a cloud template and bind the security group resource to a machine NIC by using constraint tags on the existing security group in the cloud template and on the existing security group in the data-collected resource. You can also make this association by connecting the objects on the cloud template design canvas, similar to how you associate networks to machines.

When you drag and drop a security group resource onto the cloud template design canvas, it can be of type *existing* or *new*. If it's an *existing* security group type, add a tag constraint value as prompted. If it's a *new* security group type, you can configure firewall rules.

- An existing security group allocated with tag constraints and associated with a machine NIC in the cloud template
You can associate a security group resource with a machine NIC (in a machine resource) in the cloud template by matching tags between the two resources.

As an example for NSX-T when tags are specified in the source endpoint, you can use NSX-T tags specified in your NSX-T application. You can then use an NSX-T tag, specified as a constraint on a network resource in a cloud template, where the network resource is connected to a machine NIC in the cloud template. NSX-T tags allow you to dynamically group machines by using a pre-defined NSX-T tag that is data-collected from the NSX-T source endpoint. Use a logical port when you create the NSX-T tag in NSX-T.

- Firewall rules in an on-demand security group resource in a cloud template

You can add firewall rules to an on-demand security group in a cloud template.

For information about available firewall rules, see [More about security group and tag resources in VMware Aria Automation cloud templates](#).

Learn more

For information about defining security groups in network profiles, see [Learn more about network profiles in VMware Aria Automation](#).

For information about viewing and changing security groups settings in infrastructure resource pages, see [Security resources in VMware Aria Automation](#).

For information about defining security groups in cloud templates, see [More about security group and tag resources in VMware Aria Automation cloud templates](#).

For examples of security group resources in cloud templates, see [Network, security group, and load balancer resource examples in Automation Assembler](#).

Using load balancer settings in network profiles in VMware Aria Automation

Using load balancer settings

You can configure load balancer settings in your network profile configuration.

You can add an existing load balancer to a network profile by using the **Load Balancer** tab.

You can add a load balancer to a cloud template design by associating it to a network profile that contains one or more load balancers or directly by using a load balancer resource in the cloud template design canvas or code.

Examples for including a load balancer VIP based on security group use in a network profile

There are two types of security groups that you can use in a network profile – an existing security group that you select from the **Security Groups** tab and an on-demand security group that you create by using an isolation policy on the **Network Policies** tab.

When a load balancer VIP is associated to a security group based on network profile settings, the security group configuration is supplied by the network profile.

The following table illustrates some sample scenarios.

Cloud template design topology - associated resources	Network profile configuration	Security group membership
One-armed load balancer with VIP on private network, and a machine on the same private network.	The selected network profile uses isolation policy defined as an on-demand security group.	The machine NIC and the load balancer VIP are added to the isolation security group.
One-armed load balancer with VIP on private network, and a machine on the same private network.	The selected network profile uses an existing security group and uses isolation policy defined as an on-demand security group.	The machine NIC and the load balancer VIP are added to the isolation security group and the existing security group.
Two-armed load balancer with VIP on a public network and machine on a private network.	The selected network profile uses an existing security group and uses isolation policy defined as an on-demand security group.	The machine NIC and the load balancer VIP are added to the isolation security group and the existing security group.
Two-armed load balancer with VIP on a public network and a machine on a private network.	The selected network profile uses an existing security group.	The machine NIC and the load balancer VIP are added to the existing security group.
Two-armed load balancer, VIP is on network 1 and the machine is on network 2.	Two network profiles: • Network profile 1: Uses an existing security group 1. • Network profile 2: Uses an existing security group 2.	The load balancer lands on network profile 1 and the machine lands on network profile 2. The load balancer VIP is added to security group 1 and the machine NIC is added to security group 2.

Learn more

For information about adding load balancer resources to a cloud template design, see [More about load balancer resources in VMware Aria Automation cloud templates](#).

For examples of cloud template designs that include load balancers, see [Network, security group, and load balancer resource examples in Automation Assembler](#).

How do I configure a network profile to support an on-demand network for an external IPAM integration in VMware Aria Automation

How do I configure a network profile to support an on-demand network for an external IPAM integration
You can configure a network profile to support blocks of IP addresses for an on-demand network when that network profile is used in a VMware Aria Automation cloud template that uses external IPAM integration.

While the following prerequisites apply to the person who creates or edits the network profile, the network profile itself would be applicable when used by a cloud template deployment that contains an IPAM integration. To learn about vendor-specific IPAM integration points, see [configure-a-third-party-ipam-integration-point-single.dita](#).

This sequence of steps is shown in the context of an IPAM provider integration workflow. See [Tutorial: Configuring a provider-specific external IPAM integration for VMware Aria Automation](#).

- Verify that you have cloud administrator credentials. See [Credentials required for working with cloud accounts in VMware Aria Automation](#).
- Verify that you have the cloud administrator user role. See [What are the user roles](#).
- Verify that you have an account with the external IPAM provider, for example [Infoblox](#) or [Bluecat](#), and that you have the correct access credentials to your organization's account with the IPAM provider. In this example workflow, the IPAM provider is Infoblox.
- Verify that you have an IPAM integration point for the IPAM provider and that the IPAM package used to create the IPAM integration supports on-demand networks. See [Add an external IPAM integration for Infoblox in VMware Aria Automation](#).
- While the Infoblox IPAM package supports on-demand networks, if you are using an external IPAM integration for a different provider, verify that their IPAM integration package supports on-demand networks.

Using an existing integration for a particular external IPAM provider, you can provision on-demand network to create of a new network in the external IPAM system.

Using this process, you configure a block of IP addresses instead of supplying a parent CIDR (as is done when using VMware Aria Automation's internal IPAM). The IP address block is used during on-demand network provisioning to segment the new network. The IP blocks are data-collected from the external IPAM provider, provided the integration supports on-demand networking. For example, when using an Infoblox IPAM integration, IP blocks represent Infoblox network containers.

When you use an on-demand network profile and an external IPAM integration in a cloud template, the following events occur when the cloud template is deployed:

- A network is created in the external IPAM provider.
- A network is also created in VMware Aria Automation, reflecting the new network configuration from the IPAM provider, including settings such as CIDR and gateway properties.
- The IP address for the deployed virtual machine is fetched from the newly created network.

NOTE

You can assign an IPv6 address space to single and dual stacked workloads when an IPv6 address is requested per integration with an external IPAM system. This capability requires that the integrated external IPAM plug-in also supports IPv6.

In this on-demand networking example, you configure a network profile to allow a cloud template deployment to provision a machine to an on-demand network in vSphere by using Infoblox as the external IPAM provider.

For related information, see [How do I configure a network profile to support an existing network for an external IPAM integration in VMware Aria Automation](#). Both network configuration examples fit within the overall vendor-specific workflow for external IPAM integration at [Tutorial: Configuring VMware Cloud on AWS for VMware Aria Automation](#).

1. To configure a network profile, click **Infrastructure > Configure > Network Profiles** in the Automation Assembler service.
2. Click **New Network Profile**.
3. Click the **Summary** tab and specify the following sample settings:
 - Specify a vSphere cloud account/region, for example `vSphere-IPAM-OnDemandA/Datacenter`. This example assumes use of a vSphere cloud account that is not associated with an NSX cloud account.
 - Name the network profile, for example `Infoblox-OnDemandNP`.
 - Add a capability tag for the network profile, for example `infoblox_ondemandA`. **Make note of the capability tag value, as you must also use it as a cloud template constraint tag to make the network profile association to be used when provisioning the cloud template.**
4. Click the **Network Policies** tab and specify the following sample settings:
 - From the **Isolation policy** drop-down menu, select **On-demand network**.

This option allows you to use external IPAM IP blocks. Depending on the cloud account, new options appear. For example, the following options appear when using a vSphere cloud account that is associated to an NSX cloud account:

- Transport zone
- Tier-0 logical router
- Edge cluster

For this example, the vSphere cloud account is not associated to NSX, so the **Network domain** menu option appears.

- Leave the **Network domain** option blank.
5. Click **External** as the address management **Source**.
 6. Click **Add IP Block**, which opens the **Add IPAM IP Block** page.
 7. From the **Provider** menu on the **Add IPAM IP Block** page, select an existing external IPAM integration. For example, select the *Infoblox Integration* integration point from [Add an external IPAM integration for Infoblox in VMware Aria Automation](#) in the example workflow.
 8. From the **Address spaces** menu, select one of the available and listed IP blocks, for example **10.23.118.0/24** and add it.
- If the IPAM provider supports address spaces, the **Address spaces** menu appears. For an Infoblox integration, address spaces are represented by Infoblox network views.
9. Select a **Subnet size**, such as **/29 (-6 IP addresses)**.
 10. Click **Create**.

A network profile is created that can be used to provision an on-demand network using the specified external IPAM integration. The following sample cloud template shows a single machine to be deployed to a network that is defined by this new network profile.

```
formatVersion: 1
inputs: {}
resources:
  Cloud_Machine_1:
    type: Cloud.Machine
    properties:
      image: ubuntu
      flavor: small
      networks:
        - network: '${resource.Cloud_Network_1.id}'
          assignment: static
  Cloud_Network_1:
    type: Cloud.Network
    properties:
```

```

networkType: private

constraints:

- tag: infoblox_ondemandA

```

NOTE

When the cloud template is deployed, the first available network in the specified IP block is fetched and considered to be the network CIDR. If you are using an NSX network in the cloud template, you can instead set the CIDR of the network manually by using the network property `networkCidr`, as shown below, to manually set a CIDR and override the settings for IP blocks and subnet size that are specified in the associated network profile.

`Cloud_Network_1:`

```

type: Cloud.Network

properties:

networkCidr: 10.10.0.0/16

```

How do I configure a network profile to support an existing network for an external IPAM integration in VMware Aria Automation

How do I configure a network profile to support an existing network for an external IPAM integration to support IP address ranges for an existing network when that network profile is used in a VMware Aria Automation cloud template that uses external IPAM integration, you can configure a network profile.

An example is provided within the context of a vendor-specific sample workflow at [Configure a network and network profile to use external IPAM for an existing network in VMware Aria Automation](#). The overall vendor-specific workflow for external IPAM integration is at [Tutorial: Configuring VMware Cloud on AWS for VMware Aria Automation](#).

NOTE

You can assign an IPv6 address space to single and dual stacked workloads when an IPv6 address is requested per integration with an external IPAM system. This capability requires that the integrated external IPAM plug-in also supports IPv6.

For related information, see [How do I configure a network profile to support an on-demand network for an external IPAM integration in VMware Aria Automation](#).

NSX Projects and VPCs in network profiles

VMware Aria Automation supports discovering networks and security groups from NSX Projects and VPCs which can be added to network profiles.

What are NSX Projects and VPCs and how are they used in VMware Aria Automation

In previous releases, VMware Aria Automation could only use NSX networks and security groups that are part of the `/infra` branch included in the **Default** view of the NSX Manager UI. Starting with 8.18.1, VMware Aria Automation supports the discovery of networks and security groups included in all NSX Projects and Virtual Private Clouds (VPCs) configured in NSX Manager. These networks and security groups can be added to network profiles which can be selected for allocation to your cloud templates.

An NSX Project enables multi-tenancy for NSX network and security objects where each project is analogous to a tenant. A NSX VPC is an additional layer of tenancy that you can configure within an existing project. Both NSX Projects and

VPCs are primarily configured and managed in NSX Manager by an administrator. For more information on NSX Projects and VPCs and how to add them in your NSX Manager environment, go to [NSX Multi-tenancy](#).

VMware Aria Automation collects information about three types of NSX Project and VPC infrastructure objects:

- NSX Project segments
- NSX VPC subnets
- NSX Project and VPC groups

Within VMware Aria Automation segments and subnets are treated as networks, while groups are treated as security groups.

Modifying VPC subnets can have certain limitations in VMware Aria Automation depending on their IP configuration. Subnets with a manual IP configuration include CIDR routing which cannot be modified in VMware Aria Automation. However, you can still update the IP range of these subnets by clicking the **Manage IP Ranges** button. Subnets with an automatic IP configuration in NSX cannot be modified in VMware Aria Automation. You cannot create IP ranges of these subnets since the IPAM is managed by NSX and the **Manage IP Ranges** button is greyed out.

Information regarding segments and subnets is displayed under **Infrastructure > Resources > Networks**. Information regarding security groups is displayed under **Infrastructure > Resources > Security**. If a given network or security group is part of an NSX Project or VPC, this information is displayed in the **NSX Project/VPC** column.

Networks and security groups that are part of an NSX Project and/or VPC include three new custom properties.

Custom Property	Description
NsxProjectAndVpc	The names of the NSX Project and, if applicable for the specific network or security group, NSX VPC.
NsxProjectId	The ID of the NSX Project.
NsxVpcId	The ID of the NSX VPC.

Allocation logic for Network Interface Controllers (NICs)

VMware Aria Automation allocation logic prioritizes security groups based on the hierarchy of the networks to which the NIC or NICs are connected. The highest priority is given to /infra level segments, followed by Project segments, and finally VPC subnets. /infra level security groups are always prioritized if available. However, if the deployment selects security groups from either NSX Projects or VPCs, certain limitations apply. If a NSX Project security group is selected, for example, all NICs assigned to this security group must land on segments in this specific NSX Project or subnets in the VPC or VPCs included under the NSX Project. If a VPC security group is selected, all NICs assigned to this security group can only land on subnets in this specific VPC. If you select multiple security groups in a network profile, only those that follow this allocation logic are selected for the NIC based on the network selection.

NOTE

If you perform a day 2 operation on a deployed cloud template that changes the constraint tags of an existing network, the operation can fail even if the specified network can be found. This is caused by the new network not complying with the security groups associated with the existing NICs specified during the initial day 0 deployment. In such a scenario, you receive an error message similar to the following:

```
Operation: 'Update.Network': Unable to find a valid subnet for network
'Network Name ' of type 'EXISTING' with constraints '[{"tag":"public:subnetType"}, {"tag":"DEV-VPC:vpc"}]' in network profile 'NetP'. Filtered subnets [DEV-VPC-PUBLIC-SUB] NSX projects [DEV-PRO / DEV-VPC] are not compatible with NSX projects [DEV-PRO / DEV-VPC1, DEV-PRO] of security groups [DEV-VPC1-GRP1, DEV-PROJ-GRP].
```

How to add Automation Assembler storage profiles that account for different requirements

How to add storage profiles

An Automation Assembler storage profile describes the kind of storage to be deployed.

Storage is usually profiled according to characteristics such as service level or cost, performance, or purpose, such as backup.

Select **Infrastructure > Configure > Storage Profiles** and click **New Storage Profile**.

Learn more about storage profiles in VMware Aria Automation

Learn more about storage profiles

A cloud account region contains storage profiles that let the cloud administrator define storage for the region in VMware Aria Automation.

What does a storage profile do

Storage profiles include disk customizations, and a means to identify the type of storage by capability tags. Tags are then matched against provisioning service request constraints to create the desired storage at deployment time.

Storage profiles are organized under cloud-specific regions. One cloud account might have multiple regions, with multiple storage profiles under each.

Vendor-independent placement is possible. For example, you might have three different vendor accounts and a region in each. Each region includes a storage profile that is capability tagged as *fast*. At provisioning time, a request containing a *fast* hard constraint tag looks for a matching *fast* capability, regardless of which vendor cloud is supplying the resources. A match then applies the settings from the associated storage profile during creation of the deployed storage item.

NOTE

Different cloud storage might have different performance characteristics but still be considered the *fast* offering by the administrator who tagged it.

You can use a capability tag in your storage profile and set that tag as a soft constraint in the storage section of a virtual machine's properties in the cloud template. This action helps the VM prefer that storage profile for placement during deployment. If a matching tag is not present in the storage profile, then the default storage profile for that region is selected during deployment.

Capability tags that you add to storage profiles should not identify actual resource targets. Instead, they describe types of storage. For related information, see [Storage resources in VMware Aria Automation](#).

Default provisioning type

The storage profile provisioning type only establishes a default behavior. The setting doesn't necessarily affect placement and might be overridden by a property in the cloud template.

For example, you might set the storage profile for thin provisioning. In most cases, requests would create thin provisioning storage by default. However, if the cloud template has the `provisioningType` property set to `eager-zero`, the cloud template overrides the default of thin.

NOTE

When you want exact control, it's better to add capability and constraint tags labeled for the desired provisioning type.

For the provisioning type default, a cloud template property overrides a storage profile default, and a storage profile default overrides a default from a vCenter storage policy.

Disk allocation with machines

In a project with multiple cloud zones that belong to different cloud accounts, a disk follows the machine even if the disk isn't attached to the machine. This behavior keeps the resources together to prevent failure when you decide to attach the disk later.

For example, the following design won't work. The cloud template attempts to use location constraints to separate the disk, but the deployment returns a `No matching placement` error instead.

If you need to place a disk in a different cloud account, use a separate deployment to deploy the disk.

resources:

```
Machine1:
  type: Cloud.vSphere.Machine
  properties:
    image: ubuntu
    flavor: small
  constraints:
    - tag: 'location:siteA'

Disk1:
  type: Cloud.vSphere.Disk
  properties:
    capacityGb: 1
  constraints:
    - tag: 'location:siteB'
```

Using affinity filters for improved storage/compute recommendations

While earlier VMware Aria Automation releases used a storage filter that selected the first eligible storage option and passed it to downstream filters, the storage filter now passes all the eligible storage options to downstream filters. This allows the compute spread policy to consider and evaluate multiple storage profiles and provide improved storage selections.

First class and standard disks

By using the **Disk type** option on the storage profile page, or by using the VMware Aria Automation API, you can create a storage profile to support first class disk (FCD) or standard disk storage. In effect, the first class disk option creates a vSphere storage profile.

- First class disk

First class disks can exist independent from a vSphere virtual machine. A first class disk also has life-cycle management capabilities that can operate independently of a virtual machine. First class disks are available for vSphere 6.7 Update 2 and later, and are currently implemented in VMware Aria Automation as an API-only feature.

For information about FCD storage, including the capabilities that are available from the VMware Aria Automation API, and links to the API documentation itself, see [What can I do with first class disk storage in VMware Aria Automation](#).

- Standard disk

Standard disk storage is created and managed as an integrated component of a virtual machine.

For information about standard disk storage, see [What can I do with standard disk storage in VMware Aria Automation](#) and [What can I do with persistent disk storage in VMware Aria Automation](#).

Storage profile and datastore priority

The priority value of storage profiles and datastore or datastore clusters allows users to manually define how they are selected during deployment.

NOTE

The assigned storage profile priority does not override the default storage profile. The default storage profile is selected when no constraint tags are included in the relevant cloud template. In such a case, the default storage profile is selected even if it has the lowest priority value of all eligible storage profiles.

You can set the storage profile priority by entering the desired value in the **Priority** text box. The highest priority value is zero.

Storage profile priority is considered only after the eligible storage profiles are filtered by other factors such as capability tags and available capacity.

The datastore information is found under the **Datastore** tab. Datastores included in the storage profile can be managed in the following ways:

- Show all datastores and datastore clusters included in the datacenter.
- Manually add datastores or datastore clusters that you want to be associated with the storage profile.
- Dynamically add datastores or datastore clusters based on tags.

To set the datastore priority, select one or more datastores or datastore clusters and click **Set priority**. Similarly to storage profiles, the highest priority value is zero.

During deployment, VMware Aria Automation first checks the priority of eligible storage profiles and then the priority of the associated datastores or clusters. If multiple storage profiles have the same priority, the latest updated storage profile is selected. If multiple datastores or datastore clusters have the same priority value, they are selected based on available capacity.

For example, your environment might include the storage profiles **profile_01** and **profile_02** with a priority value of one and **profile_03** with a priority value of two. While the first two storage profiles have the same priority, **profile_02** was updated more recently, so it is selected for deployment. After selecting the storage profile, VMware Aria Automation checks the priority and available capacity of the datastores and datastore clusters. For example, let's say **profile_02** includes two datastores with the same priority value. In this scenario the datastore with highest available capacity is chosen.

NOTE

If two storage profiles have the same priority and one of them has a compute resource specified while the other does not, higher priority is given to the storage profile with the specified compute resource.

Azure server-side disk encryption

For Azure resources, if you elect to support encryption in a managed disk storage profile, you also select disk encryption that has an associated key. Available encryption and keys correspond to the disk encryption sets configured in Azure for the location.

How to use Pricing Cards in VMware Aria Automation

How do I use pricing cards

Automation Assembler pricing cards help cloud administrators define and assign the pricing policy for the monetary impact of your individual deployments to help you manage resources.

NOTE

For pricing to work on multi-tenant environments, you must have a separate VMware Aria Operations instance for each VMware Aria Automation tenant.

Pricing cards define the rates for a pricing policy. The pricing policy can then be assigned to specific projects to define a total price. After creating a VMware Aria Operations or CloudHealth endpoint, a predefined default rate card is available with a cost equal to price configuration on the **Infrastructure > Pricing Cards** tab. You can create pricing cards that apply to projects only or cloud zones. By default, all new pricing cards are applied to projects.

NOTE

If you change the **All pricing cards are applied to** setting, all existing pricing card assignments are deleted. Also, if the VMware Aria Operations endpoint is deleted from Automation Assembler, all pricing cards and assignments are also deleted.

The price of a deployment over time appears on both the deployment card and project as the month-to-date price, which resets to zero at the beginning of each month. The component cost breakdowns are available in the deployment details. Providing this information at the deployment level informs the cloud administrator, but it also helps the members understand the impact their work might have on budgets and long-term development.

You can choose to display pricing information from users in Automation Assembler and Automation Service Broker by selecting the **Display pricing information** button. If left disabled, the pricing information is hidden from Automation Assembler and Automation Service Broker users.

How is price calculated

The initial price that you see at the deployment level for your compute and storage resources are based on industry standard benchmark rates, and then calculated over time. The rate is applied to hosts and the service calculates the CPU and memory rates. The server recalculates the price every 6 hours.

New policies, assignments, and upfront pricing are priced during the next occurring data collection cycle. By default, the data collection cycle is run every 5 minutes. It can take up to 6 hours for new policies or changes to be updated in projects and deployments.

How do I estimate the price of my deployments and projects

Before deploying a catalog item, you can use the upfront price as a price estimate for your deployment. To view the price in Automation Assembler, you must have a VMware Aria Operations integration endpoint configured with pricing enabled and currency preset.

Daily Price Estimate

×

 Guest OS and one time prices are excluded in this estimate.

	price-service-f309c00	\$0.54
	Cloud_vSphere_Machine_1	\$0.53
	Compute	\$0.39
	Storage	\$0.03
	Additional charges	\$0.11
	Cloud_vSphere_Disk_1	\$0.01
	Storage	\$0.01

CLOSE

For an upfront price estimation, the size of boot disk per VM is always 8 GB.

The upfront price of a deployment is a daily price estimate, based on the allocation of a resource, for a given catalog item before it is deployed. After a catalog item is deployed, you can view the month-to-date price as an aggregate of the upfront price on the **Deployment** and **Infrastructure > Projects** tabs. Upfront pricing is supported for private cloud resources such as vSphere machine and vSphere disk, Automation Assembler catalog items, and cloud agnostic items with vCenter configured for private cloud.

NOTE

Upfront pricing is not supported for public cloud resources, or non- vSphere machine or disk private cloud resources.

To estimate the cost of your deployment, from the Catalog select a catalog item and click **Request > Calculate**. If the price is acceptable, click **Submit**.

You can use project pricing cards to estimate the total price of all your projects.

To estimate the cost of a project, on the Infrastructure Pricing Card page next to **All pricing cards are applied to** setting, click **Edit** and select **Projects**.

If you change the **All pricing cards are applied to** setting, all existing pricing card assignments are deleted. Create pricing cards and assignments using a cost-based approach.

How to create pricing cards for vSphere and VMware Cloud on AWS in VMware Aria Automation

[How to create pricing cards for vSphere and VMware Cloud on AWS](#)

Depending on the pricing strategy determined by the cloud administrator for private cloud deployments, you can create and assign a pricing card to projects or cloud zones.

Before you can create or assign pricing cards, you must configure and enable pricing and configure currency in VMware Aria Operations to work with Automation. When configuring VMware Aria Operations with Automation, ensure that both applications are set to the same timezone.

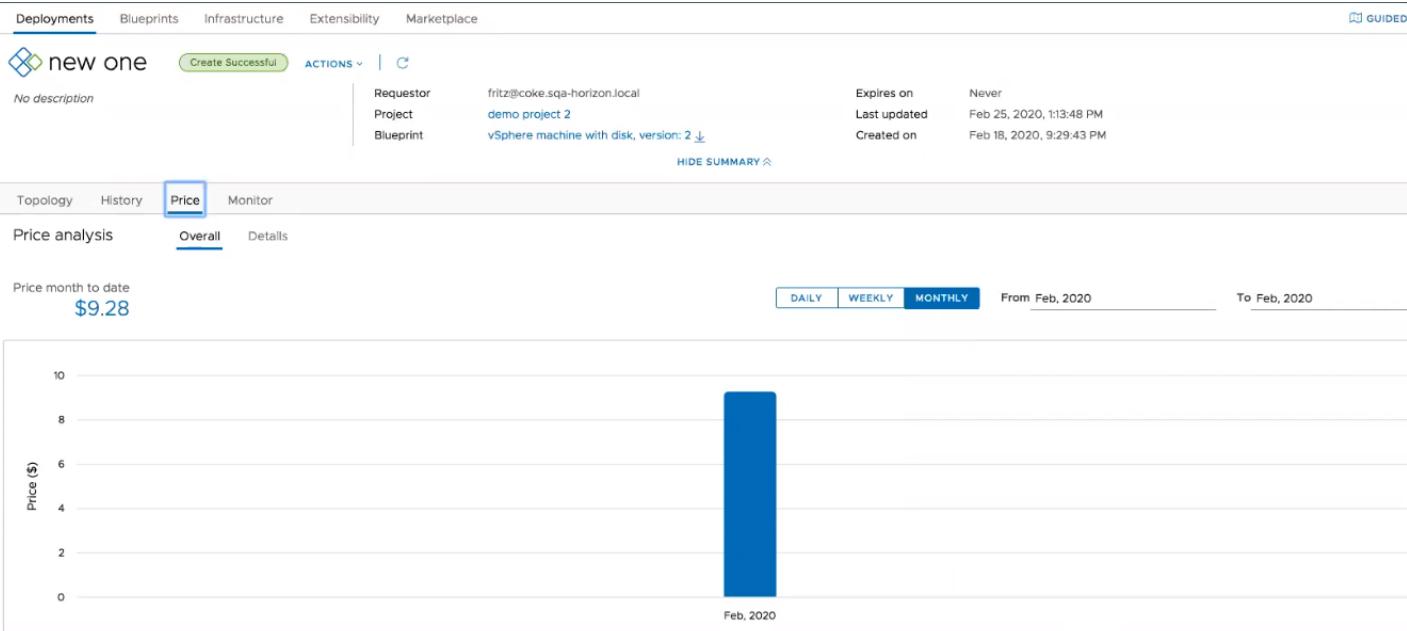

You must configure a VMware Aria Operations endpoint before you can configure pricing cards. To configure the VMware Aria Operations endpoint, navigate to **Infrastructure > Connections > Integrations > Add Integration**.

NOTE

When multiple VMware Aria Operations endpoints are added they must not monitor the same vCenter.

Pricing cards are customizable based on user-selected parameters. After configuring a pricing card, you can assign it to one or more projects and cloud zones determined by the pricing strategy.

You can manually refresh the price server at any time on the VMware Aria Operations **Endpoint** page, **Infrastructure > Integrations > VMware Aria Operations Endpoint**. In the vCenter servers section, click **Sync**. When manually refreshing the price server using the **Sync** option, the price is recalculated for all projects in the organization. Depending on how many projects your organization has this process might be intensive and take time.

After creating and assigning a pricing card, you can view the price history of your deployments and projects. To view the price history, navigate to your deployment and click **Price**. The price analysis provides an overview and detailed view of the deployment price along with the price month-to-date value. You can change the graphical representation to display the deployment price as daily, weekly, or monthly values. Also, you can specify an exact date range or month for the price history.

To view the price breakdown by cost component, click **Details**.

Prices are determined by costed component types.

Table 20: Costed Component Types

Blueprint Component Type	Service Name/Object Type	Blueprint Resource Type	Comments
Cloud Agnostic	Machine	Cloud.Machine	If an agnostic machine is configured with vSphere, you can view deployment cost.

Table continued on next page

Continued from previous page

Blueprint Component Type	Service Name/Object Type	Blueprint Resource Type	Comments
	Disk	Cloud.Volume	If an agnostic disk is attached to a virtual machine that is configured with vSphere, you can view deployment cost.
vSphere	vSphere machine	Cloud.vSphere.Machine	Deployed using a cloud-specific cloud template.
	vSphere disk	Cloud.vSphere.Disk	Deployed using a cloud-specific cloud template attached to a virtual machine.
VMware Managed Cloud (VMC)	vSphere machine	Cloud.vSphere.Machine	VMC only supports rate-based pricing cards (cost based pricing cards are not supported).
	vSphere disk	Cloud.vSphere.Disk	

1. Navigate to **Infrastructure > Pricing Cards > New Pricing Card**.
2. On the **Summary** tab, enter a name and description for the pricing card. Once the policy is defined on the pricing tab, the Overview table is populated with pricing card rates.

NOTE

The currency unit is determined by the valued selected in VMware Aria Operations.

3. Optional. Select the **Default for unassigned projects?** check box to assign this pricing card to all unassigned projects by default.
4. Click **Pricing**, and configure the details of your pricing policy.

Table 21: Pricing Policy Configuration

Parameter	Description
Basic Charges	<p>Enter a name and description for your policy. Select cost or rate based.</p> <ul style="list-style-type: none"> • Cost - The cost is defined in VMware Aria Operations. If selected, a multiplication factor is required. For example, if you select 1.1 as a factor, the cost is multiplied by 1.1 resulting in a 10% increase to the calculated cost. The price equation using cost is: $<\text{cost}> \times <\text{multiplication factor}> = \text{Price}$ • Rate - If selected, you must use absolute values to determine the cost. The price equation using rate is: $<\text{Rate}> = \text{Price}$. Select a rate interval from the drop down list to specify how this rate is charged. <p>In the basic charges section, you define the cost or rate for CPU, memory, storage, and additional miscellaneous costs.</p>

Table continued on next page

Continued from previous page

Parameter	Description
Guest OSes	<p>You can define a Guest OS charge by clicking Add Charge. Enter the guest OS name and define the charging method and base rate.</p> <ul style="list-style-type: none"> Recurring - enter a base rate and define recurring interval as the charge period. The absolute rate value is required and it is added to the overall price. One time - define the one-time base rate charge. The absolute value is required and it is added as a one time price. Rate Factor - A multiplication factor is required that is applied to the select charge category. For example, if you select CPU Charge and a rate factor of 2. The Guest OS CPU is charged as 2 times the standard cost value. <p>You can add multiple Guest OS items with different rates by clicking Add Charge and configuring an additional charge policy.</p> <p>NOTE Upfront charges for each Guest OS are not shown on the summary page, even though they are part of the policy.</p>
Tags	<p>You can define a tag charge by clicking Add Charge. Select the tag name and define the charging method and base rate.</p> <ul style="list-style-type: none"> Recurring - enter a base rate and define recurring interval as the charge period. The absolute rate value is required and it is added to the overall price. One time - define the one-time base rate charge. The absolute value is required and it is added as a one time price. Rate Factor - A multiplication factor is required that is applied to the select charge category. <p>Select how to charge the tag based on powered on state.</p> <p>You can add multiple tags with different rates by clicking Add Charge and configuring an additional charge policy.</p> <p>NOTE Additional charges in the calculated final price include on tags on VMs and does not include tags on disks and networks.</p>

Table continued on next page

Continued from previous page

Parameter	Description
Custom Properties	<p>You can define a Custom Property charge by clicking Add Charge. Enter the property name and value, and define the charging method and base rate.</p> <ul style="list-style-type: none"> Recurring - enter a base rate and define recurring interval as the charge period. The absolute rate value is required and it is added to the overall price. One time - define the one-time base rate charge. The absolute value is required and it is added as a one time price. Rate Factor - A multiplication factor is required that is applied to the select charge category. <p>Select how to charge the custom property based on powered on state.</p> <p>You can add multiple custom properties with different rates by clicking Add Charge and configuring an additional charge policy.</p>
Overall Charges	<p>Define any additional charge you would like to add to the pricing policy. You can add both one time and recurring charges.</p>

One time charges are not shown in the price estimate of a catalog item or on the **Summary** tab. Only the daily price estimate for a given catalog item is shown.

- Click the **Assignments** tab and click **Assign Projects**. Select one or more projects to assign the pricing card to.

NOTE

By default pricing cards are applied to projects. On the **Infrastructure > Pricing Cards** tab, you can select to apply pricing cards to cloud zones. If cloud zones were selected, you would click **Assign Cloud Zones** on the **Assignments** tab.

- Click **Create** to save and create your pricing policy.

Your new pricing policy appears on the **Pricing Cards** page. To view or edit the policy details and configuration click **Open**.

How to use tags to manage Cloud Assembly resources and deployments

Creating a tagging strategy

You must carefully plan and implement an appropriate tagging strategy based on your organization's IT structure and goals to maximize Automation Assembler functionality and minimize potential confusion.

While tagging serves several common purposes, your tagging strategy must be tailored to your deployment needs, structure, and goals.

Best practices for tagging

Some general characteristics of an effective tag strategy:

- Design and implement a coherent strategy for tagging that relates to the structure of your business and communicate this plan to all applicable users. A strategy must support your deployment needs, use clear human readable language, and be understandable to all applicable users.
- Use simple, clear, and meaningful names and values for tags. For instance, tag names for storage and network items should be clear and coherent so that users can readily understand what they are selecting or reviewing tag assignments for a deployed resource.
- Though you can create tags using a name with no value, as a best practice, it is more appropriate to create an applicable value for each tag name, as this makes the tag usage clear to other users.
- Avoid creating duplicate or extraneous tags. For example, only create tags on storage items that relate to storage issues.

Tagging implementation

Map out your primary considerations for a basic tagging strategy. The following list shows typical considerations to consider when mapping your strategy. Be aware that these considerations are representative rather than definitive. You might have other considerations that are highly relevant to your use cases. Your specific strategy must be appropriate for your specific use cases.

- How many different environments do you deploy to. Typically, you will create tags that represent each environment.
- How are your compute resources structured and used to support deployments.
- How many different regions or locations do you deploy to. Typically, you will create tags, at the profile level, that represents each of these different regions or locations.
- How many different storage options are available for deployments, and how do you want to characterize them. These options should be represented by tags.
- Categorize your networking options and create tags to accommodate all applicable options.
- Typical deployment variables. For example, how many different environments do you deploy to. Typically, many organizations have Test, Dev, and Production environments at a minimum. You will want to create and coordinate constraint tags and cloud zone capability tags that match so that you can easily set up deployments to one or more of these environments.
- Coordinate tags on network and storage resources so that they make logical sense in context of the network and storage profiles in which they are used. The resource tags can serve as a finer level of control over the resource deployment.
- Coordinate cloud zone and network profile capability tags, and other capability tags, with constraint tags. Typically, your administrator will create capability tags for cloud zones and network profiles first, and then other users can design cloud templates with constraints that match these capability tags.

After you understand the important considerations for your organization, you can plan appropriate tag names that address these considerations in a logical manner. Then, create an outline of your strategy and make it available to all users with privileges to create or edit tags.

As a useful implementation approach, you can begin by tagging all of your compute infrastructure resources individually. As noted, use logical categories for tag names that relate to the specific resource. For instance, you might tag storage resources as tier1, tier2, etc. Also, you might tag compute resources based on their operating system, such as Windows, Linux, etc.

After you tag resources, you can then consider the approach to creating tags for cloud zone and storage and network profiles that best suits your needs.

Using capability tags in Automation Assembler

In Automation Assembler, capability tags enable you to define deployment capabilities for infrastructure components. Along with constraints, they function as the basis of placement logic in VMware Aria Automation.

You can create capability tags on compute resources, cloud zones, images and image maps, and networks and network profiles. The pages for creating these resources contain options for creating capability tags. Alternatively, you can use the Tag Management page in Automation Assembler to create capability tags. Capability tags on cloud zones and network

profiles affect all resources within those zones or profiles. Capability tags on storage or network components affect only the components on which they are applied.

Typically, capability tags might define characteristics such as location for a compute resource, adapter type for a network, or tier level for a storage resource. They can also define environment location or type and any other business considerations. As with your overall tagging strategy, you should organize your capability tags in a logical manner for your business needs.

Automation Assembler matches capability tags from cloud zones with constraints on cloud templates at deployment time. So, when creating and using capability tags, you must understand and plan to create appropriate cloud template constraints so that matching will occur as expected.

For example, the cloud zone section in the [WordPress infrastructure example](#) included with the documentation describes how to create dev and test tags for the OurCo-AWS-US-East and OurCo AWS-US-West cloud zones. In this tutorial, these tags indicate that the OurCo-AWS-US-East zone is a development environment, and the OurCo-AWS-US_West zone is a test environment. If you create analogous constraint tags in cloud templates, these capability tags enable you to direct deployments to the desired environments.

Tag inheritance

Automation Assembler uses tag inheritance to selectively propagate tags on cloud accounts and compute resources that correspond to that cloud account.

NOTE

Tag propagation behavior does not apply to storage profiles. This means that VMware Aria Automation will not automatically select the constraint for storage profiles, so users must manually add the required constraint tag for it to be selected and applied to storage profiles.

The following example illustrates how tag inheritance works.

Compute resources

- Cluster1 with tag cluster-1
- Cluster2 with tag cluster-2
- Cluster3 with tag cluster-3

Vm resource:

```
properties:
constraints:
  - tag: 'cluster-01'
```

Cloud Account

vSphere cloud account with all three of the tags: cluster-1, cluster-2, and cluster-3

While consolidating tags on compute resources, Automation Assembler also considers the cloud account level tags. Hence, the effective tags on the computes are cluster-1, cluster-2 and cluster-3 and this is why when we provide any of these tags as shown in the preceding example, all the compute resources become eligible for placement and the machine can land on any of the compute hosts.

As a best practice, to minimize unexpected results and tag clutter, any given tag should be applied only at the cloud account level if that tag is an appropriate capability for all subordinate compute resources.

Using constraint tags in Automation Assembler

Tags added to projects and cloud templates function as constraint tags when they are used to match capability tags on infrastructure resources, profiles, and cloud zones. In the case of cloud templates, Automation Assembler uses this matching functionality to allocate resources for deployments.

Automation Assembler enables you to use constraint tags in two primary ways. The first way is when configuring projects and images. You can use tags as constraints to associate resources with the project or image. The second is in cloud templates where tags specified as constraints are used to select resources for deployments. Constraints applied in both of these ways are merged in cloud templates to form a set of deployment requirements that define resources available for a deployment.

How constraint tags work on projects

When configuring Automation Assembler resources, cloud administrators can apply constraint tags on projects. In this way, administrators can apply governance constraints directly at the project level. All constraints added at this level are applied to every cloud template requested for the applicable project, and these constraint tags take precedence over other tags.

If constraint tags on the project conflict with constraint tags on the cloud template, the project tags take precedence, thus allowing the cloud administrator to enforce governance rules. For example, if the cloud administrator creates a `location: london` tag on the project, but a developer places a `location: boston` tag on the cloud template, the former will take precedence and the resource is deployed to infrastructure containing the `location: london` tag.

There are three types of constraints tags that users can apply on projects: network, storage, and extensibility. You can apply as many instances of each tag type as needed. Project constraints can be hard or soft. By default they are hard. Hard constraints allow you to rigidly enforce deployment restrictions. If one or more hard constraints are not met, the deployment will fail. Soft constraints offer a way to express preferences that will be selected if available, but the deployment won't fail if soft constraints are not met.

How constraint tags work in cloud templates

In cloud templates, you add constraint tags to resources as YAML code to match the appropriate capability tags that your cloud administrator created on resources, cloud zones and storage and network profiles. In addition, there are other more complex options for implementing constraint tags. For example, you can use a variable to populate one or more tags on a request. This enables you to specify one or more of the tags at request time.

Create constraint tags by using the `tag` label under a constraint heading in the cloud template YAML code. Constraint tags from projects are added to the constraint tags created in cloud templates.

Automation Assembler supports a simple string formatting to make using constraints easier in YAML files:

```
[!]tag_key[:tag_value][:hard|:soft]
```

By default Automation Assembler creates a positive constraint with hard enforcement. The tag value is optional, though recommended, as in the rest of the application.

NOTE

Only the hard or soft delimiters are officially supported as extensions to the basic `tag key:value` format. Attempting to use other delimiters will likely cause errors.

The following WordPress with MySQL example shows YAML constraint tags that specific location information for compute resources.

```
name: "wordPressWithMySql"
```

```
components:
```

```

mysql:
  type: "Compute"
  data:
    name: "mysql"
    # ... skipped lines ...
wordpress:
  type: "Compute"
  data:
    name: "wordpress"
    instanceType: small
    imageType: "ubuntu-server-1604"
    constraints:
      - tag: "!location:eu:hard"
      - tag: "location:us:soft"
      - tag: "!pci"
    # ... skipped lines ...

```

For more information about how to work with cloud templates, see [Part 3: Design and deploy the example template](#).

How hard and soft constraints work in projects and cloud templates

Constraints in both projects and cloud templates can be hard or soft. The preceding code snippet shows examples of hard and soft constraints. By default all constraints are hard. Hard constraints allow you to rigidly enforce deployment restrictions. If one or more hard constraints are not met, the deployment will fail. Soft constraints express preferences that apply if available, but they won't cause a deployment to fail if not met.

If you have a series of hard and soft constraints on a specific resource type, the soft constraints can also serve as tie breakers. That is, if multiple resources meet a hard constraint, the soft constraints are used to select the actual resource used in the deployment.

For example, let's say that you create a hard storage constraint with a tag of `location:boston`. If no storage in the project matches this constraint, any related deployment will fail.

NOTE

Soft constraints on networks can be used to select networks within a network profile, but do not affect the selection of the network profile itself.

Standard tags

Automation Assembler applies standard tags to some deployments to support analysis, monitoring, and grouping of deployed resources.

Standard tags are unique within Automation Assembler. Unlike other tags, users do not work with them during deployment configuration, and no constraints are applied. These tags are applied automatically during provisioning on AWS, Azure,

and vSphere deployments. These tags are stored as system custom properties, and they are added to deployments after provisioning.

The list of standard tags appears below.

Table 22: Standard tags

Description	Tag
Organization	org:orgID
Project	project:projectId
Requester	requester:username
Deployment	deployment:deploymentID
Cloud template reference (if applicable)	blueprint:blueprintID
Component name in blueprint	blueprintResourceName:CloudMachine_1
Placement Constraints: applied in blueprint, request parameters, or via IT policy	constraints:key:value:soft
Cloud Account	cloudAccount:accountID
Zone or profile, if applicable	zone:zoneID, networkProfile:profileID, storageProfile:profileID

How Automation Assembler processes tags

In Automation Assembler, tags express capabilities and constraints that determine how and where resources are allocated to provisioned deployments during the provisioning process.

Automation Assembler uses a specific order and hierarchy of operations in resolving tags to create provisioned deployments. Understanding the basics of this process will help you to implement tags efficiently to create predictable deployments.

The following list summarizes the high level operations and sequence that Automation Assembler uses to resolve tags and define a deployment:

- Cloud zones are filtered by several criteria, including availability and profiles; tags in profiles for the region the zone belongs to are matched at this point.
- Zone and compute capability tags are used to filter the remaining cloud zones by hard constraints.
- Out of the filtered zones, priority is used to select a cloud zone. If there are several cloud zones with the same priority, they are sorted by matching soft constraints, using a combination of the cloud zone and compute capabilities.
- After a cloud zone is selected, a host is selected by matching a series of filters, including hard & soft constraints as expressed in cloud templates.

How do I set up a simple tagging structure

This topic describes a basic approach and options for a logical Automation Assembler tagging strategy. You can use these examples as a starting point for an actual deployment, or you can devise a different strategy that better suits your needs.

Typically, the cloud administrator is the primary individual responsible for creating and maintaining tags. This topic refers to the WordPress use case described elsewhere in the Automation Assembler documentation to illustrate how tags can be added to some key items. It also describes possible alternatives and extensions to the tagging examples that appear in the WordPress use case.

See [Tutorial: Setting up and testing multi-cloud infrastructure and deployments in Automation Assembler](#) for more information about the WordPress use case.

The WordPress use case describes how to place tags on cloud zones and storage and network profiles. These profiles are like organized packages of resources. Tags placed on profiles apply to all items within the profile. You can also create and place tags on storage resources and individual network items as well as on compute resources, but these tags apply

only to the specific resources on which they are placed. When setting up tags, it is usually best to begin by tagging compute resources, and then you can add tags to profiles and cloud zones later. Also, you use these tags to filter the list of compute resources for a cloud zone.

For example, while you can place tags on storage profiles as shown in this use case, you can also place tags on individual storage policies, data stores, and storage accounts. Tags on these resources enable you to exercise finer control over how storage resources are deployed. During processing in preparation for deployment, these tags are resolved as a next level of processing after the profile tags.

As an example of how you might configure a typical customer scenario, you could place a tag of `region: eastern` on a network profile. This tag would apply to all resources within that profile. Then you could place a tag of `networktype:pci` on a pci network resource within the profile. A cloud template with constraints of `eastern` and `pci` would create deployments that use this pci network for the eastern region.

1. Tag your compute infrastructure resources in a logical and appropriate manner.

It is particularly important that you tag compute resources in a logical manner so that you can find them using the search function on the Compute tab of the Create Cloud Zone page. Using this search function, you can quickly filter the compute resources associated with a cloud zone. If you tag Storage and Networks at the profile level, you may not need to tag individual storage and network resources.

- a) Select **Resources > Compute** to view the compute resources that have been imported for your Automation Assembler instance.
- b) Select each compute resource as appropriate and click **Tags** to add a tag to the resource. You can add more than one tag to each resource if appropriate.
- c) Repeat the previous step for storage and network resources as appropriate.

2. Create cloud zone and network profile capability tags.

You can use the same tags for both cloud zones and network profiles, or you can create unique tags for each item if that makes more sense for your implementation.

In network profiles, you can place tags on the entire profile as well as on subnets within the profile. Tags applied at the profile level apply to all components, such as subnets, within that profile. Tags on subnets apply only to the specific subnet on which they are placed. During tag processing, the profile level tags take precedence over the subnet level tags.

For information about adding tags to cloud zones or network profiles, see the cloud zone and network sections of the [WordPress infrastructure example](#).

In this example we create three simple tags that appear throughout the use case documentation for Automation Assembler cloud zone and network profile tags. These tags identify the environment for the profile components.

- `zone:test`
- `zone:dev`
- `zone:prod`

3. Create storage profile tags for your storage components.

Typically, storage tags identify the performance level of storage items, such as tier1 or tier2, or they identify the nature of storage items, such as pci.

For information about adding tags to storage profiles, see the storage section of the [WordPress infrastructure example](#).

- `usage:general`
- `usage:fast`

After you create a basic tagging structure, you can begin working with it and add or edit tags as appropriate to refine and extend your tagging capabilities.

How to work with resources in VMware Aria Automation

How to work with resources

A cloud administrator can review VMware Aria Automation resources that are exposed through data collection.

The cloud administrator can label resources with capability tags to affect where VMware Aria Automation cloud templates are deployed.

In addition to the views provided here, you can also manage various resources using the Resources tab. See [Managing resources in](#).

Compute resources in VMware Aria Automation

Compute resources

A cloud administrator can review compute resources that are exposed through data collection.

The cloud administrator might choose to apply tags directly to the resources to label capabilities for matching purposes in VMware Aria Automation provisioning.

Network resources in VMware Aria Automation

Network resources

In VMware Aria Automation, cloud administrators can view and edit the network resources that have been data-collected from the cloud accounts and integrations that are mapped to your project.

After you add a cloud account to your Automation Assembler infrastructure, for example by using the **Infrastructure > Connections > Cloud Accounts** menu sequence, data collection discovers the cloud account's network and security information. That information is then available for to use in networks, network profiles, and other definitions.

Networks are the IP-specific components of an available network domain or transport zone. If you're an Amazon Web Services or Microsoft Azure user, think of networks as subnets.

You can display information about the networks in your project by using the **Infrastructure > Resources > Networks** page.

The Automation Assembler**Networks** page contains information such as:

- Networks and load balancers that are defined externally in the network domain of your cloud account, for example in vCenter, NSX-T, or Amazon Web Services.
- Networks and load balancers that have been deployed by the cloud administrator.
- IP ranges and other network characteristics that have been defined or modified by your cloud administrator.
- External IPAM provider IP ranges for a particular address space in an provider-specific external IPAM integration.

For more information about networks, see the following information, signpost help for various settings on the **Networks** page, and [Learn more about network profiles in VMware Aria Automation](#).

Networks

vSphere networks, regular NSX networks, and global (federated) NSX networks are supported.

You can view and edit networks and their characteristics, for example to add tags or remove support for public IP access. You can also manage network settings such as DNS, CIDR, gateway, and tag values. You can also define new, and manage existing, IP ranges within a network.

For existing networks you can change the IP range and tag settings by selecting the network's checkbox and selecting either **Manage IP Ranges** or **Tags**. Otherwise you can select the network itself to edit its information.

Tags provide a means for matching appropriate networks, and optionally network profiles, to network components in cloud templates. Network tags are applied to every instance of that network, regardless of any network profiles in which the network may reside. Networks can be instanced into any number of network profiles. Regardless of network profile residency, a network tag is associated with that network wherever the network is used. Network tag matching occurs with other components in the cloud template after the cloud template has been matched with one or more network profiles.

Machine tags are defined in the cloud template and apply to the machine if deployed to a vCenter. Machines that are connected to an NSX-T local manager or global manager are also tagged in the cloud template. Note that machine tagging is different than machine NIC (network interface) tagging.

- Using global (federated) NSX networks

NSX-T global networks are networks that are defined by the NSX-T global manager and apply to one or more NSX-T local managers. For global networks, existing and public networks are supported for NSX-T global manager and local manager cloud accounts and the vCenter cloud accounts that are associated to the local managers. Local manager representation of stretched networks is defined within a transport zone. The transport zone is an NSX-T local manager construct that defines the span of NSX-T networks for vCenter hosts and clusters.

Automation Assembler enumerates, or data collects, existing and public networks. You can create a global network by adding an existing or public network on an NSX-T global manager. The global network can then be consumed by all the associated local managers. Global networks can span one, all, or a subset of the associated local managers.

You can provision a machine on a global network by using a static IP assignment. DHCP is not supported.

You can create the following types of global networks on a global manager:

1. Overlay - an overlay network is associated with a Tier-0/Tier-1 local manager and automatically stretches to all the sites connected to the Tier-0/Tier-1 local manager. For each local manager, the default overlay transport zone is used.
2. VLAN - a VLAN network applies to a single local manager and the transport zone can be manually selected.

Global networks are listed on the **Infrastructure > Resources** page with all the cloud accounts that they apply to.

The following Day 2 operations are supported for global networks:

- Reconfigure a network in a cloud template definition from a global network to a local network and vice versa.
- Scale-out/scale-in of machines on global networks.

For more information about using global networks in cloud templates, see [More about network resources in VMware Aria Automation cloud templates](#).

- Using VLAN segments in non-federated NSX networks

You can provision NSX-T VLAN segments by specifying one or more VLAN IDs on a private NSX network type. Use this technique when, for example, your overall design prohibits you from provisioning overlay networks on NSX-T. This option requires that you select a VLAN transport zone in a supporting network profile.

When using non-federated networks, you can provision private NSX on-demand VLAN segments when the network segments are used with a Policy API-type of NSX-T cloud account. VLAN segments are not connected to a Tier-1 router, therefore only private networks support VLAN segment specification. Once created, VLAN segments that are provisioned by VMware Aria Automation can also be used as existing networks in other VMware cloud templates.

To use VLAN segments, you must first configure the intended network profile to allow subnet isolation for the on-demand network. You must specify a VLAN transport zone in the network profile. If you specify an overlay transport zone, the network profile cannot be used for VLAN specifications. An example of VLAN transport zone selection in a network profile is shown below. For related information about configuring network profiles, see [Learn more about network profiles in VMware Aria Automation](#).

The screenshot shows the 'Network Policies' tab selected in the top navigation bar. Below it, a section titled 'Isolation policy' is set to 'On-demand network'. Under 'Network Resources', there's a note about providing on-demand network resources. On the left, a list includes 'Transport zone *' (marked with a red asterisk), 'External network', 'Tier-0 logical router', and 'Edge cluster'. A large yellow arrow points from the 'Transport zone' field to a dropdown menu on the right. This dropdown has a search bar at the top and a list of options: 'nsx-overlay-transportzone' (selected and highlighted in blue), 'Overlay', 'nsx-vlan-transportzone', 'VLAN', 'overlay-tz-cmbu-w01-nsx10.eng.vmware.com', and 'Overlay' again.

You specify one or more VLAN segments, or arrays of VLAN IDs, by using the `vlanIds` property in the `Cloud.NSX.Network` component in the VMware cloud template YAML. To specify multiple `vlanIds` values in the private network `Cloud.NSX.Network` component, use a separate row entry for each value. The VMware Aria Automation API requires that you specify multiple VLAN values in a comma-separated list, but using that format in the cloud template YAML is unsupported. The supported VLAN values range between 0 to 4094. For sample cloud template YAML code, see [Network, security group, and load balancer resource examples in Automation Assembler](#).

For information about reusing networks, see [How to reuse VMware Aria Automation networking and security resources in Automation Assembler](#).

IP Ranges

Use an IP range to define or make changes to the start and end IP address for a particular network in your organization. You can display and manage IP ranges for listed networks. If the network is managed by an external IPAM provider, you can manage IP ranges in connection with the associated IPAM integration point.

Click **New IP Range** to add an additional IP range to the network. You can specify an **internal IP range**, or if there is a valid IPAM integration available you can specify an **External IP range**.

You cannot include the default gateway in an IP range. The subnet IP range cannot include the subnet gateway value.

If you are using an external IPAM integration for a particular IPAM provider, you can use the **External IP range** to select an IP range from an available external IPAM integration point. This process is described within the context of an overall external IPAM integration workflow at [Configure a network and network profile to use external IPAM for an existing network in VMware Aria Automation](#).

NOTE

When an IP range from an external IPAM provider is deleted in the external IPAM application, the IP range is automatically deleted during enumeration in VMware Aria Automation. The deleted IP range is no longer visible or available for network association in VMware Aria Automation, thus avoiding orphaned IP address ranges.

VMware Aria Automation allows you to apply and manage an IP address range across multiple vSphere and NSX networks. Shared IP range support is provided for both internal and external IPAM. You can set a single IP range on an NSX stretch network such that machines on that network can use IP addresses that are assigned from the single IP address even if they are deployed to different vCenters.

IP Addresses

You can see the IP addresses that are currently used by your organization and display their status, for example available or allocated. The IP addresses that are displayed are either IP addresses that are managed internally by VMware Aria Automation or IP addresses that are designated for deployments that contain an external IPAM provider integration. External IPAM providers manage their own IP address allocation.

If the network is managed internally by VMware Aria Automation, and not by an external IPAM provider, you can also release IP addresses.

When using internal IPAM and releasing IP addresses, for example after deleting a machine that had been using the IP addresses or clicking **Release IP address** for a selected network, there is a wait period between when the unused addresses are released and when they become available for reuse. The wait period, or release timeout period, allows the DNS cache to clear. The IP addresses can then be allocated to a new machine. By default, the IP address release wait period is 30 minutes. You can change the wait period by clicking **Infrastructure > Administration > Settings** and changing the **IP release timeout** value.

- During the release timeout period, relevant IP addresses are listed as released. When the release timeout period has expired, they are listed as available.
- The system checks every 5 minutes for newly released IP addresses, so even if the release timeout value is 1 minute it can take between 1 and 6 minutes for released IP addresses to become available, depending on when the last check was run. The 5 minute checking interval applies to all values other than 0.
- If you set the release timeout value to 0, IP addresses are released immediately and become available immediately.
- The release timeout value applies to all cloud accounts in the organization.

Updating vSphere networks after NSX migration to C-VDS

For information about updating vSphere networks in VMware Aria Automation after NSX-T migration from N-VDS to C-VDS, see [Updating networking resources in after N-VDS to C-VDS migration in](#).

Load Balancers

You can manage information about available load balancers for the account/region cloud accounts in your organization. You can open and display the configured settings for each available load balancer. You can also add and remove tags for a load balancer.

For more information about using load balancers in cloud templates, see [More about load balancer resources in VMware Aria Automation cloud templates](#).

Network Domains

The network domains list contains related and non-overlapping networks.

Security resources in VMware Aria Automation

Security resources

After you add a cloud account in Automation Assembler, data collection discovers the cloud account's network and security information and makes that information available for use in network profiles and other options.

Security groups and firewall rules support network isolation. Security groups are data-collected. Firewall rules are not data-collected.

Using the **Infrastructure > Resources > Security** menu sequence, you can view on-demand security groups that have been created in Automation Assembler cloud template designs and existing security groups that were created in source applications, such as NSX-T and Amazon Web Services. Available security groups are exposed by the data collection process.

You can use a tag to match the machine interface (NIC) with a security group in a cloud template definition or in a network profile. You can view the available security groups and add or remove tags for selected security groups. A cloud template author can assign one or more security groups to a machine NIC to control security for the deployment.

In the cloud template design the `securityGroupType` parameter in the security group resource is specified as `existing` for an existing security group or `new` for an on-demand security group.

Existing security groups

Existing security groups are displayed and classified in the **Origin** column as `Discovered`.

Existing security groups from the underlying cloud account endpoint, such as NSX-V, NSX-T, or Amazon Web Services applications, are available for use.

A cloud administrator can assign one or more tags to an existing security group to allow it to be used in a cloud template. A cloud template author can use a `Cloud.SecurityGroup` resource in a cloud template design to allocate an existing security group by using tag constraints. An existing security group requires at least one constraint tag be specified in the security resource in the cloud template design.

If you edit an existing security group directly in the source application, such as in the source NSX application rather than in Automation Assembler, the updates are not visible in Automation Assembler until you data collection runs and data collects the associated cloud account or integration point from within Automation Assembler. Data collection runs automatically every 10 minutes.

Existing security groups are supported for NSX-T global manager and local manager cloud accounts and the vCenter cloud accounts that are associated to the local managers. Automation Assembler enumerates, or data collects, existing security groups and attaches them to the machine's network interfaces (NICs). You can create a global security group by adding an existing security group on an NSX-T global manager. The global security group can then be consumed by the associated local managers. Global security groups can span one, all, or a subset of the associated local managers.

- Global existing security groups are supported and enumerated for all defined regions.
- Global security groups are listed on the **Infrastructure > Resources** page with all the cloud accounts that they apply to.
- You can associate a machine interface (NIC) with an existing global security group directly in a cloud template or in the selected network profile.
- The following Day 2 operations are supported for global security groups:
 - Security group reconfiguration in a cloud template from a global to a local security group and vice versa.
 - Scale-out/scale-in of machines that are associated with global security groups.

On-demand security groups

On-demand security groups that you create in Automation Assembler, either in a cloud template or in a network profile, are displayed and classified in the **Origin** column as `Managed by Automation Assembler`. On-demand security groups that you create as part of a network profile are internally classified as an isolation security group with pre-configured firewall rules and are not added to a cloud template design as a security group resource. On-demand security groups that you create in a cloud template design, and that can contain express firewall rules, are added as part of a security group resource that is classified as `new`.

NOTE

You can create firewall rules for on-demand security groups for NSX-V and NSX-T directly in a security group resource in cloud template design code. The **Applied To** column does not contain security groups that are classified or managed by an NSX Distributed Firewall (DFW). Firewall rules that apply to applications are for east/west DFW traffic. Some firewall rules can only be managed in the source application and cannot be edited in Automation Assembler. For example, ethernet, emergency, infrastructure, and environment rules are managed in NSX-T.

On-demand security groups are not currently supported for NSX-T global manager cloud accounts.

Learn more

For more information about using security groups in network profiles, see [Learn more about network profiles in VMware Aria Automation](#).

For information about defining firewall rules, see [Using security group settings in network profiles and cloud template designs in VMware Aria Automation](#).

For more information about using security groups in a cloud template, see [More about security group and tag resources in VMware Aria Automation cloud templates](#).

For cloud template design code samples that contain security groups, see [Network, security group, and load balancer resource examples in Automation Assembler](#).

Storage resources in VMware Aria Automation**Storage resources**

A cloud administrator can work with storage resources and their capabilities, which are discovered through VMware Aria Automation data collection from associated cloud accounts.

Storage resource capabilities are exposed through tags that typically originate at the source cloud account. A cloud administrator can choose to apply additional tags directly to storage resources though, using Automation Assembler. The additional tags might label a specific capability for matching purposes at provisioning time.

VMware Aria Automation supports standard disk and first class disk capabilities. First class disk is available for vSphere only.

- [What can I do with standard disk storage in VMware Aria Automation](#)
- [What can I do with first class disk storage in VMware Aria Automation](#)

Capabilities on storage resources become visible as part of the definition of an Automation Assembler storage profile. See [Learn more about storage profiles in](#) .

First class disks that have been data-collected appear on the **Resources > Deployments > Volumes** view.

Learn more about resources in Automation Assembler**Learn more about resources**

Automation Assembler can expose additional information around data-collected resources, such as pricing cards.

How does data collection work in VMware Aria Automation**How does data collection work**

After initial data collection, resource data collection occurs automatically every 10 minutes. The data collection interval is not configurable and you cannot manually initiate data collection.

You can discover information about resource data collection and image synchronization for an existing cloud account in the Status section of its page. Do so by selecting **Infrastructure > Connections > Cloud Accounts** and then clicking **Open** on the existing cloud account of your choice.

You can open an existing cloud account and see its associated endpoint version in the **Status** section of its page. If the associated endpoint has been upgraded, the new endpoint version is discovered during data collection and reflected in the **Status** section on the cloud account's page.

Resource data collection

Data collection occurs every 10 minutes. Each cloud account displays when its data collection last completed.

Status

- Data collection completed 2 minutes ago. (i)
- Image synchronization completed 1 hour ago. (i)
- Available for deployment. (i)

SYNC IMAGES

UPDATE

Image data collection

Image synchronization occurs every 24 hours. You can initiate image synchronization for some cloud account types. To initiate image synchronization, open the cloud account (**Infrastructure > Cloud Accounts**) then select and open the existing cloud account) and click the **Sync Images** button. There is no image synchronization option for NSX cloud accounts.

NOTE

Images are internally classified as either public or private. Public images are shared and are not specific to a particular cloud subscription or organization. Private images are not shared and are specific to a specific subscription. Public and private images are automatically synchronized every 24 hours. An option on the cloud account page allows you to trigger synchronization for private images.

The cloud account page displays when image synchronization was last completed.

Status

- Data collection completed 2 minutes ago. (i)
- Image synchronization completed 1 hour ago. (i)
- Available for deployment. (i)

SYNC IMAGES

UPDATE

To facilitate fault tolerance and high availability in deployments, each NSX-T data center endpoint represents a cluster of three NSX managers. For related information, see [Create an NSX-T cloud account in VMware Aria Automation](#).

Cloud accounts and onboarding plans

When you create a cloud account, all machines that are associated to it are data-collected and then displayed on the **Resources > Virtual Machines** page. If the cloud account has machines that were deployed outside of Automation Assembler, you can use an onboarding plan to allow Automation Assembler to manage the machine deployments.

For information about adding cloud accounts, see [Adding cloud accounts to Automation Assembler](#).

For information about onboarding unmanaged machines, see [What are onboarding plans in Automation Assembler](#).

Updating networking resources in VMware Aria Automation after N-VDS to C-VDS migration in NSX-T

Updating network resources after NSX-T N-VDS to C-VDS migration

After NSX-T migration from NSX Virtual Distributed Switch (N-VDS) to converged VDS (C-VDS), you must update impacted vSphere network resources in VMware Aria Automation to continue using those resources in new and existing cloud templates and deployments.

After N-VDS to C-VDS migration, your vSphere networks may appear to be missing from VMware Aria Automation network profiles in which they are members. To avoid losing these vSphere type networks, and continue to allocate them in existing and new deployments, you must manually update all listed C-VDS networks in VMware Aria Automation Assembler.

NOTE

While users do not need the VMware Cloud on AWS Cloudadmin role to create VMware Cloud on AWS cloud accounts in VMware Aria Automation for N-VDS, they do need that permission level to access C-VDS assets after N-VDS to C-VDS migration. Active Directory members with containerized permissions need host switch-level access (ReadOnly) to migrated C-VDS resources in VMware Aria Automation. Cloud Administrator group (Cloudadmin role) users have host switch-level permissions. VMware Aria Automation users who are not members of the VMware Cloud on AWS Cloud Administrator group cannot access migrated C-VDS resources.

- Active Directory members who are assigned the Cloud admin role in VMware Cloud on AWS prior to the N-VDS to C-VDS migration in NSX-T have the Cloudadmin role in VMware Cloud on AWS after N-VDS to C-VDS migration, and thus have the required access level to migrated C-VDS resources.
- Active Directory members who are not assigned the Cloud admin role in VMware Cloud on AWS before N-VDS to C-VDS migration in NSX-T must be assigned the Cloud admin role after the migration.
- For related information about VMware Cloud on AWS and VMware Aria Automation credentials, see [Credentials required for working with cloud accounts in VMware Aria Automation](#).

NOTE

This procedure is specific to actions needed in VMware Aria Automation to update *vSphere* networks after N-VDS to C-VDS migration has been performed in NSX-T. There is no action needed in VMware Aria Automation on *NSX* networks after N-VDS to C-VDS migration; *NSX* networks require no manual intervention after N-VDS to C-VDS migration.

NSX networks that are attached to vCenter cloud accounts, as well as to VMware Cloud on AWS cloud accounts, are supported and do not require the manual intervention described in this procedure. However, *NSX* networks that are attached to VMware Cloud on Dell cloud accounts may require the manual intervention described here. For related information, see [VMware Cloud on AWS \(VMConAWS\)](#) and [VMware Cloud on Dell EMC Migration from NVDS to VDS \(82487\)](#).

While an NSX-T administrator can migrate NSX-T on VDS (N-VDS) network types to converged VDS (C-VDS) network types in NSX, this action impacts existing vSphere network resources in VMware Aria Automation. The VMware Aria Automation administrator can perform post-migration actions to reconcile those resources in VMware Aria Automation with the associated changes in NSX-T and vCenter. Note that C-VDS, or simply VDS, is also referred to elsewhere as vSphere Virtual Distributed Switch (VDS).

For related information about NSX-T converged VDS (C-VDS), see VMware Knowledge Base article [NSX-T on VDS \(79872\)](#).

NOTE

This sample scenario illustrates the steps needed to reconcile resources in a VMware Aria Automation environment after N-VDS to C-VDS migration. You can use this example and procedure in VMware Aria Automation 8.5 and later to reconcile changes made in vCenter after migrating from N-VDS to C-VDS in NSX-T.

Example: VMware Aria Automation resources pre-migration

This example illustrates sample NSX-T resources in a sample VMware Aria Automation environment prior to N-VDS to C-VDS migration.

- This example contains NSX-T and vCenter cloud accounts.
- The example contains several vSphere networks.

Name	Account / Region	Zone	Network Domain	CIDR	Support Public IP	Default for Zone	Origin	Tags
seg-1	NSX-VC / 1-folder-1716/l-datacenter-1716	seg-1		11.0.0.0/16	--	--	Discovered	seg1-nvds
seg-2	NSX-VC / 1-folder-1716/l-datacenter-1716	seg-2		12.0.0.0/16	--	--	Discovered	seg2-nvds
seg-3	NSX-VC / 1-folder-1716/l-datacenter-1716	seg-3		13.0.0.0/16	--	--	Discovered	seg3-nvds
seg-4	NSX-VC / 1-folder-1716/l-datacenter-1716	seg-4		14.0.0.0/16	--	--	Discovered	seg4-nvds
seg-5	NSX-VC / 1-folder-1716/l-datacenter-1716	seg-5		15.0.0.0/16	--	--	Discovered	seg5-nvds
seg-6	NSX-VC / 1-folder-1716/l-datacenter-1716	seg-6		16.0.0.0/16	--	--	Discovered	seg6-nvds
seg-7	NSX-VC / 1-folder-1716/l-datacenter-1716	seg-7		17.0.0.0/16	--	--	Discovered	seg7-nvds
seg-8	NSX-VC / 1-folder-1716/l-datacenter-1716	seg-8		18.0.0.0/16	--	--	Discovered	seg8-nvds

- The example network configuration contains CIDR and DNS settings.

The screenshot shows the 'Infrastructure' tab in the Cloud Assembly interface. A network segment named 'seg-5' is being configured. The configuration includes:

- Name:** seg-5
- Account / region:** NSXT-VC / 1-folder-1716/1-datacenter-1716
- Network domain:** seg-5
- Domain:** vSphere.local
- IPv4 CIDR:** 15.0.0.0/16
- IPv4 default gateway:** 15.0.0.1
- IPv6 CIDR:** (empty)
- IPv6 default gateway:** (empty)
- DNS servers:** 10.158.25.200, 10.118.183.252
- DNS search domains:** (empty)
- Support public IP:** (unchecked)
- Default for zone:** (unchecked)
- Origin:** Discovered from cloud account
- Tags:** seg5-mvds (selected), Enter a new tag

At the bottom are 'SAVE' and 'CANCEL' buttons.

- The example also includes existing IP ranges.

The screenshot shows the 'IP Ranges' tab in the Cloud Assembly interface. The table lists 8 IP ranges across different segments:

	Name	Description	Network	Provider	Start IP Address	End IP Address	Tags
<input type="checkbox"/>	seg1-ipr		seg-1	Cloud Assembly	11.0.0.2	11.0.255.254	
<input type="checkbox"/>	seg2-ipr		seg-2	Cloud Assembly	12.0.0.2	12.0.255.254	
<input type="checkbox"/>	seg3-ipr		seg-3	Cloud Assembly	13.0.0.2	13.0.255.254	
<input type="checkbox"/>	seg4-ipr		seg-4	Cloud Assembly	14.0.0.2	14.0.255.254	
<input type="checkbox"/>	seg5-ipr		seg-5	Cloud Assembly	15.0.0.2	15.0.255.254	
<input type="checkbox"/>	seg6-ipr		seg-6	Cloud Assembly	16.0.0.2	16.0.255.254	
<input type="checkbox"/>	seg7-ipr		seg-7	Cloud Assembly	17.0.0.2	17.0.255.254	
<input type="checkbox"/>	seg8-ipr		seg-8	Cloud Assembly	18.0.0.2	18.0.255.254	

At the bottom right, it says '8 IP ranges'.

- The example contains a network profile (**ex-np**) which contains several N-VDS (N-VDS) networks, including **seg-5**.

Name	Account / Region	Zone	Network Domain	CIDR	Support Public IP	Default for Zone	Origin	Tags
seg-1	NSX-T-VC / 1-folder-1716/f-datacenter-1716	seg-1	seg-1	11.0.0.0/16	--	--	Discovered	seg1-nvds
seg-2	NSX-T-VC / 1-folder-1716/f-datacenter-1716	seg-2	seg-2	12.0.0.0/16	--	--	Discovered	seg2-nvds
seg-3	NSX-T-VC / 1-folder-1716/f-datacenter-1716	seg-3	seg-3	13.0.0.0/16	--	--	Discovered	seg3-nvds
seg-4	NSX-T-VC / 1-folder-1716/f-datacenter-1716	seg-4	seg-4	14.0.0.0/16	--	--	Discovered	seg4-nvds
seg-5	NSX-T-VC / 1-folder-1716/f-datacenter-1716	seg-5	seg-5	15.0.0.0/16	--	--	Discovered	seg5-nvds
seg-6	NSX-T-VC / 1-folder-1716/f-datacenter-1716	seg-6	seg-6	16.0.0.0/16	--	--	Discovered	seg6-nvds
seg-7	NSX-T-VC / 1-folder-1716/f-datacenter-1716	seg-7	seg-7	17.0.0.0/16	--	--	Discovered	seg7-nvds
seg-8	NSX-T-VC / 1-folder-1716/f-datacenter-1716	seg-8	seg-8	18.0.0.0/16	--	--	Discovered	seg8-nvds

- In this example, the existing **seg5** network component is shown with sample cloud template syntax. The network is tagged as an N-VDS network. The example illustrates needed post-migration updates to the **seg5** network later in the workflow.

```

1  formatVersion: 1
2  inputs: {}
3  resources:
4    - Cloud_SecurityGroup_2:
5      type: Cloud.SecurityGroup
6      properties:
7        securityGroupType: new
8        rules:
9          - name: r1
10         direction: inbound
11     Cloud_SecurityGroup_1:
12       type: Cloud.SecurityGroup
13       properties:
14         securityGroupType: new

Storage Network Custom properties

Example: Post-migration Step 1 – Run data collection after N-VDS to C-VDS migration and enumeration

In the above section, screen shots were used to illustrate the infrastructure used in an example VMware Aria Automation environment, concluding with the output cloud template and deployment.

After you or another administrator perform N-VDS to C-VDS migration in NSX-T, wait at least 10 minutes to allow VMware Aria Automation to perform its periodic data collection and enumeration process to fetch and display impacted resources in VMware Aria Automation.

After allowing VMware Aria Automation data collection to complete, click **Infrastructure > Networks** to view and access available C-VDS networks. Notice the **seg5** network, as shown below.

Name	Account / Region	Zone	Network Domain	CIDR	Support Public IP	Default for Zone	Origin	Tags
seg-8	NSXT-VC / 1-folder-1716/1-datacenter-1716	4	CVDS-nsxvswitch1-datacenter-4	18.0.0.0/16	--	--	Discovered	seg8
seg-7	NSXT-VC / 1-folder-1716/1-datacenter-1716	4	CVDS-nsxvswitch1-datacenter-4	17.0.0.0/16	--	--	Discovered	seg7
seg-6	NSXT-VC / 1-folder-1716/1-datacenter-1716	4	CVDS-nsxvswitch1-datacenter-4	16.0.0.0/16	--	--	Discovered	seg6
seg-5	NSXT-VC / 1-folder-1716/1-datacenter-1716	4	CVDS-nsxvswitch1-datacenter-4	15.0.0.0/16	--	--	Discovered	seg5
seg-4	NSXT-VC / 1-folder-1716/1-datacenter-1716	4	CVDS-nsxvswitch1-datacenter-4	14.0.0.0/16	--	--	Discovered	seg4
seg-3	NSXT-VC / 1-folder-1716/1-datacenter-1716	4	CVDS-nsxvswitch1-datacenter-4	13.0.0.0/16	--	--	Discovered	seg3
seg-2	NSXT-VC / 1-folder-1716/1-datacenter-1716	4	CVDS-nsxvswitch1-datacenter-4	12.0.0.0/16	--	--	Discovered	seg2
seg-1	NSXT-VC / 1-folder-1716/1-datacenter-1716	4	CVDS-nsxvswitch1-datacenter-4	11.0.0.0/16	--	--	Discovered	seg1
CVDS-nsxvswitch1-DVUp-links-89	NSXT-VC / 1-folder-1716/1-datacenter-1716	4	CVDS-nsxvswitch1-datacenter-4	--	--	--	Discovered	
2-switch-380	NSXT-VC / 1-folder-1716/1-datacenter-1716	4	CVDS-nsxvswitch1-datacenter-4	--	--	--	Discovered	
1-switch-149	NSXT-VC / 1-folder-1716/1-datacenter-1716	4	CVDS-nsxvswitch1-datacenter-4	--	--	--	Discovered	

Example: Post-migration Step 2 – Add previously defined CIDR and DNS to migrated C-VDS networks

Edit a migrated C-VDS network to add CIDR and DNS details that had been specified in the pre-migration N-VDS definition and change the network tagging.

1. Add CIDR and DNS details that had been defined in its pre-migration N-VDS definition
2. Add a new tag for the sample C-VDS **seg-5** network segment, such as *seg5-cvds*.

The screenshot shows the VMware Cloud Assembly interface with the Infrastructure tab selected. On the left, a sidebar lists various categories like Deployments, Design, Kubernetes Zones, Flavor Mappings, etc. The main panel displays the configuration for a network segment named 'seg-5'. Key settings shown include the network's account/region, network domain, domain name, IP ranges, and DNS configurations. A 'Tags' section at the bottom allows for adding specific identifiers to the resource.

Note that the original N-VDS **seg-5** network was tagged as *seg5-nvds*, as seen in earlier screens. The change in resource tagging details is required by network reconfiguration. VMware Aria Automation requires that you include a different tag name in the cloud template for the C-VDS network than the tag used in the original N-VDS network. The changed tagging identifies a change in the cloud template when generating a valid redeployment.

Example: Post-migration Step 3 – Add updated IP range information

You can edit network IP ranges to IP range details that had been specified in the pre-migration N-VDS definition, by using a command line API or by using a menu sequence in VMware Aria Automation.

- Option 1: Use the API to update IP range data, as shown in the following sample screen.

PATCH : {{host}}/iaas/api/network-ip-ranges/{{subnet-range-id}}

Headers :

- Authorization : Bearer {{token}}

Payload :

```
{
  "fabricNetworkIds": ["{{subnet-id}}"]
}
```

- Option 2: Use the user interface to update IP range data, as shown in the following sample screen.

Name	Account / Region	CIDR	Tags
seg-1	J-VC / 1-folder-173/1-datacenter-173	200.0.0.0/16 1010::0/16	seg1
seg-2	J-VC / 1-folder-173/1-datacenter-173	200.0.0.0/16 1010::0/16	seg2

Example: Post-migration Step 4 – Update network profiles to correct missing networks

Post-migration, N-VDS networks are reconciled and deleted from VMware Aria Automation Assembler after data collection and enumeration. Impacted network profiles (such as the example **ex-np**) have missing networks. To correct the missing networks issue, update each N-VDS network as a C-VDS network, as shown below.

Name	Account / Region	Zone	Network Domain	CIDR	Support Public IP	Default for Zone	Origin	Tags
seg-1	NSX-T-VC / 1-folder-1716/f-datacenter-1716		CVDS-nsxswitchl-datacenter-4	11.0.0.0/16	--	--	Discovered	seg1-cvds
seg-2	NSX-T-VC / 1-folder-1716/f-datacenter-1716		CVDS-nsxswitchl-datacenter-4	12.0.0.0/16	--	--	Discovered	seg2-cvds
seg-3	NSX-T-VC / 1-folder-1716/f-datacenter-1716		CVDS-nsxswitchl-datacenter-4	13.0.0.0/16	--	--	Discovered	seg3-cvds
seg-4	NSX-T-VC / 1-folder-1716/f-datacenter-1716		CVDS-nsxswitchl-datacenter-4	14.0.0.0/16	--	--	Discovered	seg4-cvds
seg-5	NSX-T-VC / 1-folder-1716/f-datacenter-1716		CVDS-nsxswitchl-datacenter-4	15.0.0.0/16	--	--	Discovered	seg5-cvds
seg-6	NSX-T-VC / 1-folder-1716/f-datacenter-1716		CVDS-nsxswitchl-datacenter-4	16.0.0.0/16	--	--	Discovered	seg6-cvds
seg-7	NSX-T-VC / 1-folder-1716/f-datacenter-1716		CVDS-nsxswitchl-datacenter-4	17.0.0.0/16	--	--	Discovered	seg7-cvds
seg-8	NSX-T-VC / 1-folder-1716/f-datacenter-1716		CVDS-nsxswitchl-datacenter-4	18.0.0.0/16	--	--	Discovered	seg8-cvds

Example: Post-migration Step 5 – Update network constraints in cloud templates

For existing deployments, you must update network constraints in cloud template to match the new C-VDS networks in the updated network profiles. Updated network constraints are also needed to perform iterative deployments and to reconfigure networks from their original vSphere N-VDS representation to vSphere C-VDS representation.

For new deployments, the specified C-VDS resources are used, thus this step is not required. Iterative deployments and network reconfiguration simply work as designed.

1. For this example, change network constraints in the cloud template from `seg5-nvds` to `seg5-cvds`, as shown below.

```

1 formatVersion: 1
2 inputs: {}
3 resources:
4   - Cloud_SecurityGroup_2:
5     type: Cloud.SecurityGroup
6     properties:
7       securityGroupType: new
8       rules:
9         - name: r1
10        direction: inbound
11      Cloud_SecurityGroup_1:
12        type: Cloud.SecurityGroup
13        properties:
14          securityGroupType: new
15          rules:
16            - name: r2
17            direction: outbound
18      Cloud_vSphere_Machine_1:
19        type: Cloud.vSphere.Machine
20        properties:
21          image: i6
22          flavor: fm
23          customizationSpec: Linux
24          networks:
25            - network: ${resource.Cloud_vSphere_Network_1.id}
26            assignment: static
27            securityGroups:
28              - ${resource.Cloud_SecurityGroup_1.id}
29      Cloud_vSphere_Network_1:
30        type: Cloud.vSphere.Network
31        properties:
32          networkType: existing
33          constraints:
34            - tag: seg5-cvds
35

```

2. Perform an iterative deployment to reconfigure the network, as shown below.

3. After successful redeployment, notice that the network custom properties display the updated constraints, as shown below.

CSG-1 Update Successful

Owner	Requestor	Expires on
apriyank@vmware.com	apriyank@vmware.com	Never

Use the Insights dashboard to monitor resource capacity and notify project owners in VMware Aria Automation

How to monitor resource capacity and notify project owners using the Insights dashboard

A cloud administrator can monitor and manage infrastructure resources and deployment optimizations within each cloud zone. By visualizing real-time insights, and reviewing suggested actions for the resources you support, you can proactively help project owners manage their resource capacity and optimize their deployments.

You can use the **Insights** dashboard to explore metric data for the resources and deployments in cloud zones within the projects that you manage. Use that information, provided from a combination of VMware Aria Automation and your integrated VMware Aria Operations application, to make any needed adjustments to memory, CPUs, and so on, or share that information with your team so that they can be better informed and make any needed adjustments.

The Insights dashboard enables you to contact some or all of the project owners who have deployments in the cloud zone that contain reclaimable resource capacity. The cloud zone insights display reclaimable capacity for projects and deployments.

Contacted project owners see notification on their deployment's **Alerts** page. The notification contains their name and the name of (and link to) each deployment that can be optimized.

The **Insights** dashboard is available for vSphere and VMware Cloud on AWS cloud zones, provided that the cloud accounts are configured in both VMware Aria Automation and VMware Aria Operations and are being monitored in VMware Aria Operations.

Prerequisites

- Review [Resource management and deployment optimization using VMware Aria Operations metrics in VMware Aria Automation](#).
- Verify that you have VMware Aria Automation cloud administrator credentials and have enabled HTTPS access on port 443. See [Credentials required for working with cloud accounts in VMware Aria Automation](#).
- Verify that you have the VMware Aria Automation cloud administrator user role. See [What are the user roles](#).
- Configure VMware Aria Automation integration with VMware Aria Operations.
- Configure the VMware Aria Automation adapter in VMware Aria Operations.

For related information, see [Application Integration](#) in [VMware Aria Operations product documentation](#).

About VMware Aria Operations and the collected resource capacity metrics

VMware Aria Operations collects capacity metrics for the same infrastructure resources that you and the teams that you support use in VMware Aria Automation. By integrating VMware Aria Automation with VMware Aria Operations, the VMware Aria Operations metric data is made available and displayed for each managed project in an **Insights** dashboard within each cloud zone.

Project data is parsed to the VMware Aria Automation dashboard from the integrated VMware Aria Operations application. The Insights dashboard displays the following information:

- CPU utilization percentage relative to capacity
- Memory utilization percentage relative to capacity
- Storage utilization percentage relative to capacity
- Calculated CPU and memory demand history and projected demand
- Option to contact owners of some or all of the deployments in a cloud zone that can be optimized by reclaiming resources, for example by resizing or deleting machines. Optimization data is calculated in the order of days.

The Insights dashboard is available for vSphere resources.

A trend widget displays the compute components of a cloud zone (such as clusters and hosts), their CPU GHz usage relative to CPU capacity, and their memory GB usage relative to memory capacity.

Information about the roles that are required to use alerts is available at [Custom user roles in VMware Aria Automation](#).

For related information, see [Resource management and deployment optimization using VMware Aria Operations metrics in VMware Aria Automation](#).

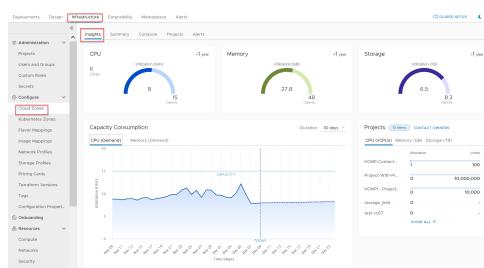

Procedure

Open a cloud zone to discover its capacity metrics and optionally fetch information about project deployments that can be optimized. Data is collected and supplied by the associated VMware Aria Operations application.

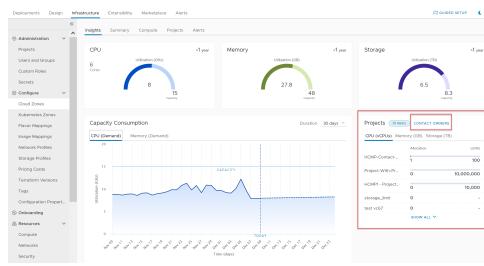

- From Automation Assembler, click **Infrastructure > Configure > Cloud Zones** and select a cloud zone.

- Click the **Insights** tab and examine the insights dashboard.

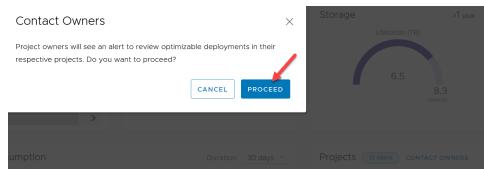

The following example displays CPU, memory, and storage capacity information for the resources that are used by projects in the cloud zone.

- To notify the project owner of any deployments that can be optimized, click **Contact Owner** in the **Projects** section. Notifications appear on the **Alerts** tab page.

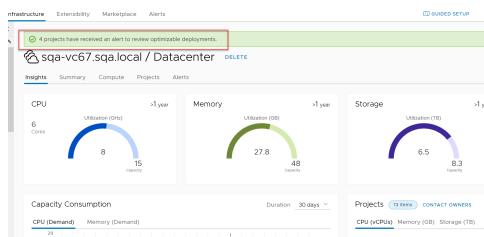

- To fetch optimization information about each deployment for the project, click **Proceed**.

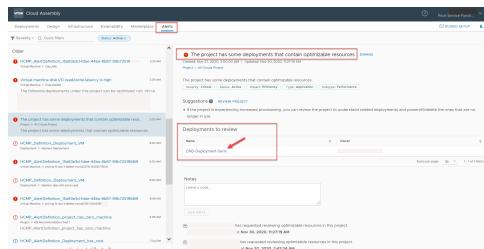

If the project contains deployments that can be optimized, that information is conveyed to the project owner on the Automation Assembler **Alerts** tab.

- A message appears indicating the number of deployments that can be optimized.

Notification information about these resources and deployments is available to the project owner on the Automation Assembler **Alerts** tab. For this example, that notification information includes the name of, and a link to, each deployment that can be optimized, as shown in the following example:

Next steps

Use the information that you have obtained from the **Insights** dashboard to make any needed adjustments to the resources that you manage. Open the **Alerts** page to obtain additional information, suggested actions, and links to deployments that can be optimized. See [How to use Alerts to manage resource capacity, performance, and availability in VMware Aria Automation](#).

How to use Alerts to manage resource capacity, performance, and availability in VMware Aria Automation

How to manage resource capacity, performance, and availability by using Alerts

As a cloud administrator, you need to know when VMware Aria Automation capacity, performance, and availability are becoming problematic so that you can proactively react before users begin to run out of resources.

You can display a range of alerts provided by the associated VMware Aria Operations application. Alerts are available for vSphere and VMware Cloud on AWS resource objects. Use information in alerts to modify the resources and deployments that you manage, or share that information with your team so they can modify objects that they manage.

NOTE

To examine and act on project deployments that you should consider optimizing, see [How to use Alerts to optimize deployments in VMware Aria Automation](#).

Alerts are currently available for vSphere and VMware Cloud on AWS resource objects only. The **Alerts** tab is only available if access to VMware Aria Operations is configured.

The VMware Aria Automation alerts threshold values are set in VMware Aria Operations. Some VMware Aria Automation alerts are currently predefined. Alerts notifications are also set in VMware Aria Operations. For information about setting alert definitions and configuring notifications, see the VMware Aria Operations product documentation.

Prerequisites

- Review [Resource management and deployment optimization using VMware Aria Operations metrics in VMware Aria Automation](#).
- Verify that you have VMware Aria Automation cloud administrator credentials and have enabled HTTPS access on port 443. See [credentials-for-cloud-accounts.dita#GUID-F58886C2-D5DF-4878-B9F4-515FBB363E4D-en.dita](#).
- Verify that you have the VMware Aria Automation cloud administrator user role. See [What are the user roles](#).
- Configure VMware Aria Automation integration with VMware Aria Operations.
- Configure the VMware Aria Automation adapter in VMware Aria Operations.
- Configure the roles that are need to manage alerts. See [Custom user roles in VMware Aria Automation](#).
For related information, see [See Integrate VMware Aria Automation with VMware Aria Operations and Application Integration in vRealize Operations Cloud product documentation](#).

Role capabilities include:

- Cloud administrators can manage cloud zone alerts.
- Project administrators can manage project alerts.
- Service broker administrators can manage deployment alerts.

About VMware Aria Operations and resource alerts

VMware Aria Operations collects health, usage, and other metrics for the same infrastructure resources and deployments that you manage in VMware Aria Automation. By integrating VMware Aria Automation with VMware Aria Operations, that monitored data is made available to you in VMware Aria Automation by using the **Alerts** tab in the Automation Assembler main menu .

The alerts data provided by VMware Aria Operations includes heath and risk threshold concerns for cloud templates, deployments, organizations, and projects. It also contains information about deployments that can be optimized, based on the owner being contacted by an action taken on the cloud zone **Insights** tab. For related information, see [How to use Alerts to optimize deployments in VMware Aria Automation](#).

Alert details for each deployment include:

- Project name
- Deployment name (and link to the deployment) that contain resources that can be optimized
- Suggested actions
- Potential cost savings from reclamation and optimization
- Total number of virtual CPUs used by the deployment
- Total amount of RAM memory used by the deployment
- Total amount of storage used by the deployment
- Virtual machines in the deployment that are recommended for reclamation and optimization, including resource name, idle machines, powered off machines, oversized and undersized machines, underutilized machines, and machine snapshots

By using the **Contact project owners** option on the cloud zone Insights dashboard, you can see a summary of all projects that have reclaimable capacity (CPU, memory, and storage) in the cloud zone and provide an alert to some or all of the project owners.

Procedure

You can display alerts threshold information about the resources that you manage by using filtering options on the **Alerts** page. Alerts data is supplied by your associated VMware Aria Operations application. Suggested actions are provided for each alert.

You can also select a deployment from the **Deployments to review** section to open and optimize that deployment.

1. From within the Automation Assembler service, click the **Alerts** tab in the main menu.
2. To control the how alerts are displayed, experiment with the available filters. For example, select the **Resources** option from the filters drop-down menu.
3. To display alerts and suggested actions for those alerts, use quick filter options in the selector panel.
 - Display alerts about cloud zone resources.
VMware Aria Operations can monitor time remaining, capacity remaining, reclaimable capacity, and so on.
 - Display alerts about virtual machine resources.
The majority of virtual machine alerts pertain to on/off status, latency, and so on.
 - Display alerts about deployment resources.
The deployment alerts pertain to reclaimable resources and right-sizing.
 - Display alerts about project resources.
The project alerts pertain to reclaimable resources and allocation limits.

4. Explore other filter types and their quick filtering options to further control the list of alerts.
 - Use the **Impacts** quick filters of health, risk, and efficiency.
 - Use the **Severity** quick filters of critical, immediate, warning, and information.
 - Use the **Status** quick filters of active, cancelled, and dismissed.
 - Use the **Subtype** filters of availability, performance, and capacity.
 - Use the **Type** quick filters of application, hardware, infrastructure, storage, and network.
5. Take any needed actions based on alerts data and suggestions.

Next steps

To learn about other actions that are available, see [How to use Alerts to optimize deployments in VMware Aria Automation](#).

You can also display capacity **Insights** for cloud zone-based resources in projects that you manage. For information about using VMware Aria Operations- supplied **Insights** data in VMware Aria Automation, see [Use the Insights dashboard to monitor resource capacity and notify project owners in VMware Aria Automation](#).

How to use Alerts to optimize deployments in VMware Aria Automation

How to optimize deployments by using Alerts

As a cloud administrator or project owner, you can monitor and manage machine resources for best possible optimization by using data that is obtained from VMware Aria Operations and displayed in VMware Aria Automation.

When you connect VMware Aria Automation with VMware Aria Operations, you can access data-collected information about resources in the projects that you manage. Alerts and insights data is provided to inform you of various concerns about the projects that you manage, and provide an easy means to communicate optimization suggestions and supporting data collected from VMware Aria Operations to project owners easily and efficiently without ever leaving the VMware Aria Automation application. For example, you can see reclaimable resource capacity, with specific cost savings, for each deployment in a cloud zone. Where a cloud zone contains multiple deployments that can be optimized, you can notify some or all of the project and deployment owners.

Deployment optimization alerts can be generated from the Insights dashboard. See [Use the Insights dashboard to monitor resource capacity and notify project owners in VMware Aria Automation](#). You can contact project owners so that they can open a named deployment to be optimized from a link provided on the **Alerts** page. As well, project owners can open their deployments directly and use the **Optimize** tab to perform available optimization tasks. Actions that a project owner can take include reclaiming resources by deleting non-critical deployments, and stopping further provisioning within a cloud zone.

NOTE

To learn about other resource remediation actions that you can take, see [How to use Alerts to manage resource capacity, performance, and availability in VMware Aria Automation](#).

Prerequisites

See [How to use Alerts to manage resource capacity, performance, and availability in VMware Aria Automation](#) for needed credentials and configuration information for accessing VMware Aria Operations data in VMware Aria Automation.

To request that project owners be alerted of deployments that are optimizeable, see [Use the Insights dashboard to monitor resource capacity and notify project owners in VMware Aria Automation](#).

About

Each deployment contains an **Optimize** tab. The following optimization parameters are available:

- Machines that can be rightsized - Displays information and actions for oversized and undersized machines in the deployment, along with optimization cost savings.
- Machines that are under-utilized - Displays information and actions for idle or powered off machines in the deployment, along with optimization cost savings.
- Machine snapshots - Displays information and actions for machine snapshots if machines in the deployment contain snapshots, along with optimization cost savings.

As an administrator, you can notify project owners that they have deployments to optimize. Notifications appear on the **Alerts** tab in Automation Assembler.

The **Alerts** tab is only available if access to VMware Aria Operations is configured. Project owners can open and optimize their deployments to respond to alerts.

Procedure

You can display alerts threshold information about the resources that you manage by using filtering options on the **Alerts** page. Alerts data is supplied by your associated VMware Aria Operations application. Suggested actions are provided for each alert. In this example the project owner opens their deployment from a link supplied on an alert notification. The deployment's **Optimize** tab displays available machine parameters to optimize.

- As a project owner or administrator, click the **Alerts** tab in the main menu.

- Find an alert that contains information about a deployment that can be optimized and click the deployment name from **Deployments to review** to open that deployment and display its **Optimize** tab.

- When the deployment opens, click the **Optimize** tab.

- If there are underutilized machines, examine and act on idle and powered off machines. You can power off or delete an undersized deployment.
- If there are machines that can be rightsized, examine and act on any oversized and undersized machines in the deployment.
- If one or more of the machines in the deployment contains a snapshot, you can delete or export each snapshot.
- When you are finished, confirm that the deployment has been optimized to your satisfaction and close the deployment

Next steps

To learn about other actions that are available, see [How to use Alerts to manage resource capacity, performance, and availability in VMware Aria Automation](#).

You can also display capacity **Insights** for cloud zone-based resources in projects that you manage. For information about using VMware Aria Operations- supplied **Insights** data in VMware Aria Automation, see [Use the Insights dashboard to monitor resource capacity and notify project owners in VMware Aria Automation](#).

What can I do with standard disk storage in VMware Aria Automation

What can I do with standard disk storage

Standard disks can be persistent or non-persistent.

VMware Aria Automation supports two categories of storage – standard disk and first class disk. First class disk is only available for vSphere.

- vSphere

vSphere supports dependent (default), independent persistent, and independent non-persistent standard disks. For related information, see [What can I do with persistent disk storage in VMware Aria Automation](#).

When you deploy a vSphere virtual machine with one or more disks, the disk resource name depends on your custom naming conventions. However, the disk .vmdk file name follows the default vSphere naming convention, for example, machineName_index, and is provided in the disk **diskFile** custom property. For example, [your datastore]Cloud_Machine_{index number}-{identifier}/Cloud_Machine-{index number}-{identifier}.vmdk. The disk file name will be the same as the disk name. To use this convention, you must turn the feature on by making the following changes to your VMware Aria Automation instance using the API. To make the changes, you must have a bearer token.

`https://<host>/provisioning/config/toggles`

```
{
  "key": "enable.vsphere.default.disk.file.naming",
  "value": "true"
}
```

When you delete a virtual machine, its dependent and independent non-persistent disks are also deleted.

When you delete a virtual machine, its independent persistent disks are not deleted.

You can create a snapshot of dependent and independent non-persistent disks. You cannot create a snapshot of an independent persistent disk.

vSphere cloud zone storage limits that you defined in each project are evaluated when you deploy a cloud template that includes independent non-persistent or independent persistent disks, or when you run a day relevant day 2 action. A request might fail if the disk requested exceeds the limits.

- Amazon Web Services (AWS) EBS

You can attach an EBS volume to an AWS compute instance or detach an EBS volume from an AWS compute instance.

When you delete a virtual machine, its attached EBS volume is detached but not deleted.

- Microsoft Azure VHD

Attached disks are always persistent.

When you delete a virtual machine, you specify whether to remove its attached storage disks.

- Google Cloud Platform (GCP)

Attached disks are always persistent.

Persistent disks are located independently from your virtual machine instances, so you can detach or move persistent disks to keep your data even after you delete your instances.

When you delete a virtual machine, its attached disk is detached but not deleted. For related information, see [Learn more about storage profiles in VMware Aria Automation](#).

What can I do with persistent disk storage in VMware Aria Automation

What can I do with persistent disk storage

Persistent disks preserve valuable data from accidental deletion.

In a cloud template, under a volume, you can add the `persistent: true` property to have the disk survive Automation Assembler or Automation Service Broker deletions. Persistent disks aren't removed during deployment deletion nor Day 2 delete or remove disk operations.

Because of that, persistent disks can remain in your infrastructure even after a deployment deletion or disk deletion. To remove them, you can use the following techniques.

- Explicitly pass the purge flag as a query parameter using the DELETE API.
- Delete them directly from your cloud endpoint.

Note that there is no Automation Assembler or Automation Service Broker user interface for removing them.

What can I do with first class disk storage in VMware Aria Automation

What can I do with first class disk storage

A first class disk (FCD) provides storage life-cycle management on virtual disks as a disk-as-a service or as EBS-like disk storage that allows you to create and manage disks independently of vSphere virtual machines.

VMware Aria Automation supports two categories of storage disks – standard disk and first class disk. First class disk functionality is supported for vSphere only. VMware Aria Automation currently provides first class disk functionality as an API-only capability.

A first class disk has its own life-cycle management capabilities that operate independently from a VM. One way that a first class disk differs from an independent persistent disk, is that you can use a first class disk to create and manage snapshots independent of a VM.

You can create a new VMware Aria Automation storage profile to support either first class disk capabilities or standard disk capabilities. See [Learn more about storage profiles in VMware Aria Automation](#) and [Storage resources in VMware Aria Automation](#).

You can also add a `Cloud.vSphere.Disk` first class disk element in your VMware Aria Automation cloud templates and deployments to support vSphere first class disks. First class disks that have been data-collected appear on the [Resources > Resources > Volumes](#) page.

In vCenter, first class disks are also referred to as *Improved Virtual Disks (IVD)* or *managed virtual disks*.

Capabilities

Using VMware Aria Automation API capabilities, you can:

- Create, list, and delete a first class disk.
- Resize a first class disk.
- Attach and detach a first class disk.
- Create and manage first class disk snapshots.
- Convert an existing standard disk to first class disk

The following scenarios are not supported:

- Provisioning VMs from snapshots on a datastore cluster.

- Owning and sharing device-based storage blocks by users and tenants.
- Creating and restoring VM snapshots.
- Attaching storage across multiple VMs and across clusters.

API use case documentation for creating and managing first class disk (FCD) storage in VMware Aria Automation is available in the *Creating and Using a First Class Disk* section of the VMware Aria Automation Programming Guide for your VMware Aria Automation release. Locate the version-specific Programming Guide on the [VMware Aria Automation Documentation](#) landing page.

For related API documentation for FCD, see the First Class Disk section of the [Virtual Disk Development Kit programming guide](#).

Considerations and limitations

First class disk considerations and limitations currently include:

- First class disk is available for vSphere VMs only.
- vSphere 6.7 Update 2 or later is required to use first class disks.
- Provisioning first class disks on datastore clusters is not supported.
- Volume multi-attach is not supported for first class disks.
- First class disks with snapshots cannot be resized.
- First class disks with snapshots cannot be deleted.
- First class disk snapshot hierarchy can only be constructed by using the `createdAt` API option.
- The minimum VM hardware version required to attach a first class disk is vmx-13 (ESX 6.5 compatible).
- Cloud zone storage limits that you defined in each project are evaluated when you deploy a cloud template that includes a first class disk, or when you run a day relevant day 2 action. A request might fail if the disk requested exceeds the limits.

How to reuse VMware Aria Automation networking and security resources in Automation Assembler

How to reuse networking and security resources

Configured networking components such as networks, load balancers, and security groups, can be treated as reusable objects. These objects can be inserted into Automation Assembler templates to quickly add a predefined set of network, security group, and/or load balancer settings. This capability, which is sometimes referred to as infrastructure-as-code or provider networks, allows you to reuse predefined networking and security configurations in multiple templates and/or deployments.

A configured networking component is simply an Automation Assembler template that consists of only a networking component, or a security group, or a load balancer that has been configured with settings and saved as a stand-alone template. These templates can be inserted into other templates to quickly add a previously specified configuration. Only Cloud Admins can create, define, and then save a configured networking component template. However, after a Cloud Admin creates the template, the template can be inserted into (and reused as a resource chunk) within other templates by a designer who does not have Cloud Admin privileges.

The following considerations impact whether a configured networking component can be used:

- Deployment environment, such as simple, distributed, load-balanced, or HA.
- User role assignments, specifically Cloud Admin or non-Cloud Admin. Only Cloud Admins can create the reusable configured networking component template. But non-Cloud Admins can insert a configured networking component template into their own templates. However, non-Cloud Admins cannot change the configured networking component content /settings after they are inserted into their own templates.

How to manage infrastructure capacity for VMware Aria Automation

How to manage infrastructure capacity

As a cloud administrator, you can set values that control how resources are allocated for deployments for your entire organization.

While you can use placement policies on cloud zones and in projects to control the distribution of workloads at deployment time, the methods presented here are used to prevent overallocation and set limits at the organization level.

Each of the resource checks described in this article operate independently. They are not dependent on one another.

What to do first

- Ensure that you have the organization owner role and Automation Assembler Administrator service role. You will need them to get an authentication token and run the commands. See [What are the user roles](#).
- Get an authentication topic. Locate the [API Programming Guide](#) for your version and see "Getting Your Authentication Token" in that guide.

Prevent memory overallocation

Some systems allow you to deploy resources even if the host or cluster does not have sufficient resources. For example, you successfully deploy a virtual machine, but you cannot turn it on due a lack of storage or memory.

To avoid deploying resources that you cannot turn on, you can set the PREVENT_COMPUTE_MEMORY_OVERALLOCATION configuration property to TRUE. This change ensures that VMware Aria Automation tracks how much memory is allocated on each host or cluster. It then uses that value to prevent provisioning to hosts or clusters that are fully utilized, preventing overallocation. The allocated memory is calculated by adding up all the managed virtual machines in the host or cluster. Virtual machines that were provisioned outside VMware Aria Automation, discovered, but have not yet been onboarded are not counted.

This is a global property.

1. To add the property, go to `https://your_automation_URL/iaas/api/swagger/ui/#/Property/patchConfigurationProperty`.
2. Click **Try it out**.
3. For the value, enter `true`.
4. For the key, enter `PREVENT_COMPUTE_MEMORY_OVERALLOCATION`.
5. Click **Execute**.

To reset the preventing property and allow overallocation, set the value to `false`.

Set memory allocation limits

You can set a percentage value that is used as the maximum amount of memory for a host or cluster. This value is the allocation limit. You can set a conservative value of less than 100%. You can also set a value over 100% if you have a clear understanding of how your resources are allocated and want to fine tune the limit.

For example, you have a host or cluster with 100 GB of total memory and you set the value at 50%. VMware Aria Automation considers the host to have 50 GB of total memory. Or, you can set the value to 120%. VMware Aria Automation then considers the host to have 120 GB of memory.

You can set a global property and a host- or cluster-specific property. Any host- or cluster-specific value setting takes precedence over the global setting. This allows you to set a global default value and then set a more refined value for particular hosts or clusters.

To set the global limit:

1. To add the property, go to `https://your_automation_URL/iaas/api/swagger/ui/#/Property/patchConfigurationProperty`.
2. Click **Try it out**.

3. For the value, enter 50.
4. For the key, enter DEFAULT_MAX_ALLOWED_COMPUTE_MEMORY_ALLOCATION_PERCENT.
5. Click **Execute**.

To set a host and cluster limit:

1. To retrieve the host or cluster ID, referred to in the API as fabric computes, go to https://your_automation_URL/iaas/api/swagger/ui/#/Fabric%20Compute/getFabricComputes and click **Try it out**.
2. Locate and copy the ID for the host or cluster that you want apply the limit to.
3. To add the property, go to https://your_automation_URL/iaas/api/swagger/ui/#/Fabric%20Compute/updateFabricCompute.
4. Click **Try it out**.
5. Enter the host or cluster ID that you retrieved using the **Get** command.
6. Enter the property and value.
For example, "maximumAllowedMemoryAllocationPercent": 120
7. Click **Execute**.

Ignore powered off VMs when calculating allocated memory

If you want to ignore powered off machines when calculating memory allocated on each host or cluster, you can set a property to exclude powered off VMs. This property affects the deployment process and day 2 power on and off actions.

This property is valid only if PREVENT_COMPUTE_MEMORY_OVERALLOCATION is set to TRUE

To set the neglect memory property:

1. To add the property, go to https://your_automation_URL/iaas/api/swagger/ui/#/Property/patchConfigurationProperty.
2. Click **Try it out**.
3. For the value, enter true.
4. For the key, enter NEGLECT_POWERED_OFF_VMS_MEMORY_OVERALLOCATION.
5. Click **Execute**.

To reset the property, set the value to false. If you turn off the property after using the capabilities, the you might see some of your deployments exceeding the limits.

Prevent storage overallocation of datastores

When you turn on the property, the amount of storage allocated on each datastore is tracked and that value is used to prevent provisioning to datastores where the provisioning request exceeds the available allocated storage.

The amount is calculated by summing the memory of all the managed disks on the datastore. Machines that are provisioned outside VMware Aria Automation, discovered, but not yet onboarded are not included in the calculation.

Set this global property.

1. To add the property, go to https://your_automation_URL/iaas/api/swagger/ui/#/Property/patchConfigurationProperty.
2. Click **Try it out**.
3. For the value, enter true.
4. For the key, enter PREVENT_COMPUTE_STORAGE_OVERALLOCATION.
5. Click **Execute**.

Set storage allocation limits

You can set a percentage value that is used as the maximum amount of storage for a datastore. This value is the allocation limit. You can set a conservative limit of less than 100%. You can also set a value over 100% if you have a clear understanding of how your resources allocation and you want to fine tune the limit.

For example, you have a datastore with 100 GB of total storage and you set the value to 50%. VMware Aria Automation considers the datastore to have 50 GB of total storage. Or, you can set the value to 120%. VMware Aria Automation then considers the host to have 120 GB of storage.

You can set a global property and a datastore specific property. Any datastore-specific value setting takes precedence over the global setting. This method allows you to set a global default value and then set a more refined value for particular datastores.

To set the global limit:

1. To add the property, go to https://your_automation_URL/iaas/api/swagger/ui/#/Property/patchConfigurationProperty.
2. Click **Try it out**.
3. For the value, enter 50.
4. For the key, enter `DEFAULT_MAX_ALLOWED_STORAGE_ALLOCATION_PERCENT`.
5. Click **Execute**.

To set a limit on a specific datastore:

1. To retrieve the host or cluster ID, referred to in the API as fabric computes, go to https://your_automation_URL/iaas/api/swagger/ui/#/Fabric%20vSphere%20Datastore/getFabricVsphereDatastore and click **Try it out**.
2. Locate and copy the ID for the datastore that you want to apply the limit to.
3. To add the property, go to https://your_automation_URL/iaas/api/swagger/ui/#/Fabric%20vSphere%20Datastore/updateFabricVsphereDatastore.
4. Click **Try it out**.
5. Enter the datastore ID that you retrieved using the **Get** command.
6. Enter the property and value.
For example, `"maximumAllowedStorageAllocationPercent":120`
7. Click **Execute**.

Prevent CPU overallocation

Some systems allow you to deploy resources even if the host or cluster does not have sufficient resources. For example, you successfully deploy a virtual machine, but you cannot turn it on due to insufficient virtual CPUs.

To avoid deploying resources that you cannot turn on, you can set the `PREVENT_COMPUTE_CPU_OVERALLOCATION` configuration property to TRUE. This change ensures that VMware Aria Automation tracks how many virtual CPU threads are allocated on each host or cluster. It then uses that value to prevent provisioning to hosts or clusters that are fully utilized, preventing overallocation. The allocated CPUs is calculated by adding up all the managed virtual machines in the host or cluster. Virtual machines that were provisioned outside VMware Aria Automation, discovered, but have not yet been onboarded are not counted.

This is a global property.

1. To add the property, go to https://your_automation_URL/iaas/api/swagger/ui/#/Property/patchConfigurationProperty.
2. Click **Try it out**.
3. For the value, enter `true`.

4. For the key, enter `PREVENT_COMPUTE_CPU_OVERALLOCATION`.
5. Click **Execute**.

To reset the preventing property and allow overallocation, set the value to `false`.

Set CPU allocation limits

You can set a percentage value that is used as the maximum number of virtual CPU threads for a host or cluster. This value is the allocation limit. You can set a conservative value of less than 100%. You can also set a value over 100% if you have a clear understanding of how your resources are allocated and want to fine tune the limit.

For example, you have a host or cluster with 10 CPUs and you set the value at 50%. VMware Aria Automation considers the host to have 5 CPUs. Or, you can set the value to 120%. VMware Aria Automation then considers the host to have 12 CPUs.

You can set a global property and a host- or cluster-specific property. Any host- or cluster-specific value setting takes precedence over the global setting. This allows you to set a global default value and then set a more refined value for particular hosts or clusters.

To set the global limit:

1. To add the property, go to https://your_automation_URL/iaas/api/swagger/ui/#/Property/patchConfigurationProperty.
2. Click **Try it out**.
3. For the value, enter 50.
4. For the key, enter `DEFAULT_MAX_ALLOWED_COMPUTE_CPU_ALLOCATION_PERCENT`.
5. Click **Execute**.

To set a host and cluster limit:

1. To retrieve the host or cluster ID, referred to in the API as fabric computes, go to https://your_automation_URL/iaas/api/swagger/ui/#/Fabric%20Compute/getFabricComputes and click **Try it out**.
2. Locate and copy the ID for the host or cluster that you want apply the limit to.
3. To add the property, go to https://your_automation_URL/iaas/api/swagger/ui/#/Fabric%20Compute/updateFabricCompute.
4. Click **Try it out**.
5. Enter the host or cluster ID that you retrieved using the **Get** command.
6. Enter the property and value.
For example, `"maximumAllowedCpuAllocationPercent": 120`
7. Click **Execute**.

Ignore powered off VMs when calculating allocated CPUs

If you want to ignore powered off machines when calculating CPUs allocated to each host or cluster, you can set a property to exclude powered off VMs. This property affects the deployment process and day 2 power on and off actions.

This property is valid only if `PREVENT_COMPUTE_CPU_OVERALLOCATION` is set to `TRUE`

To set the neglect CPU property:

1. To add the property, go to https://your_automation_URL/iaas/api/swagger/ui/#/Property/patchConfigurationProperty.
2. Click **Try it out**.
3. For the value, enter `true`.

4. For the key, enter NEGLECT_POWERED_OFF_VMS_CPU_OVERALLOCATION.
5. Click **Execute**.

To reset the property, set the value to `false`. If you turn off the property after using the capabilities, the you might see some of your deployments exceeding the limits.

How to work with audit logs in VMware Aria Automation

How to work with audit logs

To discover status information about reportable VMware Aria Automation actions, use audit logs.

VMware Aria Automation creates an audit log when you perform a reportable action, such as when you deploy a cloud template or catalog item, perform a Day 2 action on a resource or deployment, or create, delete, or update a property group. Audit logs display a status value or a message for each reportable action type, depending on the action. They can also contain information about the action, such as a timestamp, message, user name, project name, and trace ID value.

Audit logging captures information for the following reportable actions:

- Catalog deployment operations
 - Cloud template operations
 - Day 2 deployment operations
 - Day 2 resource action operations
- Each of the above four action types creates an initial audit log with a *Submitted* status. Based on how the action is completed, an additional log is created that displays a *Successful*, *Failed*, or *Canceled* status.
- Create, delete, and update property group operations
 - Create, delete, and update product feature toggle operations
 - Create, delete, and update policy operations in Automation Service Broker- such as Day 2 actions, lease, content sharing, approval, deployment limit, and resource quota policy operations
 - Create, delete, and update extensibility subscription operations
- Each of the above four action types creates a message in the audit log display screen.

Searching, displaying, and exporting an audit log

You can filter your search for, and display of, audit logs. You can also output audit logs in CSV format.

To display audit logs, use the following procedure.

1. Log in to VMware Aria Automation as an Automation Assembler administrator and open the Automation Assembler service.
2. Select the **Infrastructure** tab and click **Activity > Audit Log**.
3. Open and review the audit log or logs of interest.

How to apply governance to your resources using Automation Assembler and Automation Service Broker

How to apply governance to your resources

As a cloud administrator, you want to apply rules or policies that govern your resources. This governance allows you to manage access, cost, security, consumption, approvals, and other policies by using governance options in Automation Assembler and Automation Service Broker.

Background management of deployments

You can create policies that apply rules that control activities such as who can run what day 2 actions, how long leases are active before the system reclaims the resources, set consumption quota, and other policies, including who must approve different requests.

You define these policies in Automation Service Broker, but apply to all VMware Aria Automation resources. To get started, see [Setting up policies](#).

Configuring Multi-provider tenant resources with VMware Aria Automation

In multi-tenancy environments, customers can manage allocation of resources on a per-tenant basis using Virtual Private Zones (VPZs).

In VMware Aria Automation, you can configure multi-tenancy environments by using VMware Aria Suite Lifecycle and Workspace ONE Access. These tools let you set up multi-tenancy and create and configure tenants. After tenants are configured, provider administrators can create Virtual Private Zones in Automation Assembler and then they can assign zones to tenants by using the Automation Assembler Manage Tenants functionality.

Multi-tenancy relies on coordination and configuration of three different VMware products as outlined below:

- Workspace ONE Access - This product provides the infrastructure support for multi-tenancy and the Active Directory domain connections that provide user and group management within tenant organizations.
- VMware Aria Suite Lifecycle - This product supports the creation and configuration of tenants for supported products, such as VMware Aria Automation. In addition, it provides some certificate management capabilities.
- VMware Aria Automation - Providers and users log in to VMware Aria Automation to access tenants in which they create and manage deployments.

When configuring multi-tenancy, users should be familiar with all three of these products and their associated documentation.

How do I create a Virtual Private Zone for VMware Aria Automation

Provider administrators can create a Virtual Private Zone (VPZ) to allocate infrastructure resources to tenants in a multi-organization VMware Aria Automation environment. Administrators can also use VPZ's to control resource allocation in single tenant deployments.

- Enable and configure multi-tenancy on your VMware Aria Automation deployment using VMware Aria Suite Lifecycle and VMware Workspace ONE Access.
- Create tenant administrators as appropriate for your tenant configuration.
- If you want to use NSX, you must create an appropriate NSX cloud account in your provider organization.

You can use Virtual Private Zones to allocate resources such as images, networks, and storage resources. VPZs function much as cloud zone on a per tenant basis but they are designed specifically for use with multi tenant deployments. For any given project, you can use either cloud zones or VPZ's but not both. Also, there is a one to one relationship between VPZ's and tenants. That is, a VPZ can be assigned to only one tenant at a time.

NOTE

You configure image and flavor mappings for a VPZ on the Tenant Management page.

You can create a VPZ with or without NSX. If you create a zone without NSX, there are limits regarding NSX-related functionality on vSphere endpoints.

- Security (groups, firewall)
- Network components (NAT)

1. In Automation Assembler, select **Infrastructure > Configure > Virtual Private Zones**.

The VPZ page shows all existing zones and enables you to create zones.

2. Click **New Virtual Private Zone**.

New Virtual Private Zone

The screenshot shows the 'New Virtual Private Zone' configuration interface. On the left, there's a sidebar with three tabs: 'Compute', 'Storage', and 'Network'. The main area is titled 'Summary' and contains several configuration fields:

- Name ***: A text input field with the placeholder 'MyZone'.
- Description**: A large text area for entering zone details.
- Account / region ***: A search bar with the placeholder 'Search for regions'.
- Placement policy ***: A dropdown menu set to 'DEFAULT'.
- Capability tags**: A text input field with the placeholder 'Enter capability tags' and an info icon.

There are four selections on the left side of the page that you can use to configure summary information and infrastructure components for the zone.

3. Enter Summary information for the new zone.
 - a) Add a Name and Description.
 - b) Select an Account to which the zone applies.
 - c) Select the Placement Policy.

Placement policy drives host selection for deployments within the specified cloud zone.

- Default - Distributes compute resources across clusters and hosts randomly. This selection works at an individual machine level. For example, all machines in a particular deployment are distributed randomly across the available clusters and hosts that satisfy the requirements.
- binpack - Places compute resources on the most loaded host that has enough available resources to run the given compute.
- spread - Provisions deployment compute resources to the cluster or host with the least number of virtual machines. For vSphere, Distributed Resource Scheduler (DRS) distributes the virtual machines across the hosts. For example, all requested machines in a deployment are placed on the same cluster, but the next deployment might select another vSphere cluster depending on the current load.

4. Select the Compute resource for the zone.

Add compute resources as appropriate for the cloud zone. Initially, the filter selection is Include all Compute and the following list shows all available compute resources, and they are allocated to the applicable zone. You have two additional options for adding compute resources to a cloud zone.

- Manually select compute - Select this menu item if you want to select compute resources manually from the list below. After you select them, click Add Compute to add the resources to the zone.
- Dynamically include compute by tags - Select this menu item if you want to select compute resource to be added to the zone based on tags. All compute resources are shown until you add appropriate tags. You can select or enter one or more tags in the Include compute with these tags option.

For either compute selection, you can remove one or more of the compute resources shown on the page by selecting the box to the right and clicking Remove.

- Enter or select tags as appropriate.
- Select Storage on the left menu and select the Storage policy and other storage configurations for the zone.
- On the left menu, select Network and define the networks and, optionally, a network policy to use with this zone. You can also configure load balancers and security groups for selected network policies.

Network	<ul style="list-style-type: none"> All existing networks associated with this VPZ appear in the table on the Networks tab. Click Add Network to see all networks associated with the selected region. add a network for use with this zone. Select a network and click Tags to add one or more tags to the specified network. Select Manage IP Ranges to specify the IP Range through which users can access this network. If applicable, click the Network Policies tab and select an isolation policy.
Network policies	<p>If configured, select a network policy to use with this zone to enforce an isolation policy for outbound and private networks.</p> <ul style="list-style-type: none"> Select an isolation policy if desired. Select a Tier-0 logical router and an Edge cluster if desired.
Load Balancers	Click Add Load Balancer to configure load balancers for the account/region cloud accounts.
Security Groups	Click Add Security Group to use security groups to apply firewall rules to provisioned machines.

The Virtual Private Zone is created with the specified resource allocations.

Cloud administrators can associate the VPZ with a project.

- In Automation Assembler, select **Administration > Projects**
- Select the Provisioning tab.
- Click **Add Zone** and choose Add Virtual Private Zone.
- Select the desired VPZ from the list.
- You can set the provision priority and limits on the number of instances, the amount of memory available and the number of CPUs available.
- Click **Add**.

Manage Virtual Private Zone configuration for VMware Aria Automation tenants

Provider administrators can manage Virtual Private Zones (VPZs) within Automation Assembler to control infrastructure resource allocation on a per tenant basis. Using the Tenant Management page, administrators can view tenants and VPZ zones and enable or disable VPZs for tenants.

- Set up multi-tenancy and create Virtual Private Zones as appropriate for your deployment.
- Configure global image and flavor mappings for the VPZ and tenant configuration using the image mapping and flavor mapping menu selections on the left side of the Tenant Management page in Automation Assembler. See [Create global image and flavor mapping for VMware Aria Automation tenants](#).

You can override these global assignments now or later using the tenant specific image and flavor mapping selections at the top of the Tenant Management page. See [Configure tenant specific image and flavor mappings for](#).

By default, Virtual Private Zones are not allocated to any tenants. You must allocate VPZ's on this page in order to use them with your tenants.

When initially created, VPZ's are enabled by default. An enabled VPZ is ready to be allocated and used with the specified tenant. When VPZ's are disabled, they cannot be used for provisioning or allocated to a tenant. A VPZ can be disabled but still allocated for a tenant.

When a provider administrator navigates to the Tenant Management page, the page shows all available tenants and the administrator can select one. After a tenant is selected, the page shows VPZs currently allocated for that tenant, if any.

The administrator can use this page to allocate VPZs to the selected tenant.

When a VPZ is allocated, tenant administrators can add it to their projects, and it becomes available for provisioning by tenant users. After a VPZ is allocated to one tenant, it can be allocated to another tenant.

After a VPZ is enabled, it is ready for use within the specified tenant. Provider administrators can disable VPZ's to facilitate maintenance or tenant re-configuration, and they can provide notification to users of the disablement. If you want to make a VPZ unavailable to a tenant on a more permanent basis, you can de-allocate it. If an existing VPZ is de-allocated from a tenant for some reason, it cannot be used to create deployments from that tenant.

1. In Automation Assembler select Manage Tenants.

The Tenant Management page shows all tenants configured for the administrator's organization in a card view.

2. Click on a tenant to select it.
3. Click the infrastructure management tab to see all allocated VPZ's for the tenant
4. Select **Allocate Virtual Private Zone** to open a dialog that shows all zones not currently allocated to tenants. allocate the zone to a tenant.
5. Select one or more zones on the dialog and click **Allocate To Tenant**.

After VPZs are allocated, tenant administrators can assign them to projects.

Provider administrators can use the card view of tenants to monitor and manager status of VPZs.

- If you want to disable a tenant, click **Disable** on the card for the tenant.
- To enable a tenant, click **Enable** on the card for the tenant.
- If you want to de-allocate a tenant, click **Deallocate** on the card for that tenant.

Create global image and flavor mapping for VMware Aria Automation tenants

Provider administrators can select or create global image and flavor mappings that can be assigned to VMware Aria Automation tenants.

Global image and flavor mapping enables you to quickly set up mappings that apply to multiple tenants. You can also quickly update these mappings. The tenant management page also enables you to create tenant specific image and flavor mappings that can override the default configurations.

NOTE

Image and flavor mappings configured on the Tenant Management page apply only to tenants as configured and are not applicable to the broader provider organization.

1. In Automation Assembler select Manage Tenants.

The Tenant Management page shows all tenants configured for the administrator's organization in a card view.

2. Select Image Mapping on the Tenant Management page left menu.

The Image Mapping page displays all image currently configured for tenants in Automation Assembler and indicates whether the mappings are global or associated with a specific tenant.

Create Image Mapping

Account / region *

Image Name *

Image *

Constraints

Scope *

Cloud Configuration

1

CANCEL **CREATE**

3. Select **Add Image Mapping** to add an image mapping for use with tenants.

- a) Select the Account/Region to which the image mapping will apply.
- b) Enter a name for the image mapping and select the specific image instance or version to which it relates.
- c) Enter any desired constraint tags.

- d) Select the scope for the image mapping. The scope can be either All tenants, or global, or you can select a specific tenant to which the image mapping will apply.
4. If desired, you can use a cloud configuration script to define custom OS characteristics for deployments.

For example, based on whether you are deploying a cloud template to a public or private cloud, you can apply specific user permissions, OS permissions, or other conditions to the image. A cloud configuration script adheres to a `cloud-init` format for Linux-based images or a `cloudbase-init` format for Windows-based images. See [Learn more about image mappings in VMware Aria Automation](#) for more information.

5. Click **Create** to create the image mapping.
 6. Select **Add Flavor Mapping** to add a flavor mapping for use with tenants.

The screenshot shows the 'Create Flavor Mapping' dialog. It includes fields for Account/Region, Name, Value, and Scope. The 'Scope' field is set to 'All tenants'. There are 'CANCEL' and 'CREATE' buttons at the bottom.

- a) Select the Account/Region to which the flavor mapping will apply.
 b) Enter a name for the flavor mapping you are creating.
 c) Select the Size parameters for the flavor mapping you are creating.
 You can specify the number of processors and the amount of memory for this flavor.
 d) Select the scope for the flavor mapping. The scope can be either All tenants, or global, or you can select a specific tenant to which the flavor mapping will apply. All tenants applies to all tenants in the provider administrator's organization.
7. Click **Create** to create the flavor mapping.

After you create global mappings, these mapping will show up on the Flavor Mapping or Tenant Mapping tabs on the Tenant Management page for applicable tenants.

You can edit or delete global image and flavor mappings on this page. To edit a mapping select it and make the desired changes.

Configure tenant specific image and flavor mappings for VMware Aria Automation

Automation Assembler enables you to configure global image and flavor mappings that are available to all Virtual Private Zones (VPZs) within your organization. Alternatively, you can override the global settings and configure tenant specific image and flavor mappings as appropriate for your deployments.

- Enable multi-tenancy and configure tenants for your deployment.
- Create appropriate VPZs.

Typically, a cloud administrator configures global image and flavor mappings using the left navigation links on the Tenant Management page, and these mappings apply across the board for all of your tenants. In some cases, you may want to create custom, tenant-specific, image and flavor mappings for specific tenants and the Tenant Management page supports this option.

Image and flavor mapping are shown on their respective tabs on the Tenant Management page. Click on any of the existing image and flavor mappings to edit them. To delete an image or flavor mapping, select the mapping and then click **Delete**.

1. Select Tenant Management on the Automation Assembler main menu.
2. Select the tenant for which you wish to configure custom image or flavor mapping.
3. Select the Image Mapping link on the top of the page, then click **Add Image Mapping**.

The Create Image Mapping dialog appears.

4. Ensure that the Account/Region specified is correct and add a name for the mapping in the **Image Name** text box.
5. Select the underlying machine image to use in the **Image** drop-down.
6. Add constraint tags if applicable for your image usage.
7. Select the appropriate **Scope** for the image.
 - Click the Available for this tenant only radio button if you want this image mapping to be available only for use by the selected tenant.
 - Click the Shared Across tenants radio button if you want this image mapping to be available for use by other tenants.

8. Click **Create** to save the image mapping as configured.

9. Select the Flavor Mapping link at the top of the page and then click **Add Flavor Mapping** to create a flavor mapping.

The Create Flavor Mapping dialog appears.

10. Ensure that the Account/Region specified is correct and add a name for the mapping in the **Name** text box.

11. Specify the flavor CPU and memory settings in the **Value** field.

12. Select the appropriate **Scope** for the image.

- Click the Available for this tenant only radio button if you want this image mapping to be available only for use by the selected tenant.
- Click the Shared Across tenants radio button if you want this image mapping to be available for use by other tenants.

13. Click **Create** to save the flavor mapping as configured.

Tenant-specific image and flavor mappings are configured as specified.

Create extensibility subscriptions for providers or tenants

Provider and tenant administrators can create extensibility subscriptions to access VMware Aria Automation Orchestrator workflows. VMware Aria Automation Orchestrator workflows are triggered based on events if there is a subscription for some event topics which corresponds to a particular lifecycle phase of the application.

Configure tenants and virtual private zones as appropriate for your deployment.

The characteristics of an extensibility subscription differ depending on whether the subscription was created by a provider administrator or a tenant administrator.

- The Tenant administrator can create a subscription but cannot specify organization scope. That subscription will be activated on events triggered by tenant only.
- The Provider administrator can create a subscription and specify provider scope. The subscription will behave just like tenant subscription or non multi-tenant environment. It will be activated based on events coming from the Provider.
- The Provider can create a subscription and specify the tenant scope. The subscription is activated based on events coming from any Tenant. It is not activated by events coming from Provider.

Subscriptions trigger VMware Aria Automation Orchestrator workflows based on specific events. They do not invoke extensibility actions. Currently only a single VMware Aria Automation Orchestrator instance is supported for any particular provider organization. For more information about events, event topics, and subscriptions see [Extensibility terminology](#).

1. In VMware Aria Automation, navigate to the Subscriptions page and click **New Subscription**.

2. Enter a **Name** and **Description** for the subscription.

3. Make sure the Enable Subscription radio button is On.

You can leave this button in the Off position if you don't want the subscription to be immediately active.

4. If you are a provider administrator, select the appropriate **Organization Scope**.

The organization scope options are either provider or tenant. If you select tenant, then the project scope is any project and cannot be changed. If you select provider, you can specify the project scope using the selection at the bottom of the Subscriptions page.

5. Select the **Event Topic** to which you wish to subscribe.

6. Select one or more workflows.

Providers and tenants can view the returned events for a specific deployment on the Events page in Automation Assembler. The displayed results depend on your role and the organization scope.

- If organization scope is Provider, then providers will see events based on their actions in same provider organization.
- If organization scope is Tenant, tenants will see the events, but the provider cannot see them. Events always live in the organization of the publisher.

1. Select **Extensibility > Events** in Automation Assembler.

2. In the Events page Search box, enter the deployment ID for which you wish to view events.

The page displays events that match the search criteria.

Working with legacy Virtual Private Zones in newer versions of VMware Aria Automation

The configuration options for VPZs have changed in Automation Assembler. You can update or work with legacy Virtual Private Zones in current versions of VMware Aria Automation.

In VMware Aria Automation 8.2 users configured image and flavor mappings within VPZs. In newer versions of VMware Aria Automation, users create image and flavor mappings on a per-tenant basis, which increases efficiency and configuration flexibility especially in deployments with large numbers of tenants. While there is no way to migrate legacy VPZs created in VMware Aria Automation 8.2 there are several options for using them with newer versions of VMware Aria Automation.

The first, and most flexible, option is to delete the legacy image and flavor mappings from the older VPZs and re-configure them with new mappings created on the Tenant Management page.

1. Select **Infrastructure > Configure > Virtual Private Zones** to open the VPZ page.
2. Select Image Mapping to view the existing mapping.
3. Select mappings and click to delete them.
4. Select Image Mapping to view the existing mapping.
5. Select mappings and click to delete them.
6. Close the VPZ page.
7. Select Tenant Mapping and create select a global mapping for the applicable tenants or create a tenant specific mapping.

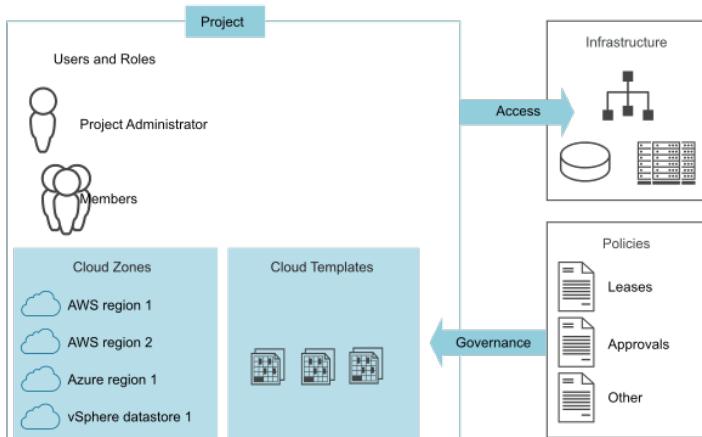

Alternatively, you can use legacy vPZs with newer versions of vRA in their existing configuration. The legacy image and flavor mappings still function as configured, but their configuration options are read only on the VPZ page. This options offers less flexibility than the first option.

Adding and managing Automation Assembler projects

Adding and managing projects

Projects control who has access to Automation Assembler cloud templates and where the templates are deployed. You use projects to organize and govern what your users can do and to what cloud zones they can deploy cloud templates in your cloud infrastructure.

Cloud administrators set up the projects, to which they can add users and cloud zones. Anyone who creates and deploys cloud templates must be a member of at least one project.

How do I add a project for my Automation Assembler development team

How do I add a project for my development team

You create a project to which you add members and cloud zones so that the project members can deploy their cloud templates to the associated zones. As the Automation Assembler administrator, you create a project for a development team. You can then assign a project administrator or you can operate as the project administrator.

- Verify that you configured the cloud zones. See [Building your Automation Assembler resource infrastructure](#).
- Verify that you configured the mappings and profiles for the regions that include as cloud zones for this project. See [Building your Automation Assembler resource infrastructure](#).
- Verify that you have the necessary permissions to perform this task. See [What are the user roles](#).
- Determine who you are designating as the project administrator. To understand what the project administrator can do in Automation Assembler, see [What are the user roles](#).

- If you are adding Active Directory groups to projects, verify that you configured Active Directory groups for your organization. See [Edit group role assignments in VMware Aria Automation](#) in *Administering VMware Aria Automation*. If the groups are not synchronized, they are not available when you try to add them to a project.

When you create a cloud template, you first select the project to associate it with. The project must exist before you can create the cloud template.

Ensure that your projects support the business needs of the development team.

- Does the project provide the resources that support the team's goals. For an example of how the infrastructure resources and a project support a cloud template, see [Tutorial: Setting up and testing multi-cloud infrastructure and deployments in Automation Assembler](#).
- Do your project members require or expect their deployments to be shared or private. Shared deployments are available to all the project members on the Deployments page, not only the deploying member. You can change the deployment sharing state at anytime.

When you share the deployment with project members, the members can run the same day 2 action. To manage the ability of members to run day 2 actions, you can create day 2 policies in Automation Service Broker. The policies apply to Automation Assembler and Automation Service Broker deployments.

To learn more about the day 2 policies, see [How do I entitle deployment users to day 2 actions using policies](#).

This procedure is based on creating an initial project that includes only the basic configurations. As your development team creates and deploys their cloud templates, you might modify to the project. You can add constraints, custom properties, and other options to improve deployment efficiencies. See the articles available in [Learn more about projects](#).

1. Select **Infrastructure > Administration > Projects**, and click **New Project**.
2. Enter the project name.
3. Click the **Users** tab.
 - a) To make deployments by project members accessible only to the requesting user, turn off **Deployment sharing**. To ensure that you can assign the ownership of a deployment to another member of the project, verify that the **Deployment sharing** is turned on.
 - b) Add users or user groups with assigned roles.
User roles based on groups allows users to come and go from your Active Directory groups rather than requiring the project administrator to constantly update the individual users in the project. For example, if deployment ownership is based on groups, you can change the ownership of a deployment to the group. Any notifications are sent to all the group members, allowing anyone to respond.
4. Click the **Provisioning** tab and add one or more cloud zones.
Add any cloud zones and virtual private zones that contain the resources that support the cloud templates deployed by the project users.
For each zone, you can set a zone priority and you can limit the amount of resources that the project can use. For more information about limits see [Using cloud zone resource limits](#).
5. If the workloads requested for this project take more than two hours to deploy, enter a longer value for the **Timeout**.
The default value is two hours.
6. Click **Create**.
7. To test your project with the project cloud zones, click **Test Configuration** on the Projects page.
The simulation runs a standardized hypothetical deployment test against the project cloud zone resources. If it fails, you can review the details and correct your resource configuration.

Get started with cloud templates. See [Designing your Automation Assembler deployments](#).

Learn more about Automation Assembler projects

Learn more about projects

Projects are the connector between cloud templates and resources. The more you understand about how they work and how you can make them work for you, the more effective your Automation Assembler development and deployment process will be.

Using Automation Assembler project tags and custom properties

Using project tags and custom properties

As an administrator, you can add project-level governance constraints or custom properties when the requirements of the project are different from the Automation Assembler cloud templates. In addition to constraint tags, you can add resource tags that are added to deployed resources during the provisioning process so that you can manage the resources.

What are project resource tags

A project resource tag operates as a standardized identifying tag that you can use to manage the deployed compute resources and ensure compliance.

The resource tags defined in a project are added to all the machine resources deployed that are part of that project along with any machine-specific tags. You can then use the standard tagging to manage the resources using other applications, for example, monitor spending cost using CloudHealth, and, importantly, to ensure compliance. The project resource tags are not added to other resources such as network or storage.

For example, as a cloud administrator, you want to use an application like CloudHealth to manage costs. You add the `costCenter:eu-cc-1234` tag to a project dedicated to developing a European Union human resources tool. When the project team deploys from this project, the tag is added to the deployed machine resources. You then configure the costing tool to identify and manage the resources that include this tag. Other projects with other cost centers would have alternative values to go with the key.

What are project constraint tags

A project constraint operates as a governance definition. It is a `key:value` tag that defines what resources the deployment request consumes or avoids in the project cloud zones.

The deployment process looks for tags for the networks and storage that match the project constraints, and deploys based on matching tags.

The extensibility constraint is used to specify which VMware Aria Automation Orchestrator integrated instance to use for extensibility workflows.

Consider the following formats when you configure project constraints.

- **key:value** and **key:value:hard**. Use this tag, in either format, when the cloud template must be provisioned on resources with the matching capability tag. The deployment process fails when no matching tag is found. For example, a cloud template deployed by the members of a project must be provisioned on a PCI-compliant network. You use `security:pci`. If no networks are found in the project cloud zones, the deployment fails, ensuring no insecure deployments.
- **key:value:soft**. Use this tag when you prefer a matching resource, but you want the deployment process to proceed without failing and can accept resources where the tag does not match. For example, you prefer that the project members deploy their cloud templates to a less expensive storage, but you do not want storage availability to interfere with their ability to deploy. You use `tier:silver:soft`. If there is no storage tagged tier:silver in the project cloud zones, the cloud template still deploys on other storage resources.
- **!key:value**. Use this tag, with hard or soft, when you want to avoid deploying to resources with a matching tag. Importantly, the project constraint tags have a higher priority than the cloud template constraint tags and override them at deployment time. If you have a cloud template where this must never happen, you can use the

`failOnConstraintMergeConflict:true` in the template. For example, if your project has a network `loc:London` constraint, but the cloud template is `loc:mumbai`, but rather than the project location taking precedence, you want the deployment to fail with a constraint conflict message, you add a property similar to the following sample.

constraints:

- tag: 'loc:mumbai'

`failOnConstraintMergeConflict:true`

How might I use project custom properties

You can use a project custom property for reporting, to trigger and populate extensibility actions and workflow, and to override cloud template level properties.

Adding a custom property to a deployment allows you to use the value in the user interface or to retrieve it using the API so that you can generate reports.

Extensibility can also use a custom property for an extensibility subscription. For more information about extensibility, see [Extending and automating application life cycles with extensibility](#).

A cloud template might have a particular property value that you want to change for a project. You can provide an alternative name and value as a custom property.

You can also encrypt the property value so that neither you nor your users can see the value that is included in the deployment. For example, you can encrypt a password that all users in the project use, but that you do not want visible. After you encrypt the value and save the project, you cannot unmask or replace the value. If you clear the **Encrypted** check box, the value is removed. You must re-enter a value.

Using cloud zone resource limits in Automation Assembler projects

Using cloud zone resource limits in projects

When you configure a project, you add cloud zones. You can define the resource limits for each cloud zone, allowing you to conserve resources where needed.

The possible limits include the number of instances, memory, and CPUs.

vSphere storage limits

For vSphere cloud zones only, you can configure storage limits for deployed resources that are based on vSphere VM templates and content library items. Storage limits consider the actual capacity for thick and thin resource provisioning so that you cannot over-provision using thin provisioning. First class disks and vSphere independent disks are also considered in the storage limits. Storage limits do not apply to OVA/OVF templates that are outside of the content library.

The storage limits are evaluated when you request a deployment and when you make changes to the deployment using the resize disk, resize boot disk, remove disk, and the update count actions. Like initial provisioning, thick and thin provisioning are considered to prevent over-provisioning. These storage limits do not apply to other resource types such as AWS, Microsoft Azure, or Google Cloud Platform.

As you add each zone and apply limits, don't limit the project resources so narrowly that the members cannot deploy their cloud templates.

When your users submit a deployment request, the zones are evaluated to determine which zones have the resources to support the deployment. If more than one zone supports the deployment, then the priority is evaluated and the workload is placed on the one with the higher priority, which is the lowest integer.

Ignore powered off VMs when evaluating usage for limits

In addition to setting limits for cloud zones in the project, you can also configure the limits to ignore powered off VMs when calculating memory and CPU usage. This property affects the deployment process and day 2 power on and off actions.

For example, when you add a cloud zone to a project, you apply a limit of 5120 MB memory and 5 CPUs. You then deploy a templates that consume the amount and reach the limit. The next deployment fails. However, you know that two of the VMs are powered off and you want to ignore the usage of the powered off VMs and deploy an additional template. You can set a global property for your organization that ignores powered off machines with determining resource usage.

To ignore powered off VMs, you can set a global property.

1. To add the property, go to https://your_automation_URL/iaas/api/swagger/ui/#/Property/patchConfigurationProperty.
2. Click **Try it out**.
3. For the value, enter `true`.
4. For the key, enter `NEGLECT_POWERED_OFF_VMS_RESERVATION`.
5. Click **Execute**.

To reset the property, set the value to `false`. If you turn off the property after using the capabilities, the you might see some of your deployments exceeding the limits.

When you turn the property on and off, VMware Aria Automation recalculates the CPU, memory, storage, and instance count usage.

For more information about capacity management, see [How to manage infrastructure capacity for VMware Aria Automation](#).

How do project-level placement policies affect resource allocation in VMware Aria Automation

Using project-level placement policies

As an administrator, you can define the placement policy for projects where more than one cloud zone is eligible as the deployment target zone. For example, you might have a project where you want to deploy cloud templates based on the set priority, you might want to balance the deployed resources across multiple zones based on which one has the best VM to host ratio, or you might want to balance the VMs based on the amount of free resources in the zones. .

Allocation considerations

For a default or spread placement policy.

- If the deploying user has permission to manage cloud accounts that are in maintenance mode, the allocation process can select a cloud account that is in maintenance mode because the user might need to run a test deployment before closing the maintenance window.
- If the user does not have permission to manage cloud accounts, then the cloud accounts that are in maintenance mode are filtered out of the allocation process.
- Hosts that are in maintenance mode are counted as part of the spread ratio. To exclude a host in maintenance from the ratio calculation, you must set the power state to off.

For a spread policy.

- Ratios are calculated based on hosts. The hosts can be standalone or part of a cluster.
- If a standalone host is powered off, it is not counted as part of the ratio.
- If a host that is part of a cluster is powered off, the powered off state is not reflected in the cluster and the host is still considered when calculating the ratio.

For a spread by memory policy.

- The amount of available memory is calculated by identifying the amount of memory of all the hosts in the cloud zone and identifying the allocated memory of all the currently deployed virtual machines. However, there are variations based on whether the project is evaluating private cloud zones, public cloud zones, or a mix of private and public.
 - Projects with only private cloud zones.

To determine available memory for private cloud zones, the total memory of the hosts in the zone is retrieved.

The amount of memory allocated to all the managed virtual machines is retrieved. The allocated memory is divided by the total memory to determine the ratio, which is inversely proportional to the size of the zone or cluster. The zone or cluster with the smallest ratio is considered to have the most available memory because it has the largest amount of free memory proportional to its size.

- Projects with only public cloud zones.

It is not possible to determine the free memory for public cloud zones. Therefore, the amount of memory allocated to all the managed virtual machines is retrieved. The cloud zones are ordered by the amount of allocated memory so that the zone with the least amount of allocated memory is prioritized first.

- Projects with a mix of private and public cloud zones.

To determine the amount of available memory, the private cloud zone with the largest amount of total memory, which is retrievable information, is made the baseline that is used for all the public cloud zones.

To determine available memory for private cloud zones, the total memory of the hosts in the zone is retrieved. The amount of memory allocated to all the managed virtual machines is retrieved. The allocated memory is divided by the total memory to determine the ratio, which is inversely proportional to the size of the zone or cluster. The zone or cluster with the smallest ratio is considered to have the most available memory because it has the largest amount of free memory proportional to its size.

How to set the placement policy

If you have multiple cloud zones in a project that are equally eligible as the target for a deployment, the deployment request evaluates where to place them based on how you have the **Placement policy** configured.

1. Select **Infrastructure > Projects** and create or select a project.
2. In the project, click the **Provisioning** tab.
3. Select a policy.

Placement policy	Description
Default	<p>Deploys the requested resources to the first cloud zone that matches the requirements.</p> <p>Select Default when you want the workloads deployed in the priority order and don't mind utilizing all the resources on a host.</p> <p>If this option is selected, the VM and Hosts values are not retrieved.</p>
Spread	<p>Deploys the requested resources to the cloud zone with the smallest number of virtual machines per hosts.</p> <p>Select Spread when you want to distribute the workloads across hosts, utilizing resources broadly across hosts.</p> <p>If this option is selected, the number of VMs and hosts are retrieved from the cloud zone resources and evaluated.</p>

Table continued on next page

Continued from previous page

Placement policy	Description
Spread by Memory	<p>Deploys the requested resources to the cloud zone with the largest amount of free memory.</p> <p>Select Spread by Memory when you want the workloads placed on hosts with the largest amount of unallocated memory.</p> <p>If this option is selected, the identification of the zone with the most free memory depends on whether the project contains only private cloud zones, public cloud zones, or a mix. See the allocation considerations above.</p>

4. Click **Save**.

Review how the policy is applied

After you configure the project-level placement policy, you can view where the system plans to deploy the cloud template in a provisioning diagram.

1. Select **Design > Cloud Templates** and select or configure a template that uses the project to which you selected a policy.
2. Click **Test**.
3. When the test completes successfully, click **Provisioning Diagram** in the test results.
4. The diagram will resemble one of the two examples.

Policy Type	Provisioning diagram
Default	 <p>The screenshot shows the "Request Details" interface with the "MACHINE ALLOCATION" tab selected. At the top, there's a "Project: Project WLP" section with network, storage, extensibility, and placement policy constraints. Below this, two vCenter accounts are listed: "vCenter Account 241-1/Datacenter" and "vCenter Account 241-2/Datacenter". Each account has priority, instances, memory, and storage settings. Arrows point from these accounts to their respective "Flavors" sections. The "Flavors" section for vCenter Account 241-1 shows "smalld241" as available mappings. The "Flavors" section for vCenter Account 241-2 shows "smvd241" as available mappings. Arrows point from these flavors to their respective "Images" sections. The "Images" section for vCenter Account 241-1 shows "centos" as available mappings. The "Images" section for vCenter Account 241-2 also shows "centos" as available mappings. Arrows point from these images to the "Cloud zone" sections. The "Cloud zone" section for vCenter Account 241-1 lists "Cloud zone: vCenter Account 241-1 / Datacenter (vCenter Account 241-1 / Datacenter)" with priority 0, instances 0/Unlimited, memory Unlimited/Unlimited, storage 0/0, placement policy Default, total VMs 0, and VMs to hosts ratio 0.00. It also lists "Zone aggregated tags (1)" with "Cluster-ComputeCluster" and "Type-ResourcePool" selected. The "Cloud zone" section for vCenter Account 241-2 lists "Cloud zone: vCenter Account 241-2 / Datacenter (vCenter Account 241-2 / Datacenter)" with similar settings. Both sections have a note: "Other cloud zone was more applicable, by priority and matching constraints."</p>

Policy Type	Provisioning diagram
Spread	

- If you are ready to deploy, return to the cloud template and click **Deploy**.

Placement policy evaluation during the allocation process

The following diagram helps you understand when the policy is evaluated during the allocation process and when the target zone and host are identified.

What are the project prices in Automation Assembler

What are the project costs

The costs available in your Automation Assembler projects help you manage the resource expenses associated with entire projects. The project also includes the individual deployment costs.

The screenshot shows the 'Ansible-Project' details page. The left sidebar includes sections for Administration, Projects, Users and Groups, Custom Roles, Secrets, Configure (Cloud Zones, Kubernetes Zones, Flavor Mappings, Image Mappings, Network Profiles, Storage Profiles, Pricing Cards, Terraform Versions, Tags, Configuration Properties), Onboarding, and Resources. The main content area shows a table of deployment history:

Deployment Name	Description	Requestor	Created On	Expiring In	Price
AnsibleTower-Demo		sakshi@vmware.com	Jan 26, 2021	Never expires	\$3.07
Check-Delete		louisw@vmware.com	Jan 18, 2021	Never expires	\$3.04
Ansible vSphere		skarvadim@vmware.com	Jan 19, 2021	Never expires	\$3.01
WT with 2 machines		jjumonv@vmware.com	Feb 14, 2021	Never expires	\$0.61
Create with templates		jjumonv@vmware.com	Feb 14, 2021	Never expires	\$0.32
Ansible		skarvadim@vmware.com	Jan 07, 2021	Never expires	\$0.31
Create with job templates		jjumonv@vmware.com	Feb 14, 2021	Never expires	\$0.31

7 deployments

SAVE CANCEL

The cost information that you see for a project and for the individual deployments appears after at least one deployment associated with the project is provisioned. The costs are calculated and updated daily so that you can track the cost of a deployment over time. The initial values are based on industry benchmarks.

Cloud administrators can adjust the values to reflect your actual costs.

For more information, see [How to use Pricing Cards in](#).

How do Automation Assembler projects work at deployment time

How do projects work at deployment time

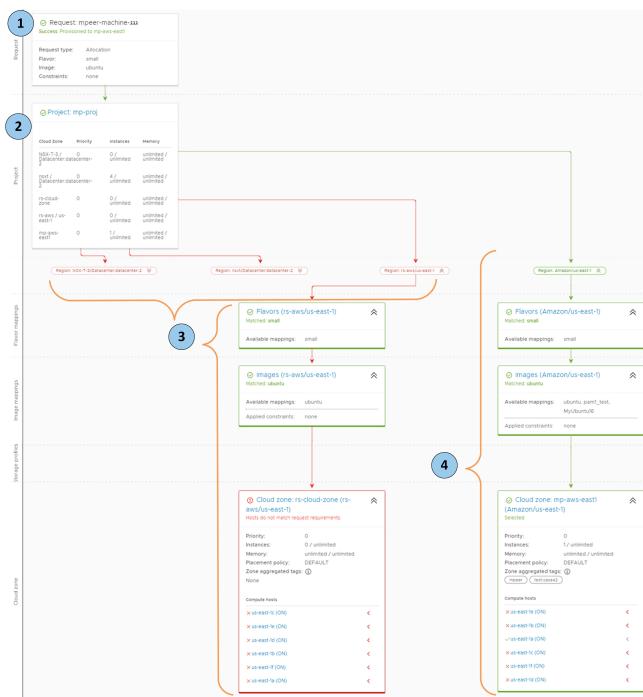

Projects control user access to the cloud zones and user ownership of the provisioned resources. Whether you are a cloud administrator or a cloud template developer, you must understand how the projects work at deployment time so that you can manage your deployments and troubleshoot any problems.

As a cloud administrator who is setting up projects for various teams, you must understand how projects determine where cloud template components are deployed. This understanding helps you create projects that support cloud template developers and to troubleshoot failed deployments.

When you create a cloud template, you first associate it with a project. At deployment time, the cloud template requirements are evaluated against the project cloud zones to find the best deployment location.

The following workflow illustrates the process.

1. You submit a cloud template deployment request.
2. The project evaluates the template and project requirements, for example, flavor, image, and constraint tags. The requirements are compared to the project cloud zones to locate a zone that supports the requirements.
3. These zones did not have the resources to support the request.
4. This cloud zone supports the request requirements and the template is deployed to this cloud zone account region.

Designing your Automation Assembler deployments

Designing your deployments

Deployments begin with cloud templates, formerly called blueprints, which are encoded specifications that define machines, applications, and services to create on cloud resources by way of Automation Assembler.

How cloud templates work

Templates can target specific cloud vendors or be cloud agnostic. The cloud zones assigned to your project determine which approach you might take. Check with your cloud administrator so that you know what kind of resources make up your cloud zones.

Automation Assembler template creation is an infrastructure-as-code process. You start by adding resources in the design canvas. Then, you complete the details using the code editor. The code editor allows you to type code directly or enter values in a form.

Before you create a cloud template

You can create an Automation Assembler template at any time. To deploy it, however, you first need to [define your cloud resource infrastructure](#) and [create a project](#) that includes that infrastructure.

Getting started with creating and designing cloud templates in VMware Aria Automation

Getting started with creating and designing cloud templates

You use the Design page in Automation Assembler to create and design VMware Aria Automation cloud template specifications for the machines and applications that you want to provision, including property groups, custom resources, and resource actions.

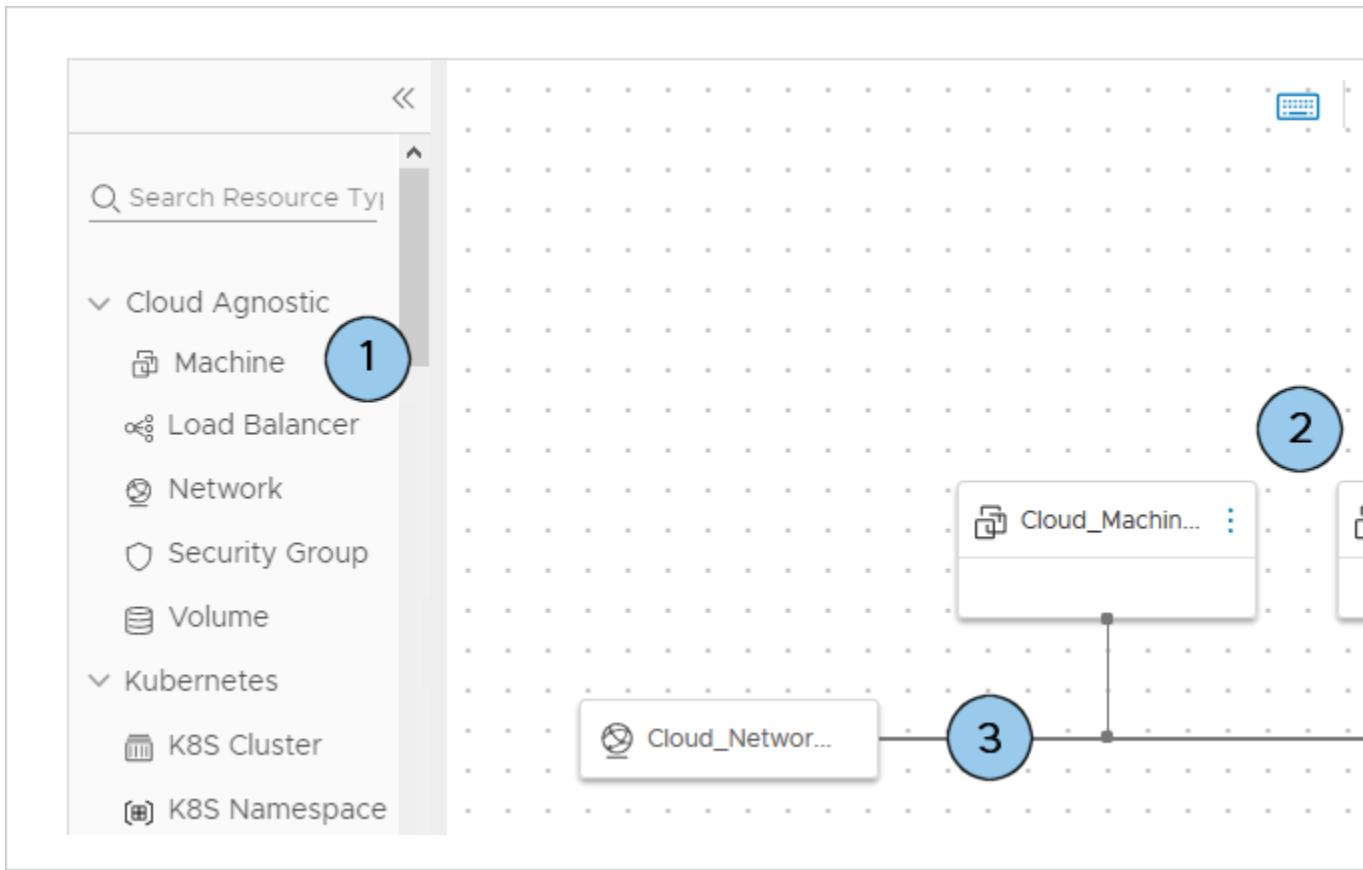

How to use the Design page

To create a cloud template from scratch, go to **Design > Templates**. Then, click **New from > Blank canvas**.

Note that other options allow you to create the template from either existing Terraform code or from another, existing Automation Assembler template to which you have access.

Once you have created the template, you can populate it by adding and configuring resources as shown below.

1. Locate resources.
2. Drag resources to the canvas.
3. Connect resources.
4. Configure resources by editing the cloud template code.

Selecting and adding resources to the design canvas

Resources appear at the left of the design page for selecting and dragging.

Cloud agnostic resources	You can deploy cloud agnostic resources to any cloud vendor. At provisioning time, the deployment uses cloud specific resources that match. For example, if you expect a cloud template to deploy to both AWS and vSphere cloud zones, use cloud agnostic resources.
Cloud vendor resources	<p>Vendor resources, such as those specific to Amazon Web Services, Microsoft Azure, Google Cloud Platform, or VMware vSphere, can only be deployed to matching AWS, Azure, GCP, or vSphere cloud zones.</p> <p>You can add cloud agnostic resources to a cloud template that contains cloud specific resources for a particular vendor. Just be aware of what the project cloud zones support in terms of vendor.</p>
Configuration management resources	Configuration management resources depend on your integrated applications. For example, a Puppet resource can monitor and enforce the configuration of the other resources.

Connecting resources

Use the Automation Assembler design canvas graphical controls to connect resources.

Resources must be compatible for a connection. For example:

- Connecting a load balancer to a cluster of machines.
- Connecting a machine to a network.
- Connecting external storage to a machine.

IMPORTANT

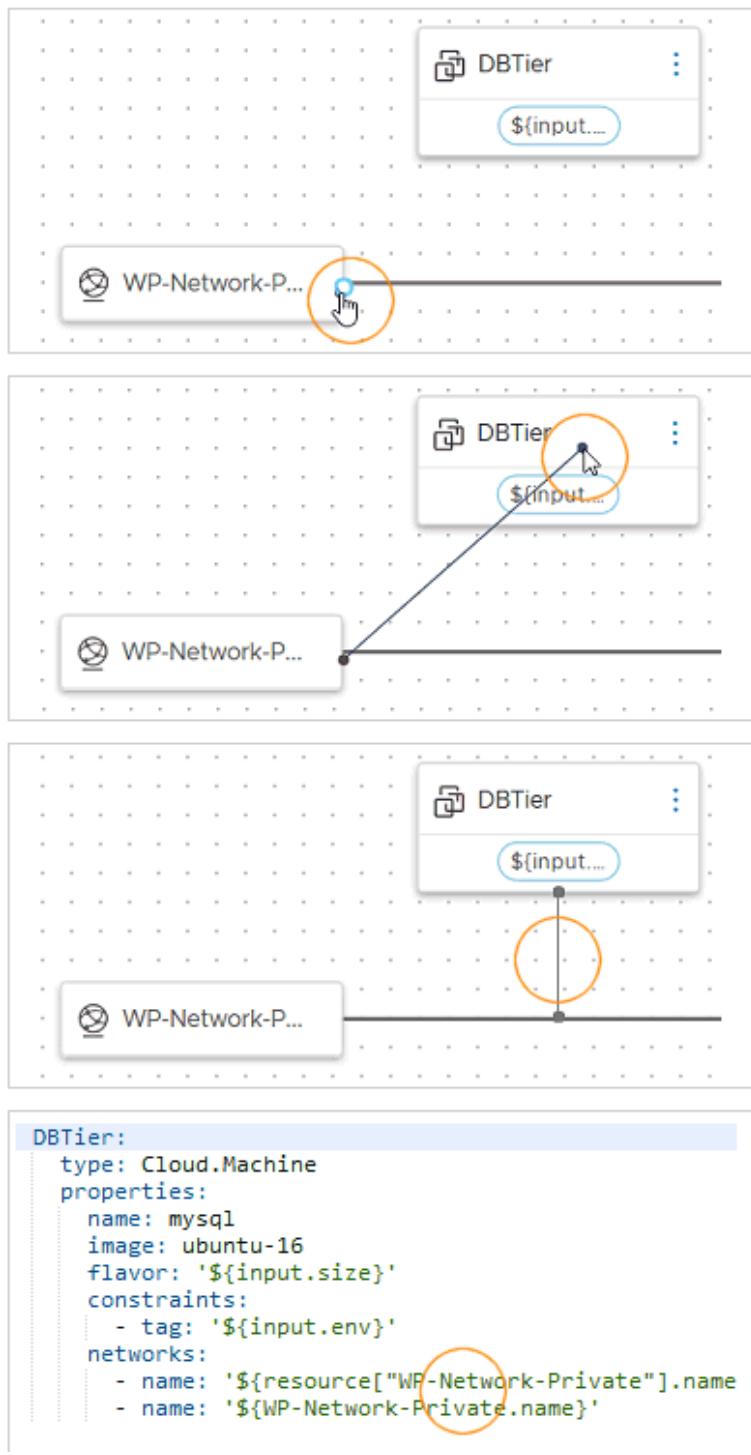

A solid line connector requires that the two resources be deployed in the same cloud zone. If you add conflicting constraints to the resources, deployment might fail.

For example, you can't deploy connected resources where constraint tags force the placement of one to a zone in us-west-1, and the other to a zone in us-east-1.

Solid or dashed arrows only indicate a dependency, not a connection. For more about dependencies, see [Creating bindings and dependencies between resources](#) in .

To connect, hover over the edge of a resource to reveal the connection bubble. Then, click and drag the bubble to the target resource and release.

In the code editor, additional code for the source resource appears in the target resource code.

In the figure, the SQL machine and private network are connected, so they must be deployed in the same cloud zone.

Editing cloud template code

The code editor allows you to type, cut, copy, and paste code directly. If you're uncomfortable editing code, you can click a resource that's already in the design canvas, click the code editor **Properties** tab, and enter values there. Property values that you enter appear in the code as if you had typed them directly.

The screenshot shows the VMware Aria Automation interface for creating a cloud template. On the left, the template code is displayed:

```

WebTier:
type: Cloud.Machine
properties:
  name: wordpress
  flavor: '${input.size}'
  image: ubuntu
  count: '${input.count}'
constraints:
  - tag: '${input.env}'
networks:
  - network: '${resource["WP-Network-Private"].id}'
    assignPublicIpAddress: true
storage:
  disks:
    - capacityGb: '${input.archiveDiskSize}'
      name: ArchiveDisk
cloudConfig:
#cloud-config
repo_update: true
repo_upgrade: all

packages:
  - apache2
  - php
  - php-mysql
  - libapache2-mod-php

```

The right side of the interface shows various configuration properties:

- Count:** `\${input.count}`
- Image Type:** ubuntu
- Flavor ***: \${input.size}
- Storage**
- Constraints**
- Tags** (represented by a table with columns for Tag and Value)
- Maximum Capacity**: 1 (of the disk in GB)
- Size of boot disk in GB**: 1
- Networks** (represented by a table with a plus sign to add more)

Note that you can copy and paste code from one cloud template to another.

[Video - Creating and designing cloud templates](#)

Refer to this VMware channel YouTube [video](#) for a helpful overview on how to create and design cloud templates in VMware Aria Automation.

Getting code completion help in your Automation Assembler template

Code completion help for your template

Adding Automation Assembler resources to the template and connecting those resources in the design canvas only creates starter code. To fully configure your template resources, edit the template code.

The code editor allows you to type code directly or enter property values into a form. To help with direct code creation, the Automation Assembler editor includes syntax completion and error checking features.

Editor Hints	Example
Available values	<pre> 10 Cloud_Machine_2: 11 type: Cloud.Machine 12 properties: 13 image: '' 14 flavor: '' 15 16 networks small flavor 17 - name 18 Cloud_Network_1 large flavor 19 type: Cloud.Network 20 properties: 21 name: '' 22 networkType: existing </pre>
Allowed properties	<pre> 10 Cloud_Machine_2: 11 type: Cloud.Machine 12 properties: 13 image: '' 14 flavor: '' 15 16 tags: array 17 18 Cloud_Network_1 storage: object 19 type: Cloud.Network 20 properties: 21 name: string 22 23 imageRef: string 24 25 count: integer 26 27 constraints: array 28 29 cloudConfig: string </pre>
Child properties	<pre> 10 Cloud_Machine_2: 11 type: Cloud.Machine 12 properties: 13 image: '' 14 flavor: '' 15 constraints: 16 17 networks tag: string 18 - name 19 Cloud_Network_1: 20 type: Cloud.Network </pre>

Creating bindings and dependencies between resources in Automation Assembler

Bindings and dependencies

When you deploy an Automation Assembler template, one resource might need another resource to be available first.

IMPORTANT

Arrows only indicate a dependency, not a connection. To connect resources so that they communicate, see [Getting started with creating and designing cloud templates in VMware Aria Automation](#).

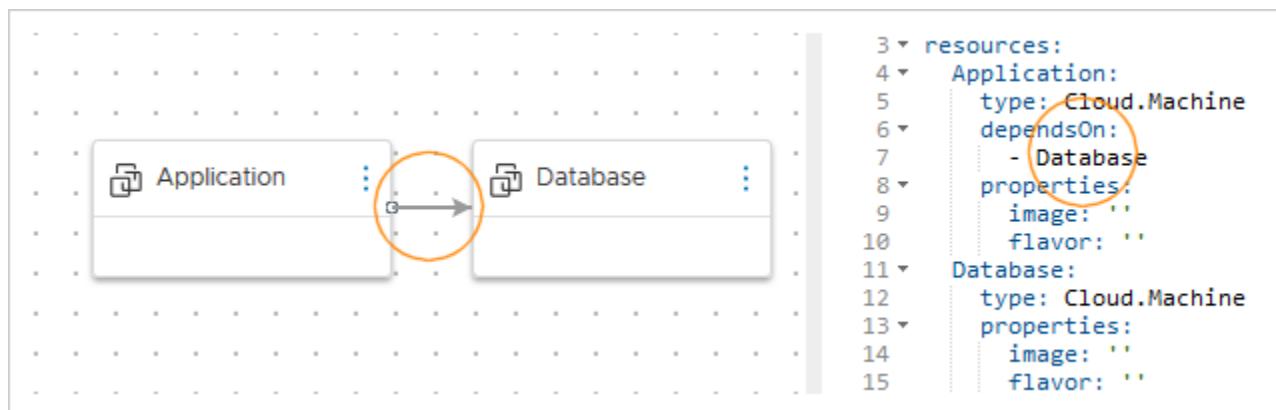

Explicit dependencies

Sometimes, a resource needs another to be deployed first. For example, a database server might need to exist first, before an application server can be created and configured to access it.

An explicit dependency sets the build order at deployment time, or for scale in or scale out actions. You can add an explicit dependency using the graphical design canvas or the code editor.

- Design canvas option—draw a connection starting at the dependent resource and ending at the resource to be deployed first.
- Code editor option—add a `dependsOn` property to the dependent resource, and identify the resource to be deployed first.

An explicit dependency creates a solid arrow in the canvas.

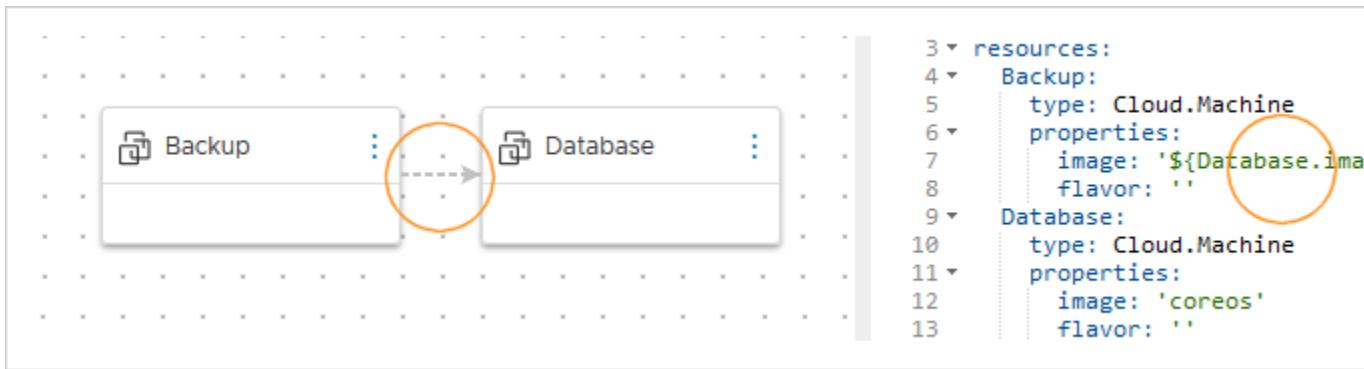

Property bindings

Sometimes, a resource property needs a value found in a property of another resource. For example, a backup server might need the operating system image of the database server that is being backed up, so the database server must exist first.

Also called an implicit dependency, a property binding controls build order by waiting until the needed property is available before deploying the dependent resource. You add a property binding using the code editor.

- Edit the dependent resource, adding a property that identifies the resource and property that must exist first.
- A property binding creates a dashed arrow in the canvas.

Versioning your Automation Assembler template

Template versioning

As a cloud template developer, you can safely capture a snapshot of a working design before risking further changes.

At deployment time, you can select any of your versions to deploy.

Capturing a cloud template version

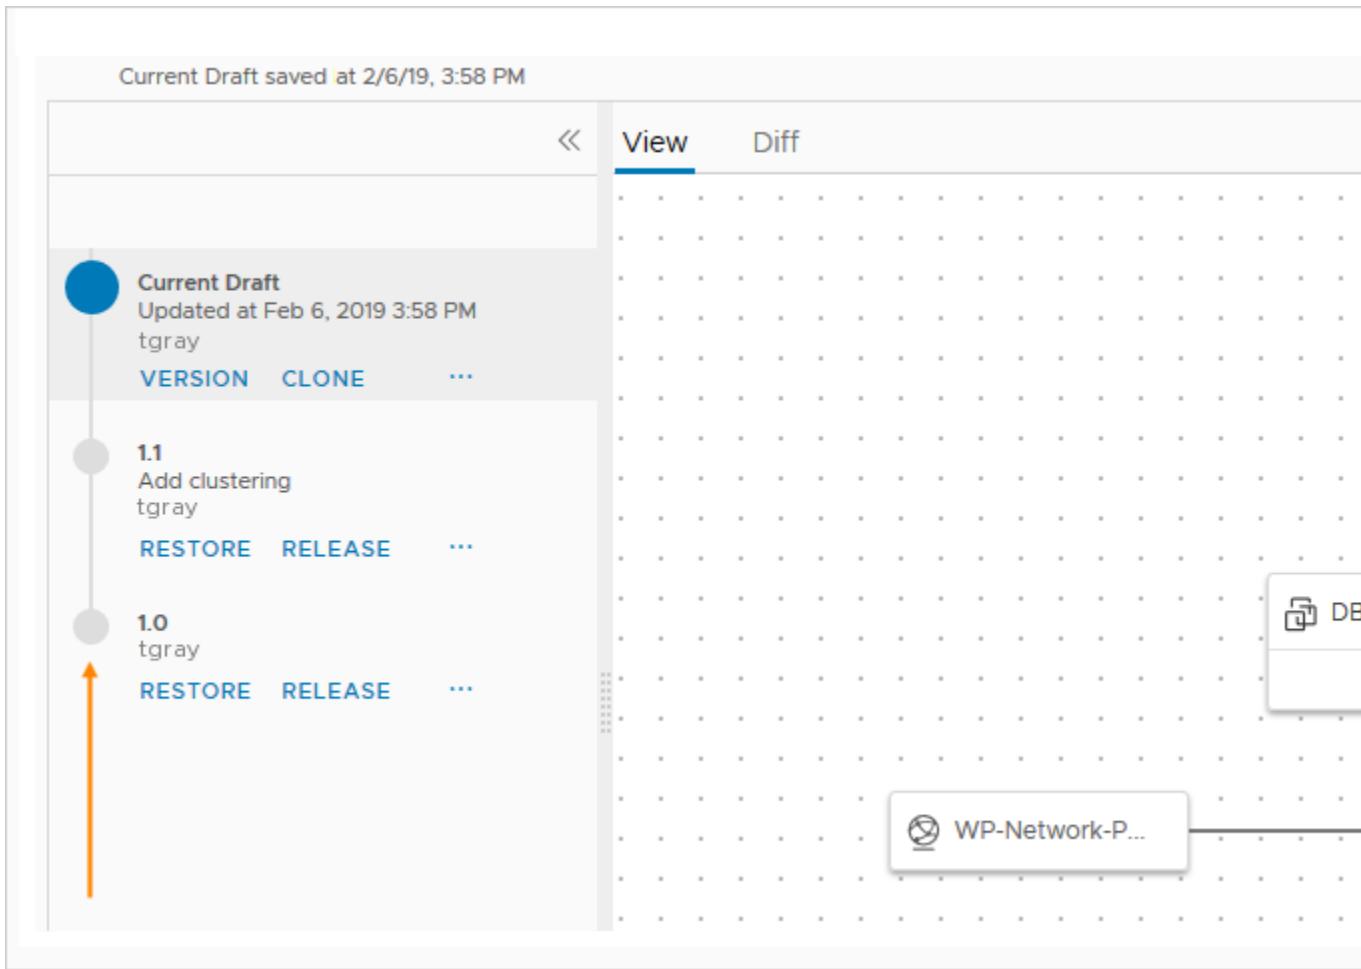

From the design page, click **Version**, and provide a name.

The name must be alphanumeric, with no spaces, and only periods, hyphens, and underscores allowed as special characters.

Restoring an older version

From the design page, click **Version History**.

On the left, select an older version to inspect it in the canvas and code editor. When you find the version that you want, click **Restore**. Restoring overwrites the current draft without removing any named versions.

Releasing a version to Automation Service Broker

From the design page, click **Version History**.

On the left, select a version and release it.

You can't release a Current Draft until you version it.

Reimporting the version in Automation Service Broker

To enable the new version for catalog users, reimport it.

In Automation Service Broker, go to **Content & Policies** > **Content Sources**.

In the list of sources, click the source for the project that contains the cloud template with the newly released version.

Click **Save & Import**.

Comparing cloud template versions

When changes and versions accumulate, you might want to identify differences among them.

In Automation Assembler, from the Version History view, select a version, and click **Diff**. Then, from the **Diff against** dropdown, select another version to compare to.

Note that you can toggle between reviewing code differences or visual topology differences.

Cloning a cloud template

Although it's not the same as saving a version, from the design page, **Actions > Clone** makes a copy of the current template for alternative development.

Specifying formatVersion in your Automation Assembler cloud template

Template formatVersion specification

After versioning your cloud template, you can change the `formatVersion` value in your YAML to support additional deployment features.

The `formatVersion` appears at the top of your YAML and its value determines what you can specify in your VMware cloud template.

- `formatVersion: 1` includes template specifications for `inputs` and `resources`. It automatically applies to all basic cloud templates.

To learn more about a basic template see [Reviewable cloud template](#).

- `formatVersion: 2` adds template specifications for `metadata`, `variables`, and `outputs`. It automatically applies to the cloud templates for AI Workstation and AI Kubernetes Clusters that are deployed using Private AI Automation Services, but supports any kind of deployment.

For information about deploying AI Workstation and AI Kubernetes Clusters see [How do I deploy Private AI catalog items](#).

As a cloud template administrator, you can use the specifications included with `formatVersion: 2` to make deployments more accessible to your users. The following code samples are pruned to show examples of how to use the `formatVersion: 2` template specifications in your YAML.

How do I use the metadata template specification

Use `metadata` to hide or unhide the day 2 operations that appear for your users.

`metadata:`

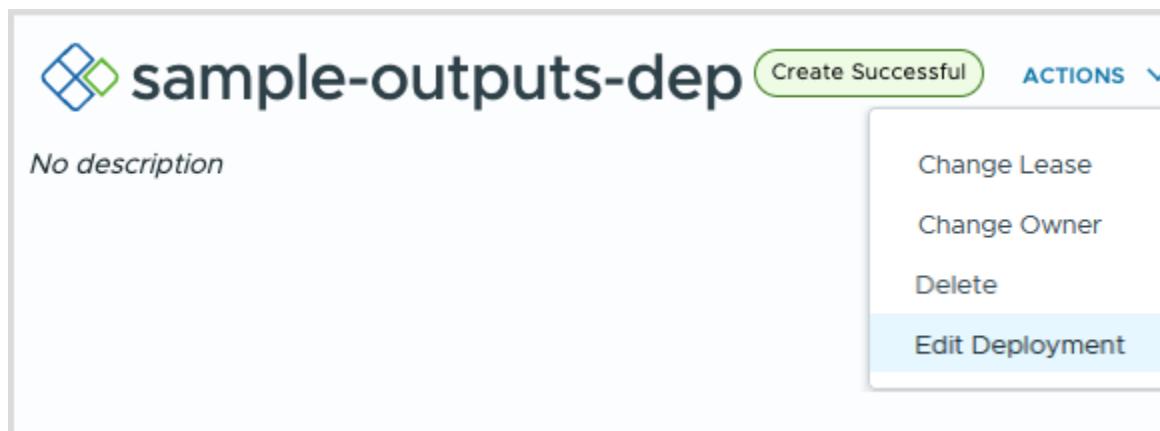

`deploymentSettings:`

```
  disableUpdateDay2Action: true
```

```
  hideDisabledDay2Actions: true
```

- When `disableUpdateDay2Action` is `true`, users do not see the **Update** day 2 operation in the Actions menu. If the user does not have permission to update, the option appears unavailable (dimmed).
- When `hideDisabledDay2Actions` is `true`, any day 2 operation that has been deactivated for the user will not appear in the Actions menu.

The **Update** and **Change Project** day 2 actions are hidden in the following example.

How do I use the variables template specification

Use `variables` to specify values that are reused multiple times within a template, such as in dynamic configurations. A variable definition can include plain strings, inputs, and refer to other variables. You reference the variables that you define in the `resources` and `outputs` sections of the template.

`variables:`

```
applications:
  - name: Appl
    port: 3000
    showAppInfo: true
  - name: App2
    port: 4000
    showAppInfo: false
```

How do I use the outputs template specification

Use `outputs` to define the deployment information that you want to make available to your user. All outputs are displayed on the deployment details page under **User Events**, except for `__deploymentOverview` values which appear under the deployment **Overview**.

The `outputs` example includes:

- variables defined in the variables template specification
- resources defined in a resources section and included in the following code sample
- `__deploymentOverview` written in Markdown

`outputs:`

```
secret1name:
  value: ${resource.secret-data1.object.metadata.name}

secret2name:
  value: ${resource.secret-data2.object.metadata.name}

__deploymentOverview:
  value: |
    ### Deployment details
    %{if starts_with(resource.CCI_Supervisor_Namespace_1.name, 'dummy')}
      This is a dummy namespace with name ${resource.CCI_Supervisor_Namespace_1.name}
    %{else}
      This is a real namespace with name ${resource.CCI_Supervisor_Namespace_1.name}
    %{endif}

  %{for app in variable.applications}
    ##### App details
    %{if app.showAppInfo}
      App name - ${app.name}, App port - ${app.port}
    %{else}
```

```

App info is hidden because showAppInfo is ${app.showAppInfo}

${endif}

${endfor}

##### Handle bars bindings.

```

The below values will update dynamically if the values change.

Note that we use '\{\}' to indicate handle bars expressions

```

secret 1 resource version - {{resource.secret-data1.object.metadata.resourceVersion} }

resources:

CCI_Supervisor_Namespace_1:
  type: CCI.Supervisor.Namespace
  properties:
    name: ${input.namespaceName}
    regionName: private-ai-foundation-dsdunnjz
    className: vpaif-quickstart-3
  secret-data1:
    type: CCI.Supervisor.Resource
    properties:
      context: ${resource.CCI_Supervisor_Namespace_1.id}
    manifest:
      apiVersion: v1
      kind: Secret
      metadata:
        name: nvaie-apikey
      type: Opaque
      stringData:
        username: $oauthtoken
        password: ${input.ngcPortalAccessKey}
  secret-data2:
    type: CCI.Supervisor.Resource

```

```

properties:

context: ${resource.CCI_Supervisor_Namespace_1.id}

manifest:

apiVersion: v1

kind: Secret

metadata:

name: nvaie-apikey1

type: Opaque

stringData:

username: $oauthhtoken

password: ${input.ngcPortalAccessKey}

```

The following construct examples are provided in the __deploymentOverview.

- The if construct is a conditional expression based on boolean inputs.

```

`${if starts_with(resource.CCI_Supervisor_Namespace_1.name, 'dummy') }

This is a dummy namespace with name ${resource.CCI_Supervisor_Namespace_1.name}

`${else}

This is a real namespace with name ${resource.CCI_Supervisor_Namespace_1.name}

`${endif}

```

- The for loop enables iterating over arrays. For every app listed in the array, if conditions are evaluated and variable values are assigned and displayed as output.

```

`${for app in variable.applications}

##### App details

`${if app.showAppInfo}

App name - ${app.name}, App port - ${app.port}

`${else}

App info is hidden because showAppInfo is ${app.showAppInfo}

`${endif}

`${endfor}

```

- In the handlebars expression, variable bindings update dynamically as the actual values change. The variable is enclosed in double curly braces {{ }} and in this example, the expression is a dot-separated path.

```
secret 1 name - {{resource.secret-data1.object.metadata.resourceVersion}}
```

Where do template specifications appear in the UI

outputs that you defined appear in your deployment.

- __deploymentOverview is a special kind of output that appears in the deployment **Overview**.

Owner	fri
Requestor	fr

Handle bars bindings.

The below values will update dynamically if the values change. Note that we use '{{' to indicate handle bars expressions

secret 1 resource version - 51497147

- All other outputs such as secret1name and secret2name appear in the deployment under the **User Events** tab.

The screenshot shows the VMware Aria Automation interface for a template named "sample-outputs-dep". The status bar at the top indicates "Create Successful". The template details include:

- Owner:** fritz [REDACTED].local
- Requestor:** fritz [REDACTED].local
- Project:** vaaif-quickstart-3
- Template:** test-doc-works
- Expires on:** Never
- Last updated:** May 14, 2024, 12:18:08 PM
- Created on:** May 14, 2024, 12:17:15 PM

The "User Events" tab is selected, showing a log entry from May 14, 2024, 12:17:15 PM: "CREATE fritz@coke.sqa...". Below this, the "Outputs" section lists "secret1name" and "secret2name" with values "nvaie-apikey" and "nvaie-apikey1" respectively. The "Inputs" section lists "showAppinfo" (true), "namespaceName" (sample-outputs-new-ns), and "ngcPortalAccessKey" (*****).

User input in VMware Aria Automation requests

User input in requests

As a cloud template designer, you use input parameters so that users can make custom selections at request time.

How inputs work

When users supply inputs, you no longer need to save multiple copies of templates that are only slightly different. In addition, inputs can prepare a template for day 2 operations. See [How to use cloud template inputs for VMware Aria Automation day 2 updates](#).

The following inputs show how you might create one cloud template for a MySQL database server, where users can deploy that one template to different cloud resource environments and apply different capacity and credentials each time.

Testing Basic X

Environment	env:dev	i
Tier Machine	small	i
Size *		
Database	ouradmin	
Username *		
Database	
Password *		

CANCEL
TEST

Adding input parameters

Add an `inputs` section to your template code, where you set the selectable values.

In the following example, machine size, operating system, and number of clustered servers are selectable.

`inputs:`

```

wp-size:
  type: string
  enum:
    - small
    - medium
  description: Size of Nodes
  title: Node Size

wp-image:
  type: string
  enum:
    - coreos
  
```

```
- ubuntu

title: Select Image/OS

wp-count:

  type: integer

  default: 2

  maximum: 5

  minimum: 2

title: Wordpress Cluster Size

description: Wordpress Cluster Size (Number of nodes)
```

If you're uncomfortable editing code, you can click the code editor **Inputs** tab, and enter settings there. The following example shows some inputs for the MySQL database mentioned earlier.

Cloud Template Inputs

+ NEW EDIT X DELETE

<input type="checkbox"/>	Name	Title	Type	Default Value
<input type="checkbox"/>	size	Tier Machine Size	string	
<input type="checkbox"/>	username	Database Username	string	
<input type="checkbox"/>	userpassword	Database Password	string	****
<input type="checkbox"/>	databaseDiskSize	MySQL Data Disk Size	number	4

Edit Cloud Template Input: size

Name * size

Title Tier Machine Size

Description Size of Nodes

Type string

Encrypted

Referencing input parameters

Next, in the resources section, you reference an input parameter using `${input.property-name}` syntax.

If a property name includes a space, delimit with square brackets and double quotes instead of using dot notation: `${input["property name"]}`

IMPORTANT

In cloud template code, you cannot use the word `input` except to indicate an input parameter.

resources:

WebTier:

```
type: Cloud.Machine  
properties:  
  name: wordpress  
  flavor: '${input.wp-size}'  
  image: '${input.wp-image}'  
  count: '${input.wp-count}'
```

Nested input

If you want to organize or categorize inputs, nested input is supported. In the following example, the CPU and memory are together under a parent heading of `level`.

NOTE

A group of nested inputs is different than creating and referencing a [formal property group](#).

inputs:

```
cluster:  
  type: integer  
  title: Cluster  
  default: 1  
  minimum: 1  
  maximum: 4
```

level:

```
  type: object  
  properties:  
    cpu:  
      type: integer  
      title: CPU  
      default: 1  
      minimum: 1  
      maximum: 4
```

```
    memory:
```

```
type: integer  
title: Memory  
default: 2048  
minimum: 2048  
maximum: 4096
```

In the `resources` section, to reference the nested input, include the parent in the path.

```
resources:  
  
Disk_1:  
  type: Cloud.vSphere.Disk  
  allocatePerInstance: true  
  
  properties:  
    capacityGb: 1  
    count: ${input.cluster}  
  
Machine_1:  
  type: Cloud.vSphere.Machine  
  allocatePerInstance: true  
  
  properties:  
    totalMemoryMB: ${input.level.memory}  
  
    attachedDisks:  
      - source: ${slice(resource.Disk_1[*].id, count.index, count.index + 1)[0]}  
    count: ${input.cluster}  
    imageRef: ubuntu  
    cpuCount: ${input.level.cpu}
```

Optional versus required input

For all types except Boolean, user entry is optional by default. To require input, do one of the following:

- Set a default value.
- When you have no nested inputs, add the `populateRequiredOnNonDefaultProperties` property:
inputs:

```
cluster:  
  type: integer  
  populateRequiredOnNonDefaultProperties: true  
  title: Cluster  
  minimum: 1  
  maximum: 4
```

Note that you can also apply this setting when referencing a [formal property group](#):

```
inputs:  
  pgmachine:  
    type: object  
    populateRequiredOnNonDefaultProperties: true  
    $ref: /ref/property-groups/machine
```

- With nested inputs, add the `populateRequiredForNestedProperties` property:
inputs:

```
cluster:  
  type: integer  
  title: Cluster  
  default: 1  
  minimum: 1  
  maximum: 4  
  
level:  
  type: object  
  properties:  
    cpu:  
      type: integer  
      populateRequiredForNestedProperties: true  
      title: CPU  
      minimum: 1  
      maximum: 4  
  
    memory:
```

```

type: integer
populateRequiredForNestedProperties: true
title: Memory
minimum: 2048
maximum: 4096

```

Note that you can also apply this setting when a [formal property group](#) reference is nested:

```

level:
  type: object
  properties:
    cpu:
      type: integer
      populateRequiredForNestedProperties: true
      title: CPU
      minimum: 1
      maximum: 4
    memory:
      type: integer
      populateRequiredForNestedProperties: true
      title: Memory
      minimum: 2048
      maximum: 4096
    pgrequester:
      type: object
      populateRequiredForNestedProperties: true
      $ref: /ref/property-groups/requesterDetails

```

Optional input—To force input to remain optional, set an empty default value using tick marks:

```

owner:
  type: string
  minLength: 0
  maxLength: 30
  title: Owner Name
  description: Account Owner

```

```
default: ''
```

Sending inputs to VMware Aria Automation Orchestrator

To supply a cloud template input to a VMware Aria Automation Orchestrator action, take the following steps. With VMware Aria Automation Orchestrator actions, the Inputs form is easier to use than typing directly in the cloud template code.

1. In the VMware Aria Automation Orchestrator instance integrated with VMware Aria Automation, verify that the action you want exists.
2. In the template design page in Automation Assembler, go to the **Inputs** tab, and click to add a new input.
3. Select a type, and select **External source**.
4. Next to Action, click the **Select** button.
5. Use the Action search field to locate and select the VMware Aria Automation Orchestrator action.
6. Enter or select any action parameters.

After you save and create the input, it appears in the cloud template code as a \$dynamicDefault input. For example:

```
inputs:
```

```
backupnetwork:
```

```
type: string
```

```
$dynamicDefault: /data/vro-actions/com.insanpaolo/getBackupNetworkVLAN?
network={{abcdef123456}}&tenant={{abcdef123456}}
```

NOTE

If the VMware Aria Automation Orchestrator workflow you send inputs to runs for too long, causing a delay of more than 30 seconds, it might cause timeout issues in VMware Aria Automation.

List of input properties

Property	Description
const	Used with oneOf. The real value associated with the friendly title.
default	Prepopulated value for the input. The default must be of the correct type. Do not enter a word as the default for an integer.
description	User help text for the input.
encrypted	Whether to encrypt the input that the user enters, true or false. Passwords are usually encrypted. You can also create encrypted properties that are reusable across multiple cloud templates. See Secret properties .
enum	A drop-down menu of allowed values. Use the following example as a format guide. enum: - value 1 - value 2
format	Sets the expected format for the input. For example, (25/04/19) supports date-time. Allows the use of the date picker in Automation Service Broker custom forms.
items	Declares items within an array. Supports number, integer, string, Boolean, or object.
maxItems	Maximum number of selectable items within an array.
maxLength	Maximum number of characters allowed for a string. For example, to limit a field to 25 characters, enter maxLength: 25.
maximum	Largest allowed value for a number or integer.
minItems	Minimum number of selectable items within an array.
minLength	Minimum number of characters allowed for a string.
minimum	Smallest allowed value for a number or integer.

Table continued on next page

Continued from previous page

Property	Description
oneOf	<p>Allows the user input form to display a friendly name (title) for a less friendly value (const). If adding the <code>default</code> property shown above in this table, set that default to a const value, not a title.</p> <p>Valid for use with types string, integer, and number.</p>
pattern	<p>Allowable characters for string inputs, in regular expression syntax.</p> <p>For example, '<code>[a-z]+</code>' or '<code>[a-zA-Z@#\$]+</code>'</p>
properties	Declares the key:value properties block for objects.
readOnly	Used to provide a form label only.
title	<p>Used with oneOf. The friendly name for a const value. The title appears on the user input form at deployment time.</p>
type	<p>Data type of number, integer, string, Boolean, or object.</p> <p>IMPORTANT A Boolean type adds a blank checkbox to the request form. Leaving the box untouched does not make the input False.</p> <p>To set the input to False, users must check and then clear the box.</p>
writeOnly	Hides keystrokes behind asterisks in the form. Cannot be used with enum. Appears as a password field in Automation Service Broker custom forms.

Additional examples

String with enumeration

```

image:
  type: string
  title: Operating System
  description: The operating system version to use.

enum:
  - ubuntu 16.04
  - ubuntu 18.04

default: ubuntu 16.04

```

```

shell:
  type: string
  title: Default shell

```

Description: The default shell that will be configured for the created user.

enum:

- /bin/bash
- /bin/sh

Integer with minimum and maximum

count:

type: integer

title: Machine Count

description: The number of machines that you want to deploy.

maximum: 5

minimum: 1

default: 1

Array of objects

tags:

type: array

title: Tags

description: Tags that you want applied to the machines.

items:

VMware Aria Automation Orchestrator actions as inputs

VMware Aria Automation Orchestrator actions as inputs

In an Automation Assembler template, Automation Orchestrator actions can be included as cloud template inputs.

Adding an Automation Orchestrator action to cloud template inputs

To use Automation Orchestrator actions as cloud template inputs, follow these guidelines.

1. In the instance of Automation Orchestrator that is embedded with VMware Aria Automation, create an action that does what you want.
The Automation Orchestrator action must only include primitive string, integer, number, and boolean types. Automation Orchestrator types are not supported.

In this simple example, the Automation Orchestrator action collects three inputs and returns a hard-coded string.

The screenshot shows two overlapping windows. The top window is titled 'Script' and contains the following code:

```
General Script Version History Audit
Runtime
JavaScript
stringInput : string
numberInput : number
booleanInput : boolean
1 return "test";
```

The bottom window is titled 'Inputs' and lists three inputs:

Input Name	Type	Value	Remove
stringInput	string	string	<input type="checkbox"/>
numberInput	number	number	<input type="checkbox"/>
booleanInput	boolean	boolean	<input type="checkbox"/>

2. In Automation Assembler, create or edit a cloud template.
3. In the code editor, click the **Inputs** tab, and **New Cloud Template Input**.
4. To add the Automation Orchestrator action inputs, click the type, and click **Constant**. Separately add each Automation Orchestrator action input as a new cloud template input.

New Cloud Template Input

Name * numberInput

Display Name Number for VRO

Description

Type  NUMBER

Default value source  Constant External source

Default value

5. After adding the action inputs, create another new cloud template input, click the type, click **External source**, and click **Select**.

New Cloud Template Input

Name * vroAction

Display Name VRO Action

Description

Type STRING INTEGER NUMBER BOOLEAN OBJECT ARRAY

Default value source Constant External source

Action Add an existing action

6. In **Action**, search for and select the Automation Orchestrator action that you created, and click **Save**.

Add an existing action X

Action *

com.form.service.test

CANCEL SAVE

When deploying the cloud template, the Automation Orchestrator action settings appear in the input form for the requesting user.

Values for VRO

String for VRO

VRO Action

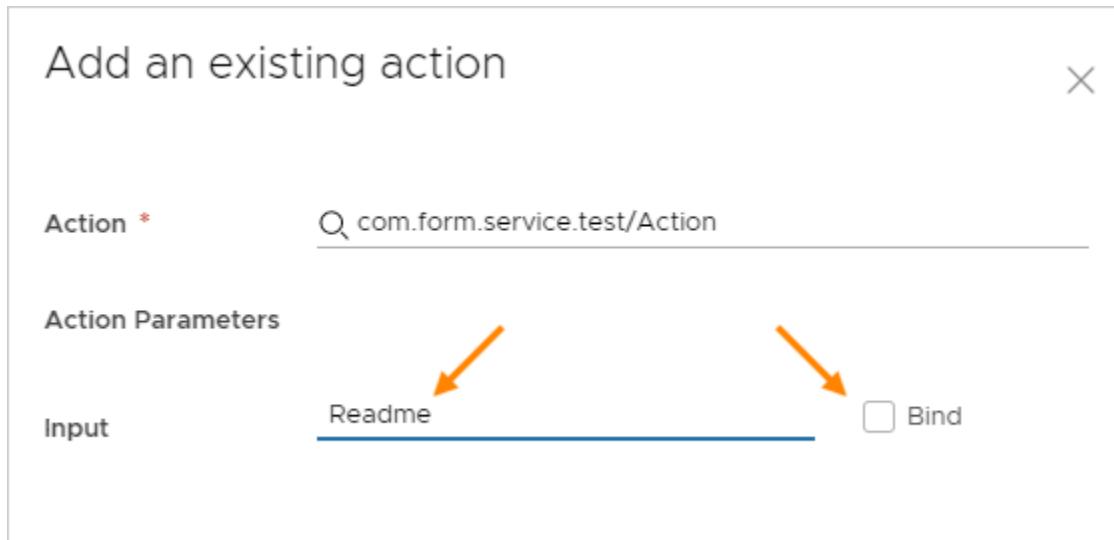

Number for VRO

On-Off for VRO

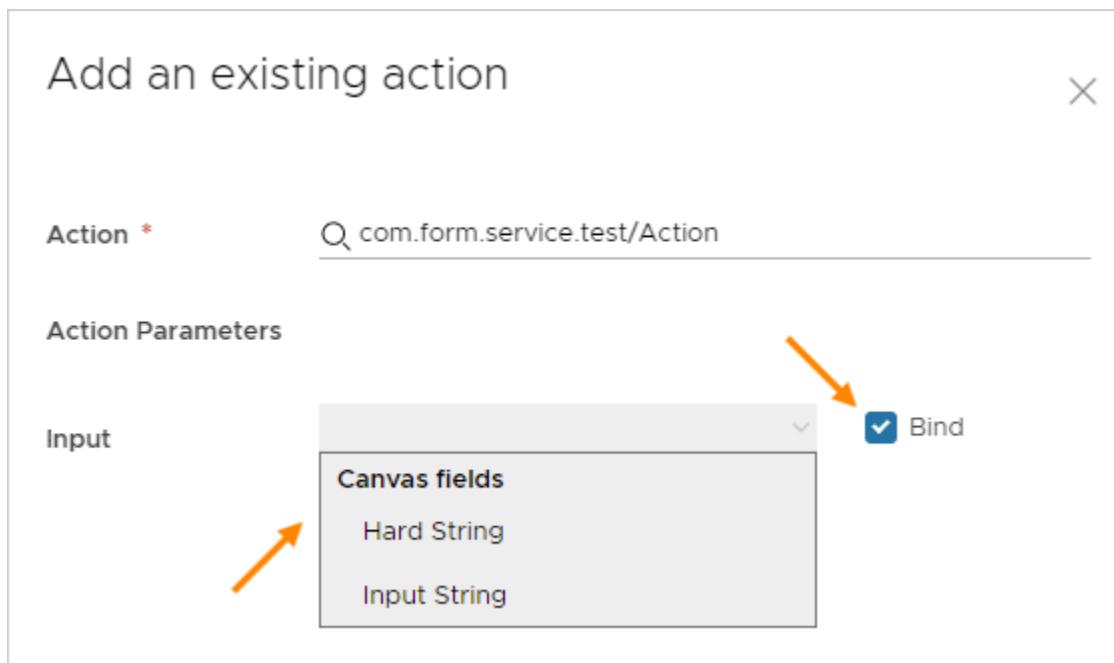

Configurable defaults

To populate the input form with default values, do one of the following when adding the Automation Orchestrator action as the external source.

- Manually supply the default property value.
Clear the **Bind** option, and enter the value.

- Use another property value from the inputs already in the cloud template.
Select the **Bind** option, and select a property from the drop-down list.

Adding Automation Orchestrator enumerated input selections

To create an Automation Orchestrator based selection list in an input form, do the following when adding to the cloud template inputs.

1. In Automation Orchestrator, create an action that maps the values that you want for the list.
2. In Automation Assembler, when adding the cloud template input, expand **More Options**.
3. For **Pairs**, click **External source**, click **Select**, and add the Automation Orchestrator action that you created.

NOTE

If you also create a default value when adding the property, that default must exactly match one of the enumerated values from the Automation Orchestrator action.

The screenshot shows the configuration of a script action named "returnImageProperties".

Script Tab:

- Script content:

```
1 var props = new Properties();
2 props.put("ubuntu", "UBUNTU");
3 props.put("windows", "WINDOWS");
4 return props;
```
- Buttons: RUN, Audit

Action Configuration:

- More Options checkbox (unchecked)
- Format dropdown
- Minimum length input field
- Maximum length input field
- Pattern input field
- Pairs section:
 - Values radio button (unchecked)
 - Key Values radio button (unchecked)
 - External source radio button (selected)
- Action: com.vmware.form.service.test/returnImage
- Properties: **SELECT** button

Values for VRO (dropdown content):

- String for VRO dropdown:
 - UBUNTU
 - WINDOWS
- VRO Action dropdown
- Number for VRO input field
- On-Off for VRO checkbox

Reusing a group of properties in Automation Assembler

Property groups

When you have Automation Assembler properties that always appear together, you can assemble them into a property group.

You can quickly add a property group to different Automation Assembler designs, which saves the time of adding the same multiple properties one by one. In addition, you have a single place to maintain or modify the set of properties, which ensures their consistent application.

Only users with the Automation Assembler Administrator role may create, update, or delete a property group. The administrator can share a property group with an entire organization or limit its use to only within a project.

CAUTION

A property group might be included in many cloud templates, including ones that are already released to the catalog. Changes to a property group can affect other users.

There are two types of property groups.

- **Inputs**

Input property groups gather and apply a consistent set of properties at user request time. Input property groups can include entries for the user to add or select, or they might include read-only values that are needed by the design.

Properties for the user to edit or select can be readable or encrypted. Read-only properties appear on the request form but can't be edited. If you want read-only values to remain totally hidden, use a constant property group instead.

- **Constants**

Constant property groups silently apply known properties. In effect, constant property groups are invisible metadata. They provide values to your Automation Assembler designs in a way that prevents a requesting user from reading those values or even knowing that they're present. Examples might include license keys or domain account credentials.

The two property group types are handled very differently by Automation Assembler. When you create a property group, you must first select whether to create inputs or constants. You can't create a blended property group nor convert an existing set of properties and their property group from one type to the other.

Input property groups in Automation Assembler

Input property groups

Automation Assembler input property groups usually include related settings for the user to enter or select. They might also include read-only values needed by the cloud template design.

Creating the input property group

1. Go to **Design > Property Groups**, and click **New Property Group**.
2. Select **Input Values**.
3. Name and describe the new property group.

Name	Property group names must be unique within a given organization. Only letters, numbers, and underscores are permitted.
Display Name	Add a heading for the entire group of properties, which appears on the request form.
Description	Explain what this set of properties is for.

Table continued on next page

Continued from previous page

Scope	Decide whether an administrator may share the property group with the whole organization. Otherwise, only one project can access the property group. Although you can always add or modify properties in the group, the scope is permanent and can't be changed later.
Project	When the scope is project-only, this project can access the property group.

4. To add a property to the group, click **New Property**.

The panel for adding a new property is very similar to the Inputs tab of the Automation Assembler design page code editor.

Name	Free-form name for the individual property. Only letters, numbers, and underscores are permitted.
Display Name	Add an individual property name to appear on the request form.
Type	String, Integer, Number, Boolean (T/F), Object, or Array.
Default Value	Preset value entry that appears in the request form. The presence of default values affects whether input is optional or required. For more information, see User input in requests .
Encrypted	When selected, obscures the value when entering it into the request form and in the subsequent deployment. Encrypted properties can't have a default value.
Read-only	An uneditable but visible value in the request form. Requires a default.
More Options	Options that vary according to property type. Expand the drop-down, add any additional settings, and click Create .

In the following example, the property being added represents the operating system image, and the requesting user can select from two.

NOTE

The operating systems shown in the example figure must already be part of the configured Automation Assembler infrastructure.

New Property

Name *

5. Add more properties to the group, and click **Save** when finished.

Properties 2 items

Add at least one property in order to create a property group

+ NEW PROPERTY **X DELETE**

	Name	Display Name	Type
<input type="checkbox"/>	image	Machine Image	string
<input type="checkbox"/>	flavor	Machine Flavor	string

Adding the property group to cloud template inputs

Even for a long list of property inputs, you only need to add the property group to make them all part of the request form.

1. In the cloud template design page, above the editing area on the right, click the **Inputs** tab.
2. Click **New Cloud Template Input**.
3. Name and describe the property group.

Name	Enter something similar to the property group name that you created earlier.
Display Name	Enter the same heading that you created earlier for the entire group of properties, which appears on the request form.
Type	Select Object .
Object Type	Select Property Group .
Property groups list	Select the property group that you want. Only property groups that are created and available for your project appear. Note that constant property groups don't appear.

New Cloud Template Input X

Name *	<input type="text" value="pgmachine"/>				
Display Name	<input type="text" value="Machine Properties"/>				
Description	<input type="text"/>				
Type	<input type="button" value="STRING"/> <input type="button" value="INTEGER"/> <input type="button" value="NUMBER"/> <input type="button" value="BOOLEAN"/> <input style="background-color: #0070C0; color: white; font-weight: bold; border: 1px solid #0070C0; border-radius: 5px; padding: 2px 10px;" type="button" value="OBJECT"/> <input type="button" value="ARRAY"/>				
Select Object Type	<input type="radio"/> Properties <input checked="" type="radio"/> Property Groups				
Select from the existing property groups <div style="border: 1px solid #ccc; padding: 5px; margin-top: 10px;"> <input type="text" value="Q"/> <table border="0" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="width: 10%;">Name</th> <th style="width: 90%;">Description</th> </tr> </thead> <tbody> <tr> <td style="background-color: #e0e0e0;">machine</td> <td></td> </tr> </tbody> </table> </div>		Name	Description	machine	
Name	Description				
machine					

4. Click **Create**.

The process creates cloud template inputs code similar to the following example.

inputs:

```

pgmachine:
  type: object
  title: Machine Properties
  $ref: /ref/property-groups/machine

pgrequester:
  
```

```
type: object
title: Requester Details
$ref: /ref/property-groups/requesterDetails
```

You may also enter code directly into the Automation Assembler design page, and take advantage of the automatic prompting as you type \$ref: /ref/p... in the code editor.

Binding cloud template resources to the property group

To make use of property group input values, add bindings under the resource.

Depending on what kind of values are in a property group, you might want to reference them individually. You can enter them separately, by property group name and property name.

```
resources:
Cloud_Machine_1:
  type: Cloud.Machine
  properties:
    image: '${input.pgmachine.image}'
    flavor: '${input.pgmachine.flavor}'
```

You can also quickly add an entire set of values to a resource by referencing an entire property group.

```
resources:
Cloud_Machine_1:
  type: Cloud.Machine
  properties:
    requester: '${input.pgrequester}'
```

Completed code

When you're finished with the inputs and resources, the finished code looks similar to the following example.

```
>> ↗  Code  Properties  Inputs  
1  formatVersion: 1  
2  inputs:  
3  pgmachine:  
4    type: object  
5    title: Machine Properties  
6    $ref: /ref/property-groups/machine  
7  pgrequester:  
8    type: object  
9    title: Requester Details  
10   $ref: /ref/property-groups/requesterDetails  
11  count:  
12    type: integer  
13    title: 'Machine Count'  
14  resources:  
15  Cloud_Machine_1:  
16    type: Cloud.Machine  
17  properties:  
18    image: '${input.pgmachine.image}'  
19    flavor: '${input.pgmachine.flavor}'  
20    count: '${input.count}'  
21    requester: '${input.pgrequester}'  
22
```

Upon deployment request, your property groups appear for the requesting user to complete.

VMware Aria Automation Orchestrator actions in an input property group

VMware Aria Automation Orchestrator actions in a property group

In an Automation Assembler input property group, you can add dynamic interaction with VMware Aria Automation Orchestrator.

Adding a VMware Aria Automation Orchestrator action to an input property group

To add dynamic interaction with VMware Aria Automation Orchestrator to an input property group, follow these guidelines.

1. In the instance of VMware Aria Automation Orchestrator that is embedded with VMware Aria Automation, create an action that does what you want.

The VMware Aria Automation Orchestrator action must only include primitive string, integer, number, and boolean types. VMware Aria Automation Orchestrator types are not supported.

In this simple example, the VMware Aria Automation Orchestrator action collects three inputs and returns a hard-coded string.

The screenshot shows the VMware Aria Automation Orchestrator interface. At the top, there are tabs: General, Script (which is selected), Version History, and Audit. Below the tabs, there's a section for Runtime, currently set to JavaScript. Under the Runtime section, there are three input fields: stringInput (string type), numberInput (number type), and booleanInput (boolean type). Below these inputs is a code editor containing the following JavaScript:

```
1 return "test";
```

Below the code editor is a modal window titled "Inputs". It contains a button labeled "ADD NEW INPUT" and three input rows:

Action Input	Type	Value	Remove	Constant
stringInput	string	Q	X	<input type="checkbox"/>
numberInput	number	Q	X	<input type="checkbox"/>
booleanInput	boolean	Q	X	<input type="checkbox"/>

2. In Automation Assembler, start the process of creating or editing an input property group. See [Input property groups in](#) if necessary.
3. To add the VMware Aria Automation Orchestrator action inputs to a property group, add new properties, click the type, and click **Constant**.

Separately add each VMware Aria Automation Orchestrator action input.

New Property

Name * numberInput

Display Name Number for VRO

Description

Type  NUMBER

Default value source  Constant External source

Default value

4. After adding the inputs, add a new property, click the type, click **External source**, and click **Select**.

New Property

Name * vroAction

Display Name VRO Action

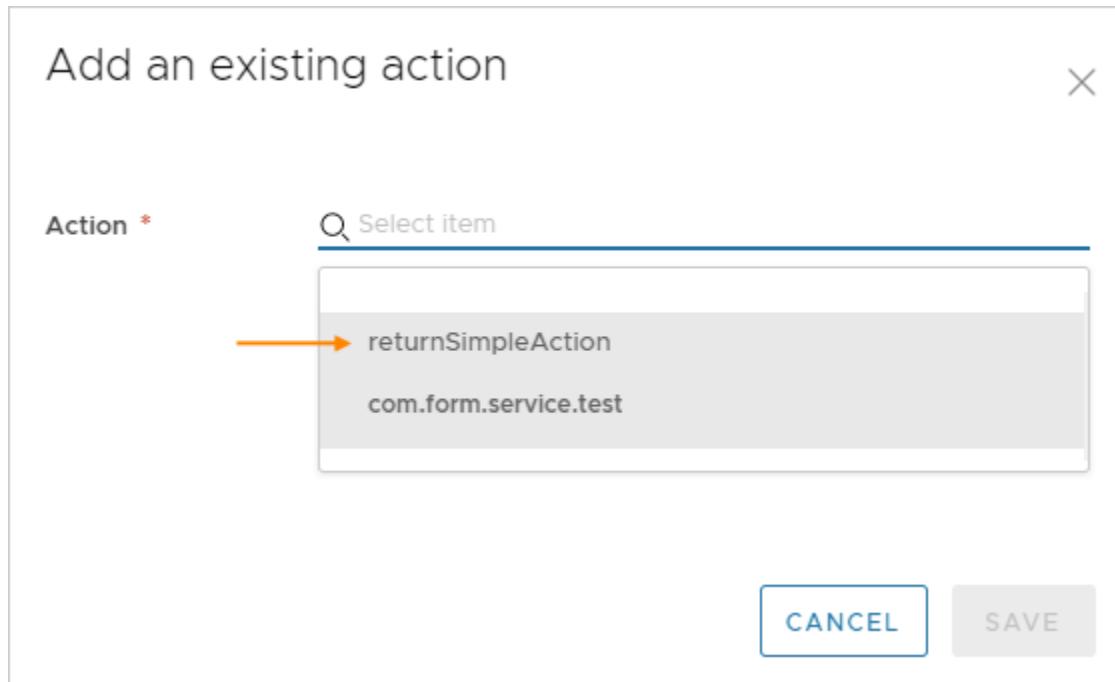

Description

Type STRING INTEGER NUMBER BOOLEAN OBJECT ARRAY

Default value source Constant External source

Action Add an existing action

5. In **Action**, search for and select the VMware Aria Automation Orchestrator action that you created, and click **Save**.

6. Save the property group, and add it to your cloud template. See [Input property groups in](#) if necessary. When deploying the cloud template, the VMware Aria Automation Orchestrator action property group appears in the input form for the requesting user.

Values for VRO	
String for VRO	<input type="text"/>
VRO Action	<input type="text" value="test"/>
Number for VRO	<input type="text"/>
On-Off for VRO	<input type="checkbox"/>

Configurable defaults

To populate the input form with default values, do one of the following when adding the VMware Aria Automation Orchestrator action as the external source.

- Manually supply the default property value.
Clear the **Bind** option, and enter the value.

Add an existing action

Action * com.form.service.test/Action

Adding VMware Aria Automation Orchestrator enumerated input selections

To create a VMware Aria Automation Orchestrator based selection list in an input form, do the following when adding to a property group.

1. In VMware Aria Automation Orchestrator, create an action that maps the values that you want for the list.
2. In Automation Assembler, when adding a property to the group, expand **More Options**.
3. For **Pairs**, click **External source**, click **Select**, and add the VMware Aria Automation Orchestrator action that you created.

NOTE

If you also create a default value when adding the property, that default must exactly match one of the enumerated values from the VMware Aria Automation Orchestrator action.

The screenshot shows the configuration of a VMware Aria Automation action named "returnImageProperties".

Script Tab: Contains the following JavaScript code:

```
1 var props = new Properties();
2 props.put("ubuntu", "UBUNTU");
3 props.put("windows", "WINDOWS");
4 return props;
```

Pairs Section: Set to "External source".

Action Section: Action is "com.vmware.form.service.test/returnImage".

Values for VRO (Dropdown): Shows "String for VRO" with options "UBUNTU" and "WINDOWS".

Constant property groups in Automation Assembler

Constant property groups

Automation Assembler constants allow you to silently apply known key-value pairs to your designs.

How constants work

The key appears in the cloud template code, and the value becomes part of deployments that are based on that cloud template. Constants require the `propgroup` binding under the resource.

The `propgroup` binding is only used with constant property groups, not input property groups.

Secret properties

If you expect to add an secret property to a property group, create the secret property before proceeding. See [Secret properties](#).

Creating the constant property group

1. Go to **Design > Property Groups**, and click **New Property Group**.
2. Select **Constant Values**.
3. Name and describe the new property group.

Name	Property group names must be unique within a given organization. Only letters, numbers, and underscores are permitted.
Display Name	Leave blank. No heading appears on the request form.
Description	Explain what this set of constants is for.
Scope	<p>Decide whether an administrator may share the property group with the whole organization. Otherwise, only one project can access the property group.</p> <p>Although you can always add or modify properties in the group, the scope is permanent and can't be changed later.</p> <p>Secrets—if you expect to add a secret property to the property group, you must use single project scope. Secret properties are saved only at the project level.</p>
Project	When the scope is project-only, this project can access the property group.

4. To add a constant property to the group, click **New Property**.
5. Enter a name that acts as the key, and a description.
6. Select a property type.
7. Enter the constant value that you want, and click **Create**.
 - String, integer, and number types use direct entry.
 - For a secret string value, select from the list of secret properties for the project.
 - The boolean type uses a selection box to indicate true.
 - For the object or array type, replace `null` with the value that you want.

New Property

Name *

Description

Type

Select Type Constant value Secret

New Property

Name *

Description

Type

Select Type Constant value Secret

Constant value

Search

	Name
<input checked="" type="radio"/>	AccountNum
<input type="radio"/>	password
<input type="radio"/>	RemoteAcc

8. Add more constants to the group, and click **Save** when finished.

The screenshot shows the 'Properties' section of the VMware Aria Automation interface. At the top, it says 'Properties' and '3 items'. Below that, a message says 'Add at least one property in order to create a property group'. There are two buttons: '+ NEW PROPERTY' and 'X DELETE'. A table lists three properties:

	Name	Display Name
<input type="checkbox"/>	payerFederal	
<input type="checkbox"/>	payerCostCenter	
<input type="checkbox"/>	payerAccountNumber	

Binding cloud template resources to the property group

To silently use constant values within a resource, add `propgroup` bindings under the resource.

You can quickly add an entire set of constants to a resource by referencing the property group itself.

resources:

```
Cloud_Machine_1:
  type: Cloud.Machine
  properties:
    payerInfo: '${propgroup.payerDetails}'
```

Alternatively, you can add individual constants from the property group to selected parts of your design.

resources:

```
Cloud_Machine_1:
  type: Cloud.Machine
  properties:
    payerAccount: '${propgroup.payerDetails.payerAccountNumber}'
    payerCost: '${propgroup.payerDetails.payerCostCenter}'
    payerFed: '${propgroup.payerDetails.payerFederal}'
```

Learn more about Automation Assembler property groups

Learn more about property groups

One Automation Assembler property group might be included in many cloud templates, which affects how you need to manage property groups.

Modifying a property group

Changes to an Automation Assembler property group affect every cloud template that uses it. When the changed version of the cloud template is released, those changes also affect Automation Service Broker catalog users.

The property group list and property group editing pages show the number of cloud templates that include the property group. To see which cloud template would be affected by a change, click the number.

The screenshot shows the VMware Aria Automation interface. At the top, there is a header bar with the title "Property Groups" and a sub-header "61 items". Below the header is a search bar with a magnifying glass icon and a "Filter" button. There are two buttons at the top left: "+ NEW PROPERTY GROUP" and "X DELETE". On the right side of the header, there is a "Cloud Templates" section with a count of "2" and a blue arrow pointing to the right.

Name	Type	Properties	Cloud Templates	Last Modified
machine	Input	2	2	Apr 12, 2023
mh_const	Constant	5	1	Apr 12, 2023

Below the table, there is a section titled "Cloud Templates" with an orange arrow pointing to the right and a count of "2".

Under the "Properties" section, there is a sub-section titled "Properties" with a count of "2 items". It includes a "New Property" button and a "Delete" button. The properties listed are:

Name	Display Name	Type
image	Machine Image	string
flavor	Machine Flavor	string

Before modifying a property group, make sure that the change is acceptable to everyone who is creating or updating deployments based on the cloud templates listed.

Deleting a property group

Deleting a property group would cause errors in every cloud template that uses it.

You cannot delete a property group until you manually remove it from all of the cloud templates in which it is included. To remove a property group from a cloud template, open the cloud template in the design canvas.

- Input property groups

Under the Inputs tab, select and remove the property group. Alternatively, use the code editor to delete the associated property group in the `inputs` section of the code.

- Constant property groups

Use the code editor to delete the associated `propgroup` entry or entries in the `resources` section of the code.

NOTE

You cannot delete a property group if it is included in a versioned cloud template. Versioned cloud templates are read-only.

Automation Assembler resource flags for requests

Resource flags for requests

Automation Assembler includes several cloud template settings that adjust how a resource is handled at request time.

Resource flag settings aren't part of the resource object properties schema. For a given resource, you add the flag settings outside of the properties section as shown.

```
resources:
  Cloud_Machine_1:
    type: Cloud.Machine
    preventDelete: true
    properties:
      image: coreos
      flavor: small
    attachedDisks:
      - source: '${resource.Cloud_Volume_1.id}'
  Cloud_Volume_1:
    type: Cloud.Volume
    properties:
      capacityGb: 1
```

Resource Flag	Description
allocatePerInstance	<p>When set to true, resource allocation can be customized for each machine in a cluster. If you're using extensibility, true causes the <code>compute.allocation.pre</code> extensibility event topic to run multiple times when deploying more than one cloud machine.</p> <p>The default is false, which allocates resources equally across the cluster, resulting in the same configuration for each machine. In addition, day 2 actions might not be separately possible for individual resources.</p>

Table continued on next page

Continued from previous page

Resource Flag	Description
	Per instance allocation allows count.index to correctly apply the configuration for individual machines. For code examples, see Machine and disk clusters in .
createBeforeDelete	<p>Some update actions require that the existing resource be removed and a new one be created. By default, removal is first, which can lead to conditions where the old resource is gone but the new one wasn't created successfully for some reason.</p> <p>Set this flag to true if you need to make sure that the new resource is successfully created before deleting the previous one.</p>
createTimeout	<p>The Automation Assembler default timeout for resource allocate, create, and plan requests is 2 hours (2h). In addition, a project administrator can set a custom default timeout for these requests, applicable throughout the project.</p> <p>This flag lets you override any defaults and set the individual timeout for a specific resource operation. See also updateTimeout and deleteTimeout.</p>
deleteTimeout	<p>The Automation Assembler default timeout for delete requests is 2 hours (2h). In addition, a project administrator can set a different default timeout for delete requests, applicable throughout the project.</p> <p>This flag lets you override any defaults and set the individual timeout for a specific resource delete operation. See also updateTimeout and createTimeout.</p>
dependsOn	<p>This flag identifies an explicit dependency between resources, where one resource must exist before creating the next one. For more information, see Creating bindings and dependencies between resources in.</p>
dependsOnPreviousInstances	<p>When set to true, create cluster resources sequentially. The default is false, which simultaneously creates all resources in a cluster.</p> <p>For example, sequential creation is useful for database clusters where primary and secondary nodes must be created, but secondary node creation needs configuration settings that connect the node to an existing, primary node.</p>
forceRecreate	<p>Not all update actions require that the existing resource be removed and a new one be created. If you want an update to remove the old resource and create a new one, independent of whether the update would have done so by default, set this flag to true.</p>

Table continued on next page

Continued from previous page

Resource Flag	Description
ignoreChanges	<p>Users of a resource might reconfigure it, changing the resource from its deployed state.</p> <p>If you want to perform a deployment update but not overwrite the changed resource with the configuration from the cloud template, set this flag to true.</p>
ignorePropertiesOnUpdate	<p>Users of a resource might customize certain properties, and those properties might be reset to their original cloud template state during an update action.</p> <p>To prevent any properties from being reset by an update action, set this flag to true.</p>
preventDelete	<p>If you need to protect a created resource from accidental deletion during updates, set this flag to true. If a user deletes the deployment, however, the resource is deleted.</p>
recreatePropertiesOnUpdate	<p>Users of a resource might reconfigure properties, changing the resource from its deployed state. During an update, a resource might or might not be recreated. Resources that aren't recreated might remain with properties in changed states.</p> <p>If you want a resource and its properties to be recreated, independent of whether the update would have done so by default, set this flag to true.</p>
updateTimeout	<p>The Automation Assembler default timeout for update requests is 2 hours (2h). In addition, a project administrator can set a different default timeout for update requests, applicable throughout the project.</p> <p>This flag lets you override any defaults and set the individual timeout for a specific resource update operation. See also deleteTimeout and createTimeout.</p>

Automation Assembler expressions

Expressions

For increased flexibility, you can add expressions to cloud template code in Automation Assembler.

How expressions work

Automation Assembler expressions use the `${ expression }` construct, as shown in the following examples.

NOTE

Automation Assembler expressions aren't the same as regular expressions. See the [expression syntax](#) for Automation Assembler.

The following code samples are pruned to show only the important lines. The entire, unedited cloud template appears at the end.

Examples

At deployment time, allow the user to paste in the encrypted key needed for remote access:

```

inputs:
  sshKey:
    type: string
    maxLength: 500

resources:
  frontend:
    type: Cloud.Machine
    properties:
      remoteAccess:
        authentication: publicKey
        sshKey: '${input.sshKey}'

```

For deploying to VMware Cloud on AWS, set the folder name to the required name of *Workload*:

```

inputs:
  environment:
    type: string
    enum:
      - AWS
      - vSphere
      - Azure
      - VMC
      - GCP
    default: vSphere

resources:
  frontend:
    type: Cloud.Machine
    properties:
      folderName: '${input.environment == "VMC" ? "Workload" : ""}'

```

At deployment time, tag the machine with an all-lowercase *env* tag that matches the selected environment:

```

inputs:
  environment:
    type: string
    enum:

```

```

- AWS
- vSphere
- Azure
- VMC
- GCP

default: vSphere

resources:

frontend:

  type: Cloud.Machine

  properties:

    constraints:

      - tag: '${"env:" + to_lower(input.environment)}'

```

Set the number of machines in the front-end cluster to one (small) or two (large). Note that the large cluster is set by process of elimination:

```

inputs:

  envsize:
    type: string
    enum:
      - Small
      - Large

resources:

frontend:

  type: Cloud.Machine

  properties:

    count: '${input.envsize == "Small" ? 1 : 2}'

```

Attach machines to the same *Default* network by binding to the property found in the network resource:

```

resources:

frontend:

  type: Cloud.Machine

  properties:

    networks:
      - network: '${resource.Cloud_Network_1.name}'

```

```

apitier:
  type: Cloud.Machine
  properties:
    networks:
      - network: '${resource.Cloud_Network_1.name}'

Cloud_Network_1:
  type: Cloud.Network
  properties:
    name: Default
    networkType: existing

```

Encrypt access credentials submitted to the API:

```

resources:
  apitier:
    type: Cloud.Machine
    properties:
      cloudConfig: |
        #cloud-config
      runcmd:
        - export apikey=${base64_encode(input.username:input.password)}
        - curl -i -H 'Accept:application/json' -H 'Authorization:Basic :$apikey' http://
example.com

```

Discover the address of the API machine:

```

resources:
  frontend:
    type: Cloud.Machine
    properties:
      cloudConfig: |
      runcmd:
        - echo ${resource.apitier.networks[0].address}

apitier:
  type: Cloud.Machine
  properties:
    networks:

```

```
- network: '${resource.Cloud_Network_1.name}'
```

Complete cloud template

```
inputs:
  environment:
    type: string
    enum:
      - AWS
      - vSphere
      - Azure
      - VMC
      - GCP
    default: vSphere

  sshKey:
    type: string
    maxLength: 500

  envsize:
    type: string
    enum:
      - Small
      - Large

resources:
  frontend:
    type: Cloud.Machine
    properties:
      folderName: '${input.environment == "VMC" ? "Workload" : ""}'
      image: ubuntu
      flavor: medium
      count: '${input.envsize == "Small" ? 1 : 2}'
    remoteAccess:
      authentication: publicPrivateKey
      sshKey: '${input.sshKey}'
    cloudConfig: |
```

```

packages:
  - nginx

runcmd:
  - echo ${resource.apitier.networks[0].address}

constraints:
  - tag: '${"env:" + to_lower(input.environment)}'

networks:
  - network: '${resource.Cloud_Network_1.name}'

apitier:
  type: Cloud.Machine

  properties:
    folderName: '${input.environment == "VMC" ? "Workload" : ""}'
    image: ubuntu
    flavor: small
    cloudConfig: |
      #cloud-config
      runcmd:
        - export apikey=${base64_encode(input.username:input.password)}
        - curl -i -H 'Accept:application/json' -H 'Authorization:Basic :$apikey' http://
example.com

    remoteAccess:
      authentication: publicPrivateKey
      sshKey: '${input.sshKey}'

  constraints:
    - tag: '${"env:" + to_lower(input.environment)}'

networks:
  - network: '${resource.Cloud_Network_1.name}'

Cloud_Network_1:
  type: Cloud.Network

  properties:
    name: Default
    networkType: existing

  constraints:

```

```
- tag: '${"env:" + to_lower(input.environment)}'
```

Automation Assembler expression syntax

Expression syntax

The expression syntax exposes all of the available capabilities of expressions in Automation Assembler templates.

NOTE

Automation Assembler expressions aren't the same as regular expressions (regex).

The following syntax is only partly represented in the examples shown in [expressions](#).

Literals

The following literals are supported:

- Boolean (true or false)
 - Integer
 - Floating point
 - String
- Backslash escapes double quote, single quote, and backslash itself:

" is escaped as \"

' is escaped as '\'

\ is escaped as \\

Quotes only need to be escaped inside a string enclosed with the same type of quote, as shown in the following example.

"I am a \"double quoted\" string inside \"double quotes\"."

- Null

Environment variables

Environment names:

- orgId
- projectId
- projectName
- deploymentId
- deploymentName
- blueprintId
- blueprintVersion
- blueprintName
- requestedBy (user)
- requestedAt (time)

Syntax:

env.ENV_NAME

Example:

```
 ${env.blueprintId}
```

Resource variables

Resource variables let you bind to resource properties from other resources.

Syntax:

```
resource.RESOURCE_NAME.PROPERTY_NAME
```

Resource names cannot contain dashes or dots. Underscores are allowed.

Examples:

- `${resource.db.id}`
- `${resource.db.networks[0].address}`
- `${resource.app.id}` (Return the string for non-clustered resources, where count isn't specified. Return the array for clustered resources.)
- `${resource.app[0].id}` (Return the first entry for clustered resources.)

Resource self variables

Resource self variables are allowed only for resources supporting the allocation phase. Resource self variables are only available (or only have a value set) after the allocation phase is complete.

Syntax:

```
self.property_name
```

Example:

```
 ${self.address} (Return the address assigned during the allocation phase.)
```

Note that for a resource named `resource_x`, `self.property_name` and `resource.resource_x.property_name` are the same and are both considered self-references.

Conditions

Syntax:

- Equality operators are `==` and `!=`.
- Relational operators are `<> <=` and `>=`.
- Logical operators are `&&` | `!` and `!`.
- Conditionals use the pattern:

$$\text{condition-expression?true-expression:false-expression}$$

Examples:

```
 ${input.count < 5 && input.size == 'small'}
```

```
 ${input.count < 2 ? "small":"large"}
```

Cluster count index

Syntax:

```
count.index
```

Examples:

- Return the node type for clustered resources:
 `${count.index == 0 ? "primary":"secondary"}`
- Set the size of each disk during allocation:
 inputs:

```
  disks:
    type: array
    minItems: 0
    maxItems: 12
    items:
      type: object
      properties:
        size:
          type: integer
          title: Size (GB)
          minSize: 1
          maxSize: 2048
  resources:
    Cloud_vSphere_Disk_1:
      type: Cloud.vSphere.Disk
      allocatePerInstance: true
      properties:
        capacityGb: '${input.disks[count.index].size}'
        count: '${length(input.disks)}'
```

- For more examples, see [Machine and disk clusters in .](#)

Arithmetic operators

Syntax:

Operators are `+-/*` and `%`.

Example:

```
 ${(input.count + 5) * 2}
```

String concatenation

Syntax:

`${'ABC' + 'DEF'}` evaluates to ABCDEF.

Operators [] and .

The expression follows ECMAScript in unifying the treatment of the [] and . operators.

So, `expr.identifier` is equivalent to `expr["identifier"]`. The identifier is used to construct a literal whose value is the identifier, and then the [] operator is used with that value.

Example:

`${resource.app.networks[0].address}`

In addition, when a property includes a space, delimit with square brackets and double quotes instead of using dot notation.

Incorrect:

`input.operating system`

Correct:

`input["operating system"]`

Construction of map

Syntax:

`${{'key1':'value1', 'key2':input.key2}}`

Construction of array

Syntax:

`${['key1', 'key2']}`

Example:

`${[1,2,3]}`

Functions

Syntax:

`${function(arguments...)}`

Example:

`${to_lower(resource.app.name)}`

Table 23: Functions

Function	Description
abs(number)	Absolute number value
avg(array)	Return average of all values from array of numbers
base64_decode(string)	Return decoded base64 value
base64_encode(string)	Return base64 encoded value
ceil(number)	Returns the smallest (closest to negative infinity) value that is greater than or equal to the argument and is equal to a mathematical integer
contains(array, value)	Check if array contains a value
contains(string, value)	Check if string contains a value
digest(value, type)	Return digest of value using supported type (md5, sha1, sha256, sha384, sha512)
ends_with(subject, suffix)	Check if subject string ends with suffix string
filter_by(array, filter)	Return only the array entries that pass the filter operation filter_by([1,2,3,4], x => x >= 2 && x <= 3) returns [2, 3] filter_by({'key1':1, 'key2':2}, (k,v) => v != 1) returns [{"key2": 2}]
floor(number)	Returns the largest (closest to positive infinity) value that is less than or equal to the argument and is equal to a mathematical integer
format(format, values...)	Return a formatted string using Java Class Formatter format and values.
from_json(string)	Parse json string
from_yaml(yamlText, decode_binary=true/false)	Convert YAML into JSON format.
join(array, delim)	Join array of strings with a delimiter and return a string
json_path(value, path)	Evaluate path against value using XPath for JSON .
keys(map)	Return keys of map
length(array)	Return array length
length(string)	Return string length
map_by(array, operation)	Return each array entry with an operation applied to it map_by([1,2], x => x * 10) returns [10, 20] map_by([1,2], x => to_string(x)) returns ["1", "2"] map_by({'key1':1, 'key2':2}, (k,v) => {k:v*10}) returns [{"key1":10}, {"key2":20}]
map_to_object(array, keyname)	Return an array of key:value pairs of the specified key name paired with values from another array

Table continued on next page

Continued from previous page

Function	Description
	<pre>map_to_object(resource.Disk[*].id, "source") returns an array of key:value pairs that has a key field called source paired with disk ID strings. Note that map_by(resource.Disk[*].id, id => {'source':id}) returns the same result. If multiple arguments are passed to the map_to_object function, then it returns an array of nested objects, where the keys are part of the nested object, and the values are set on the innermost key. map_to_object(resource.Cloud_vSphere_Machine_1[*].address, "ip", "addr") returns an array of objects in the following format: { "ip" : { "addr" : <value> } } The value of the innermost key is paired with the address of a machine in the Cloud_vSphere_Machine_1 cluster. There is one object per machine in the cluster. If there are three machines in the cluster, then there are three entries in the object: { "ip": { "addr": <value> } , "ip": { "addr": <value> } }</pre>

Table continued on next page

Continued from previous page

Function	Description
	,
	"ip":
	{ "addr": <value> }
	}
matches(string, regex)	Check if string matches a regex expression
max(array)	Return maximum value from array of numbers
merge(map, map)	Return a merged map
min(array)	Return minimum value from array of numbers
not_null(array)	Return the first entry which is not null
now()	Return current time in ISO-8601 format
range(start, stop)	Return a series of numbers in increments of 1 that begins with the start number and ends just before the stop number
replace(string, target, replacement)	Replace string containing target string with target string
reverse(array)	Reverse entries of array
slice(array, begin, end)	Return slice of array from begin index to end index
split(string, delim)	Split string with a delimiter and return array of strings
starts_with(subject, prefix)	Check if subject string starts with prefix string
substring(string, begin, end)	Return substring of string from begin index until end index
sum(array)	Return sum of all values from array of numbers
to_json(value)	Serialize value as json string
to_lower(str)	Convert string to lower case
to_number(string)	Parse string as number
to_string(value)	Return string representation of the value
to_upper(str)	Convert string to upper case
to_yaml(jsonText):	Convert JSON back to YAML format.
trim(string)	Remove leading and trailing spaces
url_encode(string)	Encode string using url encoding specification
uuid()	Return randomly generated UUID
values(map)	Return values of map

Troubleshooting

The YAML language uses a colon and space (" : ") as the separator between key and value in key-value pairs. Expression syntax depends on YAML, so a space after a colon can sometimes cause an expression to fail.

For example, the space between "win" : and "lin" in the following expression causes a failure.

```
 ${contains(input.image,"Windows") == true ? "win" : "lin"}
```

The working expression omits the space.

```
 ${contains(input.image,"Windows") == true ? "win" :"lin"}
```

If an expression continues to fail, try enclosing the entire expression in tick marks as shown.

```
ezOS: '${contains(input.image,"Windows") == true ? "win" :"lin"}'
```

Secret Automation Assembler properties

Secret properties

A secret Automation Assembler property is a reusable, encrypted value that project users may add to their cloud template designs.

Secure access keys and credentials are typical examples of secret properties. Once created and saved, a secret property value can never be unencrypted or read.

Creating a secret property

1. Log in to Automation Assembler with project administrator role privileges.
2. Go to **Infrastructure > Administration > Secrets**, and click **New Secret**.
3. Enter a unique property name for the secret, without spaces or special characters.
The name is the visible identifier for the secret.
4. Scope the secret to the entire organization or to specific projects.
To assign the secret to one or more projects, click **Assign Projects**, select your projects, and click **Add**.

You can't associate a secret with the same project twice. You also can't associate two secrets with the same name with the entire organization.

5. Enter the secret value.
When typing, the value is obscured by default, which protects it if the screen is shared.

If needed, you can click the eye symbol to reveal and verify a value. After it is saved, a secret value becomes encrypted in the database and can never be re-exposed.

6. Optionally, enter a longer description of the secret property.
7. Click **Create**.

Create Secret

Name * [i](#)

Scope Organization [i](#)
 Projects [i](#)

Value * [e](#) [i](#)

Description

Assign Projects

Add projects that you want to associate this secret with. [i](#)

+ ASSIGN PROJECTS		X REMOVE
<input type="checkbox"/>	Project Name	
<input type="checkbox"/>	admin-project	
CREATE		CANCEL

[Adding a secret property to a cloud template](#)

Project users may add a secret property as a binding in cloud template code.

Note that starting to type the '\${secret.' characters reveals a selection list of secrets that have been created for the project.

If two secrets with the same name but different values exist at the project level and at the organization level, the project secret takes precedence. The organization secret is not available for selection in the cloud template.

type: Cloud.Machine

properties:

```

name: ourvm
image: mint20
flavor: small
remoteAccess:
  authentication: publicPrivateKey
  sshKey: '${secret.ourPublicKey}'
  username: root

```

To add a secret property to a Terraform configuration, see [Using a secret property in a Terraform configuration](#).

Remote access to an Automation Assembler deployment

Remote access

To remotely access a machine that Automation Assembler has deployed, you add properties, before deployment, to the cloud template for that machine.

For remote access, you can configure one of the following authentication options.

NOTE

In cases where keys need to be copied, you might also create a `cloudConfig` section in the cloud template, to automatically copy the keys upon provisioning. The specifics aren't documented here, but [Machine initialization in](#) provides general information about `cloudConfig`.

Generate a key pair at provisioning time

If you don't have your own public-private key pair for remote access authentication, you can have Automation Assembler generate a key pair.

Use the following code as a guideline.

1. In Automation Assembler, before provisioning, add `remoteAccess` properties to the cloud template as shown in the example.

The `username` is optional. If you omit it, the system generates a random ID as the `username`.

Example:

```

type: Cloud.Machine
properties:
  name: our-vm2
  image: Linux18
  flavor: small
  remoteAccess:
    authentication: generatedPublicPrivatekey
    username: testuser

```

2. In Automation Assembler, provision the machine from its cloud template, and bring it to a started-up state.

- The provisioning process generates the keys.
3. Locate the key name in the **Resources > Deployments > Topology** properties.
 4. Use the cloud provider interface, such as the vSphere client, to access the provisioned machine command line.
 5. Grant read permission to the private key.
`chmod 600 key-name`
 6. Go to the Automation Assembler deployment, select the machine, and click **Actions > Get Private Key**.
 7. Copy the private key file to your local machine.
A typical local file path is `/home/username/.ssh/key-name`.
 8. Open a remote SSH session, and connect to the provisioned machine.
`ssh -i key-name user-name@machine-ip`

Supply your own public-private key pair

Many enterprises create and distribute their own public-private key pairs for authentication.

Use the following code as a guideline.

1. In your local environment, obtain or generate your public-private key pair.
For now, just generate and save the keys locally.
2. In Automation Assembler, before provisioning, add `remoteAccess` properties to the cloud template as shown in the example.
The `sshKey` includes the long alphanumeric found within the public key file `key-name.pub`.

The username is optional and gets created for you to log in with. If you omit it, the system generates a random ID as the username.

Example:

```
type: Cloud.Machine
properties:
  name: our-vm1
  image: Linux18
  flavor: small
  remoteAccess:
    authentication: publicPrivateKey
    sshKey: ssh-rsa Iq+5aQgBP3ZNT4o1baP5Ii+dstIcowRRkyobbfpA1mj9tslf
      qGxvU66PX9IeZax5hZvNWFgjw6ag+ZlzendOLhVdVow49f274/mIRild7UUW...
    username: testuser
```

3. In Automation Assembler, provision the machine from its cloud template, and bring it to a started-up state.
4. Using the cloud vendor client, access the provisioned machine.
5. Add the public key file to the home folder on the machine. Use the key that you specified in `remoteAccess.sshKey`.
6. Verify that the private key file counterpart is present on your local machine.
The key is typically `/home/username/.ssh/key-name` with no `.pub` extension.
7. Open a remote SSH session, and connect to the provisioned machine.
`ssh -i key-name user-name@machine-ip`

Supply an AWS key pair

By adding an AWS key pair name to the cloud template, you can remotely access a machine that Automation Assembler deploys to AWS.

Be aware that AWS key pairs are region specific. If you provision workloads into us-east-1, the key pair must exist in us-east-1.

Use the following code as a guideline. This option works for AWS cloud zones only.

```
type: Cloud.Machine
properties:
  image: Ubuntu
  flavor: small
  remoteAccess:
    authentication: keyPairName
    keyPair: cas-test
constraints:
  - tag: 'cloud:aws'
```

Supply a username and password

By adding a username and password to the cloud template, you can have simple remote access to a machine that Automation Assembler deploys.

Although it is less secure, logging in remotely with a username and password might be all that your situation requires. Be aware that some cloud vendors or configurations might not support this less secure option.

1. In Automation Assembler, before provisioning, add `remoteAccess` properties to the cloud template as shown in the example.
Set the username and password to the account that you expect to log in with.

Example:

```
type: Cloud.Machine
properties:
  name: our-vm3
  image: Linux18
  flavor: small
  remoteAccess:
    authentication: usernamePassword
    username: testuser
    password: admin123
```

2. In Automation Assembler, provision the machine from its cloud template, and bring it to a started-up state.

3. Go to your cloud vendor's interface, and access the provisioned machine.
4. On the provisioned machine, create or enable the account.
5. From your local machine, open a remote session to the provisioned machine IP address or FQDN, and log in with the username and password as usual.

SCSI disk placement with Automation Assembler

SCSI disk placement

To manage a SCSI disk, you must specify and know its SCSI controller and logical unit number (LUN). For a vSphere disk object, you can use Automation Assembler to assign both values in the cloud template.

The ability to use different SCSI controllers is important for performance and is required for some deployment types, such as Oracle Real Application Clusters (RAC).

NOTE

Automation Assembler only processes virtual devices configured with the SCSI controller.

SCSI controller and LUN disk properties

To assign a SCSI controller and LUN, add the following cloud template properties:

```
SCSIController
```

```
unitNumber
```

You also have the option to omit the properties, in which case assignment follows a predictable default. Automation Assembler no longer deploys SCSI disks in random order, which made them difficult to manage.

SCSI controllers and disks are numbered in order, with zero being first. Each SCSI controller can support SCSI disks with unit numbers 0–15.

NOTE

If the SCSI controller type is VMware Paravirtual, VMware Aria Automation 8.18.1 or later connected to vCenter 6.7 or later supports up to 64 disks per controller with unit numbers 0-64. For information about SCSI controller types, see [Virtual Machine Hardware Available to vSphere Virtual Machines](#).

Option 1: Set both SCSI controller and unit number

You may fully specify both properties as shown in the following example. If so, assignment of the SCSI controller and unit number match the values that you enter.

```
resources:
```

```
Cloud_vSphere_Machine_1:
  type: Cloud.vSphere.Machine
  properties:
    image: centos
    cpuCount: 1
    totalMemoryMB: 1024
  attachedDisks:
    - source: '${resource.Cloud_vSphere_Disk_1.id}'
```

```

    - source: '${resource.Cloud_vSphere_Disk_2.id}'
    - source: '${resource.Cloud_vSphere_Disk_3.id}'
```

Cloud_vSphere_Disk_1:

type: Cloud.vSphere.Disk

properties:

capacityGb: 1

SCSIController: SCSI_Controller_2unitNumber: 0

Cloud_vSphere_Disk_2:

type: Cloud.vSphere.Disk

properties:

capacityGb: 1

SCSIController: SCSI_Controller_2unitNumber: 1

Cloud_vSphere_Disk_3:

type: Cloud.vSphere.Disk

properties:

capacityGb: 1

SCSIController: SCSI_Controller_3unitNumber: 4

Option 2: Set only the SCSI controller

You may specify the SCSI controller and omit the unit number. In this case, assignment of the SCSI controller matches the value you enter. The unit number is set to the first available unit number under that controller.

```

resources:
Cloud_vSphere_Machine_1:
type: Cloud.vSphere.Machine
properties:
image: centos
cpuCount: 1
totalMemoryMB: 1024
attachedDisks:
    - source: '${resource.Cloud_vSphere_Disk_1.id}'
    - source: '${resource.Cloud_vSphere_Disk_2.id}'
    - source: '${resource.Cloud_vSphere_Disk_3.id}'
```

Cloud_vSphere_Disk_1:

```

type: Cloud.vSphere.Disk
properties:
  capacityGb: 1
  SCSIController: SCSI_Controller_0
Cloud_vSphere_Disk_2:
type: Cloud.vSphere.Disk
properties:
  capacityGb: 1
  SCSIController: SCSI_Controller_0
Cloud_vSphere_Disk_3:
type: Cloud.vSphere.Disk
properties:
  capacityGb: 1
  SCSIController: SCSI_Controller_1

```

Option 3: Omit both properties

You may omit the SCSI controller and unit number. In this case, assignment is set to the first available SCSI controller, and the first available unit number under that controller.

```

resources:
Cloud_vSphere_Machine_1:
type: Cloud.vSphere.Machine
properties:
  image: centos
  cpuCount: 1
  totalMemoryMB: 1024
attachedDisks:
  - source: '${resource.Cloud_vSphere_Disk_1.id}'
  - source: '${resource.Cloud_vSphere_Disk_2.id}'
  - source: '${resource.Cloud_vSphere_Disk_3.id}'
Cloud_vSphere_Disk_1:
type: Cloud.vSphere.Disk
properties:
  capacityGb: 1

```

```

Cloud_vSphere_Disk_2:
  type: Cloud.vSphere.Disk
  properties:
    capacityGb: 1

Cloud_vSphere_Disk_3:
  type: Cloud.vSphere.Disk
  properties:
    capacityGb: 1

```

Not an option: LUN only

You cannot omit the SCSI controller and specify only a unit number. Doing so might result in a deployment where multiple SCSI controllers have a disk of that number but, for management purposes, you won't know which disk is which.

Using inputs to set the SCSI controller and LUN

To make the design more dynamic, use inputs so that the user may specify which SCSI controller and unit number at request or update time.

```

inputs:
  diskProperties:
    type: array
    minItems: 1
    maxItems: 10
    items:
      type: object
      properties:
        size:
          type: integer
        SCSIController:
          type: string
          title: SCSI Controller
          enum:
            - SCSI_Controller_0
            - SCSI_Controller_1
            - SCSI_Controller_2
            - SCSI_Controller_3
  unitNumber:

```

```
type: integer
title: Unit Number

resources:

app:
  type: Cloud.vSphere.Machine
  allocatePerInstance: true
  properties:
    flavor: small
    image: centos
    attachedDisks: '${map_to_object(slice(resource.disk[*].id, 0, 4), ''source'')}'
```

disk:

```
type: Cloud.vSphere.Disk
allocatePerInstance: true
properties:
  capacityGb: '${input.diskProperties[count.index].size}'
  SCSIController: '${input.diskProperties[count.index].SCSIController}'
  unitNumber: '${input.diskProperties[count.index].unitNumber}'
  count: ${length(input.diskProperties)}
```

The screenshot shows a configuration dialog box with the following fields:

- size**: A text input field containing the value "1".
- SCSI Controller**: A dropdown menu currently set to "SCSI_Controller_0".
- Unit Number**: A text input field containing the value "2".
- CANCEL** and **APPLY** buttons at the bottom right.

Machine initialization in Automation Assembler

Machine initialization

You can apply machine initialization in Automation Assembler by running commands directly or, if deploying to vSphere-based cloud zones, through customization specifications.

How commands and customization specifications work

- Commands
A cloudConfig section in your cloud template code holds the commands that you want to run.
- Customization specifications
A property in your cloud template code references a vSphere customization specification by name.

Commands and customization specifications might not mix

When deploying to vSphere, proceed carefully if you attempt to combine cloudConfig and customization specification initialization. They aren't formally compatible and might produce inconsistent or unwanted results when used together.

For an example of how commands and customization specifications interact, see [static IP addresses in](#).

vSphere customization specifications in Automation Assembler templates

vSphere customization specifications

When deploying to vSphere based cloud zones in Automation Assembler, customization specifications can apply guest operating system settings at deployment time.

Enabling the customization specification

The customization specification must exist in vSphere, at the target that you deploy to.

Edit the cloud template code directly. The following example points to an automation-assembler-linux customization specification for a WordPress host on vSphere.

```
resources:
  WebTier:
    type: Cloud.vSphere.Machine
    properties:
      name: wordpress
      cpuCount: 2
      totalMemoryMB: 1024
      imageRef: 'Template: ubuntu-18.04'
      customizationSpec: 'automation-assembler-linux'
      folderName: '/Datacenters/Datacenter/vm/deployments'
```

Whether to use customization specifications or cloudConfig commands

If you want the provisioning experience to match what you are currently doing in vSphere, continuing to use customization specifications might be the best approach. However, to expand to hybrid or multiple cloud provisioning, a more neutral approach is cloudConfig initialization commands.

For more about cloudConfig sections in cloud templates, see [Configuration commands in templates](#).

Commands and customization specifications might not mix

When deploying to vSphere, proceed carefully if you attempt to combine embedded cloudConfig command and customization specification initialization. They aren't formally compatible and might produce inconsistent or unwanted results when used together.

For an example of how commands and customization specifications interact, see [static IP addresses in](#).

Configuration commands in Automation Assembler templates

Configuration commands

You can add a cloudConfig section to Automation Assembler template code, in which you add machine initialization commands that run at deployment time.

cloudConfig command formats

- Linux—initialization commands follow the open [cloud-init](#) standard.
- Windows—initialization commands use [Cloudbase-init](#).

Linux [cloud-init](#) and Windows [Cloudbase-init](#) don't share the same syntax. A cloudConfig section for one operating system won't work in a machine image of the other operating system.

What cloudConfig commands can do

You use initialization commands to automate the application of data or settings at instance creation time, which can customize users, permissions, installations, or any other command-based operations. Examples include:

- Setting a hostname
- Generating and setting up SSH private keys
- Installing packages

Where cloudConfig commands can be added

You can add a cloudConfig section to cloud template code, but you can also add one to a machine image in advance, when configuring infrastructure. Then, all cloud templates that reference the source image get the same initialization.

You might have an image map and a cloud template where both contain initialization commands. At deployment time, the commands merge, and Automation Assembler runs the consolidated commands.

When the same command appears in both places but includes different parameters, only the image map command is run.

See [Learn more about image mappings in VMware Aria Automation](#) for additional details.

Syntax in cloudConfig commands

Faulty cloudConfig commands can result in a resource that isn't correctly configured or behaves unpredictably.

To cancel a deployment when there is a syntax error in `#cloud-config` statements, add the following property.

```
cloudConfigSettings:
  deploymentFailOnCloudConfigRuntimeError: true
```

In the following cloud template, the `- mkdir` command isn't on a new line under `runcmd`: as required, so the directory will never be created. The `deploymentFailOnCloudConfigRuntimeError: true` property fails the deployment because of the error.

```
formatVersion: 1
inputs: {}
resources:
  Cloud_vSphere_Machine_1:
    type: Cloud.vSphere.Machine
    properties:
      image: img1
      cpuCount: 1
      totalMemoryMB: 1024
    cloudConfigSettings:
      deploymentFailOnCloudConfigRuntimeError: true
    cloudConfig: |
      #cloud-config
      runcmd:- mkdir -p /tmp/test-dir
```

If you omit the property or set it to `false`, deployment continues even if `cloudConfig` commands fail.

In addition, the property requires the `#cloud-config` line. If you omit the line, deployment continues regardless of the property setting.

Correct:

```
cloudConfigSettings:
  deploymentFailOnCloudConfigRuntimeError: true
cloudConfig: |
  #cloud-config
  runcmd:
    - mkdir -p /tmp/test-dir
```

Incorrect:

```
cloudConfigSettings:
  deploymentFailOnCloudConfigRuntimeError: true
```

```
cloudConfig: |
  runcmd:
    - mkdir -p /tmp/test-dir
```

Example cloudConfig commands

The following example cloudConfig section is taken from [the WordPress use case](#) cloud template code for the Linux-based MySQL server.

NOTE

To ensure correct interpretation of commands, always include the pipe character `cloudConfig: |` as shown.

```
cloudConfig: |
  #cloud-config
  repo_update: true
  repo_upgrade: all
  packages:
    - apache2
    - php
    - php-mysql
    - libapache2-mod-php
    - php-mcrypt
    - mysql-client
  runcmd:
    - mkdir -p /var/www/html/mywordpresssite && cd /var/www/html && wget https://wordpress.org/latest.tar.gz && tar -xzf /var/www/html/latest.tar.gz -C /var/www/html/mywordpresssite --strip-components 1
    - i=0; while [ $i -le 5 ]; do mysql --connect-timeout=3 -h ${DBTier.networks[0].address} -u root -pmysqlpASSWORD -e "SHOW STATUS;" && break || sleep 15; i=$((i+1)); done
    - mysql -u root -pmysqlpASSWORD -h ${DBTier.networks[0].address} -e "create database wordpress_blog;"
    - mv /var/www/html/mywordpresssite/wp-config-sample.php /var/www/html/mywordpresssite/wp-config.php
    - sed -i -e s/"define( 'DB_NAME', 'database_name_here' );"/"define( 'DB_NAME', 'wordpress_blog' );"/ /var/www/html/mywordpresssite/wp-config.php && sed -i -e s/"define( 'DB_USER', 'username_here' );"/"define( 'DB_USER', 'root' );"/ /var/www/html/mywordpresssite/wp-config.php && sed -i -e s/"define( 'DB_PASSWORD', 'password_here' );"/"define( 'DB_PASSWORD', 'mysqlpassword' );"/ /var/www/html/mywordpresssite/wp-config.php && sed -i -e s/"define( 'DB_HOST', 'localhost' );"/"define( 'DB_HOST', '${DBTier.networks[0].address}' );"/ /var/www/html/mywordpresssite/wp-config.php
```

```
- service apache2 reload
```

If a cloud-init script behaves unexpectedly, check the captured console output in `/var/log/cloud-init-output.log` when troubleshooting. For more about cloud-init, see the [cloud-init documentation](#).

Commands and customization specifications might not mix

When deploying to vSphere, proceed carefully if you attempt to combine embedded cloudConfig command and customization specification initialization. They aren't formally compatible and might produce inconsistent or unwanted results when used together.

For an example of how commands and customization specifications interact, see [static IP addresses in](#).

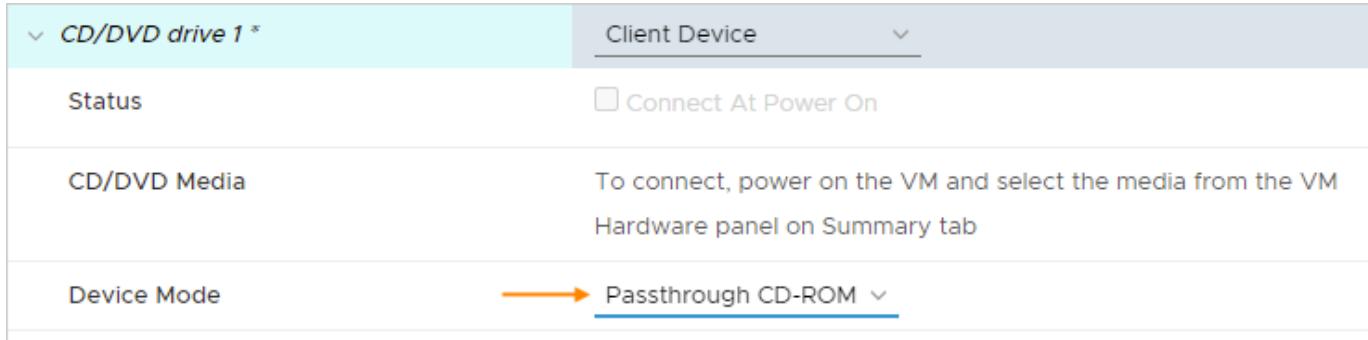

vSphere templates for initialization in Automation Assembler

vSphere templates

When your Automation Assembler template deploys an image based on a vSphere template, the vSphere template must be configured in advance to support cloud-init.

To configure a vSphere template to support cloud-init, take the following steps.

1. On the virtual machine that will become the template, install cloud-init.
For example, use `yum` to install cloud-init on CentOS, or `apt-get` to install on Ubuntu.
2. Set the CD-ROM of the virtual machine to passthrough mode.

3. From the guest operating system command line, run `cloud-init clean`.

NOTE

When `cloud-init clean` finishes, do not modify the virtual machine any further.

4. Shut down the virtual machine and convert it to a template.

vSphere static IP addresses in Automation Assembler

vSphere static IP addresses

When deploying to vSphere in Automation Assembler, you can assign a static IP address but must take care not to introduce conflicts between cloudConfig initialization commands and customization specifications.

Sample designs

The following designs safely apply a static IP address without any conflict between cloud template initialization commands and customization specifications. All contain the assignment: `static network setting`.

Day 2 customizations

Like an initial deployment, a Day 2 action also might include network configuration. To skip customization during Day 2 actions, add the following property:

```
customizeGuestOsDay2: false
```

Designs that won't work or might produce unwanted results

- The cloud-init code doesn't contain network assignment commands, and the customizeGuestOs property is false. Neither initialization commands nor customization spec are present to configure network settings.
- The cloud-init code doesn't contain network assignment commands, and the ovfProperties property is set. Initialization commands aren't present, but ovfProperties blocked the customization spec.
- The cloud-init code contains network assignment commands, and the customizeGuestOs property is missing or set to true. Application of the customization spec conflicts with initialization commands.

Other workarounds for cloud-init and customization specs

When deploying to vSphere, you can also customize an image to work around cloud-init and customization spec conflicts. See the following external repository for more information.

- [vSphere Image Preparation Scripts](#)

Delayed deployment in Automation Assembler

Delayed deployment

A virtual machine might need to be fully initialized before proceeding with Automation Assembler deployment.

For example, deploying a machine that is still installing packages and starting a web server might lead to conditions where a fast user tries to reach the application before it's available.

Be aware of the following considerations when using this feature.

- The feature makes use of the [cloud-init](#) phone_home module and is available when deploying Linux machines.
- Phone home isn't available for Windows because of [Cloudbase-init](#) limitations.
- Phone home can affect deployment order like an explicit dependency, but has more flexibility around timing and processing options.
See [Creating bindings and dependencies between resources](#) in .
- Phone home requires a cloudConfig section in the cloud template.
- Your creativity is a factor. Initialization commands might include embedded wait time between operations, which can be used in concert with phone home.
- Cloud template-based phone home won't work if the machine template already contains phone_home module settings.
- The machine must have outbound communication access back to Automation Assembler.

To introduce a deployment delay in Automation Assembler, add a `cloudConfigSettings` section to the cloud template:

```
cloudConfigSettings:
```

```
  phoneHomeShouldWait: true
  phoneHomeTimeoutSeconds: 600
  phoneHomeFailOnTimeout: true
```

Property	Description
phoneHomeShouldWait	Whether to wait for initialization, true or false.
phoneHomeTimeoutSeconds	When to decide whether to proceed with deployment even though initialization is still running. Default is 10 minutes.
phoneHomeFailOnTimeout	Whether to proceed with deployment after timing out, true or false. Note that even when proceeding, deployment might still fail for separate reasons.

Windows guest customization in Automation Assembler

Windows guest customization

To have Automation Assembler automatically initialize a Windows machine at deployment, prepare an image that supports Cloudbase-Init, then a cloud template that contains the appropriate commands.

The image creation process varies depending on cloud vendor. The example shown here is for vSphere.

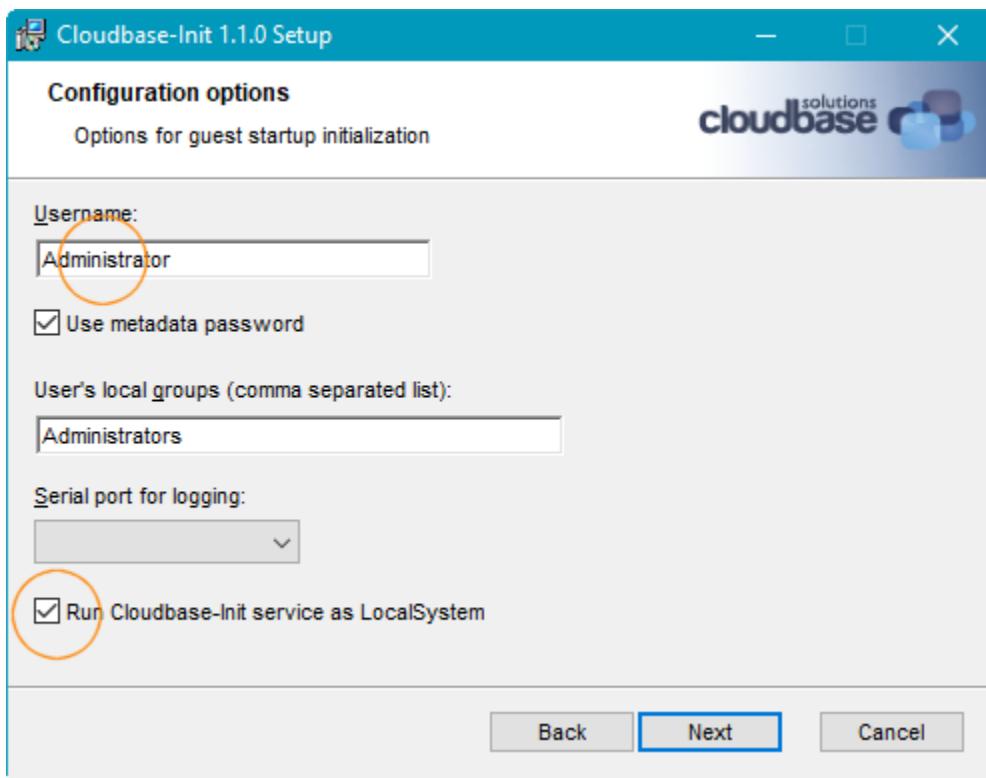

Windows Automation Assembler image for vSphere

Windows image for vSphere

For Automation Assembler to initialize a Windows machine deployed to vSphere, the image needs to be based on a vSphere template with Cloudbase-Init installed and configured.

Creating the image

1. Use vSphere to make and power on a Windows virtual machine.
2. On the virtual machine, log in to Windows.
3. Download Cloudbase-Init.
<https://cloudbase.it/cloudbase-init/#download>
4. Start the Cloudbase-Init setup .msi file.
During installation, enter **Administrator** as the username, and select the option to run as LocalSystem.

Other setup selections can remain as default values.

- Allow the installation to run, but do not close the final Completed page of the setup wizard.

IMPORTANT

Do not close the final page of the setup wizard.

- With the Completed page of the setup wizard still open, use Windows to navigate to the Cloudbase-Init installation path, and open the following file in a text editor.

conf\cloudbase-init-unattend.conf

- Set metadata_services to OvfService as shown. Add the setting if it doesn't already exist.

metadata_services=cloudbaseinit.metadata.services.ovfservice.OvfService

- Save and close cloudbase-init-unattend.conf.

- In the same folder, open the following file in a text editor.

conf\cloudbase-init.conf

- Set first_logon_behaviour, metadata_services, and plugins as shown. Add the settings if they don't already exist.

first_logon_behaviour=always

...

metadata_services=cloudbaseinit.metadata.services.ovfservice.OvfService

...

plugins=cloudbaseinit.plugins.windows.createuser.CreateUserPlugin,cloudbaseinit.plugins.windows.setuserpassword.SetUserPasswordPlugin,cloudbaseinit.plugins.common.sshpublickeys.SetUserSSHPublicKeysPlugin,cloudbaseinit.plugins.common.userdata.UserDataPlugin

n

...

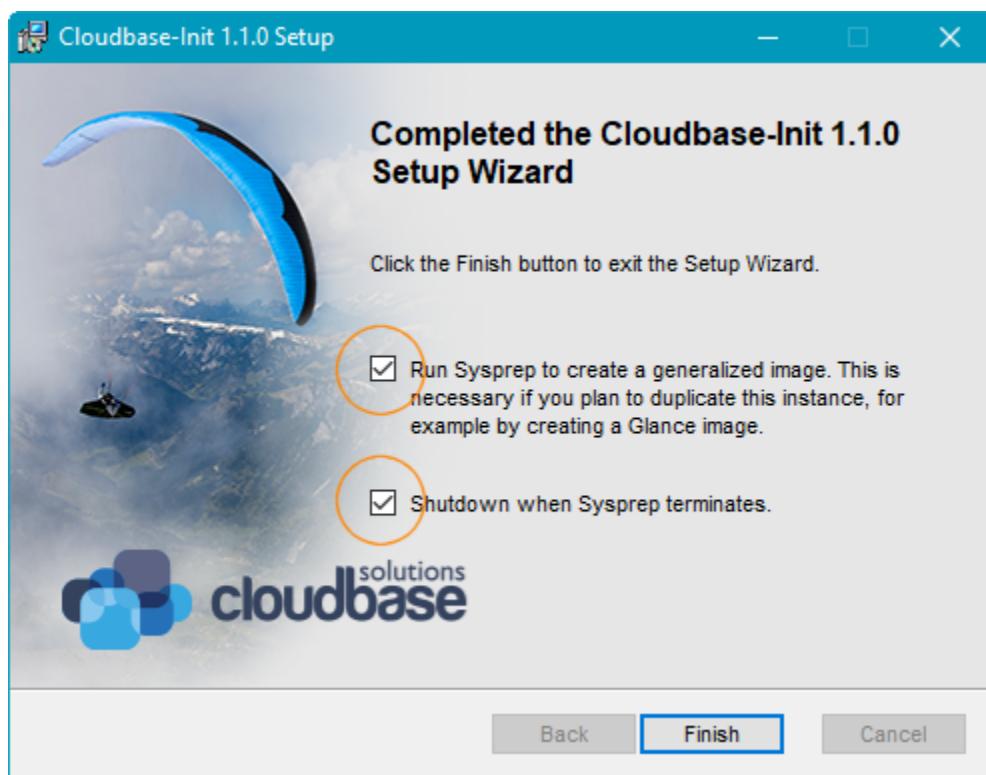

If you are using an IPAM provider to assign static IPs on Windows, include `cloudbaseinit.plugins.common.networkconfig.NetworkConfigPlugin` in your list of plugins to ensure proper IPAM integration.

11. Save and close `cloudbase-init.conf`.
12. On the Completed page of the setup wizard, select the options to run Sysprep and to shut down after Sysprep, then click **Finish**.

NOTE

VMware has seen cases where running Sysprep prevents deployments of the image from working. When deploying, Automation Assembler applies a dynamically generated customization specification, which disconnects the network interface. The pending Sysprep state in the image might cause the customization specification to fail and leave the deployment disconnected.

If you suspect that this is happening in your environment, try leaving the Sysprep options deactivated when creating the image.

13. After the virtual machine shuts down, use vSphere to turn it into a template.

Additional details

The following table expands upon the configuration entries made during setup.

Configuration Setting	Purpose
Username, CreateUserPlugin, and SetUserPasswordPlugin	After Sysprep, first boot uses CreateUserPlugin to create the username Administrator account with a blank password. SetUserPasswordPlugin allows Cloudbase-Init

Table continued on next page

Continued from previous page

Configuration Setting	Purpose
	to change the blank password to the remote access password that will be included in the cloud template.
First Logon Behavior	This setting prompts the user to change the password upon first login.
Metadata services	By listing only OvfService, Cloudbase-Init won't try to find other metadata services that aren't supported in vCenter. This results in cleaner log files, because the logs would otherwise fill with entries about failing to find those other services.
Plugins	By listing only plugins with capabilities supported by OvfService, logs are again cleaner. Cloudbase-Init runs plugins in the order specified.
Run as LocalSystem	This setting supports any advanced initialization commands that might require Cloudbase-Init to run under a dedicated administrator account.

Cloudbase-Init commands for Windows in Automation Assembler

Cloudbase-Init commands for Windows

To run Windows machine initialization at deployment time, add Cloudbase-Init commands to the Automation Assembler template code.

The example shown here is based on vSphere, but other cloud vendors should be similar.

Prerequisites

- Create infrastructure. In Automation Assembler, add your vSphere cloud account and an associated cloud zone.
- Add flavor and image mappings, and add network and storage profiles.

In your infrastructure, an image mapping must point to a Windows template that you created to support Cloudbase-Init. See [Windows image for](#).

If the template isn't listed, go to Cloud Accounts, and synchronize images. Otherwise, automatic synchronization runs every 24 hours.

- Add a project, add users, and make sure the users can provision to your cloud zone.

For more about creating infrastructure and projects, see the examples in the [WordPress use case](#).

Procedure

1. In Automation Assembler, go to the **Design** tab, and create a new cloud template.

2. Add a `cloudConfig` section with the Cloudbase-init commands that you want.

The following command examples create a new file at the Windows C: drive and set the host name.

resources:

```
Cloud_Machine_1:
```

```
  type: Cloud.Machine
```

```
  properties:
```

```

image: cloudbase-init-win-2016
flavor: small
remoteAccess:
  authentication: usernamePassword
  username: Administrator
  password: Password1234@$
cloudConfig: |
  #cloud-config
  write_files:
    content: Cloudbase-Init test
    path: C:\test.txt
  set_hostname: testname

```

For more information, see the [Cloudbase-init documentation](#).

3. Add `remoteAccess` properties so that you configure the machine for initial login to Windows.

As mentioned when you created the template, the metadata service picks up the login credentials and exposes them to `CreateUserPlugin` and `SetUserPasswordPlugin`. Note that the password must meet Windows password requirements.

4. From Automation Assembler, test and deploy the cloud template.
5. After deploying, use Windows RDP and the credentials in the template to log in to the new Windows machine and verify the customization.

In the example above, you would look for the `C:\test.txt` file, and check the system properties for the host name.

Machine and disk clusters in Automation Assembler

Machine and disk clusters

Automation Assembler template designs can deploy a cluster of machines and attach a cluster of disks.

To deploy clusters of machines and disks, take advantage of the `allocatePerInstance`[resource flag](#), and `count.index` and `map_to_object`[expression syntax](#) in your cloud templates.

The following cloud template code examples can serve as guidelines for designs that deploy clusters.

Two machines that share a disk cluster

```

resources:
  app0:
    type: Cloud.Machine
    allocatePerInstance: true
    properties:
      image: ubuntu

```

```

flavor: small
attachedDisks: '${map_to_object(slice(resource.disk[*].id, 0,2), "source")}'

app1:
  type: Cloud.Machine
  allocatePerInstance: true
  properties:
    image: ubuntu
    flavor: small
    attachedDisks: '${map_to_object(slice(resource.disk[*].id, 2,4), "source")}'

disk:
  type: Cloud.Volume
  allocatePerInstance: true
  properties:
    count: 4
    capacityGb: 5

```

Variable number of machines with one disk each

```

inputs:
  count:
    type: integer
    default: 2

resources:
  Cloud_Machine_1:
    type: Cloud.Machine
    allocatePerInstance: true
    properties:
      image: ubuntu
      flavor: small
      count: '${input.count}'
      attachedDisks: '${map_to_object(slice(resource.disk[*].id, count.index, count.index + 1), "source")}'

    disk:
      type: Cloud.Volume

```

```

allocatePerInstance: true

properties:

count: '${input.count}'

capacityGb: 5

```

Variable number of machines with two disks each

```

inputs:

count:

type: integer

default: 2

resources:

Cloud_Machine_1:

type: Cloud.Machine

allocatePerInstance: true

properties:

image: ubuntu

flavor: small

count: ${input.count}

attachedDisks: '${map_to_object(slice(resource.disk[*.id, 2*count.index,
2*(count.index + 1)), "source"))}'

disk:

type: Cloud.Volume

allocatePerInstance: true

properties:

count: ${2*input.count}

capacityGb: 5

```

Set disk sizes at request time

```

inputs:

disksize:

type: array

minItems: 2

maxItems: 2

items:

```

```

type: object
properties:
  size:
    type: integer
resources:
  app:
    type: Cloud.Machine
    allocatePerInstance: true
    properties:
      flavor: small
      image: ubuntu
      attachedDisks: ${map_to_object(slice(resource.disk[*].id, 0, 2), 'source')}
disk:
  type: Cloud.Volume
  allocatePerInstance: true
  properties:
    count: 2
    capacityGb: ${input.disksize[count.index].size}

```

Custom naming deployed resources in Automation Assembler

Custom resource naming

You can use custom naming templates to override the system naming of deployed resources to naming conventions that you define. The naming is applied at deployment time.

Due to improvements to the custom resource naming methodology, please take a moment to determine the method that is used in your instance of Automation Assembler and what your next steps should be.

To determine if you are using the new method, select **Infrastructure > Administration > Custom Names**.

- If you see an option labelled **New Custom Name**, then you are using the new global custom naming method. For more information about this method, see [Create global custom naming for deployed resources in](#) .
- If you see the enrollment option, then you must consider your choices. See the following section.

Why are there two custom naming methods

Automation Assembler has moved to a new custom naming method. The new method provides you with greater flexibility and additional naming options. It is also much easier to manage the naming across projects.

Prior to the November 2021/8.6.1 release, Automation Assembler had one method for creating custom names for deployed resources. The custom naming was defined in each project.

In the November 2021/8.6.1, Automation Assembler released a beta version of a new global custom naming method. You could now create global templates for your organization and for your projects, and assign the templates to projects as needed.

Beginning in the March 2022/8.7.1 release, you will encounter one of the following scenarios:

- If you are new to Automation Assembler, you can use the global custom naming method. The older, project-level method is not available to you.
- If you currently use Automation Assembler but you never created any custom naming templates in any of your projects, you can use the global custom naming method. The project-level method is not available to you.
- If you currently use Automation Assembler and you created at least one custom naming template in a project, you have three options:
 - You can enroll to take advantage of the new custom naming but not migrate the current custom naming templates to the new method. This is the recommended option, particularly if you have more than a few projects with already defined custom naming templates.
 - You can enroll and migrate your current project templates to the new global method. You can do this, but it is not guaranteed that all your project templates will migrate. Some might have formats that are incompatible with the global method.
 - You do not enroll and continue to use the project-by-project template method. The project-by-project method is more difficult to manage and has more limited features. To review the project-by-project method, see [Create project-by-project custom names for deployed resources in](#).

How do I enroll

You can enroll in the global custom naming by either migrating your current custom naming project templates or enrolling but not migrating. The second option is recommended.

1. Select **Infrastructure > Administration > Custom Names**.
2. Click **Enroll Now**.
3. Select an enrollment option and click **Enroll**.

Enrollment option	Description	Considerations
Do not migrate custom names from any projects	Enrolls you in the global method. You can create templates and apply them to the organization and projects.	<ul style="list-style-type: none"> • After enrollment, the current templates are not longer available. If you plan to use the same format, capture the format before enrolling so that you can create similar templates using the global method.
Migrate custom names for all projects	Enrolls you in the custom naming and creates project-level templates for each project. You can manage the templates and apply them to other projects if needed.	<ul style="list-style-type: none"> • If you have 100 projects and you migrate the templates, you will end up with 100 variations. • Some project templates might fail migration due to unsupported formats.

4. Based on how you enrolled, review where you started from and then verifying the enrollment results.
 - If you selected **Do not migrate**, create a new template and apply it to your projects. See [Create global custom naming for deployed resources in](#).
- You started with the template defined in the project.

Custom Naming

Specify the naming template to be used for machines, networks, security groups and disks provisioned in this project.

Template

nvm-\${project.name}-\${###}

Hint: Avoid conflicting names by generating digits in names. \${#####}

After enrollment, you have no defined templates and you must create the templates to use going forward. Click **New Custom Name** to get started.

Custom Names

(0 items)

Specify the naming templates to be used for resource types in the organization or projects

[+ NEW CUSTOM NAME](#)

[X DELETE](#)

After enrollment and until you create and assign a template to a project, the custom naming in the project is blank, as illustrated below. After you create a template and assign it to the project, the table will list applicable templates.

Custom Naming

The resource naming templates that apply to this project [\(1\)](#)

Naming Templates	Scope	Resource Type	Current Counter Value	Template Format	Matching Patterns Defined
No custom names found					
0 naming templates					

- If you selected **Migrate**, review and create any new templates that you need. For more information about managing your templates, see [Create global custom naming for deployed resources](#) in . You started with the templates defined in the project.

Custom Naming

Specify the naming template to be used for machines, networks, security groups and disks provisioned in this project.

Template

nvm-\${project.name}-\${###}

Hint: Avoid conflicting names by generating digits in names. \${#####}

After enrollment, the defined templates for each project are added to the Custom Names page.

8 naming templates

Create global custom naming for deployed resources in Automation Assembler

Global custom naming

As a cloud or project administrator, you have a prescribed naming convention for resources in your environment, and you want the deployed resource to follow those conventions without user interaction. You can create global naming templates for some or all deployments in Automation Assembler.

You can start by creating project-level custom names or organization-level names. Project-level custom names take precedence over organization-level names. This example starts with a simple organization custom name and then adds project-level naming.

CAUTION

If you have cloud templates or are using the API where you deploy 2000 or more resources at the same time per project, and where a custom name is applied, you might encounter a `Retries exhausted` error during deployment on some of those resources. If this scenario is common, you should not apply the new custom name to the projects or organizations where this occurs. Instead, you should use the default system naming, not the custom naming option.

What to do first

- To demonstrate the custom naming capability, these use cases need two projects. One is named Sales and one is named Marketing. For more information about creating projects, see [How do I add a project for my Automation Assembler development team](#).
- As you make choices about organization and project templates, ensure that you understand which naming conventions take precedence. See [custom-naming-global-custom-naming.dita#SECTION_142E55EE-C7A4-447C-8A2C-3132BB0FDECA-en](#).
- As you create a template using the template format, the possible properties are provided. For more information, see [custom-naming-global-custom-naming.dita#SECTION_42FD4701-27B1-4255-9ED3-122503C7EB08-en](#).

Create an organization-level custom template

When you want a default custom name template for deployments that do not have project-level templates, create templates that are organizational in scope.

1. Select **Infrastructure > Administration > Custom Names** and click **New Custom Name**.

2. Enter a **Name**.

This example uses `Prefix` and `Timestamp` for Org.

3. Select **Organization** as the Scope.

4. Click **New Naming Template** and configure the following options.

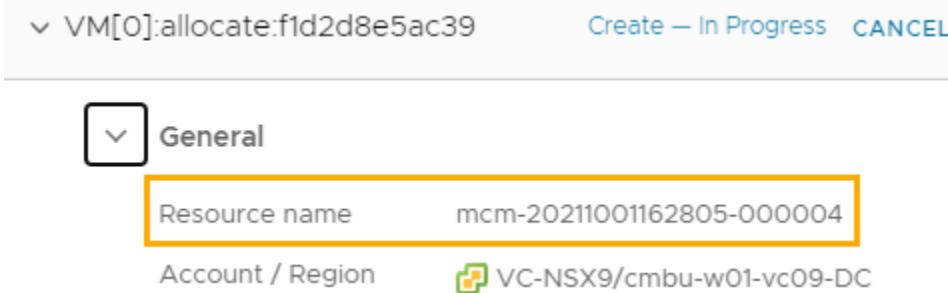

Option	Sample Value
Resource type	Machine
Validate compute name for uniqueness	Select the check box. Unique resource names ensures that you are never confused about which resource you are working with, even when working in API-based environments. The number configuration in the following template format increments to ensure uniqueness.
Template format	<code>mcm-\${timestamp}-\${#####}</code>
Starting counter value	1
Increment step	1 With this configuration, all the deployments across all the projects will increment from this starting point. In this example, where the starting counter is 1 and the increment is 1, the first deployment is numbered as 2. If you need the deployment to start at 1, then set the starting counter to zero and the increment step to 1.

5. Click **Add**.

6. Continue adding templates for other resource types using the following examples.

Resource Type Name	Naming Template Format
Machine	mcm-\${timestamp}-\${##}
Network	ntw-\${timestamp}-\${##}
Storage	stg-\${timestamp}-\${##}
Load Balancer	ldb-\${timestamp}-\${##}
Resource Group	rsg-\${timestamp}-\${##}
Gateway	gtw-\${timestamp}-\${##}
NAT	nat-\${timestamp}-\${##}
Security Group	scg-\${timestamp}-\${##}

7. Click **Create**.
8. Test the name template by deploying templates that include the defined resource types.

Create a project-level custom template with advanced pattern matching

You can create a single custom name template that you can assign to different projects. You use the advanced option to set different numbering starting points for different projects.

This example uses the machine resource.

1. Select **Infrastructure > Administration > Custom Names** and click **New Custom Name**.
2. Enter a **Name**.
This example uses Project Name with Advanced Numbering.
3. Select **Project** as the Scope.
4. Click **New Naming Template** and configure the following options.

Option	Sample Value
Resource type	Machine
Template format	\${project.name}-\${#####}
Starting counter value	1
Increment step	1 With this configuration, the deployments in the assigned projects will increment from this starting point. In this example, where the starting counter is 1 and the increment is 1, the first deployment is numbered as 2. If you need the deployment to start at 1, then set the starting counter to zero and the increment step to 1. With 1 as the starting value, ProjectA starts with 2 and ProjectB starts with 2, unless the value is overridden by an advanced matching pattern value.

5. To add more refinement to the default organization naming template, click **Advanced** and click **Add Matching Pattern**.

You can set different naming patterns to start the counter at different numbers or reset the number to 1 for each pattern. For example, the Sales project numbering starts at 100 and the Marketing project numbering starts at 200.

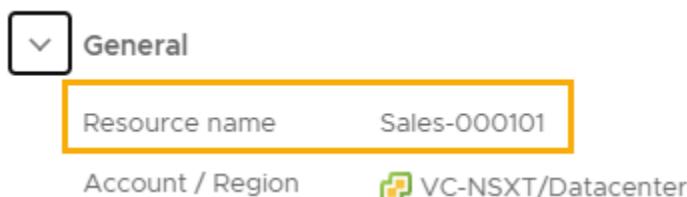

- Enter the pattern for the sales project.

Option	Sample Value
Pattern text	Sales-
Starting counter value	100

- Enter the pattern for the marketing project.

Option	Sample Value
Pattern text	Marketing-
Starting counter value	200

- Click **Add**.
- Continue adding templates for other resource types, as needed.
- Click **Assign Projects** and add the Sales and Marketing projects.
- Click **Create**.
- Test the name template by first deploying a cloud template that is in the Sales project, and then one in the Marketing project.

Example of a custom name with custom properties and project-specific values

In addition to the properties provided in the template format autofill options, you can use custom properties. To use custom properties in a custom name, you must define them in a property group.

A custom property value in the cloud template take precedence over the same property value in the custom name.

This example uses costCenter as the property and SalesCost as the value for the Sales project and MktCost as the value for the Marketing project.

- Create a property group named costingPG.
 - Select **Infrastructure > Design > Property Groups** and click **New Property Group**.
 - Click **Input Values**.
 - Enter the **Name** costingPG.
 - For the **Scope**, select **Available for any project**.
 - Click **New Property** configure the following values and enter the name costCenter.

Options	Sample Values
Name	costCenter
Type	String
Default value	research

- f. Click **Create**.
- g. Click **Create** to save the new property group.
2. Configure custom properties for the Sales project and the Marketing project.
These steps illustrate the process for the Sales project. You can repeat the steps and use the marketing project values.

- Sales property name: costingPG.costCenter. Value: SalesCost.
- Marketing property name: costingPG.costCenter. Value: MktCost.

- a. Select **Infrastructure > Administration > Projects** and open the Sales project.
- b. Click the **Provisioning** tab and locate the Custom Properties section.
- c. Enter costingPG.costCenter as the property name and SalesCost and the value.

Define custom properties	Name	Value	Encrypted
	costingPG.costCenter	SalesCost	<input type="checkbox"/>

- d. Click **Save**.
- e. Repeat the process in the Marketing project using MktCost and the property value.
3. Create a project-level custom name.
This example uses the same projects that the advanced example users. You can assign custom names to only one project at a time. To test the results of this example, you can either apply the custom name to new projects or remove the Sales and Marketing projects from the Project Name with Advanced Numbering example.

This example assumes that you have not yet assigned the Sales and Marketing projects.

- a. Select **Infrastructure > Administration > Custom Names** and click **New Custom Name**.
- b. Enter Project Name and costingPG as the **Name**.
- c. Select **Project** as the Scope.
- d. Click **New Naming Template** and configure the following options.

Table 24:

Option	Value
Resource Type	Machine
Template format	\${project.name}-\${costingPG.costCenter}-#\${#####}
Starting counter value	1
Increment step	1

- e. Click **Add**.
- f. Click **Assign Projects** and add the Sales and Marketing projects.
- g. Click **Create**.

4. Test the name template by first deploying a cloud template that is in the Sales project, and then one in the Marketing project.

Figure 3: Sales project resource name

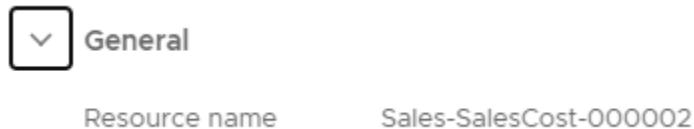

Figure 4: Marketing project resource name

Example of a custom name with property group and cloud template user inputs

This example shows you how to create a custom name based on user inputs in the template. You define two of the user inputs, operating system and size, in the cloud template. One of the user inputs, mktSite, uses a site.siteCode custom property that accepts user inputs and you add it to the cloud template.

1. Define the custom property for the marketing project.
 - a. Select **Infrastructure > Design > Property Groups** and click **New Property Group**.
 - b. Click **Input Values**.
 - c. Name and describe the property group.

Option	Value
Name	site
Scope	<p>Available for any project.</p> <p>The property group must be generally available so that the property is available to use in the custom name template format.</p>

- d. Click **New Property** configure the following values.

Option	Value
Name	siteCode
Type	String
Default value	West
More options > Enum Value	<p>Enter separate values for East, West, North, and South.</p> <p>These values represent the possible site codes that your users might select.</p>

2. Create the custom naming template.

- a. Select **Infrastructure > Custom Names > New Custom Name**.
- b. Enter the **Name** Site-OS-Size for Marketing Project.
- c. Select Projects.
Projects is selected and the only option if you already have an organization scoped custom name.
- d. Click **New Naming Template** and configure the following options.

Option	Value
Resource type	Machine
Template format	<p><code> \${site.siteCode}-\${resource.name}-#\${#####}</code></p> <p>The site.siteCode property is the one that you defined in the previous step. The resource.name is defined in the cloud template in the next step.</p>
Starting counter value	1
Increment step	1

3. Define user inputs in the template.

The user inputs included in this example include operating system and size, and a user input based on the site.siteCode custom property.

The cloud template in this step is simple for demonstration purposes. You can apply the example to one of your existing templates.

- a. Select **Design > New From > Blank canvas**.
- b. Enter the **Name** Marketing Template.
- c. In **Project** list, select Marketing.
- d. Click **Create**.
- e. Enter the code for the cloud template or use the following sample code.

Notice that the user inputs are for size and OS. You configure the variables for each input in the flavor (`${input.size}`) and image (`${input.OS}`) machine properties. Finally, the name property is used to construct the resource name (`${input.OS}-${input.size}`) that can be used in the custom naming template.

```
formatVersion: 1
```

```
inputs:
```

```
size:
```

```
  type: string
```

```
  enum:
```

```
    - small
```

```
    - medium
```

```
OS:
```

```
  type: string
```

```
  enum:
```

```
    - centos
```

```

      - ubuntu

resources:

Cloud_vSphere_Network_1:
  type: Cloud.vSphere.Network
  properties:
    networkType: existing

Cloud_Machine_1:
  type: Cloud.Machine
  properties:
    image: ${input.OS}
    flavor: ${input.size}
    name: ${input.OS}-${input.size}
  networks:
    - network: ${resource.Cloud_vSphere_Network_1.id}

```

- f. To add the site.siteCode custom property as a user input, click the **Inputs** tab in the right pane and configure the following options.

Option	Value
Name	mktSite
Display Name	Select a site
Type	Object
Select Object Type	Property Groups
Select from the existing property groups	site

- g. On the Code tab, notice that the added mktSite user input and then update the YAML to include the custom property.

For example, add site.siteCode: \${input.mktSite.siteCode} to the YAML.

```

formatVersion: 1

inputs:

size:
  type: string
  title: Select the machine size
  enum:
    - small
    - medium

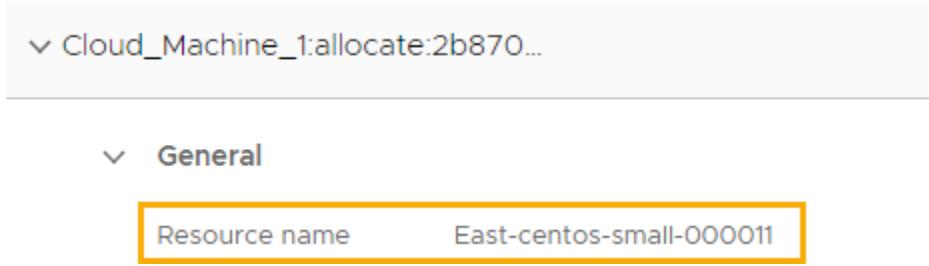

```

```

OS:
  type: string
  title: Select an operating system
  enum:
    - centos
    - ubuntu
mktSite:
  type: object
  $ref: /ref/property-groups/site
  title: Select a site
resources:
  Cloud_vSphere_Network_1:
    type: Cloud.vSphere.Network
    properties:
      networkType: existing
  Cloud_Machine_1:
    type: Cloud.Machine
    properties:
      image: ${input.OS}
      flavor: ${input.size}
      name: ${input.OS}-${input.size}
    networks:
      - network: ${resource.Cloud_vSphere_Network_1.id}
        site.siteCode: ${input.mktSite.siteCode}

```

4. Deploy the template and verify the custom machine name.
 Since West is the default value, select a site other than West.

Cloud_Machine_1:allocate:2b870...

General

Resource name	East-centos-small-000011
---------------	--------------------------

Resource naming precedence at deployment time

Based on how you configure custom naming, the names are applied to the deployed resources based on the following rules.

A common practice is to define a general organization-level naming template and then to create one or more project-level templates, depending on your project management needs.

Custom Naming Scenario	Precedence
No custom names	<ul style="list-style-type: none"> The system creates the deployment resource names for all the deployment components.
Organization-level name	<ul style="list-style-type: none"> Applies the custom naming property values and strings to all the deployments. If the deploying project has a project-level custom name, the organization-level name is overridden. If an organization-level custom name is not defined, the project-level name is used for assigned projects. If neither an organization-level nor a project-level custom name is defined, the system creates the resource names.
Project-level names	<ul style="list-style-type: none"> Applies the project-level custom naming property values and strings to all assigned projects. If an organization-level name exists, the project-level name takes precedence over the organization name. If an organization-level custom name is not defined, the project-level name is used for assigned projects. If neither an organization-level nor a project-level custom name is defined, the system creates the resource names.

Working with template formats

When defining your template format, you can use strings and properties. The primary advantage of using properties is that you can use the same properties as the format for multiple projects, but the name is derived from the value properties, which can vary by project, cloud template, platform, and other properties.

The template format properties include the provided properties, discussed here, and any custom properties that you defined in the **Design > Property Groups**.

- Valid characters
 - Spaces are not allowed.
 - For readability, you can use special characters to separate properties. The allowed characters are _ (underscore) and - (dash).
- Provided properties

Table 25: Provided Properties

Properties	Description
endpoint	Cloud account information, such as description, enter (AWS), or the name. Endpoint only applies to machines. Examples

Table continued on next page

Continued from previous page

Properties	Description
	<ul style="list-style-type: none"> • \${endpoint.desc} • \${endpoint.endpointType} • \${endpoint.name}
project	<p>Project information.</p> <p>Example</p> <ul style="list-style-type: none"> • \${project.desc} • \${project.name}
resource	<p>Includes the resource name from the cloud template, custom properties that are in the cloud template or the project.</p> <p>Example</p> <ul style="list-style-type: none"> • \${resource.name}
timestamp	<p>Date and time of the deployment. The numeric value is yyyy mm dd hh mm ss, but without the spaces. For example, 20210825120345.</p> <p>Example</p> <ul style="list-style-type: none"> • \${timestamp}
user	<p>Example</p> <ul style="list-style-type: none"> • \${user}
username	<p>Example</p> <ul style="list-style-type: none"> • \${userName}
######	<p>Number property.</p> <p>The maximum length is 19 digits.</p> <p>If you use two digits, ##, the maximum number before the numbering starts over is 99. If you use ###, the numbering restarts after 999.</p> <p>Example</p> <ul style="list-style-type: none"> • \${####}.
Custom property	<p>Custom properties must be part of property group. The property in the custom name includes the property group name and the property.</p> <p>Example</p> <ul style="list-style-type: none"> • \${propertygroup.property}

Working with the counter

In a single node instance of VMware Aria Automation, the counter increments based on the values that you define in your custom naming templates and as they are applied to the target organization and projects.

In a multi node environment, the counter attempts of increment based on the values in the template. If it encounters a contention, application of the number is attempted three time. It is possible that a request could fail after the third attempt to resolve the contention. In this case, you might see a gap in the numbering.

You might also encounter gaps in the numbering for other reasons. For example, you deploy three virtual machines. The second machine fails during provisioning. The counters for the deployed virtual machines are vm-01 and vm-03, with vm-02 missing.

If you do not use the custom naming, preferring to rely on the default naming strategy, the pools of counter values are reserved to the nodes as follows:

- Node 1: 1-300
- Node 2: 301-600
- Node 3: 601-900

This means that in a multi node environment, the number can appear to be unexpected. The number depends on which node processes the request.

List of resource types to which you can apply custom names

You can create a custom name for only one resource type or for all the resource types. Only the resource types with custom names use the template. All other resources use the default template.

For example, if you create a project-level custom name for only your machines and you have organization-level names for all the other resource types, the machine resource takes the project name and all the other resources use the organization names.

Table 26: Sample list of resources

Custom naming resource types	Deployment resource types
Machines	<ul style="list-style-type: none"> • Cloud.Machine • Cloud.vSphere.Machine • Cloud.AWS.EC2.Instance • Cloud.GCP.Machine • Cloud.Azure.Machine
Networks	<ul style="list-style-type: none"> • Cloud.Network • Cloud.vSphere.Network • Cloud.NSX.Network
Storage	<ul style="list-style-type: none"> • Cloud.Volume • Cloud.vSphere.Disk • Cloud.AWS.Volume • Cloud.GCP.Disk • Cloud.Azure.Disk
Load balancers	<ul style="list-style-type: none"> • Cloud.LoadBalancer • Cloud.NSX.LoadBalancer
Resource Groups	<ul style="list-style-type: none"> • Cloud.Azure.ResourceGroup
Gateways	<ul style="list-style-type: none"> • Cloud.NSX.Gateway

Table continued on next page

Continued from previous page

Custom naming resource types	Deployment resource types
NAT	<ul style="list-style-type: none"> Cloud.NSX.NAT
Security groups	<ul style="list-style-type: none"> Cloud.SecurityGroup
Generic	<ul style="list-style-type: none"> Resources that use the custom naming allocation helper <p>The custom naming allocation helper generates custom names for your resources during the allocation process. The Generic resource type covers all possible resources and is linked exclusively to the custom naming allocation helper.</p> <p>To learn more about the Generic resource type and the custom naming allocation helper, see Create custom names with the custom naming allocation helper.</p>

Deleting custom name templates

Deleting a template does not affect currently deployed resource naming. However, you must not delete a custom name template until you verify the impact on all the assigned projects.

You can remove a project from a naming template. The template continues to work for the other projects.

Deleting projects with custom names

If a project has a custom naming template applied, you must first remove the project from the template before you can delete the project.

Create project-by-project custom names for deployed resources in Automation Assembler

Project-by-project custom naming

As a cloud or project administrator, you can create an individual naming template in each Automation Assembler project.

- Verify that you know the naming convention that you want to use for deployments from a project.
- This procedure assumes you have or can create a simple cloud template that you use to test your custom host prefix naming.

As a cloud or project administrator where you defined resource custom naming templates at the project level prior to March 2022/8.7.1, you have the option to continue to use the method described below or you can convert your current templates to the new global templates for your organization and projects.

- For more information about enrolling in to the global templates, see [Custom naming deployed resources in](#) .
- For more information about creating global custom naming templates, see [Create global custom naming for deployed resources in](#) .

If you never created custom naming templates or are new to Automation Assembler, you only have the [global option](#).

To proceed with this method, consider the following example. Your host naming convention is to prefix a resource as *projectname-sitecode-costcenter-whereDeployed-identifier*. You configure the custom naming template for the machines for each project. Some of the template variables are pulled from the system as it is deployed, other are based on project custom properties. The custom naming template for the above prefix looks similar to the following example.

`${project.name}-${resource.siteCode}-${resource.costCenter}-${endpoint.name}-#${#####}`

The identifier, provided in the template as `${{#####}}`, shows a six digit identifier. The identifier is a counter that ensures uniqueness. The counter is global for the organization and increments across all projects, not only the current project. When you have multiple projects, do not expect a sequence from 000123 to 000124 for deployments in your current project. You can expect an increment from 000123 to 000127.

All resource names must be unique. To ensure uniqueness, use the incremental number property. The numbers increment for all deployments, including deployments that Automation Assembler names. As your system becomes more robust, and because the system applies custom names to many resource types, the numbering can appear random, but the values still ensure uniqueness. The numbers also increment when you run a test deployment.

The following list is a sample of where the custom names are applied. The list is not meant to be definitive.

Table 27: Sample list of resources to which custom names are applied

Resource Group	Resource Types
Virtual machines	<ul style="list-style-type: none"> Cloud.Machine Cloud.vSphere.Machine Cloud.AWS.EC2.Instance Cloud.GCP.Machine Cloud.Azure.Machine
Load balancers	<ul style="list-style-type: none"> Cloud.LoadBalancer Cloud.NSX.LoadBalancer
Networks	<ul style="list-style-type: none"> Cloud.Network Cloud.vSphere.Network Cloud.NSX.Network
Security groups	<ul style="list-style-type: none"> Cloud.SecurityGroup
Disks	<ul style="list-style-type: none"> Cloud.Volume Cloud.vSphere.Disk Cloud.AWS.Volume Cloud.GCP.Disk Cloud.Azure.Disk
NSX	<ul style="list-style-type: none"> Cloud.NSX.Gateway Cloud.NSX.NAT
Microsoft Azure	<ul style="list-style-type: none"> Cloud.Azure.ResourceGroup

In addition to the examples provided here, you can also add the user name, the image that is used, other built-in options, and simple strings. As you build the template, hints regarding possible options are provided.

Remember that some of the values you see are only use case examples. You won't be able to use them letter-by-letter in your environment. Think about where you would make your own substitutions, or extrapolate from the example values, in order to fit your own cloud infrastructure and deployment management needs.

1. Select **Infrastructure > Projects**.
2. Select an existing project or create a new one.
3. On the **Provisioning** tab, locate the Custom Properties section and create the properties for the site code and cost center values.

This is where you replace the values you see here with ones pertinent to your environment.

Custom Properties

Specify the custom properties that should be added to all requests in this project. ⓘ

Define custom properties	Name	Value	
	siteCode	BGL	-
	costCenter	IT-research	I - +

Custom Naming

Specify the naming template to be used for machines provisioned in this project.

Template: \${project.name}-\${resource.siteCode}-\${resource.costCenter}-\${endpoint.name}-\$####

- Create a custom property with the name **siteCode** and the value **BGL**.
 - Add another custom property with the name **costCenter** and the value **IT-research**.
4. Locate the Custom Naming section and add the following template.

```
 ${project.name}-${resource.siteCode}-${resource.costCenter}-${endpoint.name}-$####
```

You can copy in the string, but if this is your first naming template, consider using the hint text and quick select as you build the template.

- Deploy a cloud template associated with the project to verify that the custom name is applied to the resource.
- Click the **Design** tab, and then click a cloud template associated with the project.
- Deploy the cloud template.
The **Deployments** page opens, showing your deployment in process.
- When deployment is completed, click the deployment name.
- On the **Topology** tab, notice that your custom name is the resource name in the right pane.

Resource Name	Value
Resource Name	CA IX Project 1-BGL-IT-research-AWS IX West-000012
Account / Region	AWS IX West/us-west-2
Status	On

- If you deployed a test cloud template to verify the naming convention, you can delete the deployment.

Create custom naming templates for your other projects.

How to add the SaltStack Config resource in Automation Assembler designs

SaltStack Config resource

If you integrated Automation Config with VMware Aria Automation, you can apply the SaltStack Config resource to install Salt minions on virtual machines in your deployments. After the minion is deployed, you can use Automation Config's powerful configuration management, drift remediation, and state management capabilities to manage your resources.

Minions are agents that run the salt-minion service. The service subscribes to jobs published by a Salt master, which is a server that runs the salt-master service. When a specific job applies to a minion, the minion executes the job.

You can use the SaltStack Config resource to deploy minions and apply state files when you deploy Linux and Windows machines. To add or update minions and state files on existing deployments, you can run the **Attach SaltStack Resource** day 2 action. For more about the day 2 action, see [What actions can I run on Automation Assembler deployments or supported resources](#).

If you used the `saltConfiguration` property to deploy minions and state files as a day 0 action, update your templates to use the SaltStack Config resource. The `saltConfiguration` property is no longer available for use in your templates.

The **Apply Salt Configuration** day 2 action is still available for resources that use the `saltConfiguration` property.

Before you start

1. Verify that you successfully configured the Automation Config integration. See [create-a-saltstack-config-integration.dita#GUID-5555BD8D-506C-40C9-8CE9-138297FB8F30-en](#) for more information.
2. In Automation Config, verify that the FQDN name resolution from minion to master is working.
 - a. To verify the FQDN on the Salt master in Automation Config, click **Targets** and then select the **All Minions** target group.
 - b. Filter the **Minion ID** column for the value **saltmaster**.
 - c. Click **saltmaster** to see the details.
 - d. Verify that the FQDN value is correct.
3. If you are deploying minions on a Linux machine, verify that the images in vSphere that you intend to deploy with a Salt minion have SSH capabilities enabled. SSH is used to remotely access the machine and deploy the minion.
4. If you are deploying minions on a Windows machine, see [How do I deploy minions using the API \(RaaS\) in a Windows environment](#).
5. If you are deploying minions on a virtual machine that has VMware Tools installed and a Salt minion configured, verify that the VMware Tools Salt minion key appears under the **Accepted** tab in the **Minion Keys** workspace in Automation Config. See [Enable Salt minion using VMware Tools](#) for more information.

NOTE

If the VMware Tools Salt minion is an older version, deploying a minion against the virtual machine does not upgrade the Salt minion to the latest version. You must upgrade your Salt master manually. See [Upgrade the Master Plugin](#) for more information.

6. Verify that you can assign IP addresses to the machines you deploy.

Automation Config requires the machines to have public IP addresses. Use the IP addresses for the public IP CIDR range for the SDDC (software-defined data center) where your Salt master is located.

NOTE

If there is no public IP address configured for the machine, the IP address of the first NIC is used.

7. Verify that the cloud template that you are adding the minion to is deployable before you add the SaltStack Config resource properties.
8. Verify that you have the following service roles:

- a. Automation Assembler administrator
- b. Automation Assembler user
- c. Automation Service Broker administrator

These service roles are required to use the SaltStack Config resource.

Troubleshoot minion deployments

Read about some common errors users experience while deploying Salt minions using the SaltStack Config resource or the `saltConfiguration` property.

Delayed host startup

If Windows or Linux services on the host are not ready after you deploy your template, you might receive a "Minion deployment and/or state file run failed" error in Automation Assembler.

To resolve this error, upgrade the Master Plugin to the latest stable version. After you upgrade, you can enable a configuration setting in `/etc/salt/master.d/raas.conf` that allows Windows and Linux services time to become active before deploying the Salt minion. See [Upgrade the Master Plugin](#) for more information.

After you upgrade to the latest version of the Master Plugin, complete these steps to delay host startup:

1. Check the **History** tab on the deployment details page.
2. If the error message says, "Minion deployment and/or state file run failed", copy the job ID (JID) and open Automation Config.
3. In Automation Config, select **Activity > Completed** to open completed jobs.
4. In the **JID** column, click the filter icon and type the JID.
5. Click the JID to review the job results page.
6. Click the **Raw** tab to see the raw output for the job.

Windows

If the last line in the raw output for the job contains "Failed to connect to host: timed out", you must add this configuration setting to `/etc/salt/master.d/raas.conf` to delay startup by 180 seconds:

```
sseapi_win_minion_deploy_delay: 180
```

Linux

If the line last in the raw output for the job contains "Remote host is not accessible using provided credentials", you must add this configuration setting to `/etc/salt/master.d/raas.conf` to delay startup by 90 seconds:

```
sseapi_linux_minion_deploy_delay: 90
```

7. Restart the Salt master service:

```
systemctl restart salt-master
```

8. Re-deploy your template.

If the deployment was not successful, you can increase the delay parameter and re-deploy the template.

What to do next

To use the Automation Config capabilities to manage your resources, see the Automation Config documentation.

Add the Salt minion to deployments in air-gapped environments

As a template developer, you can configure and deploy a Salt minion using cloud templates for air-gapped environments.

- Ensure that the `/etc/salt/cloud.deploy.d` folder on the Automation Config server contains the latest tarball with the latest version of the [installer files](#).

- Ensure that your VM has python 3 installed and configured.
- On your VM, if you are not using the root account, create a user account and add it to the sudo group: `usermod -aG sudo salt-user`

For more information on Windows requirements, see [Spinning up Windows Minions](#).

1. On the Salt master, navigate to the RaaS configuration file located in `/etc/raas/raas`.

NOTE

If you have more than one Salt master, you must repeat these configuration steps for each Salt master.

2. Add these lines to the configuration file:

```
minion_deployment:
    airgap_install: true
```

3. In the RaaS configuration file, change the RaaS configuration settings to work in an air-gapped environment:

Setting	Notes
<code>airgap_install</code>	When set to <code>true</code> , RaaS is configured to operate in an air-gapped environment. Set to <code>false</code> to disable.
<code>sseapi_command_age_limit</code>	Sets the maximum age of a command in seconds. Entries older than the specified number of seconds are dropped automatically. The default is 0, which disables the feature.
<code>sseapi_minion_deploy_airgap</code>	Set to <code>true</code> to deploy minions in an air-gapped environment. The default is <code>False</code> .
<code>sseapi_win_minion_deploy_delay</code>	Sets the length of the time delay for minions to deploy to Windows virtual machines. The time is specified in seconds.

An example of these settings in the RaaS configuration file:

```
sseapi_command_age_limit: 180
sseapi_minion_deploy_airgap: True
sseapi_win_minion_deploy_delay: 180
```

4. Restart the RaaS service using the `service raas restart` command.
5. In Automation Assembler, configure and deploy a template without the **saltConfiguration** or **remoteAccess** sections.
6. Run the **Apply Salt Configuration** Day 2 action against the machine.

NOTE

You only need to enter your authentication credentials to run the action.

Apply Salt Configuration

Enter the information to apply a Salt configuration to this virtual machine. If this machine does not have a minion then one will be installed.

Authentication

 Remote access with existing credentials Password Private key

Username *

salt-user

Password *

.....

Master ID

Minion ID

Salt environment

State files

Variables

Example: {user:root, env:dev}

7. Navigate back to the template and verify the YAML configuration.
8. Test and deploy the template.

Terraform configurations in Automation Assembler

Terraform configurations

You can embed Terraform configurations as a resource in cloud templates in Automation Assembler.

Preparing an Automation Assembler Terraform runtime environment

Preparing a Terraform runtime environment

Designs that include Terraform configurations require access to a Terraform runtime environment that you integrate with the Automation Assembler on-premises product.

How to add a Terraform runtime

The runtime environment consists of a Kubernetes cluster that runs Terraform CLI commands to perform requested operations. In addition, the runtime collects logs and returns the results from Terraform CLI commands.

The VMware Aria Automation on-premises product requires users to configure their own Terraform runtime Kubernetes cluster. Only one Terraform runtime per organization is supported. All Terraform deployments for that organization use the same runtime.

NOTE

To run Terraform commands and states you need a Terraform runtime environment that runs on K8s. When you create your Terraform integration in on-premises VMware Aria Automation, you can choose between a managed k8s, (which is a k8s cluster that is already managed by VMware Aria Automation) or an external k8s cluster, (which is a k8s cluster that is not managed by VMware Aria Automation) and the namespace where the Terraform pods will be created. If you are using an external cluster, you must provide Kubeconfig access to the k8s cluster for the Terraform runtime target. Kubeconfig is a k8s standard and the Kubeconfig doesn't need to be an admin Kubeconfig. You can use a service account with minimum permissions, for example permission to run pods in a namespace and permission generate a Kubeconfig for use with the VMware Aria Automation Terraform runtime integration.

1. Verify that you have a Kubernetes cluster on which to run the Terraform CLI.
 - All users can supply a kubeconfig file to run the Terraform CLI on an unmanaged Kubernetes cluster.
 - Enterprise license users have the option to run the Terraform CLI on a Kubernetes cluster managed by VMware Aria Automation.In Automation Assembler, go to **Infrastructure > Resources > Kubernetes**, and verify that you have a Kubernetes cluster. See [How do I work with Kubernetes in](#) if you need to add one.
2. If the Kubernetes cluster is newly added or modified, wait for its data collection to complete.
Data collection retrieves the list of namespaces and other information, and might take up to 5 minutes depending on provider.
3. After data collection completes, go to **Infrastructure > Connections > Integrations > Add Integration**, and select the **Terraform Runtime** card.
4. Enter settings.

Figure 5: Example Terraform runtime integration

New Integration

Type: Terraform Runtime

Name *: OurOrg TF Runtime

Description:

Terraform Runtime Integration

Runtime type: Managed kubernetes cluster External kubeconfig

Kubernetes cluster *: Select a cluster

Kubernetes namespace *: Select a namespace

Runtime Container Settings

Image: projects.packages.broadcom.com/vra/terraform:latest

CPU request (Millicores): 250

CPU limit (Millicores): 250

Memory request (MB): 512

Memory limit (MB): 512

VALIDATE

Setting	Description
Name	Give the runtime integration a unique name.
Description	Explain what the integration is for.
Terraform Runtime Integration:	
Runtime type (Enterprise only)	Enterprise license users may select whether to run the Terraform CLI on a Kubernetes cluster managed by VMware Aria Automation or an unmanaged one.
Kubernetes kubeconfig (all users)	For an unmanaged Kubernetes cluster, paste in the entire contents of the kubeconfig file for the external cluster. To use an external Kubernetes runtime with a proxy server, see How to add proxy support . This option is available for all users.
Kubernetes cluster (Enterprise only)	For Kubernetes managed by VMware Aria Automation, select the cluster in which to run the Terraform CLI. The cluster and its kubeconfig file must be reachable. You can validate access to kubeconfig with a GET on /cmx/

Table continued on next page

Continued from previous page

Setting	Description
	api/resources/k8s/clusters/{clusterId}/kube-config. This option is only available for Enterprise licenses.
Kubernetes namespace	Select the namespace to use within the cluster, for creating pods that run the Terraform CLI.
Runtime Container Settings:	
Image	<p>Enter the path to the container image of the Terraform version that you want to run, for example projects.packages.broadcom.com/vra/terraform:latest</p> <p>NOTE If you previously entered a container image with vmware.com in the path, see KB 370092.</p> <p>The VALIDATE button does not check for the container image.</p>
CPU request	Enter the amount of CPU for running containers. Default is to 250 millicores.
CPU limit	Enter the maximum allowable CPU for running containers. Default is to 250 millicores.
Memory request	Enter the amount of memory for running containers. Default is 512 MB.
Memory limit	Enter the maximum allowable memory for running containers. Default is 512 MB.

5. Click **VALIDATE** and adjust settings as needed.

6. Click **ADD**.

Settings are cached. After adding the integration, you can modify settings such as the cluster or namespace, but it might take up to 5 minutes for a change to be detected and for the Terraform CLI to run under the new settings.

Troubleshooting the Terraform runtime

Some Terraform configuration deployment problems might be related to the runtime integration.

Problem	Cause	Resolution
Validation fails with an error stating that the namespace is invalid.	You modified the cluster but left the previous namespace in the UI.	Always reselect a namespace after modifying the cluster selection.
The namespace drop down is empty or doesn't list newly added namespaces.	Data collection for the cluster has not completed. Data collection takes up to 5 minutes after entering or modifying the cluster and up to 10 minutes when entering or modifying the namespace.	For a new cluster with existing namespaces, wait up to 5 minutes for data collection to complete. For a new namespace in an existing cluster, wait up to 10 minutes for data collection to complete.

Table continued on next page

Continued from previous page

Problem	Cause	Resolution
		If the problem continues, remove the cluster and re-add it under Infrastructure > Resources > Kubernetes .
Terraform CLI containers are created in a previous cluster, previous namespace, or with previous runtime settings, even after the integration account was updated.	The Kubernetes API client used by VMware Aria Automation is cached for 5 minutes.	Changes might need up to 5 minutes to take effect.
Validation or a Terraform deployment operation fails with an error stating that kubeconfig is not available.	Sometimes these errors occur because the cluster isn't reachable from VMware Aria Automation. In other cases, user credentials, tokens, or certificates are invalid.	The kubeconfig error can occur for a number of reasons and might require engagement with technical support for troubleshooting.

How to add proxy support

To have your external Kubernetes runtime cluster connect through a proxy server, follow these steps.

1. Log in to your external Kubernetes cluster server.
2. Create an empty folder.
3. In the new folder, add the following lines to a new file named Dockerfile.

```
FROM projects.registry.vmware.com/vra/terraform:latest as final
ENV https_proxy=protocol://username:password@proxy_host:proxy_port
ENV http_proxy=protocol://username:password@proxy_host:proxy_port
ENV no_proxy=.local,.localdomain,localhost
```

4. Modify the placeholder values so that the `https_proxy` and `http_proxy` environment variables include the proxy server settings that you use to access the internet.

The `protocol` will be `http` or `https` according to what your proxy server uses, which might not match the environment variable name of `https_proxy` or `http_proxy`.

5. Save and close Dockerfile.
6. From the empty folder, run the following command. Depending on your account privileges, you might need to run the command in sudo mode.

```
docker build --file Dockerfile --tag custom-terraform-runtime:1.0 .
```

The command creates a local custom-terraform-runtime:1.0 Docker image.

7. In Automation Assembler, under **Infrastructure > Connections > Integrations**, go to your Terraform runtime integration.
8. Create or edit the runtime container settings to use the custom-terraform-runtime:1.0 image:

Automation Assembler Terraform runtime with no internet access

Terraform runtime with no internet access

Automation Assembler users who need to design and run Terraform integrations while disconnected from the internet can set up their runtime environment by following this example.

NOTE

To obtain a source for image creation, setup involves briefly connecting to the internet. You might need to do those steps outside of your disconnected site if a temporary connection isn't possible.

This process assumes that you have [your own Docker registry](#) and can access its repositories without an internet connection.

Create the custom container image

1. Build a custom container image that includes the Terraform provider plug-in binaries.

The following Dockerfile shows an example of creating a custom image with the Terraform GCP provider.

The base image `projects.registry.vmware.com/vra/terraform:latest` download in the Dockerfile requires internet access to the VMware Harbor registry at `projects.registry.vmware.com`.

Firewall settings or proxy settings can cause the image build to fail. You might need to enable access to `releases.hashicorp.com` to download the Terraform provider plug-in binaries. However, you may use your private registry to supply the plug-in binaries as an option.

```
FROM projects.registry.vmware.com/vra/terraform:latest as final

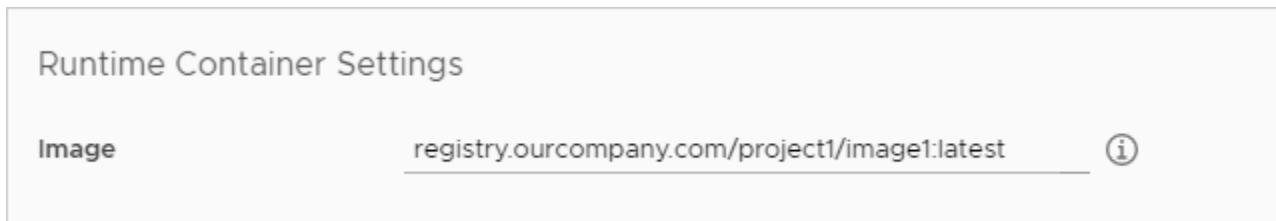

# Create provider plug-in directory
ARG plugins=/tmp/terraform.d/plugin-cache/linux_amd64
RUN mkdir -m 777 -p $plugins

# Download and unzip all required provider plug-ins from hashicorp to provider directory
RUN cd $plugins \
    && wget -q https://releases.hashicorp.com/terraform-provider-google/3.58.0/terraform-provider-google_3.58.0_linux_amd64.zip \
    && unzip *.zip \
    && rm *.zip
```

- ```
For "terraform init" configure terraform CLI to use provider plug-in directory and
not download from internet

ENV TF_CLI_ARGS_init="-plugin-dir=$plugins -get-plugins=false"

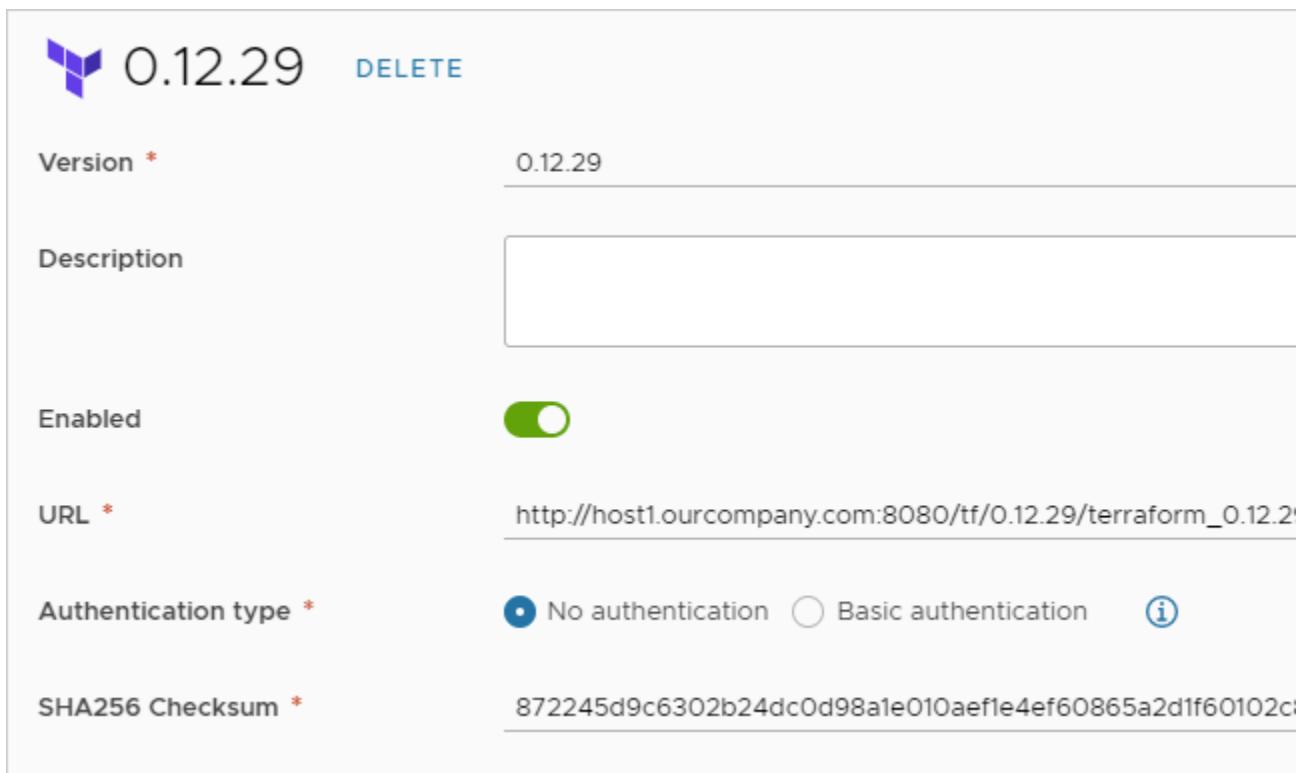

2. Build, tag, and push the custom container image to your own Docker repository at your disconnected site.
3. In Automation Assembler at your disconnected site, under Infrastructure > Connections > Integrations, go to your Terraform runtime integration.
4. Create or edit the runtime container settings to add your repository for the custom container image. The example built custom container image name is registry.ourcompany.com/project1/image1:latest.
```

### Host the Terraform CLI locally

1. Download the Terraform CLI binaries.
2. Upload the Terraform CLI binaries to your local web or FTP server.
3. In Automation Assembler, go to **Infrastructure > Configure > Terraform Versions**.
4. Create or edit the Terraform version so that it includes the URL to the Terraform CLI binaries hosted on your local server.
5. If your local web or FTP server requires login authentication, select **Basic authentication**, and enter username and password credentials that can access the server.

To change the authentication type, you must have the cloud administrator role in Automation Assembler.

The screenshot shows a configuration page for a Terraform runtime. The title is "0.12.29" with a "DELETE" button. The form fields are:

- Version \***: 0.12.29
- Description**: (empty text area)
- Enabled**: (green toggle switch)
- URL \***: http://host1.ourcompany.com:8080/tf/0.12.29/terraform\_0.12.29
- Authentication type \***: (radio buttons) No authentication (selected), Basic authentication, ⓘ
- SHA256 Checksum \***: 872245d9c6302b24dc0d98a1e010aef1e4ef60865a2d1f60102c

## Design and deploy Terraform configurations

With the runtime in place, you can add Terraform configuration files to git, design cloud templates for them, and deploy.

To get started, see [terraform-setup.dita#GUID-835425A6-A2DB-4E86-AAE7-C0F8BD8F985D-en](#).

## Troubleshooting

When deploying, open the deployment in Automation Assembler. Under the History tab, look for Terraform events, and click **Show Logs** to the right. When your local Terraform provider is working, the following messages appear in the log.

Initializing provider plugins

Terraform has been successfully initialized

For a more robust log, you can manually edit the cloud template code to add `TF_LOG: DEBUG` as shown in the following example.

resources:

```
terraform:
 type: Cloud.Terraform.Configuration
 properties:
 providers:
 - name: google
 # List of available cloud zones: gcp/us-west1
```

```

cloudZone: gcp/us-west1

environment:

Configure terraform CLI debug log settings

TF_LOG: DEBUG

terraformVersion: 0.12.29

configurationSource:

repositoryId: fc569ef7-f013-4489-9673-6909a2791071

commitId: 3e00279a843a6711f7857929144164ef399c7421

sourceDirectory: gcp-simple

```

### **Creating your own base image**

Although VMware occasionally updates the base image at `projects.registry.vmware.com/vra/terraform:latest`, that image might be out of date and contain vulnerabilities.

To build your own base image, use the following Dockerfile instead.

```

FROM alpine:latest as final

RUN apk add --no-cache git wget curl openssh

```

### **Designing for Terraform configurations in Automation Assembler**

#### Designing for Terraform configurations

With your repository and Terraform configuration files in place, you can design an Automation Assembler template for them.

1. [terraform-authoring.dita#SECTION\\_B633CA60-3BA8-4B4D-8E79-1AA9E823B11D-en](#)
2. [terraform-authoring.dita#GUID-ECC50AD0-2586-4F44-A00B-8EF53F4A2E88-en](#)
3. [terraform-authoring.dita#SECTION\\_4DBCFA58-F834-4109-B451-2B13FD80F675-en](#)
4. [terraform-authoring.dita#SECTION\\_9C1F94C4-143B-4334-8D26-C708E456E292-en](#)

#### **Prerequisites**

Set up and integrate your version control repository. See [terraform-setup.dita#GUID-835425A6-A2DB-4E86-AAE7-C0F8BD8F985D-en](#).

#### **Enable Terraform runtime versions**

You can define the Terraform runtime versions available to users when deploying Terraform configurations. Note that Terraform configurations might also include internally coded version constraints.

To create the list of allowable versions, go to **Infrastructure > Configure > Terraform Versions**.

#### **Add Terraform resources to the design**

Create your cloud template that includes Terraform configurations.

1. In Automation Assembler, go to **Design > Cloud Templates** and click **New from > Terraform**.

The Terraform configuration wizard appears.

2. Follow the prompts.

| Wizard Page                   | Setting           | Value                                                                                                                                                                                                                                                                                                                                          |
|-------------------------------|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>New Cloud Template</b>     | Name              | Give the design an identifying name.                                                                                                                                                                                                                                                                                                           |
|                               | Description       | Explain what the design is for.                                                                                                                                                                                                                                                                                                                |
|                               | Project           | Select the project that includes the repository integration where the Terraform configuration is stored.                                                                                                                                                                                                                                       |
| <b>Configuration Source</b>   | Repository        | Select the integrated repository where you stored the Terraform configuration.                                                                                                                                                                                                                                                                 |
|                               | Commit            | Select a repository commit, or leave the entry blank to use the Terraform configuration from the repository head.<br><br>Bitbucket Limitation—The number of selectable commits might be truncated because of the Bitbucket repository server configuration.                                                                                    |
|                               | Source directory  | Select a subdirectory from the repository structure that you created. The example subdirectories shown in the earlier setup were demo1, demo2, and demo3.<br><br>GitHub Enterprise Limitation—The source directory field is a plain text field in which you manually enter the name of the Terraform configuration subdirectory that you want. |
| <b>Finalize Configuration</b> | Repository        | Verify the correct repository selection.                                                                                                                                                                                                                                                                                                       |
|                               | Source directory  | Verify the correct directory selection.                                                                                                                                                                                                                                                                                                        |
|                               | Terraform version | Select the Terraform runtime version to run when deploying the Terraform configuration.                                                                                                                                                                                                                                                        |
|                               | Providers         | If the Terraform configuration included a provider block, verify the provider and cloud zone that this cloud template will deploy to.<br><br>Having no provider isn't a problem. After finishing the wizard, just edit the provider and cloud zone in the template properties to add or change the deployment target.                          |
|                               | Variables         | Select sensitive values for encryption, such as passwords.                                                                                                                                                                                                                                                                                     |
|                               | Outputs           | Verify the outputs from the Terraform configuration, which convert to expressions that your design code can further reference.                                                                                                                                                                                                                 |

3. Click **Create**.

The Terraform resource appears on the cloud template canvas, with Automation Assembler code that reflects the Terraform configuration to deploy.

The screenshot shows the VMware Aria Automation Cloud Template Editor interface. On the left, there's a workspace with a Terraform file open. The file contains two 'aws\_instance' resources. On the right, the 'Code' tab is selected, displaying the Terraform configuration code:

```

1 inputs:
2 instance_type:
3 type: string
4 default: t2.micro
5 description: AWS inst
6 department:
7 type: string
8 description: Departme
9 resources:
10 terraform:
11 type: Cloud.Terraform
12 properties:
13 variables:
14 instance_type: '$
15 department: '${in
16 providers:
17 - name: aws
18 # List of avail
19 cloudZone: blue
20 terraformVersion: 0
21 configurationSource
22 repositoryId: 428
23 commitId: '${inpu
24 sourceDirectory:

```

If desired, you can add other Automation Assembler resources to the cloud template, to combine Terraform and non-Terraform code into a hybrid design.

#### NOTE

Updating Terraform configurations in the repository doesn't synchronize the changes into your cloud template. Automatic synchronization can introduce security risks, such as newly added sensitive variables.

To capture Terraform configuration changes, rerun the wizard, choose the new commit, and identify any new sensitive variables.

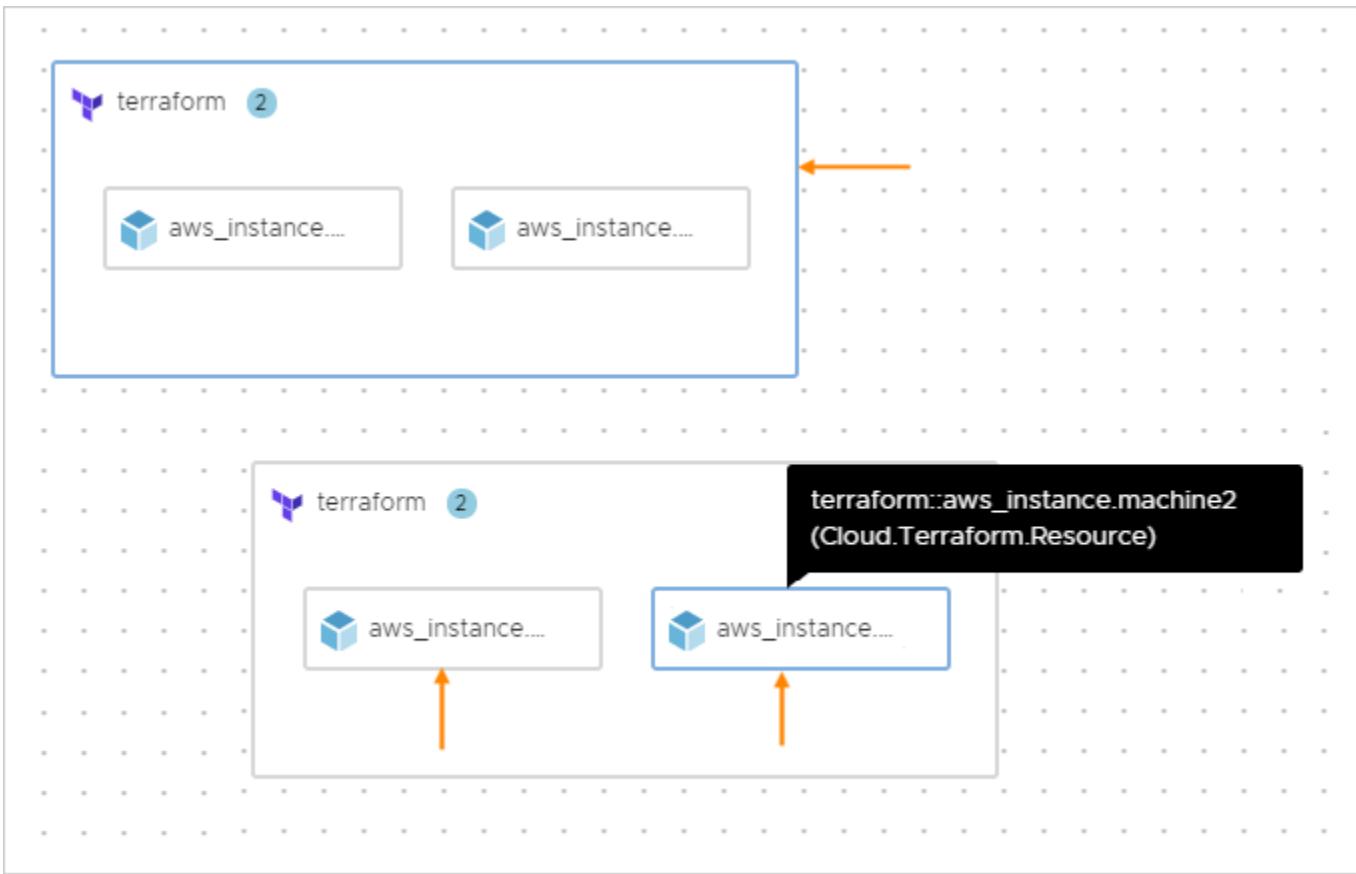

#### Deploy the cloud template

When you deploy the cloud template, the deployment **History** tab lets you expand an event such as an allocate or create phase, to inspect a log of messages from the Terraform CLI.

Approvals—In addition to the expected Terraform phases such as PLAN, ALLOCATE, or CREATE, Automation Assembler introduces governance by means of an approval phase. See [How do I configure Automation Service Broker approval policies](#) for more information about request approvals.

| Timestamp                                                                                                                                                                                                                                                                                                                                     | Status                   | Resource type                  | Resource name |

| Aug 3, 202...                                                                                                                                                                                                                                                                                                                                 | INITIALIZATION_IN_PRO... |                                |               |

After deploying, you see an outer resource that represents the overall Terraform component, with child resources inside for the separate components that Terraform created. The parent Terraform resource controls the lifecycle of the child resources.

## Using a secret Automation Assembler property in a Terraform configuration

### Using a secret property in a Terraform configuration

You can apply secret, encrypted values to Terraform configurations that you add to Automation Assembler cloud template designs.

1. In your git repository, add a Terraform configuration source file that references the secret properties as variables. In this Terraform configuration source example, API and application keys are the secret variables.

```
variable "datadog_api_key" {
 description = "Datadog API Key"
}

variable "datadog_app_key" {
 description = "Datadog App Key"
}

provider "datadog" {
 api_key = "${var.datadog_api_key}"
 app_key = "${var.datadog_app_key}"
```

```

}

Create a new monitor
resource "datadog_monitor" "default" {
 # ...
}

Create a new timeboard
resource "datadog_timeboard" "default" {
 # ...
}

```

2. In Automation Assembler, go to **Infrastructure > Administration > Secrets**, and enter your secret property values. Add secret names and corresponding values. For the names, it's easiest to simply enter the same name as the variable name from your Terraform source.

If needed, see [Secret properties](#) for more details.

| Name            | Project   |
|-----------------|-----------|
| datadog_api_key | Terraform |
| datadog_app_key | Terraform |

3. In Automation Assembler, import the Terraform configuration for use in a cloud template. Go to **Design > Cloud Templates** and click **New From > Terraform**.

#### NOTE

Even though the variables appear for selection on the last page of the wizard, you do not need to set the secret variables as sensitive. Secret Automation Assembler variables will already be encrypted and do not need the encryption that the wizard applies.

If needed, see [Designing for Terraform configurations](#) in for more details.

The example cloud template should look similar to the following code:

inputs:

```
datadog_api_key:
```

```

type: string
description: Datadog API Key

datadog_app_key:
 type: string
 description: Datadog App Key

resources:

terraform:
 type: Cloud.Terraform.Configuration

 properties:
 variables:
 datadog_api_key: '${input.datadog_api_key}'
 datadog_app_key: '${input.datadog_app_key}'

 providers: []

 terraformVersion: 0.12.29

 configurationSource:
 repositoryId: 0fbf8f5e-54e1-4da3-9508-2b701gf25f51
 commitId: ed12424b249aa50439kr1c268942a4616bd751b6
 sourceDirectory: datadog

```

4. In the code editor, for the secret values, manually change `input` to `secret` as shown.

```

terraform:
 type: Cloud.Terraform.Configuration

 properties:
 variables:
 datadog_api_key: '${secret.datadog_api_key}'
 datadog_app_key: '${secret.datadog_app_key}'

```

5. In the `inputs:` section of the code, remove the input entries that were replaced by the bindings to secret properties.

## Learn more about Terraform configurations in VMware Aria Automation

Learn more about Terraform configurations

Be aware of certain limitations and troubleshooting when you embed Terraform configurations as a resource in VMware Aria Automation.

### Limitations for Terraform configurations

- When validating a design with Terraform configurations, the TEST button checks Automation Assembler syntax but not the native Terraform code syntax.

- In addition, the TEST button doesn't validate commit IDs associated with Terraform configurations.
- For a cloud template that includes Terraform configurations, cloning the template to a different project requires the following workaround.
    - In the new project, under the **Integrations** tab, copy the `repositoryId` for your integration.
    - Open the clone template. In the code editor, replace the `repositoryId` with the one you copied.
  - In the version control repository, don't include a Terraform state file with configuration files. If `terraform.tfstate` is present, errors occur during deployment.

### **Supported day 2 actions for the parent Terraform resource**

For the parent Terraform resource, you can view or refresh the Terraform state file. For more about the state file actions, see the comprehensive list of actions at [What actions can I run on Automation Assembler deployments or supported resources](#).

### **Supported day 2 actions for child resources**

After deploying Terraform configurations, it might take up to 20 minutes for a day 2 action to become available on child resources.

For child resources in a Terraform configuration, only the following subset of day 2 actions are supported. For details about the actions, look them up in the comprehensive list of actions at [What actions can I run on Automation Assembler deployments or supported resources](#).

| Provider | Terraform Resource Type              | Supported Day 2 Actions |
|----------|--------------------------------------|-------------------------|
| AWS      | <code>aws_instance</code>            | Power On                |
|          |                                      | Power Off               |
|          |                                      | Reboot                  |
|          |                                      | Reset                   |
| Azure    | <code>azurerm_virtual_machine</code> | Power On                |
|          |                                      | Power Off               |
|          |                                      | Restart                 |
|          |                                      | Suspend                 |
| vSphere  | <code>vsphere_virtual_machine</code> | Power On                |
|          |                                      | Power Off               |
|          |                                      | Reboot                  |
|          |                                      | Reset                   |
|          |                                      | Shutdown                |
|          |                                      | Suspend                 |
|          |                                      | Create Snapshot         |
|          |                                      | Delete Snapshot         |
|          |                                      | Revert Snapshot         |
| GCP      | <code>google_compute_instance</code> | Power On                |
|          |                                      | Power Off               |
|          |                                      | Create Snapshot         |
|          |                                      | Delete Snapshot         |

### **Troubleshooting day 2 action availability**

Out-of-the-box (OOTB) day 2 actions that are missing or deactivated might need troubleshooting.

| Problem                                                                                                                                                                                                                              | Cause                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Resolution                                                                                                                                                                                                                                          |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| A Terraform resource does not have an expected OOTB day 2 action on the Actions menu.                                                                                                                                                | <p>The action might not be supported for the provider and resource type as mentioned in the previous list.</p> <p>Alternatively, the action might need up to 20 minutes to appear due to the timing of resource discovery and resource caching.</p>                                                                                                                                                                                                                 | <p>Check the provider and resource type in the design.</p> <p>Wait up to 20 minutes for data collection to complete.</p>                                                                                                                            |
| A Terraform resource does not have an expected day 2 action even after the 20 minutes to account for data collection.                                                                                                                | <p>A resource discovery problem is preventing the action from appearing.</p> <p>One way that happens is when the resource is accidentally created on an out-of-project cloud zone. For example, your project only includes a cloud account and region us-east-1 cloud zone, but the Terraform configuration includes a provider block for us-west-1, and you didn't change it at design time.</p> <p>Another possibility is that data collection isn't working.</p> | <p>Check the project cloud zones against the cloud zones in the design.</p> <p>Go to <b>Infrastructure &gt; Connections &gt; Cloud Accounts</b> and check the data collection status and last successful collection time for the cloud account.</p> |
| Even though there are no obvious problems with the resource state and data collection, a day 2 action is deactivated (gray).                                                                                                         | Occasional, intermittent timing issues and data collection failures are known to occur.                                                                                                                                                                                                                                                                                                                                                                             | The problem should resolve itself within 20 minutes.                                                                                                                                                                                                |
| The wrong day 2 action is deactivated, one that should be active based on the resource state. For example, Power Off is enabled, and Power On is deactivated, even though the resource was powered off using the provider interface. | Data collection timing can cause a temporary mismatch. If you change the power state from outside VMware Aria Automation, it takes time to correctly reflect the change.                                                                                                                                                                                                                                                                                            | Wait up to 20 minutes.                                                                                                                                                                                                                              |

## Using custom Terraform providers in VMware Aria Automation

If you want to use a custom Terraform provider, take the following steps.

In your git version control repository, under the Terraform directory that contains main.tf, add the following subdirectory structure and your custom Terraform provider ZIP file.

```
terraform.d/plugins/<HOSTNAME>/<NAMESPACE>/<TYPE>/terraform-provider-<TYPE_VERSION_TARGET>.zip
```

For example, if you downloaded [azurerm version 3.12.0](#), you create the following structure.

```
terraform.d/plugins/registry.terraform.io/hashicorp/azurerm/terraform-provider-azurerm_3.12.0_linux_amd64.zip
```

## Custom resource types for Automation Assembler cloud templates

Custom resource types

When you create a cloud template in Automation Assembler, the resource type palette includes resource types for the supported cloud account and integration endpoints. You might have use cases where you want to create cloud templates based on an expanded list of resource types. You can create custom resource types, add them to the design canvas, and create cloud templates that support your design and deployment needs.

### **Custom resource name and resource type**

The custom resource name identifies your custom resource inside the cloud template resource type palette.

The resource type of a custom resource must begin with `Custom.` and each resource type must be unique. For example, you might set `Custom.ADUser` as a resource type for a custom resource that adds Active Directory users. Although the inclusion of `Custom.` is not validated in the text box, the string is automatically added if you remove it.

### **Extensibility action custom resources**

With custom resource types, you can use extensibility actions in cloud templates to build complex applications. For example, you can use the native integration of extensibility actions with Amazon Web Services and Microsoft Azure to easily integrate with their respective services. You can create extensibility action custom resources by clicking on the **Based on** option in the custom resource editor and selecting **ABX user-defined schema**.

### **Lifecycle actions for extensibility action custom resources**

When using a extensibility action for your custom resource, you can define the following lifecycle actions:

- **Create:** this extensibility action is called when a deployment is started.
- **Read:** this extensibility action is used to retrieve the latest state of the deployed resource.
- **Update:** this extensibility action is called when a cloud template property is updated. This action is triggered only when a property is not marked with `recreateOnUpdate`.
- **Destroy:** this extensibility action is called when a deployment is deleted.

These lifecycle actions can either be selected manually from your existing extensibility actions or generated automatically by selecting **Generate Actions**. When you select **Generate Actions** you must specify the project in which the new extensibility action will be generated in.

#### **NOTE**

You can edit the extensibility actions associated with your lifecycle actions by clicking on the **Open** option next to the specific action.

### **Automation Orchestrator custom resources**

Each Automation Orchestrator custom resource is based on a SDK inventory type and is created by a Automation Orchestrator workflow that has an output which is an instance of your desired SDK type. Primitive types, such as `Properties`, `Date`, `string`, and `number` are not supported for the creation of custom resource types.

#### **NOTE**

SDK object types can be differentiated from other Automation Orchestrator property types by the colon (`:`) used to separate the plug-in name and the type name. For example, `AD:UserGroup` is an SDK object type used to manage Active Directory user groups.

You can use the built-in workflows in Automation Orchestrator, or you can create your own. Using Automation Orchestrator to create anything-as-a-service/XaaS workflows means that you can create a cloud template that adds an Active Directory user to machines at deployment time, or add a custom F5 load balancer to a deployment. You can create Automation Orchestrator custom resources by clicking on the **Based on** option in the custom resource editor and selecting **vRO inventory**.

## **Automation Orchestrator custom resource external type**

The external type property defines the type of your Automation Orchestrator custom resource. When you select a Create workflow in your custom resource type in Automation Assembler, the external type drop-down appears underneath it. The drop-down includes external type properties, that are selected from the output parameters of the Automation Orchestrator workflow. The selected workflow output properties included in the drop-down must be non-array SDK object types such as VC:VirtualMachine or AD:UserGroup.

### **NOTE**

When creating custom workflows that use the dynamic type plug-in, verify that their variables are defined by using the `DynamicTypesManager.getObject()` method.

When you define your custom resource types, you also define the scope of the availability of the select external type. The selected external type can be:

- Shared across projects.
- Available only for the selected project.

You can only have one custom resource type with a specific external type value per defined scope. For example, if you create a custom resource in your project that uses VC:VirtualMachine as an external type, you cannot create another custom resource for the same project that uses the same external type. You also cannot create two shared custom resources that use the same external type.

## **Automation Orchestrator lifecycle action validation**

When you add Create, Delete, and Update workflows as lifecycle actions to your custom resource, Automation Assembler validates that the selected workflows have correct input and output property definitions.

- The Create workflow must have an output parameter that is an SDK object type, such as SSH:Host or SQL:Database. If the selected workflow does not pass the validation, you cannot add Update or Delete workflows, or save your changes to the custom resource.
- The Delete workflow must have an input parameter that is an SDK object type that matches the external type of the custom resource.
- The Update workflow must have both an input and output parameter that is an SDK object type that matches the external type of the custom resource.

## **Custom resource property schema**

You can edit and view the custom resource properties schema by selecting the **Properties** tab. The schema includes the name, data type, property type, and, if it is available, the description of a given property. The schema also defines if a specific property is required or optional in the cloud template.

### **NOTE**

For the property schema of extensibility action custom resources, all properties are required in the cloud template.

When you add Automation Orchestrator workflows to your custom resource, their input and output parameters are added as properties. For extensibility action custom resources, you must create the property schema of extensibility action custom resources manually in the **Properties** tab.

### **NOTE**

The properties defined in the schema of extensibility action custom resources must also be returned values in the **Read** action of your custom resource and have the same names. For example, if your schema includes the properties `domain` and `location`, the **Read** action must also return the same properties with the same names.

From this tab, you can also modify and format the properties of your Automation Orchestrator or extensibility action based custom resources. For example, you can change the display name of a given property or add constraints.

**NOTE**

When adding constraints to either the item section of array fields or properties section of objects fields in the properties schema, verify that you have validated these constraints as incorrectly applied constraints can cause issues with the custom resource. For example, when adding a maximum constraint to a numbers array, you must verify that this constraint does not break the property's default value.

You can edit the property schema for custom resources by navigating to the **Properties** tab and using either the **Code** or **Form** tab.

- **Code:** Edit the property schema by using YAML content. When selecting this option, the property schema is defined by using the JSON Schema.
- **Form:** For extensibility action custom resources, by clicking **New Property**, you create a new property by configuring its name, display name, description, property type, and default value. For Automation Orchestrator custom resources, you can also hide non-required and non-computed properties from the schema by clicking **Remove Property**.

**Day 2 Operation Custom Request Forms**

You can streamline the request form of the day 2 operations included in your custom resource by adding and modifying different types of resource properties.

For example, you can bind the value of an input parameter in your request form to an external source, such as a Automation Orchestrator action that retrieves a deployment name or project name. You can also bind the value of a specific input parameter to the computed value of two other text boxes included in the same request form.

**NOTE**

This functionality is available for both custom resources and resource actions. You can customize the value of the input properties of your request form from the **Values** tab of the **Request Parameters** page of the custom resource or resource action editor.

**Day 2 Operation Request Form Validation**

You can validate the request form of your day 2 operations by adding an external validation. By using an external validation, you prevent the user from submitting the request form until the validation parameters are satisfied. You can add external validation from the **Validations** tab of the **Request Parameters** page of the custom resource or resource action editor. After selecting the tab, you can drag a **Orchestrator validation** element to the canvas and add a Automation Orchestrator action that you want to use for validation.

For example, you can create a custom resource that includes a day 2 operation for changing a user password. For such a use case, you can add a Automation Orchestrator action with `newPassword` and `confirmPassword` input parameters that use the `SecureString` type.

**NOTE**

This is a sample script for validating a user password. For your own use case, you can decide to use a different script.

```
if (newPassword != confirmPassword) {
 return 'passwords are different';
}

if (newPassword.length < 7) {
 return 'password must be at least 10 symbols';
}
```

```
return null;
```

## Adding Automation Orchestrator actions as input properties

You must manually add any Automation Orchestrator actions to your cloud template.

Create a custom resource and add it to a cloud template.

When creating a custom resource based on Automation Orchestrator workflows, the resource schema is based on the data coming from Automation Orchestrator. All workflow input and output properties are automatically added as custom resource properties. Any input properties associated with Automation Orchestrator actions must be added manually.

1. Navigate to **Design > Cloud Templates** and select your cloud template.
2. Select the custom resource from the cloud template canvas.
3. Select the **Inputs** tab, and click **New Cloud Template Input**.
4. Enter a name for the new input parameter.
5. Under **Default value source**, select **External source**.
6. Click **Select**.
7. Enter the name of the Automation Orchestrator action you want to add as an input parameter.
8. Verify the action parameters and click **Save**.
9. To finish adding the new input parameter, click **Create**.
10. Select the **Code** tab, and bind the input parameter to the resource property by using the  `${input.prop}` method.

You have added a Automation Orchestrator action as an input parameter to your custom resource.

## How to create an Automation Assembler template that adds users to Active Directory

How to create a cloud template that adds users to Active Directory

In addition to the Automation Assembler cloud template resources that you use when you create cloud templates, you can also create your own custom resources.

- Verify that you configured an Automation Orchestrator integration. See [Configure an integration in](#) .
- Verify that the workflows that you are using for the create, update, destroy, and day 2 actions exist in Automation Orchestrator and run successfully from there.
- In Automation Orchestrator, locate the resource type used by the workflows. The workflows included in this custom resource must all use the same resource type. In this use case, the resource type is `AD:User`. For more information on resource type validation, see [Custom resource types for cloud templates](#) .
- By using the built-in Active Directory workflows in your Automation Orchestrator integration, configure an Active Directory server.
- Verify that you know how to configure and deploy a machine cloud template.

Custom resources are Automation Orchestrator or extensibility action objects that you manage through Automation Assembler with the lifecycle actions defined in the custom resource. The cloud template service automatically calls up the appropriate Automation Orchestrator workflows or extensibility actions when the operation associated with a specific lifecycle action is triggered. You can extend the functionality of the resource type by also selecting Automation Orchestrator workflows or extensibility actions that can be used as day 2 operations.

This use case uses built-in workflows that are provided in the Automation Orchestrator library. It includes prescriptive values or strings to demonstrate how to perform the process. You can modify them to suit your environment.

For reference purposes, this use case uses a project named **DevOpsTesting**. You can replace this sample project with any project in your environment.

1. Create an Active Directory custom resource for adding a user in a group.

This step adds the custom resource to the cloud template design canvas as a resources type.

- a) In Automation Assembler, select **Design > Custom Resources**, and click **New Custom Resource**.
- b) Provide the following values.

Remember, except for the workflow names, these are sample values.

| Setting       | Sample Value                                                                                                                                                                                                                                                                                                                                                             |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Name          | AD user<br>This is the name that appears in the cloud template resource type palette.                                                                                                                                                                                                                                                                                    |
| Resource Type | Custom.ADUser<br>The resource type must begin with <code>Custom.</code> and each resource type must be unique.<br><br>Although the inclusion of <code>Custom.</code> is not validated in the text box, the string is automatically added if you remove it.<br><br>This resource type is added to the resource type palette so that you can use it in the cloud template. |

- c) To enable this resource type in the cloud template resource type list, verify that **Activate** option is toggled on.
- d) Select the **Scope** setting that makes the resource type available to any project.
- e) Under **Based on**, verify that **vRO Inventory** is selected as the lifecycle action provider.
- f) Select the workflows that define the resource and the day 2 actions.

#### NOTE

The selected day 2 workflows must have an input parameter that is of the same type as the external type. The external type input is not displayed in the day 2 custom form requested by the user, as it is automatically bound to the custom resource.

| Setting                    | Sample Value                                                                                                                                                                                                                                                                                                                                                                        |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Lifecycle Actions - Create | Select the <b>Create a user with a password in an organizational unit</b> workflow.<br>If you have multiple Automation Orchestrator integrations, select the workflow on the integration instance you use to run these custom resources.<br><br>After selecting the workflow, the external type drop-down menu becomes available and is automatically set to <code>AD:User</code> . |

*Table continued on next page*

*Continued from previous page*

| Setting                     | Sample Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                             | <p><b>NOTE</b><br/>           An external source type can be used only once if shared and once per project. In this use case, you are providing the same custom resource for all the projects. It does mean that you cannot use <b>AD:User</b> for any other resource types for all projects. If you have other workflows that require the <b>AD:User</b> type, you must create individual custom resources for each project.</p>                                                                          |
| Lifecycle Actions - Destroy | Select the <b>Destroy a user</b> workflow.                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Additional Actions          | <p>Select the <b>Change a user password</b> workflow. On the <b>Add Action</b> window, add a name for the action, such as <code>password_change</code> and click <b>Add</b>.</p> <p>To modify the action request form that the user responds to when they request the action, click the icon in the <b>Request Parameters</b> column.</p> <p><b>NOTE</b><br/>           For additional action workflows, verify that the workflow has a input parameter that is of the same type as the external type.</p> |

In this example, there is no appropriate application of an update workflow. A common example of an update workflow, which makes changes to the provisioned custom resource, is scaling in or scaling out a deployment.

- g) Review the schema key and type values in the **Properties** tab so that you understand the workflow inputs so that you can configure the inputs in the cloud template.

The schema lists the required and optional input values defined in the workflow. The required input values are included in the cloud template YAML.

In the **Create a user** workflow, `accountName`, `displayName`, and `ouContainer` are required input values. The other schema properties are not required. You can also use the schema to determine where you want to create bindings to other field values, workflows, or actions. Bindings are not included in this use case.

- h) To finish creating your custom resource, click **Create**.
- 2. Create a cloud template that adds the user to a machine when you deploy it.
  - a) Select **Design > Cloud Templates**, and click **New from > Blank canvas**.
  - b) Name the cloud template **Machine with an AD user**.
  - c) Select the **DevOpsTesting** project and click **Create**.
  - d) Add and configure a vSphere machine.
  - e) From the custom resource list on the left of the cloud template design page, drag the **AD user** resource type onto the canvas.

**NOTE**

You can select the custom resource by either scrolling down and selecting it from the left pane, or searching for it in the **Search Resource Types** text box. If the custom resource does not appear, click the refresh button next to the **Search Resource Types** text box.

- f) On the right, edit the YAML code to add the mandatory input values and the password.

Add an `inputs` section in the code so that users can provide the name of the users that they are adding. In the following example, some of these values are sample data. Your values might be different.

```
inputs:
 accountName:
 type: string
 title: Account name
 encrypted: true

 displayName:
 type: string
 title: Display name

 password:
 type: string
 title: Password
 encrypted: true

 confirmPassword:
 type: string
 title: Password
 encrypted: true

 ouContainer:
 type: object
 title: AD OU container
 $data: 'vro/data/inventory/AD:OrganizationalUnit'

 properties:
 id:
 type: string
 type:
 type: string
```

- g) In the resources section, add \${input.input-name} code to prompt for the user selection.

```
resources:
 Custom_ADUser_1:
 type: Custom.ADUser
 properties:
 accountName: '${input.accountName}'
 displayName: '${input.displayName}'
 ouContainer: '${input.ouContainer}'
 password: '${input.password}'
 confirmPassword: '${input.confirmPassword}'
```

3. Deploy the cloud template.
  - a) On the cloud template designer page, click **Deploy**.
  - b) Enter the **Deployment Name** AD User Scott.
  - c) Select the **Cloud Template Version** and click **Next**.
  - d) Complete the deployment inputs.
  - e) Click **Deploy**.
4. Monitor the provisioning request on the **Deployments** page to ensure that the user is added to Active Directory and that the deployment is successful.

When your tested cloud template is working, you can then begin using the **AD user** custom resource with other cloud templates.

### How to create an Automation Assembler template that includes SSH

How to create a cloud template that includes SSH

You can create custom resources that you can use to build cloud templates using Automation Orchestrator workflows. In this use case, you add a custom resource that adds an SSH host. You can then include the resource in cloud templates. This procedure also adds an update workflow so that users change the SSH configuration after deployment rather than perform individual day 2 actions.

- Verify that you configured an Automation Orchestrator integration. See [Configure an integration in](#) .
- Verify that the workflows that you are using for the create, update, destroy, and day 2 actions exist in Automation Orchestrator and run successfully from there.
- In Automation Orchestrator, locate the resource type used by the workflows. The workflows included in this custom resource must all use the same resource type. In this use case, the resource type is **SSH:Host**. For more information on resource type validation, see [Custom resource types for cloud templates](#) .
- Verify that you know how to configure and deploy a machine cloud template.

Custom resources are Automation Orchestrator or extensibility action objects that you manage through Automation Assembler with the lifecycle actions defined in the custom resource. The cloud template service automatically calls up the appropriate Automation Orchestrator workflows or extensibility actions when the operation associated with a specific lifecycle action is triggered. You can extend the functionality of the resource type by also selecting Automation Orchestrator workflows or extensibility actions that can be used as day 2 operations.

This use case uses built-in workflows provided in the Automation Orchestrator library. It includes prescriptive values or strings to demonstrate how to perform the process. You can modify them to suit your environment.

For reference purposes, this use case uses a project named **DevOpsTesting**. You can replace the project with one that you already have.

1. Create an SSH host custom resource for adding SSH to a cloud template.

This step adds the custom resource to the cloud template design canvas as a resource type.

- a) In Automation Assembler, select **Design > Custom Resources**, and click **New Custom Resource**.
- b) Provide the following values.

Remember, except for the workflow names, these are sample values.

**Table 28:**

| Setting       | Sample Value                                                                                                                                                                                                                                                                                                                                                 |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Name          | SSH Host - DevOpsTesting Project<br>This is the name that appears in the cloud template resource type palette.                                                                                                                                                                                                                                               |
| Resource Type | Custom.SSHHost<br>The resource type must begin <code>Custom.</code> and each resource type must be unique.<br><br>Although the inclusion of <code>Custom.</code> is not validated in the text box, the string is automatically added if you remove it.<br><br>This resource type is added to the design canvas so that you can use it in the cloud template. |

- c) To enable this resource type in the cloud template resource type list, verify that **Activate** option is toggled on.
- d) Select the **Scope** setting that makes the resource type available to the **DevOpsTesting** project.
- e) Under **Based on**, verify that **vRO Inventory** is selected as the lifecycle action provider.
- f) Select the workflows that define the resource.

| Setting                    | Setting                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Lifecycle Actions - Create | Select the <b>Add SSH Host</b> workflow.<br>If you have multiple Automation Orchestrator integrations, select the workflow on the integration instance you use to run these custom resources.<br><br>After selecting the workflow, the external type dropdown menu becomes available and is automatically set to <code>SSH:Host</code> . An external source type can be used only once if shared and once per project. In this use case, you are providing the custom resource for only the <b>DevOpsTesting</b> project. If you had other workflows that require the <code>SSH:Host</code> type, you |

*Table continued on next page*

*Continued from previous page*

| Setting                     | Setting                                                   |
|-----------------------------|-----------------------------------------------------------|
|                             | must create individual custom resources for each project. |
| Lifecycle Actions - Update  | Select the <b>Update SSH Host</b> workflow.               |
| Lifecycle Actions - Destroy | Select the <b>Remove SSH Host</b> workflow.               |

- g) Review the schema key and type values in the **Properties** tab so that you understand the workflow inputs so that you can configure the inputs in the cloud template.

The schema lists the required and optional input values defined in the workflow. The required input values are included in the cloud template YAML.

In the **Add SSH Host** workflow, `hostname`, `port`, and `username` are required input values. The other schema properties are not required. You can also use the schema to determine where you want to create bindings to other field values, workflows, or actions. Bindings are not included in this use case.

- h) To finish creating your custom resource, click **Create**.
2. Create a cloud template that adds the SSH host when you deploy it.
    - a) Select **Design > Cloud Templates**, and click **New from > Blank canvas**.
    - b) Name the cloud template `Machine with SSH Host`.
    - c) Select the **DevOpsTesting** project, and click **Create**.
    - d) Add and configure a vSphere machine.
    - e) From the custom resource list on the left of the cloud template design page, drag the **SSH Host - DevOpsTesting Project** resource type onto the canvas.

#### NOTE

You can select the custom resource by either scrolling down and selecting it from the left pane, or searching for it in the **Search Resource Types** text box. If the custom resource does not appear, click the refresh button next to the **Search Resource Types** text box.

A reminder that the resource type is available because it was configured for the project. If you were creating a cloud template for another project, you cannot see the resource type.

- f) On the right, edit the YAML code to add the mandatory input values.

Add an `inputs` section in the code so that users can provide the user name and the host name at deployment time. In this example, the port default is 22. In the following example, some of these values are sample data. Your values might be different.

```
inputs:
 hostname:
 type: string
 title: The hostname of the SSH Host
 username:
 type: string
 title: Username
```

- g) In the resources section, add \${input.input-name} code to prompt for the user selection.

resources:

```
Custom_SSHHost_1:
 type: Custom.SSHHost
 properties:
 port: 22
 hostname: '${input.hostname}'
 username: '${input.username}'
```

### 3. Deploy the cloud template.

- a) On the cloud template designer page, click **Deploy**.
  - b) Enter the **Deployment Name** SSH Host Test.
  - c) Select the **Cloud Template Version** and click **Next**.
  - d) Complete the deployment inputs.
  - e) Click **Deploy**.
4. Monitor the provisioning request on the **Deployments** page to ensure that the SSH host is included in the deployment and that the deployment is successful.

When your tested cloud template is working, you can then begin using the `SSH Host` custom resource with other cloud templates.

## Automation Assembler designs that prepare for day 2 changes

### Preparing for day 2

In addition to the day 2 actions already associated with Automation Assembler resource types, you have design options that let you prepare in advance for custom updates that users might need to make.

#### **CAUTION**

To change a deployment, you can edit its cloud template and reapply it, or you can use day 2 actions. However, in most cases you should avoid mixing the two approaches.

Lifecycle day 2 changes such as power on/off are usually safe, but others require caution, such as when adding disks.

For example, if you add disks with a day 2 action, and then take a mixed approach by reapplying the cloud template, the cloud template could overwrite the day 2 change, which might remove disks and cause data loss.

Day 2 preparation can involve either direct use of cloud template code, or the Automation Assembler design interface.

- You can use inputs in cloud template code so that, when you update the deployment or deployed resource, the interface prompts for fresh values.
- You can use Automation Assembler to design a custom action based on a VMware Aria Automation Orchestrator workflow or an extensibility action. Running the custom action results in the workflow or extensibility action making changes to the deployment or deployed resource.

For custom day 2 resource actions you can use the schema for deployment resource types to specify criteria for your resource action. For example, you can use the deployment name property to define which deployments can use the create resource action.

## How to use cloud template inputs for VMware Aria Automation day 2 updates

How to use cloud template inputs for day 2 updates

When designing cloud templates, VMware Aria Automation input parameters allow day 2 users to re-enter selections from the initial deployment request.

### CAUTION

Some property changes cause a resource to be re-created. For example, changing the `connection_string.name` under a `Cloud.Service.Azure.App.Service` deletes the existing resource and creates a new one.

When designing inputs to support day 2 changes, the schema [Models hosted on code.vmware.com](#) help you locate the properties that delete and re-create resources.

For information on how to create inputs, see [User input in requests](#).

For a specific day 2 example, see the next section.

## How to move a deployed machine to another network

While maintaining deployments and networks, you might need the ability to relocate machines that you deployed with Automation Assembler.

- The Automation Assembler network profile must include all subnets that the machine will connect to. In Automation Assembler, you can check networks by going to **Infrastructure > Configure > Network Profiles**. The network profile must be in an account and region that are part of the appropriate Automation Assembler project for your users.
- Tag the two subnets with different tags. The example that follows assumes that `test` and `prod` are the tag names.
- The deployed machine must keep the same IP assignment type. It can't change from static to DHCP, or vice versa, while moving to another network.

For example, you might deploy to a test network first, then move to a production network. The technique described here lets you design a cloud template in advance to prepare for such day 2 actions. Note that the machine is moved. It isn't deleted and redeployed.

This procedure only applies to `Cloud.vSphere.Machine` resources. It won't work for cloud agnostic machines deployed to vSphere.

- In Automation Assembler, go to **Design**, and create a cloud template for the deployment.
- In the inputs section of the code, add an entry that lets the user select a network.

inputs:

```
net-tagging:
 type: string
 enum:
 - test
 - prod
 title: Select a network
```

- In the resources section of the code, add the `Cloud.Network` and connect the vSphere machine to it.

- 
4. Under the `Cloud.Network`, create a constraint that references the selection from the inputs.

```

resources:

ABCServer:
 type: Cloud.vSphere.Machine
 properties:
 name: abc-server
 ...
 networks:
 - network: '${resource["ABCNet"].id}'

ABCNet:
 type: Cloud.Network
 properties:
 name: abc-network
 ...
 constraints:
 - tag: '${input.net-tagging}'

```

5. Continue with your design, and deploy it as you normally would. At deployment, the interface prompts you to select the `test` or `prod` network.
6. When you need to make a day 2 change, go to **Resources > Deployments > Deployments**, and locate the deployment associated with the cloud template.
7. To the right of the deployment, click **Actions > Update**.
8. In the Update panel, the interface prompts you the same way, to select the `test` or `prod` network.
9. To change networks, make your selection, click **Next**, and click **Submit**.

## How to create an Automation Assembler resource action to vMotion a virtual machine

How to create a resource action to vMotion a virtual machine

After you deploy a cloud template, you can run day 2 actions that change the deployment. Automation Assembler includes many day 2 actions, but you might want to provide others. You can create custom resource actions and make them available to users as day 2 actions.

- Verify that you configured an Automation Orchestrator integration. See [Configure an integration in](#).
- Verify that the workflow that you are using for the day 2 action exists in Automation Orchestrator and runs successfully there.

The custom resource actions can be based on Automation Orchestrator workflows or extensibility actions. This example of a custom day 2 resource action is meant to introduce you to the creation process for Automation Orchestrator based resource actions.

1. Create a custom resource action that uses vMotion to move a vSphere virtual machine from one host to another.
  - a) In Automation Assembler, select **Design > Resource Actions**, and click **New Resource Action**.
  - b) Provide the following values.

Remember, except for the workflow names, these are sample values.

| Setting      | Sample Value                                                                      |
|--------------|-----------------------------------------------------------------------------------|
| Name         | vSphere_VM_vMotion<br>This is the name that appears in the resource actions list. |
| Display name | Move VM<br>This is the name that users see in the deployment actions menu.        |

- c) Click the **Activate** option to enable this action in the day 2 actions menu for resources that matches the resource type.
- d) Select the resource type and workflow that define the day 2 action.

| Setting       | Sample Value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Resource Type | Select the <b>Cloud.vSphere.Machine</b> resource type. This is the resource type that is deployed as a cloud template component, not necessarily what is in the cloud template. For example, you might have a cloud agnostic machine in your cloud template, but when it is deployed on a vCenter Server, the machine is <b>Cloud.vSphere.Machine</b> . Because the action applies to the deployed type, do not use cloud agnostic types when you define your resource actions.<br><br>In this example, vMotion only works for vSphere machines, but you might have other actions that you want to run on multiple resource types. You must create an action for each resource type. |
| Workflow      | Select the <b>Migrate virtual machine with vMotion</b> workflow.<br>If you have multiple Automation Orchestrator integrations, select the workflow on the integration instance you use to run these custom resource actions.                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

2. Create a binding for the Automation Orchestrator properties to the Automation Assembler schema properties. Automation Assembler day 2 actions support three types of bindings.

| Binding type        | Description                                                                                                                                                        |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| in request          | The default value binding type. When selected, the input property is displayed in the request form and its value must be provided by the user at the request time. |
| with binding action | This option is available only for reference type inputs such as:                                                                                                   |

*Table continued on next page*

*Continued from previous page*

| Binding type | Description                                                                                                                                                                                                                                                                                          |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|              | <ul style="list-style-type: none"> <li>• VC:VirtualMachine</li> <li>• VC:Folder</li> </ul> <p>The user selects an action that performs the binding. The selected action must return the same type as the input parameter. The correct property definition is \${properties.someProperty}.</p>        |
| direct       | <p>This option is available for input properties that use primitive data types. When selected, the property, with the suitable type, is mapped directly from the schema of the input property. The user selects the property from the schema tree. Properties with different types are inactive.</p> |

In this use case, the binding is an Automation Orchestrator action that makes the connection between Automation Orchestrator VC:VirtualMachine input type used in the workflow and the Automation Assembler Cloud.vSphere.Machine resource type. By setting up the binding, you make the day 2 action seamless for the user requesting the vMotion action on a vSphere VM machine. The system provides the name in the workflow so that the user does not have to do it.

- a) After selecting the **Migrate virtual machine with vMotion** workflow, navigate to the **Property Binding** pane.
  - b) Select the binding of the `vm` input property.
  - c) Under **Binding**, select **with binding action**.  
The `findVcVmByVcAndVmUuid` action is automatically selected. This action comes preconfigured with your Automation Orchestrator integration in Automation Assembler.
  - d) Click **Save**.
3. To save the changes to your day 2 action, click **Create**.
  4. To account for the other input parameters in the workflow, you can customize the request form that users see when they request the action.
    - a) From **Resource Actions**, select your recently created day 2 action.
    - b) Click **Edit Request Parameters**.

You can customize how the request page is presented to users.

| Default Field Name                                                                       | Appearance                                                                                                              | Values                                                                                    | Constraints    |
|------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------|----------------|
| Destination resource pool for the virtual machine. Default is the current resource pool. | <ul style="list-style-type: none"> <li>• Label = Target resource pool</li> <li>• Display type = Value Picker</li> </ul> |                                                                                           |                |
| Destination host to which to migrate the virtual machine                                 | <ul style="list-style-type: none"> <li>• Label = Target host</li> <li>• Display type = Value Picker</li> </ul>          |                                                                                           | Required = Yes |
| Priority of the migration task                                                           | Label = Priority of the task                                                                                            | Value options <ul style="list-style-type: none"> <li>• Value source = Constant</li> </ul> | Required = Yes |

*Table continued on next page*

*Continued from previous page*

| Default Field Name                                                                            | Appearance                                                          | Values                                                                                                      | Constraints |
|-----------------------------------------------------------------------------------------------|---------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------|-------------|
|                                                                                               |                                                                     | In the text box, enter a comma-separated list.<br>lowPriority Low,defaultPriority Default,highPriority High |             |
| (Optional) Only migrate the virtual machine if its power on state matches the specified state | Delete this text box. vMotion can move machines in any power state. |                                                                                                             |             |

- c) Click **Save**.
- 5. To limit when the action is available, you can configure the conditions.

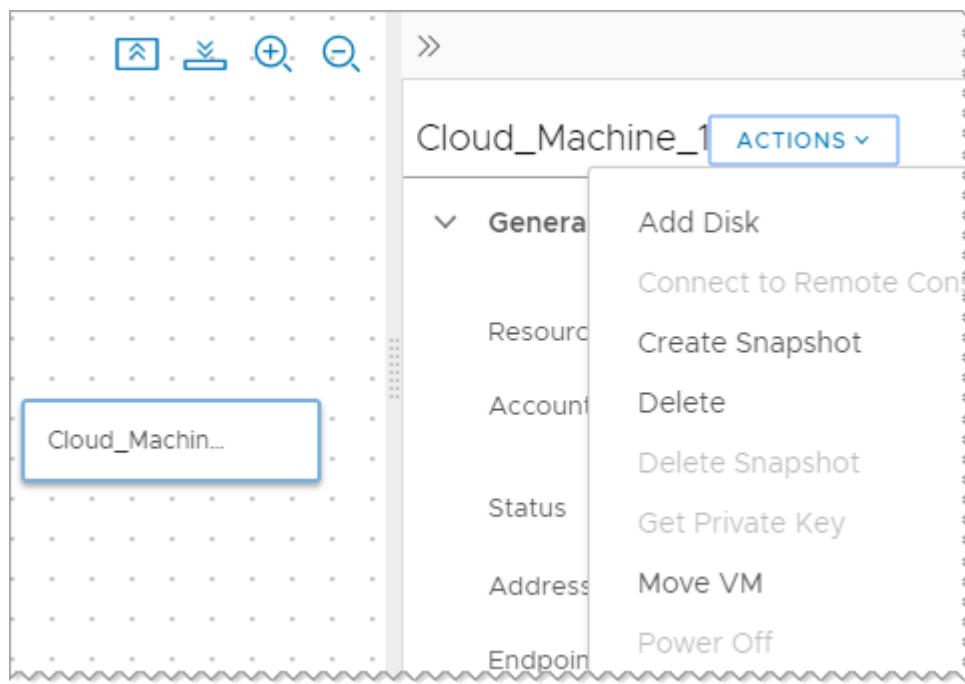

For example, you only want the vMotion action to be available when the machine has four or fewer CPUs.

- a) Toggle on **Requires condition**.
- b) Enter the condition.

| Key                                   | Operator | Value |
|---------------------------------------|----------|-------|
| <code> \${properties.cpuCount}</code> | lessThan | 4     |

If you need complex conditions, see [How to build advanced conditions for custom actions](#).

- c) Click **Update**.
- 6. Verify that the Move VM action is available for deployed machines that match the criteria.
  - a) Select **Deployments**.
  - b) Locate a deployment that includes a deployed machine that matches the defined criteria.
  - c) Open the deployment and select the machine.
  - d) Click actions in the right pane and verify that the `Move VM` action exists.

- e) Run the action.

### How to build advanced conditions for Automation Assembler custom actions

How to build advanced conditions for Automation Assembler custom actions

As an alternative to the simple conditions list in Automation Assembler, the advanced editor lets you assemble more complex criteria expressions to control when the action is available.

When creating a new resource action, select **Requires condition** and **Use advanced editor**. Then, enter the criteria expression that you want.

```

 {
 "matchExpression": [
 {
 "operator": "and",
 "clauses": [
 {
 "key": "properties.powerState",
 "operator": "eq",
 "value": "ON"
 },
 {
 "key": "syncStatus",
 "operator": "notEq",
 "value": "MISSING"
 }
]
 }
]
 }

```

The expression is a clause or list of clauses, each of which is in key-operator-value format. The preceding figure shows criteria where the target must be powered on and present.

## Clauses

| Clause | Description                                                                         | Example                                                                                                                                                                                                                                                                     |
|--------|-------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| and    | All subclauses need to be true for the expression result to be true.                | <p>Evaluate as true only when both properties.powerState is ON and syncStatus is not MISSING.</p> <pre>matchExpression:   - and:     - key: properties.powerState       operator: eq       value: ON     - key: syncStatus       operator: notEq       value: MISSING</pre> |
| or     | One or more of the subclauses need to be true for the expression result to be true. | <p>Evaluate as true whether properties.powerState is ON or OFF.</p> <pre>matchExpression:   - or:     - key: properties.powerState       operator: eq       value: ON     - key: properties.powerState       operator: eq       value: OFF</pre>                            |

## Operators

| Operator | Description                     | Example                                                                                                                                            |
|----------|---------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| eq       | Equal. Look for an exact match. | <p>Evaluate as true when properties.powerState is ON.</p> <pre>matchExpression:   - and:     - key: properties.powerState       operator: eq</pre> |

*Table continued on next page*

| Operator     | Description                                   | Example                                                                                                                                                                                                               |
|--------------|-----------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|              |                                               | <pre>matchExpression:   - and:     - key: storage.disks[0].iops       operator: lessThanEquals       value: 100</pre>                                                                                                 |
| matchesRegex | Use a regular expression to look for a match. | <p>Evaluate as true when the properties.zone is us-east-1a or us-east-1c.</p> <pre>matchExpression:   - and:     - key: properties.zone       operator: matchesRegex       value: (us-east-1)+(a c)       {1,2}</pre> |

## Examples

The following criteria expression evaluates as true when properties.tags includes a tag of key key1 and value value1.

The outer expression uses `hasAny` because `properties.tags` is an array, and you want to evaluate as true whenever `key1=value1` appears in any of the key-value pairs in the array.

In the inner expression, there are two clauses, one for the key field and one for the value field. The `properties.tags` array holds key-value tagging pairs, and you need to match both the key and value fields.

```
matchExpression:
 - key: properties.tags
 operator: hasAny
 value:
 matchExpression:
 - and:
 - key: key
 operator: eq
 value: key1
 - key: value
 operator: eq
 value: value1
```

The following criteria expression is similar to the previous example, but now evaluates as true whenever properties.tags includes either a tag of key1=value1 or key2=value2.

```

matchExpression:
 - or:
 - key: properties.tags
 operator: hasAny
 value:
 matchExpression:
 - and:
 - key: key
 operator: eq
 value: key1
 - key: value
 operator: eq
 value: value1
 - key: properties.tags
 operator: hasAny
 value:
 matchExpression:
 - and:
 - key: key
 operator: eq
 value: key2
 - key: value
 operator: eq
 value: value2

```

## **Virtual Machine reconciliation after vMotion migration**

After migrating a virtual machine through vSphere vMotion, an event is triggered which perform a reconciliation in VMware Aria Automation.

You can use vSphere vMotion to migrate your virtual machines without powering them off and as such avoiding having any downtime in your infrastructure. For more information on vSphere vMotion, go to [Migrating Virtual Machines with vSphere vMotion](#).

VMware Aria Automation supports the following migration scenarios:

- Migrating virtual machines in the vCenter instance.
- Migrating virtual machines across vCenter instances.

After initiating the migration from the vSphere Client, the data collection in VMware Aria Automation registers the migration as started and triggers an event to reconcile the migration changes. You can use the **Compute post migration reconcile status** event topic to subscribe to this event. For more information on the event topic, go to [Event topics provided with Automation Assembler](#).

After the migration finishes successfully, all the changes to the virtual machine are reconciled and can be viewed in the cloud template in which the virtual machine is added.

## **Requirements**

Before performing a vMotion migration, be aware of the following requirements:

- When performing a migration across vCenter instances, verify that both instances are added as cloud zones to the same project used in the cloud template.
- When performing a migration across vCenter instances, be aware that tags associated with the virtual machine in the source vCenter are not reconciled after migrating to the target vCenter.
- When performing a migration across vCenter instances, day 2 network reconfiguration and scaling out are not supported.
- Migration reconciliation for existing NSX-T networks is supported. However, this covers only the network itself. Additional NSX constructs such as on-demand networks, security groups, and load balancers are not reconciled.
- Verify that the virtual machine you want to migrate is not part of a cluster or is sharing resources with other virtual machines such as networks or load balancers.
- When migrating a virtual machine that uses a First Class Disk (FCD) there are certain limitations on the day 2 actions that can be performed on the virtual machine.

### **NOTE**

When migrating a virtual machine across vCenter instances, an equivalent disk is created in the target vCenter and disk can be either a normal disk or FCD. Regardless of the outcome, VMware Aria Automation continues to identify the newly created disk as a FCD after reconciliation.

| Migration type                    | Resize    | Resize Boot Disk | Resize Disk                                                                                                                                                | Add Disk       |
|-----------------------------------|-----------|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|
| Migrated in the same vCenter      | Supported | Supported        | Supported.                                                                                                                                                 | Supported      |
| Migrated across vCenter instances | Supported | Supported        | Supported. Resizes the FCD which is now associated with the new disk created in the target vCenter. The disk file is updated to point to the new location. | Not supported. |

## **Migration process and reconciliation**

1. Log in to the vSphere Client.
2. Select the virtual machine you want migrate.
3. Expand the **Actions** drop-down and select **Migrate**.
4. Select the relevant migration type for your use case.

### **NOTE**

To migrate a virtual machine across vCenter instances, select **Cross vCenter Server export**.

- Configure the remaining migration options by selecting a compute resource, storage, network, and vMotion priority.

**NOTE**

For migrations across vCenter instances, you must also provide the required details of the target vCenter.

- To begin the migration, click **Finish**.
- Log in to Automation Assembler.
- Navigate to **Resources > Deployments** and select the cloud template where your virtual machine is used.
- Select the virtual machine and expand the **Custom properties section** drop-down.
- The **migrationStatus** custom property displays the current status of the migration. The possible values of the property can be STARTED, SUCCESS, or FAILED, depending on the current progress and outcome of the migration.
- The **migrationMessage** custom property can display messages relevant to the migration. For successful migrations, this property is empty. If the migration encounters an error, this property displays a message associated with the specific error.
- After the migration finishes successfully, the changes to the virtual machine are now visible in the cloud template.

**NOTE**

For example, if you migrated the virtual machine to a new host, this change is now reflected in the **Compute host** property under the **General** drop-down.

## More Automation Assembler template examples

### More template examples

Cloud template code in Automation Assembler can be almost limitless in combination and application.

Often, an example of successful code is your best starting point for further development. When following an example, make substitutions in the template samples to apply your own settings in terms of resource types, values, and so on.

### Network, security group, and load balancer resource examples in Automation Assembler

#### Network, security, and load balancer resource examples

You can use networking, security, and load balancer resources and settings in Automation Assembler cloud templates.

For a summary of cloud template code options, see [VMware Aria Automation Resource Type Schema](#).

For related information, see:

- [More about network resources in VMware Aria Automation cloud templates](#)
- [More about security group and tag resources in VMware Aria Automation cloud templates](#)
- [More about load balancer resources in VMware Aria Automation cloud templates](#)

These examples illustrate network, security, and load balancer resources within basic cloud template designs.

### Networks

| Resource scenario                                                                                | Example cloud template design code                                                        |

## **More about network resources in VMware Aria Automation cloud templates**

### More about networks

As you create or edit your VMware Aria Automation cloud templates, use the most appropriate network resources for your objectives. Learn about the NSX and cloud-agnostic network options that are available in the cloud template.

Select one of the available network resource types based on machine and related conditions in your VMware Aria Automation cloud template.

### **Cloud agnostic network resource**

You add a cloud agnostic network by using the **Cloud Agnostic > Network** resource on the cloud template **Design** page. The resource displays in the cloud template code as a `Cloud.Network` resource type. The default resource displays as:

`Cloud_Network_1:`

```
type: Cloud.Network
properties:
 networkType: existing
```

Use a cloud agnostic network when you want to specify networking characteristics for a target machine type that is not, or might not, be connected to an NSX network.

The cloud agnostic network resource is available for these resource types:

- Cloud agnostic machine
- vSphere
- Google Cloud Platform (GCP)
- Amazon Web Services (AWS)
- Microsoft Azure
- VMware Cloud on AWS (VMC)

The cloud agnostic network resource is available for these network type (`networkType`) settings:

- public
- private

- outbound
- existing

### **vSphere network resource**

You add a vSphere network by using the **vSphere > Network** resource on the cloud template **Design** page. The resource displays in the cloud template code as a `Cloud.vSphere.Network` resource type. The default resource displays as:

```
Cloud_vSphere_Network_1:
 type: Cloud.vSphere.Network
 properties:
 networkType: existing
```

Use a vSphere network when you want to specify networking characteristics for a vSphere machine type (`Cloud.vSphere.Machine`).

The vSphere network resource is only available for a `Cloud.vSphere.Machine` machine type.

The vSphere resource is available for these network type (`networkType`) settings:

- public
- private
- existing

For examples, see [Using network settings in network profiles and cloud templates in VMware Aria Automation](#).

### **NSX network resource**

You add an NSX network by using the **NSX > Network** resource on the cloud template **Template** page. The resource displays in the cloud template code as a `Cloud.NSX.Network` resource type. The default resource displays as:

```
Cloud_NSX_Network_1:
 type: Cloud.NSX.Network
 properties:
 networkType: existing
```

Use an NSX network when you want to attach a network resource to one or more machines that have been associated to an NSX cloud account. The NSX network resource allows you to specify NSX networking characteristics for a vSphere machine resource that is associated to an NSX cloud account.

The `Cloud.NSX.Network` resource is available for these network type (`networkType`) settings:

- public
- private
- outbound
- existing
- routed - Routed networks are only available for NSX-V and NSX-T.

If you want multiple outbound or routed networks to share the same NSX-T Tier-1 router or NSX-V Edge Service Gateway (ESG), connect a single NSX gateway resource (`Cloud.NSX.Gateway`) to the connected networks in the template prior to initial deployment. If you add the gateway after deployment as a day 2 or iterative development operation, each network creates its own router.

You can use the NSX NAT resource in the template to support NAT and DNAT port forwarding rules.

Machine tags are defined in the cloud template and apply to the machine resource if it is deployed on vCenter. Machine tags are also applied to the NSX-T network if the machine resource is connected to an NSX-T network, including an NSX-T global network. NSX-T global networks are networks that are defined by the NSX-T global manager and apply to one or more NSX-T local managers. Note that machine tagging is different than machine NIC (network interface) tagging.

### **Cloud agnostic network resource with Azure, AWS, or GCP deployment intent**

Public cloud provider VMs can require specific cloud template property combinations that are not necessarily required in NSX or vSphere-based machine deployments. For examples of cloud template code that support some of these scenarios, see [Network, security group, and load balancer resource examples in Automation Assembler](#).

### **NSX gateway resource**

You can reuse or share a single NSX-T Tier-1 router or NSX-V Edge Service Gateway (ESG) within a single deployment by using a gateway resource (`Cloud.NSX.Gateway`) in the cloud template. The gateway resource represents the Tier-1 or ESG and can be connected to multiple networks in the deployment. The gateway resource can be used with outbound or routed networks only.

The `Cloud.NSX.Gateway` resource allows you to share the NSX-T Tier-1 router or NSX-V Edge Service Gateway (ESG) among connected outbound or routed networks in a deployment.

The gateway is often attached to a single outbound or routed network. However, if the gateway is attached to multiple networks, the networks must be of the same type, for example all outbound or all routed. The gateway can be connected to multiple machines or load balancers that are connected to the same outbound or routed networks. The gateway must be connected to a load balancer on the shared on-demand network so that it can reuse the NSX-T Tier-1 router or NSX-V Edge Service Gateway (ESG) created by the gateway.

To allow multiple outbound or routed networks to share the same T1 router or Edge, connect a single `Cloud.NSX.Gateway` gateway resource to all the networks initially. All the intended networks and the single gateway must be connected together before you deploy the cloud template, otherwise each network creates its own router.

For an NSX network that contains an associated compute gateway resource, the gateway settings are applied to all associated networks in the deployment. A single NSX-T Tier-1 logical router is created for each deployment and shared by all on-demand networks and load balancers in the deployment. A single NSX-V Edge is created for each deployment and shared by all the on-demand networks and load balancers in the deployment.

You can attach the gateway resource to a network as an iterative deployment update. However, doing so does not create a Tier-1 or Edge router - the initial network deployment creates the router.

For NSX-T networks that do not use an associated gateway resource, multiple on-demand networks in the cloud template continue to create multiple Tier-1 logical routers in the deployment.

If the gateway contains NAT rules, you can reconfigure or delete the NAT or DNAT rules for the Tier 1 router or Edge router. If the gateway is initially deployed with no NAT rules, it has no available day 2 actions.

### **NSX NAT resource**

The `Cloud.NSX.NAT` resource allows DNAT rules and port forwarding to be attached to all the connected outbound networks by way of the gateway resource. You can attach a NAT resource to a gateway resource for which the DNAT rules need to be configured.

**NOTE**

The `Cloud.NSX.Gateway` resource was originally available for DNAT rules. However, use of the `Cloud.NSX.Gateway` as a means of defining DNAT rules and port forwarding has been deprecated. It does remain available for backward compatibility. Use the `Cloud.NSX.NAT` cloud template resource for DNAT rules and port forwarding. A warning appears in the cloud template if you attempt to use the `Cloud.NSX.Gateway` resource type with NAT rule specifications.

The `Cloud.NSX.NAT` resource supports DNAT rules and port forwarding when connected to an outbound NSX-V or NSX-T network.

The NAT rules setting in the resource is `natRules:`. You can attach the NAT resource to the gateway resource to configure the `natRules:` entries on the gateway. DNAT rules that are specified in the resource use the associated machines or load balancers as their target.

You can reconfigure a machine NIC or compute gateway in an existing deployment to modify its `natRules:` settings by adding, reordering, editing or deleting DNAT port forwarding rules. You cannot use DNAT rules with clustered machines. You can specify DNAT rules for individual machines within the cluster as part of a day 2 operation.

**VLAN segments and private NSX-T networks**

You can specify VLAN segments for private NSX on-demand network when the network segments are used with a Policy API-type of NSX-T cloud account.

**External IPAM integration properties for Infoblox**

For information about cloud template properties that are available for use with your Infoblox external IPAM integrations, see [Using Infoblox-specific properties and extensible attributes for IPAM integrations in VMware Aria Automation cloud templates](#).

**Caveats for using a static IP assignment in a cloud template**

You can use a static IP assignment in a VMware Aria Automation cloud template only when by using VMware Aria Automation IPAM, meaning IPAM that is either the VMware Aria Automation-supplied *internal* IPAM or IPAM derived from an *external* provider plug-in that has been created by using the VMware Aria Automation IPAM SDK - for example one of the Infoblox plug-ins that are available for download from the [VMware Marketplace](#). Using a static IP assignment (`assignment:static`) is not supported within a cloud template when using a **Network Configure** event topic (which is used by either an Automation Assembler extensibility (ABX) action or a VMware Aria Automation Orchestrator workflow). Unsupported static IP assignments cause deployment failure.

For an example of a static IP assignment in a cloud template, see [Network, security group, and load balancer resource examples in Automation Assembler](#).

**Address value in General section of deployed cloud template**

When examining a deployed cloud template, the **Address** value in the **General** section of the template is the primary IP address of the machine. The primary address is often the public or otherwise accessible machine address. For vSphere deployments, the primary IP address is calculated by VMware Aria Automation. All IP addresses for all NICs, including their public, private, IPv6, static, and dynamic properties, are considered and ranked to determine the primary IP address. For non- vSphere deployments, the primary IP address of the machine is calculated by each cloud vendor's ranking system.

## **Available day 2 operations**

For a list of common day 2 operations that are available for cloud template and deployment resources, see [What actions can I run on Automation Assembler deployments or supported resources](#).

For an example of how to move from one network to another, see [How to move a deployed machine to another network](#).

## **Learn more**

For related information and examples that illustrate sample network resources and settings, see [Network, security group, and load balancer resource examples in Automation Assembler](#).

For information about defining network resources, see [Network resources in VMware Aria Automation](#).

For information about defining network profiles, see [Learn more about network profiles in VMware Aria Automation](#).

## **More about security group and tag resources in VMware Aria Automation cloud templates**

More about security groups and security tags

As you create or edit your VMware Aria Automation cloud templates, use the most appropriate security resource options to meet your objectives.

### **Cloud agnostic security group resource**

You add a security group resource by using the **Cloud Agnostic > Security Group** resource on the **Template** page. The resource displays in the cloud template code as a `Cloud.SecurityGroup` resource type. The default resource displays as:

```
Cloud_SecurityGroup_1:
 type: Cloud.SecurityGroup
 properties:
 constraints: []
 securityGroupType: existing
```

You specify a security group resource in a cloud template design as either existing (`securityGroupType: existing`) or on-demand (`securityGroupType: new`).

You can add an existing security group to your cloud template or you can use an existing security group that has been added to a network profile.

For NSX-V and NSX-T, as well as NSX-T with the policy manager switch enabled in combination with VMware Cloud on AWS, you can add an existing security group or define a new security group as you design or modify your cloud template. On-demand security groups are supported for NSX-T and NSX-V, and VMware Cloud on AWS when used with NSX-T policy manager.

For all cloud account types except Microsoft Azure, you can associate one or more security groups to a machine NIC. A Microsoft Azure virtual machine NIC (`machineName`) can only be associated to one security group.

By default, the security group property `securityGroupType` is set to `existing`. To create an on-demand security group, enter `new` for the `securityGroupType` property. To specify firewall rules for an on-demand security group, use the `rules` property in the `Cloud.SecurityGroup` section of the security group resource.

## **Existing security groups**

Existing security groups are created in a source cloud account resource such as NSX-T or Amazon Web Services. They are data collected by VMware Aria Automation from the source. You can select an existing security group from a list of available resources as part of a VMware Aria Automation network profile. In a cloud template design, you can specify an existing security group either inherently by its membership in a specified network profile or specifically by name using the `securityGroupType: existing` setting in a security group resource. If you add a security group to a network profile, add at least one capability tag to the network profile. On-demand security group resources require a constraint tag when used in a cloud template design.

You can associate a security group resource in your cloud template design to one or more machine resources.

### **NOTE**

If you intend to use a machine resource in your cloud template design to provision to a Microsoft Azure virtual machine NIC (`machineName`), you should only associate the machine resource to a single security group.

## **On-demand security groups**

You can define on-demand security groups as you define or modify a cloud template design by using the `securityGroupType: new` setting in the security group resource code.

You can use an on-demand security group for NSX-V and NSX-T, as well as Amazon Web Services when used with NSX-T Policy type, to apply a specific set of firewall rules to a networked machine resource or set of grouped resources. Each security group can contain multiple named firewall rules. You can use an on-demand security group to specify services or protocols and ports. Note that you can specify either a service or a protocol but not both. You can specify a port in addition to a protocol. You cannot specify a port if you specify a service. If the rule contains neither a service or a protocol, the default service value is Any.

You can also specify IP addresses and IP ranges in firewall rules. Some firewall rule examples are shown in [Network, security group, and load balancer resource examples in Automation Assembler](#).

When you create firewall rules in an NSX-V or NSX-T on-demand security group, the default allows the specified network traffic. The default also allows other network traffic. To control network traffic, you must specify an access type for each rule. The rule access types are:

- Allow (default) - allows the network traffic that is specified in this firewall rule.
- Deny - blocks the network traffic that is specified in this firewall rule. Actively tells the client that the connection is rejected.
- Drop - rejects the network traffic that is specified in this firewall rule. Silently drops the packet as if the listener is not online.

For an example design that uses an `access: Allow` and an `access: Deny` firewall rule, see [Network, security group, and load balancer resource examples in Automation Assembler](#).

### **NOTE**

A cloud administrator can create a cloud template design that contains only an NSX on-demand security group and can deploy that design to create a reusable existing security group resource that members of the organization can add to network profiles and cloud template designs as an existing security group.

Firewall rules support either IPv4 or IPv6 format CIDR values for source and destination IP addresses. For an example design that uses IPv6 CIDR values in a firewall rule, see [Network, security group, and load balancer resource examples in Automation Assembler](#).

## **Using constraints for security group placement**

You can control where security groups are provisioned by using constraint tags, as shown in the following example:

```

Cloud_SecurityGroup_4:
 type: Cloud.SecurityGroup
 properties:
 securityGroupType: new
 constraints:
 - tag: na

```

In this example, an on-demand security group is provisioned in endpoints (local NSX Manager cloud accounts) that have the `na` capability tag.

- If multiple endpoints satisfy the constraint, the endpoint whose cloud zone has the highest provisioning priority is selected.
- If no endpoint satisfies the constraint, the deployment fails.
- If the security group is attached to another resource, the respective endpoint of that resource must satisfy the security group constraints in addition to any placement constraints on the resource itself.

### **On-demand and existing security groups for VMware Cloud on AWS**

You can define an on-demand security group for a VMware Cloud on AWS machine in a cloud template by using the `securityGroupType: new` setting in the security group resource code.

A sample code snippet for an on-demand security group is shown below:

resources:

```

Cloud_SecurityGroup_1:
 type: Cloud.SecurityGroup
 properties:
 name: vmc-odsg
 securityGroupType: new
 rules:
 - name: datapath
 direction: inbound
 protocol: TCP
 ports: 5011
 access: Allow
 source: any

```

You can also define an existing security group for a networked VMware Cloud on AWS machine and optionally include constraint tagging, as shown in the following examples:

```

Cloud_SecurityGroup_2:
 type: Cloud.SecurityGroup
 properties:

```

```

constraints: [xyz]
securityGroupType: existing

Cloud_SecurityGroup_3:
 type: Cloud.SecurityGroup
 properties:
 securityGroupType: existing
 constraints:
 - tag: xyz

```

Iterative cloud template development is supported.

- If a security group is associated with one or more machines in the deployment, a delete action displays a message stating that the security group cannot be deleted.
- If a security group is not associated with any machine in the deployment, a delete action displays a message stating that the security group will be deleted from this deployment and the action cannot be undone. An existing security group is deleted from the cloud template, while an on-demand security group is destroyed.

## **Using NSX-V security tags and NSX-T VM tags**

You can see and use NSX-V security tags and NSX-T and NSX-T with policy VM tags from managed resources in VMware Aria Automation cloud templates.

NSX-V and NSX-T security tags are supported for use with vSphere. NSX-T security tags are also supported for use with VMware Cloud on AWS.

### **NOTE**

As with VMs deployed to vSphere, you can configure machine tags for a VM to be deployed on VMware Cloud on AWS. You can also update the machine tag after initial deployment. These machine tags allow VMware Aria Automation to dynamically assign a VM to an appropriate NSX-T security group during deployment.

You can specify NSX-V security tags by using the key: `nsxSecurityTag` and a tag value in the compute resource in the cloud template, as shown in the following example, provided that the machine is connected to an NSX-V network:

tags:

```

- key: nsxSecurityTag
- value: security_tag_1
- key: nsxSecurityTag
- value: security_tag_2

```

The specified value must correspond to an NSX-V security tag. If there are no security tags in NSX-V that match the specified `nsxSecurityTag` key value, the deployment will fail.

### **NOTE**

NSX-V security tagging requires that the machine is connected to an NSX-V network. If the machine is connected to a vSphere network, the NSX-V security tagging is ignored. In either case, the vSphere machine is also tagged.

NSX-T does not have a separate security tag. Any tag specified on the compute resource in the cloud template results in the deployed VM being associated with all tags that are specified in NSX-T. For NSX-T, including NSX-T with policy, VM tags are also expressed as a key value pair in the cloud template. The `key` setting equates to the `scope` setting in NSX-T and the `value` setting equates to the `Tag Name` specified in NSX-T.

Note that if you used the VMware Aria Automation V2T migration assistant to migrate your cloud accounts from NSX-V to NSX-T, including NSX-T with Policy, the migration assistant creates a `nsxSecurityTag` key value pair. In this scenario, or if the `nsxSecurityTag` is for any reason explicitly specified in a cloud template for use with NSX-T, including NSX-T with policy, the deployment creates a VM tag with an empty scope setting with a tag name that matches the `value` specified. When you view such tags in NSX-T, the Scope column will be empty.

To avoid confusion, do not use a `nsxSecurityTag` key pairs when for NSX-T. If you specify an `nsxSecurityTag` key value pair for use with NSX-T, including NSX-T with policy, the deployment creates a VM tag with an empty scope setting with a tag name that matches the `value` specified. When you view such tags in NSX-T, the scope column will be empty.

### **Using app isolation policies in on-demand security group firewall rules**

You can use an app isolation policy to only allow internal traffic between the resources that are provisioned by the cloud template. With app isolation, the machines provisioned by the cloud template can communicate with each other but cannot connect outside the firewall. You can create an app isolation policy in the network profile. You can also specify app isolation in a cloud template design by using an on-demand security group with a deny firewall rule or a private or outbound network.

An app isolation policy is created with a lower precedence. If you apply multiple policies, the policies with the higher weight will take precedence.

When you create an application isolation policy, an auto-generated policy name is generated. The policy is also made available for reuse in other cloud template designs and iterations that are specific to the associated resource endpoint and project. The app isolation policy name is not visible in the cloud template but it is visible as a custom property on the project page (**Infrastructure > Administration > Projects**) after the cloud template design is deployed.

For the same associated endpoint in a project, any deployment that requires an on-demand security group for app isolation can use the same app isolation policy. Once the policy is created, it is not deleted. When you specify an app isolation policy, VMware Aria Automation searches for the policy within the project and relative to the associated endpoint - If it finds the policy it reuses it, if it does not find the policy, it creates it. The app isolation policy name is only visible after its initial deployment in the project's custom properties listing.

### **Using security groups in iterative cloud template development**

When changing security group constraints during iterative development, where the security group is not associated to a machine in the cloud template, the security group updates in the iteration as specified. However, when the security group is already associated to a machine, redeployment fails. You must detach existing security groups and/or `securityGroupType` resource properties from associated machines during iterative cloud template development and then re-associate between each redeployment. The needed workflow is as follows, assuming that you have initially deployed the cloud template.

1. In the Automation Assembler template designer, detach the security group from all its associated machines in the cloud template.
2. Redeploy the template by clicking **Update an existing deployment**.
3. Remove the existing security group constraint tags and/or `securityGroupType` properties in the template.
4. Add new security group constraint tags and/or `securityGroupType` properties in the template.
5. Associate the new security group constraint tags and/or `securityGroupType` property instances to the machines in the template.
6. Redeploy the template by clicking **Update an existing deployment**.

## **Available day 2 operations**

For a list of common day 2 operations that are available for cloud template and deployment resources, see [What actions can I run on Automation Assembler deployments or supported resources](#).

### **Learn more**

For information about using a security group for network isolation, see [Security resources in VMware Aria Automation](#).

For information about using security groups in network profiles, see [Learn more about network profiles in VMware Aria Automation](#) and [Using security group settings in network profiles and cloud template designs in VMware Aria Automation](#).

For examples of using security groups in cloud templates, see [Network, security group, and load balancer resource examples in Automation Assembler](#).

## **More about load balancer resources in VMware Aria Automation cloud templates**

### More about load balancers

As you create or edit your VMware Aria Automation cloud templates, use the most appropriate load balancer resources for your objectives.

You can use NSX and cloud-agnostic load balancer resources in a cloud template to control load balancing in a deployment.

The cloud-agnostic load balancer can be deployed across multiple clouds. A cloud-specific load balancer can specify advanced settings and features that are available only to a specific cloud/topology. Cloud-specific properties are available in the NSX load balancer (Cloud.NSX.LoadBalancer) resource type. If you add these properties on a cloud-agnostic load balancer (Cloud.LoadBalancer), they are ignored if, for example, an Amazon Web Services or Microsoft Azure load balancer is provisioned, but are respected if an NSX load balancer is provisioned. Choose one of the available load balancer resource types based on conditions in your VMware Aria Automation cloud template.

You cannot connect a load balancer resource directly to a security group resource in the design canvas.

### **Cloud agnostic load balancer resource**

Use a cloud agnostic load balancer when you want to specify networking characteristics for any type of target machine.

You add a cloud agnostic load balancer by using the **Cloud Agnostic > Load Balancer** resource on the cloud template design page. The resource displays in the cloud template code as a `Cloud.LoadBalancer` resource type. The default resource displays as:

```
Cloud_LoadBalancer_1: type: Cloud.LoadBalancer
properties:
routes: []
network: ''
instances: []
internetFacing: false
```

### **NSX load balancer resource**

Use an NSX load balancer when your cloud template contains characteristics that are specific to NSX (either Policy API or Manager API methods). You can attach one or more load balancers to an NSX network or to machines that are associated to an NSX network.

You add an NSX load balancer by using the **NSX › Load Balancer** resource. The resource displays in the cloud template code as a `Cloud.NSX.LoadBalancer` resource type. The default resource displays as:

```
Cloud_NSX_LoadBalancer_1: type: Cloud.NSX.LoadBalancer
```

properties:

routes: []

network: ''

instances: []

### **Load balancer options in cloud template code**

Adding one or more load balancer resources to your cloud template allows you to specify the following settings. Some examples are available at [Network, security group, and load balancer resource examples in Automation Assembler](#).

The HTTP protocol is supported for all on-demand load balancers.

The HTTPS protocol is supported only for on-demand load balancers that are associated to an NSX cloud account whose NSX mode is set to **Policy**. NSX cloud accounts whose NSX mode is set to **Manager** cannot use the HTTPS protocol.

- Machine specification

You can specify named machine resources to participate in a load balancing pool. Alternatively you can specify that a specific machine NIC participate in the load balancer pool.

This option is available for the **NSX** load balancer resource (`Cloud.NSX.LoadBalancer`) only.

- `resource.Cloud_Machine_1.id`

Specifies that the load balancer include the machine identified in the cloud template code as `Cloud_Machine_1`.

- `resource.Cloud_Machine_2.networks[2].id`

Specifies that the load balancer only include the machine identified in the cloud template code as `Cloud_Machine_2` when it is deployed to machine NIC `Cloud_Machine_2.networks[2]`.

- Logging level

The logging level value specifies a severity level for the error log. The options are NONE, EMERGENCY, ALERT, CRITICAL, ERROR, WARNING, INFO, DEBUG, and NOTICE. The logging level value applies to all load balancers in the cloud template. This option is specific to NSX. For load balancers that have a parent, the parent logging level setting overrides any logging level setting in its children.

For related information, see topics such as [Add Load Balancers](#) in the NSX product documentation.

- Type

Use a load balancer type to specify a scaling size. The default is small. This option is specific to NSX. For load balancers that have a parent, the parent type setting overrides any type setting in its children.

- Small

Correlates to compact in NSX-V and small in NSX-T.

- Medium

Correlates to large in NSX-V and medium in NSX-T.

- Large

Correlates to quad-large in NSX-V and large in NSX-T.

- Extra Large

Correlates to xlarge in NSX-V and large in NSX-T.

For related information, see topics such as *Scaling Load Balancer Resources* in the NSX product documentation.

This option is available for the **NSX** load balancer resource (`Cloud.NSX.LoadBalancer`).

- **Algorithm (server pool)**

Use an algorithm balancing method to control how incoming connections are distributed among the server pool members. The algorithm can be used on a server pool or directly on a server. All load balancing algorithms skip servers that meet any of the following conditions:

- The Admin state is set to DISABLED.
- The Admin state is set to GRACEFUL\_DISABLE and there is no matching persistence entry.
- The active or passive health check state is DOWN.
- The connection limit for the maximum server pool concurrent connections is reached.

This option is specific to NSX.

- **IP\_HASH**

Selects a server based on a hash of the source IP address and the total weight of all the running servers.

Correlates to IP-HASH in NSX.

- **LEAST\_CONNECTION**

Distributes client requests to multiple servers based on the number of connections already on the server. New connections are sent to the server with the fewest connections. Ignores the server pool member weights even if they are configured.

Correlates to LEASTCONN in NSX-V and LEAST\_CONNECTION in NSX-T.

- **ROUND\_ROBIN**

Incoming client requests are cycled through a list of available servers capable of handling the request. Ignores the server pool member weights even if they are configured. Default.

Correlates to ROUND\_ROBIN in NSX.

- **WEIGHTED\_LEAST\_CONNECTION**

Each server is assigned a weight value that signifies how that server performs relative to other servers in the pool. The value determines how many client requests are sent to a server compared to other servers in the pool. This load balancing algorithm focuses on using the weight value to distribute the load among the available server resources fairly. By default, the weight value is 1 if the value is not configured and slow start is enabled.

Correlates to WEIGHTED\_LEAST\_CONNECTION in NSX-T. There is no correlation in NSX-V.

- **WEIGHTED\_ROUND\_ROBIN**

Each server is assigned a weight value that signifies how that server performs relative to other servers in the pool. The value determines how many client requests are sent to a server compared to other servers in the pool. This load balancing algorithm focuses on fairly distributing the load among the available server resources.

Correlates to WEIGHTED\_ROUND\_ROBIN in NSX-T. There is no correlation in NSX-V.

- **URI**

The left part of the URI is hashed and divided by the total weight of the running servers. The result designates which server receives the request. This ensures that a URI is always directed to the same server if no server goes up or down. The URI algorithm parameter has two options `uriLength=<len>` and `uriDepth=<dep>`. The length parameter range should be  $1 \leq len \leq 256$ . The depth parameter range should be  $1 \leq dep \leq 10$ .

Length and depth parameters are followed by a positive integer number. These options can balance servers based on the beginning of the URI only. The length parameter indicates that the algorithm should only consider the defined characters at the beginning of the URI to compute the hash. The depth parameter indicates the maximum directory depth to be used to compute the hash. One level is counted for each slash in the request. If both parameters are specified, the evaluation stops when either is reached.

Correlates to URI in NSX-V. There is no correlation in NSX-T.

- **HTTPHEADER**

HTTP header name is looked up in each HTTP request. The header name in parentheses is not case-sensitive. If the header is absent or does not contain any value, the round robin algorithm is applied. The **HTTPHEADER** algorithm parameter has one option `headerName=<name>`.

Correlates to **HTTPHEADER** in NSX-V. There is no correlation in NSX-T.

- **URL**

URL parameter specified in the argument is looked up in the query string of each HTTP GET request. If the parameter is followed by an equal sign = and a value, then the value is hashed and divided by the total weight of the running servers. The result designates which server receives the request. This process is used to track user identifiers in requests and ensure that a same user ID is always sent to the same server as long as no server goes up or down. If no value or parameter is found, then a round robin algorithm is applied. The URL algorithm parameter has one option `urlParam=<url>`.

Correlates to **URL** in NSX-V. There is no correlation in NSX-T.

For related information, see topics such as *Add a Server Pool for Load Balancing* in the NSX product documentation.

- **Health monitor**

Use the health monitor options to test whether a server is available. Active health monitoring for HTTP, ICMP, TCP, and UDP protocols is supported. Passive health monitoring is available for NSX-T only.

This option is specific to NSX.

- **httpMethod**

HTTP method to use to detect server status for the health check request. Methods are GET, HOST, OPTIONS, HEAD, or PUT.

- **requestBody**

Health check request body content. Used, and required, by HTTP, TCP, and UDP protocols.

- **responseBody**

Health check expected response body content. If the received string matches this response body, the server is considered healthy. Used, and required, by HTTP, TCP, and UDP protocols.

**NOTE**

If you use the UDP monitor protocol, the `UDP Data Sent` and `UDP Data Expected` parameters are required. The `requestBody` and `responseBody` properties map to these parameters.

This option is available for the NSX load balancer resource (`Cloud.NSX.LoadBalancer`).

For related information, see topics such as *Configure an Active Health Monitor* in the NSX product documentation.

- **Health check**

Use health check options to specify how the load balancer performs its health checks.

This option is only available for the NSX load balancer resource (`Cloud.NSX.LoadBalancer`).

For a sample of available health check settings, see [Network, security group, and load balancer resource examples in Automation Assembler](#).

## **NSX network types and load balancer options**

Load balancer options depend on the network that the load balancer resource is associated to in the cloud template. You can configure a load balancer relative to the network type and network conditions.

- **On-demand network**

If the load balancer components are attached to an on-demand network, a new Tier-1 router is created and attached to the Tier-0 router specified in the network profile. The load balancer is then attached to the Tier-1 router. The Tier-1

router VIP advertisement is enabled if the VIP is on an existing network. If an on-demand network is configured for DHCP, the on-demand network and load balancer share the Tier-1 router.

- Existing network

If the load balancer is attached to an existing network, the load balancer is created with the Tier-1 router of the existing network. A new load balancer is created if there is no load balancer attached to the Tier-1 router. If the load balancer already exists, new virtual servers are attached to it. If the existing network is not attached to a Tier-1 router, a new Tier-1 router is created and attached to a Tier-0 router defined in the network profile, the Tier-1 router VIP advertisement is not enabled.

VMware Aria Automation does not support an NSX-T two-arm load balancer (inline load balancer) on two different existing networks. Note that in a two-arm load balancer scenario, the VIP uplink is on an existing network while the pool member machines are connected to an on-demand network. To specify load balancing when using an existing network, you must configure a one-arm load balancer where the same existing network is used for the load balancer VIP and the pool member machines. However, if you are using a load balancer that you've selected in the network profile, you can load balance between machines on two different existing networks if there is connectivity between the two existing networks.

- Network isolation defined in the network profile

For network types of `outbound` or `private`, you can specify network isolation settings in a network profile to emulate a new security group. Because machines are attached to an existing network and isolation settings are defined in the profile, this option is similar to a load balancer created on an existing network. The difference is that to enable the data path, the Tier-1 uplink port IP is added to the isolation security group.

You can specify load balancer settings for NSX-associated networks by using an NSX load balancer resource in the cloud template design.

To learn more, see VMware blog post [vRA Cloud Assembly Load Balancer with NSX-T Deep Dive](#).

### **NSX-T load-balancer profile persistence**

VMware Aria Automation cloud templates and deployments support NSX-T load balancer persistence profile options for `SOURCE_IP` and `COOKIE` settings. For information about how to configure these settings in NSX-T so that they can be consumed by VMware Aria Automation cloud templates and deployments, see *Add a Persistence Profile* in NSX-T documentation.

### **Reconfiguring logging level or type settings when multiple load balancers share an NSX-T Tier 1 or NSX-V Edge**

When using a cloud template that contains multiple load balancers which share a Tier-1 router in the NSX-T endpoint or an Edge router in the NSX-V endpoint, reconfiguring the logging level or type settings in one of the load balancer resources does not update the settings for the other load balancers. Mismatched settings cause inconsistencies in NSX. To avoid inconsistencies when reconfiguring these logging level and/or type settings, use the same reconfiguration values for all the load balancer resources in the cloud template which share a Tier 1 or Edge in their associated NSX endpoint.

### **Available day 2 operations**

When you scale in or scale out a deployment that contains a load balancer, the load balancer is configured to include newly added machines or to stop load balancing machines that are targeted for tear down.

For a list of common day 2 operations that are available for cloud templates and deployments, see [What actions can I run on Automation Assembler deployments or supported resources](#).

### **Learn more**

For information about defining load balancer settings in a network profile, see [Learn more about network profiles in VMware Aria Automation](#).

For examples of template designs that include load balancers, see [Network, security group, and load balancer resource examples in Automation Assembler](#).

For information about VMware Avi Load Balancer resources, see [Using VMware Avi Load Balancer resources](#).

## Using VMware Avi Load Balancer resources

VMware Aria Automation supports using VMware Avi Load Balancer resources to build your infrastructure. You can also use allocation helpers with Avi Load Balancer resources in your templates.

You provision Avi Load Balancer resources using Automation Assembler templates, and you deploy those templates in the typical manner using the Automation Assembler**Design** tab functionality. After you deploy a template, you can check your Avi Load Balancer Controller to confirm that the resource was provisioned successfully.

### Avi Load Balancer resources

For more information about Avi Load Balancer resources and a list of exec and states modules, see the [Avi Load Balancer plug-in documentation](#).

The Avi Load Balancer Controller is fully integrated with the Swagger UI. You can explore API specifications and download them from the Avi Load Balancer Controller to use with Swagger tools. See [OpenAPI \(Swagger 2.0\) Specification Integration](#).

The following Avi Load Balancer resources are available in VMware Aria Automation.

| Category                                                                                                                                                             | Resource                        | Description                                                                                                                                                                                                                                                  |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Applications</b><br>Applications contain three major components, which are required for a standard application deployment – virtual services, VS VIPs, and pools. | Virtual Service                 | A virtual service is the front-end listener that defines the load balancer's characteristics and TCP/ UDP port(s). The virtual service is the primary object of the three major application components and contains a reference to both a VS VIP and a pool. |
|                                                                                                                                                                      | VS VIP                          | A VS VIP is the IP address and FQDN assigned to a virtual service. In advanced use cases, multiple virtual services can share an IP address.                                                                                                                 |
|                                                                                                                                                                      | Pool                            | A pool contains the application servers that are load-balanced. Pools also contain references to objects like application persistence profiles and back-end server health monitors.                                                                          |
| <b>Profiles</b><br>You can configure commonly used profiles within Avi Load Balancer.                                                                                | Application Persistence Profile | A persistence profile defines the settings that force a client to stay connected to the same server for a specified duration of time. Use a unique identifier for a client to ensure the client connects to the same back-end server.                        |
|                                                                                                                                                                      | Application Profile             | Application profiles set the behavior of the virtual service at an application-layer level. Application profiles control                                                                                                                                     |

| <b>Category</b> | <b>Resource</b> | <b>Description</b>                                                                                                                                                                                                                                                                                                                                               |
|-----------------|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                 |                 | things like X-Forwarded headers, HTTP security settings, caching/compression, and DDoS parameters.                                                                                                                                                                                                                                                               |
|                 | Network Profile | TCP/UDP (network) profiles define characteristics of the network protocol used by the virtual service listener. Network profiles are also used to configure a virtual service as passthrough or proxied.                                                                                                                                                         |
|                 | Health Monitor  | Health monitors are used to measure the health of the back-end servers by sending synthetic requests to an application, checking the availability via Ping or a simple TCP/UDP port check, and passively by monitoring the client experience with the server. Servers that fail the health checks are marked down, and traffic is no longer sent to that server. |

### **Avi Load Balancer resource constraints**

- On-demand networks are not supported. Only existing networks are supported. Two-arm load balancers also support existing networks only.
- Existing networks must be available in vCenter. Virtual networks created in Avi Load Balancer that are not visible to vCenter are not supported.
- Reference binding by name is used for networks. If more than one network with same name exists, then Avi Load Balancer Controller picks the first one that gets enumerated. To work around this, use the `id` for reference binding in the template.
- Only existing security groups are supported. You can deploy virtual machines that use an existing security group and are added to the pool. Machines can either be explicitly added to the pool, or they can be added dynamically by specifying the security group that the machines belong to.
- Similarly to how NSX-T load balancers behave, running the Delete day 2 operation on machines from the deployment does not update the Avi Load Balancer pool.
- The virtual IP address of the virtual service is allocated either statically or by Avi Load Balancer IPAM, not by VMware Aria Automation IPAM.
- Testing the provisioning of Avi Load Balancer resources is limited. VMware Aria Automation only checks that the resource is provisioned.
- To keep your Avi Load Balancer resource names unique, you can add the deploymentID to the resource name.

### **Using the cloud zone allocation helper with Avi Load Balancer resources**

Avi Load Balancer supports multiple cloud accounts. When designing a template, you can select the cloud account based on name. Alternatively, you can select a cloud account based on tags, in which case you must use a cloud zone allocation helper. The cloud zone allocation helper allocates a cloud zone for provisioning based on cloud account type and constraint tags.

To use the allocation helper with any Avi Load Balancer resources, your Avi Load Balancer cloud zone must be added to a project. See [Create a VMware Avi Load Balancer cloud account](#).

The following sample template shows how you might use the cloud zone allocation helper. For Avi Load Balancer resources, the cloud account type is `avilb`.

```

formatVersion: 1
inputs: {}
resources:
 Idem_AVILB_APPLICATIONS_POOL_1:
 type: Idem.AVILB.APPLICATIONS.POOL
 properties:
 name: dev-pool
 account: ${resource.Allocations_CloudZone_1.selectedCloudAccount.name}
 tier1_lr: DONT-DELETE-AVI-Admin-E2E
 vrf_ref: T1-DONT-DELETE-AVI-Admin-E2E
 lb_algorithm: LB_ALGORITHM_ROUND_ROBIN
 health_monitor_refs:
 - System-Ping
 nsx_securitygroup:
 - avinsxgroup
 Allocations_CloudZone_1:
 type: Allocations.CloudZone
 properties:
 accountType: avilb
 constraints:
 - tag: dev

```

## Provisioning Avi Load Balancer Load Balancing as a Service

### LBaaS template examples

As a cloud administrator, you can leverage the VMware Avi Load Balancer resources to build out your infrastructure. You can also use allocation helpers to provide allocation logic for your Avi Load Balancer resources.

### **Before you begin**

Before you begin with any of the template examples, you must create your Avi Load Balancer cloud account in Automation Assembler, create a project, and add the cloud zone. For instructions, see [Create a VMware Avi Load Balancer cloud account](#).

## **Simple LBaaS template**

This sample template shows how you might create a virtual service, pool, and virtual IP resources with minimal inputs.

All Avi Load Balancer resources used in this example refer to Avi Load Balancer constructs that point to the Avi Load Balancer Controller.

No machines or servers are provisioned in this template. You get the list of servers, which can be updated continuously.

The template defaults to an empty pool, but the form and input is set up so that you can enter real IPs and a normal pool is created.

```

formatVersion: 1

name: ALB - LBaaS Demo - Simple

version: 1

inputs:

 port:
 type: integer
 title: Port
 description: Traffic sent to servers will use this destination server port unless overridden by the server's specific port attribute.
 default: 80

 servers:
 type: array
 title: Servers
 description: The pool directs load balanced traffic to this list of destination servers. The servers can be configured by IP address, name, network or via IP Address Group. Leaving 0.0.0.0 will result in an empty pool being created.

 items:
 type: string
 minItems: 0
 default:
 - 0.0.0.0

resources:

 VIP:
 type: Idem.AVILB.APPLICATIONS.VS_VIP
 properties:
 name: vip-${uuid()}
 account: avi-account
 description: Managed by Aria Automation

```

```

vip:
 - vip_id: 0
 auto_allocate_ip: true
 ipam_network_subnet:
 network_ref: VMNetwork-PortGroup

VirtualService:
 type: Idem.AVILB.APPLICATIONS.VIRTUAL_SERVICE
 properties:
 name: vs-${uuid()}
 account: avi-account
 description: Managed by Aria Automation
 services:
 - port: ${input.port}
 pool_ref: ${resource.Pool.name}
 vsvip_ref: ${resource.VIP.name}

Pool:
 type: Idem.AVILB.APPLICATIONS.POOL
 properties:
 name: pool-${uuid()}
 account: avi-account
 description: Managed by Aria Automation
 default_server_port: ${input.port}
 servers: '${input.servers[0] == "0.0.0.0" ? null : map_by(input.servers, address => {"ip": {"addr": address, "type": "V4"}})}'

```

### Advanced LBaaS template

This sample template shows how you might create a virtual service, pool, and virtual IP resources connected to an existing network along with a cloud zone allocation helper. Additionally, the pool is configured with the system HTTP health monitor.

```

formatVersion: 1

name: ALB - LBaaS Demo

version: 1

inputs:

```

```
env:
 type: string
 title: Environment
 description: Select Dev or Prod ALB environment
 default: env:dev

 oneOf:
 - title: Dev ALB
 const: env:dev
 - title: Prod ALB
 const: env:prod

port:
 type: integer
 title: Port
 description: Input the server ip's to add to the pool.
 default: 80

servers:
 type: array
 title: Servers
 description: Input the server ip's to add to the pool. Leaving 0.0.0.0 will result in
an empty pool being created.
 items:
 type: string
 minItems: 0
 default:
 - 0.0.0.0

resources:
 Allocations_CloudZone_1:
 type: Allocations.CloudZone
 properties:
 accountType: avilb
 constraints:

## VMware Avi Load Balancer IPAM, vSphere, and NSX Cloud template examples

### IPAM, vSphere, and NSX Cloud template examples

The VMware Aria Automation integration with Avi Load Balancer supports virtual service virtual IP address allocation through Avi Load Balancer IPAM. You can also specify the IP inside the template or as an input.

When designing your template, keep in mind that even though some properties might not be marked as required, they might still be necessary for your template to work, depending on your use case. The following template samples provide guidance around different IPAM, vSphere, and NSX Cloud scenarios.

In some of the template samples that use the `tier1_lr` attribute, the `tier1_lr` name can be used only when the tier 1 logical router name is the same as the ID. Otherwise, you must use the tier 1 logical router full path, for example, `/infra/tier-1s/20f6a214-e8b3-4bb3-aaeb-6c06639ada23`.

### **Before you begin**

You configure Avi Load Balancer IPAM in the Avi Load Balancer Controller first, and then you configure VMware Aria Automation.

1. In the Avi Load Balancer Controller, configure the subnet and the IPAM profile.  
See [NSX Advanced Load Balancer IPAM and DNS](#).
2. Configure VMware Aria Automation.
  - a. Create your Avi Load Balancer cloud account in Automation Assembler, create a project, and add the cloud zone.  
See [Create a VMware Avi Load Balancer cloud account](#).
  - b. Configure the network for provisioning.  
Navigate to **Infrastructure > Resources > Networks**, locate the network to be used for provisioning, and configure the IPv4/IPv6 CIDR and DNS servers.  
See [Network resources in VMware Aria Automation](#).
  - c. Configure the image mapping.  
Navigate to **Infrastructure > Configure > Image Mappings** and follow the onscreen prompts to create a new image mapping.  
See [Learn more about image mappings in VMware Aria Automation](#).
  - d. Configure the network profile.  
Navigate to **Infrastructure > Configure > Network Profiles** and follow the onscreen prompts to create a new network profile.  
See [Learn more about network profiles in VMware Aria Automation](#).

## **Static IP address in VS VIP**

This Avi Load Balancer sample template includes a virtual service, a VS VIP, and a pool. A vSphere virtual machine cluster is assigned to the pool. The VS VIP has a static IP address.

```

```

### **Avi Load Balancer IPAM in VS VIP for vCenter cloud**

This Avi Load Balancer sample template is for vCenter cloud.

The VS VIP resource defines the `ipam_network_subnet` section with `network ref` and `subnet`. This definition makes Avi Load Balancer to allocate an IP address from the defined Avi Load Balancer IPAM profile when creating the VS VIP in the Avi Load Balancer Controller.

The defined cluster of pool members use a static network assignment. In Automation Assembler, you configure a network, for example, Domain, IPv4/IPv6 CIDR, a default gateway, and DNS servers. Then, you set up a network profile with a network range using this network. When clusters are created, the IP addresses from the network range are allocated to the clusters.

### **Avi Load Balancer IPAM in VS VIP for NSX Cloud**

This sample Avi Load Balancer template is for Avi Load Balancer in NSX Cloud.

To provision Avi Load Balancer on NSX Cloud, a tier 1 logical router must be defined (`tier1_lr`) and/or a VRF context (`vrf_context_ref`) in the Avi Load Balancer pool, virtual service, and VS VIP resources.

The VS VIP resource defines the `ipam_network_subnet` section with `network_ref` and `subnet`. This definition makes Avi Load Balancer to allocate an IP address from the defined Avi Load Balancer IPAM profile when creating the VS VIP in the Avi Load Balancer Controller.

### **Infoblox IPAM in VS VIP for NSX Cloud**

This sample Avi Load Balancer template is based on the Avi Load Balancer integration with Infoblox. The template uses Infoblox IPAM allocate an IP address to the VS VIP for Avi Load Balancer in NSX Cloud.

The `network_ref` attribute of the `ipam_network_subnet` section in the template is set to the full path of the network segment defined in Infoblox. Note that the `network_ref` value must be a full path, including the `/api/network/` prefix. This is different from other `ref` attributes.

## **Two distinct machine clusters in a single pool**

This sample Avi Load Balancer template has two server clusters, Cloud\_vSphere\_Machine\_1 (count = 2) and Cloud\_vSphere\_Machine\_2 (count=3), assigned to the pool. The `servers` property definition in the Idem pool differs from the regular binding properties. It connects the addresses of the two server clusters when calling the `map_to_object` function in the following way:

```

${map_to_object(resource.Cloud_vSphere_Machine_1[*].address +
resource.Cloud_vSphere_Machine_2[*].address, "ip", "addr")}

```

Other components, like the virtual service, VS VIP, health monitor, and cloud zone allocation helper are used in the regular way.

## Configuring Avi Load Balancer profiles

You can create Avi Load Balancer profiles, like application, persistence, and network profiles. You can also create, for example, a single persistence profile and provide that for another team in your organization to use later.

These sample templates cover several scenarios for creating Avi Load Balancer profiles. The first example shows how you might create a template that contains an application profile, a persistence profile, and a network profile. The second example shows a template that contains different types of persistence profiles that are available with Avi Load Balancer along with a cloud zone allocation helper. The remaining examples focus on single persistence profiles.

The template examples cover the minimum requirements for creating Avi Load Balancer profiles. When creating templates that are relevant to your organization, keep in mind that other properties might be required.

For more information about profiles, see the [Load Balancing](#) section in the *VMware NSX Advanced Load Balancer Configuration* guide.

### **Application, persistence, and network profiles**

This sample Avi Load Balancer template uses an application profile, a network profile, and a persistence profile.

The application profile determines the behavior of the virtual service. The network profile determines the type and setting of the network protocol. Both the application profile and the network profile are associated with virtual services. The persistence profile governs the settings that make a client stay connected to the same server for a specified duration of time. It is attached to an Avi Load Balancer pool.

## Using allocation helpers with Avi Load Balancer resources

### More about allocation helpers

Allocation settings are typically integrated into each resource. However, allocation can be decoupled from resources, in the form of *helpers*, which serve as a bridge between resources and your zoned and profiled infrastructure.

You can use helpers in a one-to-many configuration, where one helper provides allocation logic, such as zone placement, for several resources. You then further customize the resources according to their full list of properties as defined by the cloud provider and supported by the associated plug-in.

**Figure 6: Native properties from the cloud provider**

Because properties come from the cloud provider, allocation helpers work only with a vendor-specific selection for the design canvas. They can't be used in cloud agnostic designs. If you need a cloud agnostic template, keep using cloud agnostic resource elements and the classic, in-resource allocation approach.

You can use allocation helpers with Avi Load Balancer resources, Terraform resources, and custom resources.

## **Available allocation helpers**

The helpers provide the following allocation functions.

- Cloud zone helper  
Selects the account and zone for provisioning based on account type and constraint tags. Also resolves the provisioning priority as set in the project.
- Custom naming helper  
Generates custom names for your resources.

You can view properties for allocation helpers in the code editor. You can also view properties for allocation helpers by opening a recent deployment on the **Deployments** page and opening the right-hand pane.

## **Classic resources**

In the Automation Assembler left side menu, the earlier design resources are labeled **(Classic)**. You can use allocation helpers with Avi Load Balancer, Terraform, and custom resources, but not classic resources.

You can still add classic resources to a template. In addition, you can set up **dependencies** between them and resources that use helpers.

## **How to design**

1. In **Infrastructure**, add an account, zones, project, mappings, profiles, and capability tags in the classic way that you're already used to.
2. In the design canvas, drag in allocation helpers.
3. Drag in non-classic resources.
4. Add bindings to the helpers.  
You can write property bindings manually in the code editor or connect an allocation helper to a non-classic resource in the canvas.
5. In the code editor, configure the allocation helpers and non-classic resources.

## **Linking allocation helpers to resources**

When you link allocation helpers to resources, the following property bindings are automatically created for you in the code editor:

- `Allocations.CloudZone`
  - **Avi Load Balancer resources**: `account, cloud_ref, tenant_ref`

## **User input**

You can send user input to helpers the same way that you can send user input directly to a classic resource:

inputs:

```
my-image:
 type: string
 enum:
 - coreos
 - ubuntu
```

resources:

```

Allocations_Image_1:

type: Allocations.Image

properties:

accountType: aws

image: '${input.my-image}'

```

For more information about user inputs, see [User input in requests](#).

## Create custom names with the custom naming allocation helper in Automation Assembler

### Create custom names with the custom naming allocation helper

As a cloud administrator, you can use the custom naming allocation helper to generate custom names for your resources in Automation Assembler. You can use the custom naming allocation helper with any resource type.

After you define custom naming templates in Automation Assembler, you can use the custom naming allocation helper to reference the custom naming templates in the **Design** canvas. See [Custom resource naming](#) for more information.

These use cases demonstrate how to use the custom naming allocation helper with the **Generic** resource type and the **Machine** resource type. The **Generic** resource type covers all possible resources and is linked exclusively to the custom naming allocation helper.

#### **NOTE**

When you create a custom naming template with the **Generic** resource type, you must use the custom naming allocation helper to generate a custom name for your resource. If you do not add the allocation helper, a name will not be generated for the resource.

#### Before you begin

You must set up a cloud account and build your resource infrastructure before you can use allocation helpers. See [Adding cloud accounts](#) and [Building your resource infrastructure](#) for more information.

#### Create a Generic naming template

You must create a custom naming template to use the custom naming allocation helper. In this example, you create a **Generic**, organization-level naming template for your deployments. Organization-level naming templates are applied to all deployments by default.

You can also create project-level naming templates. See [Custom resource naming](#) for more information.

To create an organization-level naming template:

1. Select **Infrastructure > Administration > Custom Names** and click **New Custom Name**.
2. Enter a name and description for the custom naming template.
3. Select **Organization** as the scope.
4. Click **New Naming Template** and configure the following options.

| Option        | Value              |
|---------------|--------------------|
| Resource type | Generic            |
| Template name | my-custom-template |

| Template format        | resource-\${#####}                                                                                                                                                                                                                                                                                                                                                |
| Starting counter value | 1                                                                                                                                                                                                                                                                                                                                                                 |
| Increment step         | 1<br><br>With this configuration, the deployments in the assigned projects will increment from this starting point.<br><br>In this example, where the starting counter is 1 and the increment is 1, the first deployment is numbered as 2. If you need the deployment to start at 1, then set the starting counter to zero and the increment step to 1.           |

5. Click **Add**.
6. If needed, add additional custom naming templates.
7. Click **Create**.

### vSphere resource examples in Automation Assembler

#### vSphere resource examples

These code examples illustrate vSphere machine resources within Automation Assembler cloud templates.

| Example Cloud Template                                                                                                                                                                                         |

### Documented Automation Assembler template example

Reviewable cloud template

By including a thorough set of comments, this example lets you review the structure and purpose of the sections in an Automation Assembler template, formerly called a blueprint.

```

#
This WordPress cloud template is enhanced with comments to explain its
parameters.
#
Try cloning it and experimenting with its YAML code. If you're new to
YAML, visit yaml.org for general information.
#
The cloud template deploys a minimum of 3 virtual machines and runs scripts
to install packages.
#

#

#
Templates need a descriptive name and version if
source controlled in git.
#

name: WordPress Template with Comments
formatVersion: 1
version: 1
#

#
Inputs create user selections that appear at deployment time. Inputs
can set placement decisions and configurations, and are referenced
later, by the resources section.
#

inputs:
#

#
Choose a cloud endpoint. 'Title' is the visible
option text (oneOf allows for the friendly title). 'Const' is the
```

```
tag that identifies the endpoint, which was set up earlier, under the
Automation Assembler Infrastructure tab.
#

platform:
 type: string
 title: Deploy to
 oneOf:
 - title: AWS
 const: aws
 - title: Azure
 const: azure
 - title: vSphere
 const: vsphere
 default: vsphere

#

Choose the operating system. Note that the Automation Assembler
Infrastructure must also have an AWS, Azure, and vSphere Ubuntu image
mapped. In this case, enum sets the option that you see, meaning there's
no friendly title feature this time. Also, only Ubuntu is available
here, but having this input stubbed in lets you add more operating
systems later.
#

osimage:
 type: string
 title: Operating System
 description: Which OS to use
 enum:
 - Ubuntu

#

Set the number of machines in the database cluster. Small and large
```

```
correspond to 1 or 2 machines, respectively, which you see later,
down in the resources section.

dbenvsize:
 type: string
 title: Database cluster size
 enum:
 - Small
 - Large

#

Dynamically tag the machines that will be created. The
'array' of objects means you can create as many key-value pairs as
needed. To see how array input looks when it's collected,
open the cloud template and click TEST.

Mtags:
 type: array
 title: Tags
 description: Tags to apply to machines
 items:
 type: object
 properties:
 key:
 type: string
 title: Key
 value:
 type: string
 title: Value

#

Create machine credentials. These credentials are needed in
```

```
remote access configuration later, in the resources section.

username:
 type: string
 minLength: 4
 maxLength: 20
 pattern: '[a-z]+'
 title: Database Username
 description: Database Username

userpassword:
 type: string
 pattern: '[a-z0-9A-Z@#$]+'
 encrypted: true
 title: Database Password
 description: Database Password

Set the database storage disk size.

databaseDiskSize:
 type: number
 default: 4
 maximum: 10
 title: MySQL Data Disk Size
 description: Size of database disk

Set the number of machines in the web cluster. Small, medium, and large
correspond to 2, 3, and 4 machines, respectively, which you see later,
in the WebTier part of the resources section.

clusterSize:
```

```
type: string
enum:
 - small
 - medium
 - large
title: Wordpress Cluster Size
description: Wordpress Cluster Size
#

Set the archive storage disk size.

archiveDiskSize:
 type: number
 default: 4
 maximum: 10
 title: Wordpress Archive Disk Size
 description: Size of Wordpress archive disk
#

The resources section configures the deployment of machines, disks,
networks, and other objects. In several places, the code pulls from
the preceding interactive user inputs.

resources:
#

Create the database server. Choose a cloud agnostic machine 'type' so
that it can deploy to AWS, Azure, or vSphere. Then enter its property
settings.

DBTier:
 type: Cloud.Machine
```

```
properties:

Descriptive name for the virtual machine. Does not become the hostname
upon deployment.

name: mysql

Hard-coded operating system image to use. To pull from user input above,
enter the following instead.
image: '${input.osimage}'

image: Ubuntu

Hard-coded capacity to use. Note that the Automation Assembler
Infrastructure must also have AWS, Azure, and vSphere flavors
such as small, medium, and large mapped.

flavor: small

Tag the database machine to deploy to the cloud vendor chosen from the
user input. Tags are case-sensitive, so 'to_lower' forces the tag to
lowercase to ensure a match with a site's tagging convention. It's
important if platform input were to contain any upper case characters.

constraints:
- tag: '${"env:" + to_lower(input.platform)}'

```

```
Also tag the database machine with any free-form tags that were created
during user input.

tags: '${input.Mtags}'

#

Set the database cluster size by referencing the dbenvsize user
input. Small is one machine, and large defaults to two.

count: '${input.dbenvsize == "Small" ? 1 : 2}'

#

Add a variable to connect the machine to a network resource based on
a property binding to another resource. In this case, it's the
'WP_Network' network that gets defined further below.

networks:
 - network: '${resource.WP_Network.id}'

#

Enable remote access to the database server. Reference the credentials
from the user input.

remoteAccess:
 authentication: usernamePassword
 username: '${input.username}'
 password: '${input.userpassword}'

#

You are free to add custom properties, which might be used to initiate
an extensibility subscription, for example.

```

```

ABC-Company-ID: 9393

#

Run OS commands or scripts to further configure the database machine,
via operations such as setting a hostname, generating SSH private keys,
or installing packages.

cloudConfig: |
 #cloud-config
 repo_update: true
 repo_upgrade: all
 packages:
 - mysql-server
 runcmd:
 - sed -e '/bind-address/ s/^#*/#/ -i /etc/mysql/mysql.conf.d/mysqld.cnf
 - service mysql restart
 - mysql -e "CREATE USER 'root'@'%' IDENTIFIED BY 'mysqlpassword';"
 - mysql -e "GRANT ALL PRIVILEGES ON *.* TO 'root'@'%';"
 - mysql -e "FLUSH PRIVILEGES;"

#

```

```

Create the network that the database and web servers connect to.
Choose a cloud agnostic network 'type' so that it can deploy to AWS,
Azure, or vSphere. Then enter its property settings.

WP_Network:
 type: Cloud.Network
 properties:
#

Descriptive name for the network. Does not become the network name
upon deployment.

name: WP_Network
#

Set the networkType to an existing network. You could also use a
constraint tag to target a specific, like-tagged network.
The other network types are private or public.

networkType: existing
#

#
VMware hopes that you found this commented template useful. Note that
you can also access an API to create templates, or query for input
schema that you intend to request. See the following Swagger
documentation.
#
www.mgmt.cloud.vmware.com/blueprint/api/swagger/swagger-ui.html
#

```

## Attaching an existing disk in Automation Assembler

Attaching an existing disk

Your Automation Assembler template code can attach an existing, deployed disk to a newly created machine.

Use the following cloud template code example as a guideline.

```
formatVersion: 1
inputs:
 disk:
 type: string
 $data: /data/availableDisks?resourceType=Cloud.Volume
resources:
 Cloud_Machine_1:
 type: Cloud.Machine
 properties:
 image: ubuntu
 flavor: small
 attachedDisks:
 - source: ${input.disk}
```

The highlighted line is an API call that lists the disks that are available for attachment, disks unattached to any machine.

The `resourceType` parameter lets Automation Assembler list available disks by cloud account type.

|                    |                                        |
|--------------------|----------------------------------------|
| Cloud.Volume       | Disks on any cloud that you have added |
| Cloud.vSphere.Disk | Only vSphere disks                     |
| Cloud.AWS.Volume   | Only Amazon Web Services (AWS) disks   |
| Cloud.Azure.Disk   | Only Microsoft Azure disks             |
| Cloud.GCP.Disk     | Only Google Cloud Platform (GCP) disks |

When using this feature, there's no design canvas component for the existing disk that you attach. Even though there's no component on the design canvas, the attached disk appears under the storage section of the deployed machine, and under the Resources tab.

## Cores per socket and CPU count in Automation Assembler

Cores per socket and CPU count

Automation Assembler template code lets you specify a number of cores per socket for a vSphere machine resource.

You can specify the number of cores per virtual socket or the total number of sockets. For example, your licensing terms might restrict software that is licensed per socket or available operating systems might only recognize a certain number of sockets so that additional CPUs must be provisioned as additional cores.

Add the `coreCount` property to a cloud template in the vSphere machine resource.

The `coreCount` value must be less than or equal to the CPU count (`cpuCount`) value specified in the flavor mapping or in the vSphere machine resource code in the cloud template. For related information, see [Setting the number of cores per CPU in a virtual machine \(1010184\)](#).

The `coreCount` property is optional and available only for vSphere machine resources.

An example vSphere machine resource snippet is shown below.

`Cloud_vSphere_Machine_1:`

```
type: Cloud.vSphere.Machine
properties:
 cpuCount: 8
 coreCount: 4
```

Additional information about sockets and cores per socket settings is available in blog article [Virtual Machine vCPU and vNUMA Rightsizing – Guidelines](#).

### Puppet-enabled cloud template with username and password access

Puppet enabled cloud template with username and password access

In this example, you add Puppet configuration management to a cloud template deployed on a vCenter compute resource with username and password access.

- Set up a Puppet Enterprise instance on a valid network.
- Add your Puppet Enterprise instance to Automation Assembler using the Integrations feature. See [configure-puppet-integration.dita#GUID-EDEEE4C7-8EEB-424F-8DC1-E9F8CCE1F27B-en](#)
- Set up a vSphere account and a vCenter compute resource.

This procedure shows an example of how you might create a Puppet enabled deployable resource that requires username and password authentication. Username and password access means that the user must manually log in from the compute resource to the Puppet primary machine in order to invoke Puppet configuration management.

Optionally, you can configure remote access authentication which sets up configuration management in a cloud template so that the compute resource handles authentication with the Puppet primary machine. With remote access enabled, the compute resource automatically generates a key to satisfy password authentication. A valid username is still required.

See [AWS Puppet configuration management cloud template examples](#) and [Puppet configuration cloud template examples](#) for more examples of how you can configure different Puppet scenarios in Automation Assembler blueprints.

1. Add a Puppet configuration management component to a vSphere compute resource on the canvas for the desired cloud template.
  - a) Select **Infrastructure > Manage > Integrations**.
  - b) Click **Add Integration** and select Puppet.
  - c) Enter the appropriate information on the Puppet configuration page.

| Configuration | Description                                                                                    | Example Value |
|---------------|------------------------------------------------------------------------------------------------|---------------|
| Hostname      | Host name or IP address of the Puppet primary machine                                          | Puppet-Ubuntu |
| SSH Port      | SSH port for communication between Automation Assembler and Puppet primary machine. (Optional) | NA            |

| Configuration                   | Description                                                                                                                                                                                                                                  | Example Value                                      |
|---------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------|
| Autosign secret                 | The shared secret configured on the Puppet primary machine that nodes should provide to support autosign certificate requests.                                                                                                               | User specific                                      |
| Location                        | Indicate whether the Puppet primary machine is on a private or public cloud.<br><br><b>NOTE</b><br>Cross cloud deployment is supported only if there is connectivity between the deployment compute resource and the Puppet primary machine. |                                                    |
| Cloud proxy                     | Not required for public cloud accounts, such as Microsoft Azure or Amazon Web Services. If you are using a vCenter based cloud account, select the appropriate cloud proxy for your account.                                                 | NA                                                 |
| Username                        | SSH and RBAC user name for Puppet primary machine.                                                                                                                                                                                           | User specific. YAML value is '\$ {input.username}' |
| Password                        | SSH and RBAC password for Puppet primary machine.                                                                                                                                                                                            | User specific YAML value is '\$ {input.password}'  |
| Use sudo commands for this user | Select to use sudo commands for the procidd.                                                                                                                                                                                                 | true                                               |
| Name                            | Puppet primary machine name.                                                                                                                                                                                                                 | PEMasterOnPrem                                     |
| Description                     |                                                                                                                                                                                                                                              |                                                    |

2. Add the username and password properties to the Puppet YAML as shown in the following example.
3. Ensure that the value for the remoteAccess property to the Puppet cloud template YAML is set to authentication: username and password as shown in the example below.

#### vCenter username and password YAML code

The following example shows the representative YAML code for adding username and password authentication on a vCenter compute resource.

inputs:

```

username:
 type: string
 title: Username
 description: Username to use to install Puppet agent
 default: puppet

password:

```

```

type: string
title: Password
default: VMware@123
encrypted: true
description: Password for the given username to install Puppet agent

resources:

Puppet-Ubuntu:
 type: Cloud.vSphere.Machine
 properties:
 flavor: small
 imageRef: >-
 https://cloud-images.ubuntu.com/releases/16.04/release-20170307/ubuntu-16.04-
 server-cloudimg-amd64.ova
 remoteAccess:
 authentication: usernamePassword
 username: '${input.username}'
 password: '${input.password}'

Puppet_Agent:
 type: Cloud.Puppet
 properties:
 provider: PEMasterOnPrem
 environment: production
 role: 'role::linux_webserver'
 username: '${input.username}'
 password: '${input.password}'
 host: '${Puppet-Ubuntu.*}'
 useSudo: true
 agentConfiguration:
 certName: '${Puppet-Ubuntu.address}'

```

## AWS Puppet configuration management cloud template examples

There are several options for configuring cloud templates to support Puppet based configuration management on AWS compute resources.

### Puppet management on AWS with username and password

| Example of...                                                                | Sample Blueprint YAML                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## Special Automation Assembler properties

### Special properties

Automation Assembler supports a small number of properties that might be useful outside of production environments or in other special situations.

Special properties do not appear in the [VMware Aria Automation resource schema](#).

### CAUTION

The following properties should only be applied in cases where guest OS customization isn't being tested or expected.

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| awaitIp       | <p>By default, VMware Aria Automation provisioning status isn't reported as Finished until the guest OS is fully powered on and configuration has completed.</p> <p>Use of <code>awaitIp: false</code> allows provisioning to finish even though full configuration did not occur.</p> <p><b>CAUTION:</b> Use of this setting completes the provisioning process sooner but might result in an unconfigured machine with no IP address.</p> |
| awaitHostName | Similar to <code>awaitIp</code> , use of <code>awaitHostName: false</code> allows provisioning to finish even though the machine might not have been configured with a host name.                                                                                                                                                                                                                                                           |

## Other ways to create Automation Assembler templates

Other ways to create templates

In addition to building an Automation Assembler template from a blank canvas, you can take advantage of existing code.

### Cloud template cloning

To clone a template, go to **Design**, select a source, and click **Clone**. You clone a cloud template to create a copy based on the source, then assign the clone to a new project or use it as starter code for a new application.

### Uploading and downloading

You can upload, download, and share cloud template YAML code in any way that makes sense for your site. You can also modify template code by using external editors and development environments.

#### **NOTE**

A good way to validate shared template code is to inspect it in the Automation Assembler code editor on the design page.

### Integrating Automation Assembler with a repository

An integrated git source control repository can make cloud templates available to qualified users as the basis for a new deployment. See [How do I use Git integration in](#).

## Extending and automating application life cycles with extensibility

Extending and automating application life cycles

You can extend your application life cycles by using either extensibility actions or Automation Orchestrator workflows with extensibility subscriptions.

With Automation Assembler Extensibility, you can assign an extensibility action or Automation Orchestrator workflow to an event by using subscriptions. When the specified event occurs, the subscription initiates the action or workflow to run, and all subscribers are notified.

### Extensibility Actions

Extensibility actions are small, lightweight scripts of code used to specify an action and how that action is to perform. You can import extensibility actions from pre-defined Automation Assembler action templates or from a ZIP file. You can also use the action editor to create custom scripts for your extensibility actions. When multiple action scripts are linked together in one script, you create an action flow. By using action flows, you can create a sequence of actions. For information on using action flows, see [What is an action flow](#).

## Automation Orchestrator Workflows

By integrating Automation Assembler with your existing Automation Orchestrator environment, you can use workflows in your extensibility subscriptions.

### Extensibility action subscriptions

You can assign an extensibility action to an Automation Assembler subscription to extend your application life cycle.

#### NOTE

The following subscriptions are use case examples and do not cover all extensibility action functionality.

### How do I integrate Automation Assembler with ServiceNow using extensibility actions

Using extensibility actions you can integrate Automation Assembler with an Enterprise ITSM, like ServiceNow.

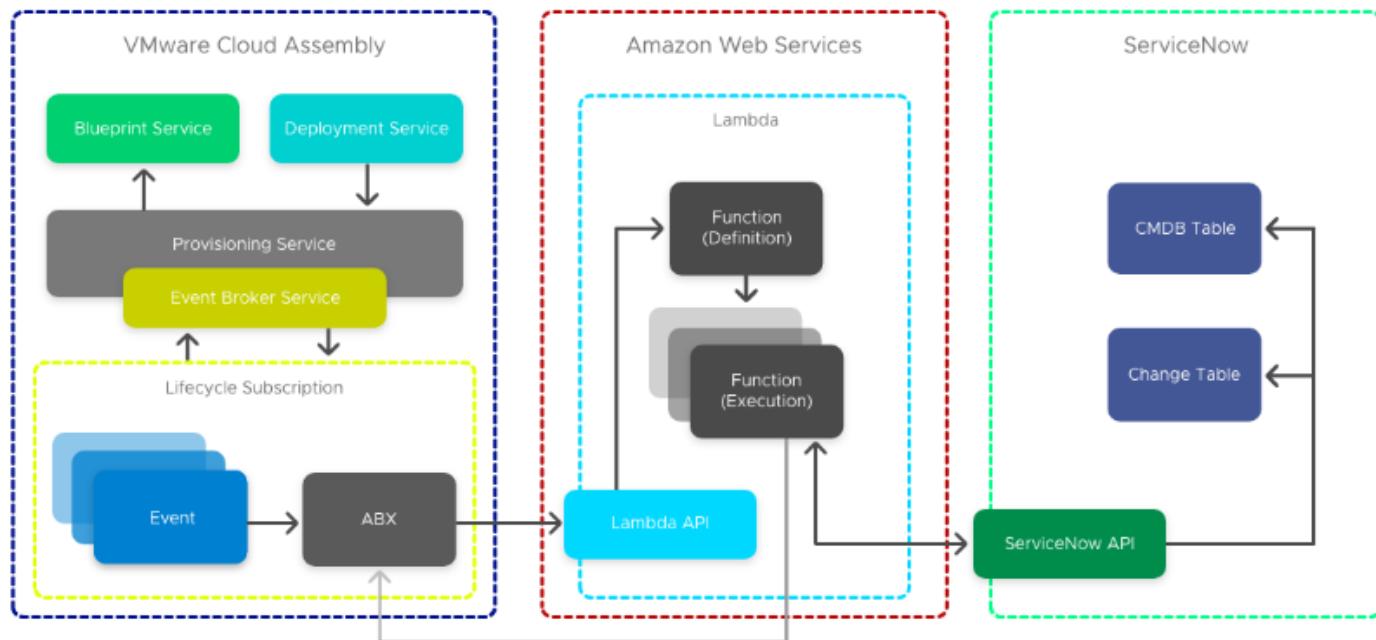

- Before configuring this integration, filter all event subscriptions with the conditional cloud template property: `event.data["customProperties"]["enable_servicenow"] === "true"`

#### NOTE

This property exists on cloud templates that require a ServiceNow integration.

- Download and install Python.

For more information on filtering subscriptions, see [Create an extensibility subscription](#).

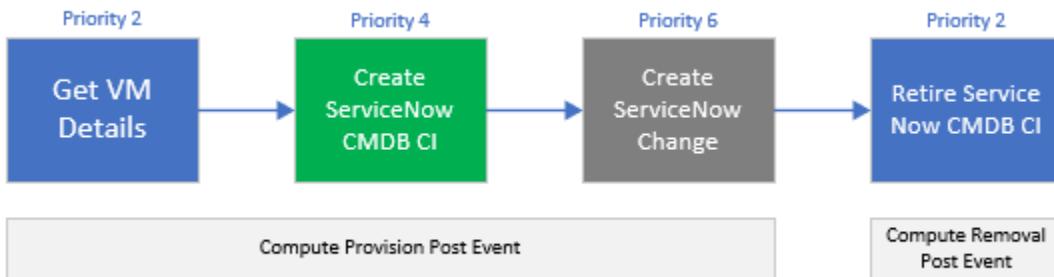

Enterprise users commonly integrate their Cloud Management Platform with an IT Service Management (ITSM) and Configuration Management Database (CMDB) platform for compliance. Following this example, you can integrate Automation Assembler with ServiceNow for CMDB and ITSM by using extensibility action scripts.

#### NOTE

You can also integrate ServiceNow with Automation Assembler by using Automation Orchestrator workflows. For information about integrating ServiceNow by using workflows, see [How do I integrate for ITSM with ServiceNow using workflows](#).

To create this integration, you use four extensibility action scripts. The first three scripts are initiated in sequence during provisioning, at the compute provision post event. The fourth script triggers at the compute removal post event.

For more information on event topics, refer to [Event topics provided with Automation Assembler](#).

### Get VM Details

The Get VM details script acquires additional payload details required for CI creation and an identity token that is stored in Amazon Web Services Systems Manager Parameter Store (SSM). Also, this script updates `customProperties` with additional properties for later use.

### Create ServiceNow CMDB CI

The Create ServiceNow CMDB CI script passes the ServiceNow instance URL as an input and stores the instance in SSM to meet security requirements. This script also reads the ServiceNow CMDB unique record identifier response (`sys_id`). It passes it as an output and writes the custom property `serviceNowSysId` during creation. This value is used to mark the CI as retired when the instance is destroyed.

#### NOTE

Additional permissions might need to be allocated to your VMware Aria Automation servicesAmazon Web Services role to allow Lambda to access the SSM Parameter Store.

### Create ServiceNow Change

This script finishes the ITSM integration by passing the ServiceNow instance URL as an input and storing the ServiceNow credentials as SSM to meet security requirements.

### Create ServiceNow Change

The retire ServiceNow CMDB CI script prompts the ServiceNow to stop and marks the CI as retired based on the custom property `serviceNowSysId` that was created in the creation script.

1. Open a command-line prompt from your Virtual Machine.
2. Run the Get VM details script.

```

from botocore.vendored import requests
import json
import boto3
client = boto3.client('ssm','ap-southeast-2')

def handler(context, inputs):
 baseUri = inputs['url']
 casToken = client.get_parameter(Name="casToken",WithDecryption=True)

 url = baseUri + "/iaas/login"
 headers = {"Accept":"application/json","Content-Type":"application/json"}
 payload = {"refreshToken":casToken['Parameter']['Value']}

```

```

results = requests.post(url,json=payload,headers=headers)

bearer = "Bearer "
bearer = bearer + results.json()["token"]

deploymentId = inputs['deploymentId']
resourceId = inputs['resourceIds'][0]

print("deploymentId: " + deploymentId)
print("resourceId:" + resourceId)

machineUri = baseUri + "/iaas/machines/" + resourceId
headers = {"Accept":"application/json","Content-Type":"application/json",
"Authorization":bearer }
resultMachine = requests.get(machineUri,headers=headers)
print("machine: " + resultMachine.text)

print("serviceNowCPUCount: "+ json.loads(resultMachine.text)["customProperties"]["cpuCount"])
print("serviceNowMemoryInMB: "+ json.loads(resultMachine.text)["customProperties"]["memoryInMB"])

#update customProperties
outputs = {}
outputs['customProperties'] = inputs['customProperties']
outputs['customProperties']['serviceNowCPUCount'] =
int(json.loads(resultMachine.text)["customProperties"]["cpuCount"])
outputs['customProperties']['serviceNowMemoryInMB'] =
json.loads(resultMachine.text)["customProperties"]["memoryInMB"]

return outputs

```

### 3. Run the CMDB configuration item creation action.

```

from botocore.vendored import requests
import json

```

```
import boto3

client = boto3.client('ssm', 'ap-southeast-2')

def handler(context, inputs):

 snowUser = client.get_parameter(Name="serviceNowUserName", WithDecryption=False)
 snowPass = client.get_parameter(Name="serviceNowPassword", WithDecryption=True)
 table_name = "cmdb_ci_vmware_instance"
 url = "https://" + inputs['instanceUrl'] + "/api/now/table/{0}".format(table_name)
 headers = {'Content-type': 'application/json', 'Accept': 'application/json'}
 payload = {
 'name': inputs['customProperties']['serviceNowHostname'],
 'cpus': int(inputs['customProperties']['serviceNowCPUCount']),
 'memory': inputs['customProperties']['serviceNowMemoryInMB'],
 'correlation_id': inputs['deploymentId'],
 'disks_size': int(inputs['customProperties']['provisionGB']),
 'location': "Sydney",
 'vcenter_uuid': inputs['customProperties']['vcUuid'],
 'state': 'On',
 'sys_created_by': inputs['__metadata']['userName'],
 'owned_by': inputs['__metadata']['userName']
 }
 results = requests.post(
 url,
 json=payload,
 headers=headers,
 auth=(snowUser['Parameter']['Value'], snowPass['Parameter']['Value'])
)
 print(results.text)

 #parse response for the sys_id of CMDB CI reference
 if json.loads(results.text)['result']:
```

```

serviceNowResponse = json.loads(results.text) ['result']
serviceNowSysId = serviceNowResponse['sys_id']
print(serviceNowSysId)

#update the serviceNowSysId customProperty
outputs = {}
outputs['customProperties'] = inputs['customProperties']
outputs['customProperties']['serviceNowSysId'] = serviceNowSysId;
return outputs

```

#### 4. Run the Creation action script.

```

from botocore.vendored import requests
import json
import boto3
client = boto3.client('ssm','ap-southeast-2')

def handler(context, inputs):
 snowUser = client.get_parameter(Name="serviceNowUserName",WithDecryption=False)
 snowPass = client.get_parameter(Name="serviceNowPassword",WithDecryption=True)
 table_name = "change_request"
 url = "https://" + inputs['instanceUrl'] + "/api/now/table/{0}".format(table_name)
 headers = {'Content-type': 'application/json', 'Accept': 'application/json'}
 payload = {
 'short_description': 'Provision CAS VM Instance'
 }
 results = requests.post(
 url,
 json=payload,
 headers=headers,
 auth=(snowUser['Parameter']['Value'], snowPass['Parameter']['Value'])
)
 print(results.text)

```

Automation Assembler is successfully integrated with ITSM ServiceNow.

When desired, you can retire your CI by using the CMDB configuration item retire action:

```
from botocore.vendored import requests
```

```
import json
import boto3
client = boto3.client('ssm', 'ap-southeast-2')

def handler(context, inputs):
 snowUser = client.get_parameter(Name="serviceNowUserName", WithDecryption=False)
 snowPass = client.get_parameter(Name="serviceNowPassword", WithDecryption=True)
 tableName = "cmdb_ci_vmware_instance"
 sys_id = inputs['customProperties']['serviceNowSysId']
 url = "https://" + inputs['instanceUrl'] + "/api/now/" + tableName + "/{0}".format(sys_id)
 headers = {'Content-type': 'application/json', 'Accept': 'application/json'}
 payload = {
 'state': 'Retired'
 }

 results = requests.put(
 url,
 json=payload,
 headers=headers,
 auth=(inputs['username'], inputs['password'])
)
 print(results.text)
```

## How do I tag virtual machines during provisioning by using extensibility actions

You can use extensibility actions along with subscriptions to automate and simplify tagging VMs.

- Access to cloud administrator credentials.
- Amazon Web Services role for Lambda functions.

As a cloud administrator, you can create deployments that are automatically tagged with specified inputs and outputs by using extensibility actions and extensibility subscriptions. When a new deployment is created against the project containing the tag VM subscription, the deployment event triggers the Tag VM script to run and the tags are automatically applied. This saves time and promotes efficiency while allowing for easier deployment management.

1. Navigate to **Extensibility > Library > Actions > New Action** and create an action with the following parameters.

| Parameter       | Description                                                             |
|-----------------|-------------------------------------------------------------------------|
| Action Name     | Extensibility action name, preferably with TagVM as a prefix or suffix. |
| Project         | Project to test the extensibility action against.                       |
| Action Template | Tag VM                                                                  |
| Runtime         | Python                                                                  |
| Script Source   | Write Script                                                            |

2. Enter Handler as the **Main function**.

3. Add tagging inputs for testing the extensibility action.

For example, `resourceNames = ["DB_VM"]` and `target = world`.

4. To save your action, click **Save**.

5. To test your action, click **Test**.

6. To exit the action editor, click **Close**.

7. Navigate to **Extensibility > Subscriptions**.

8. Click **New Subscription**.

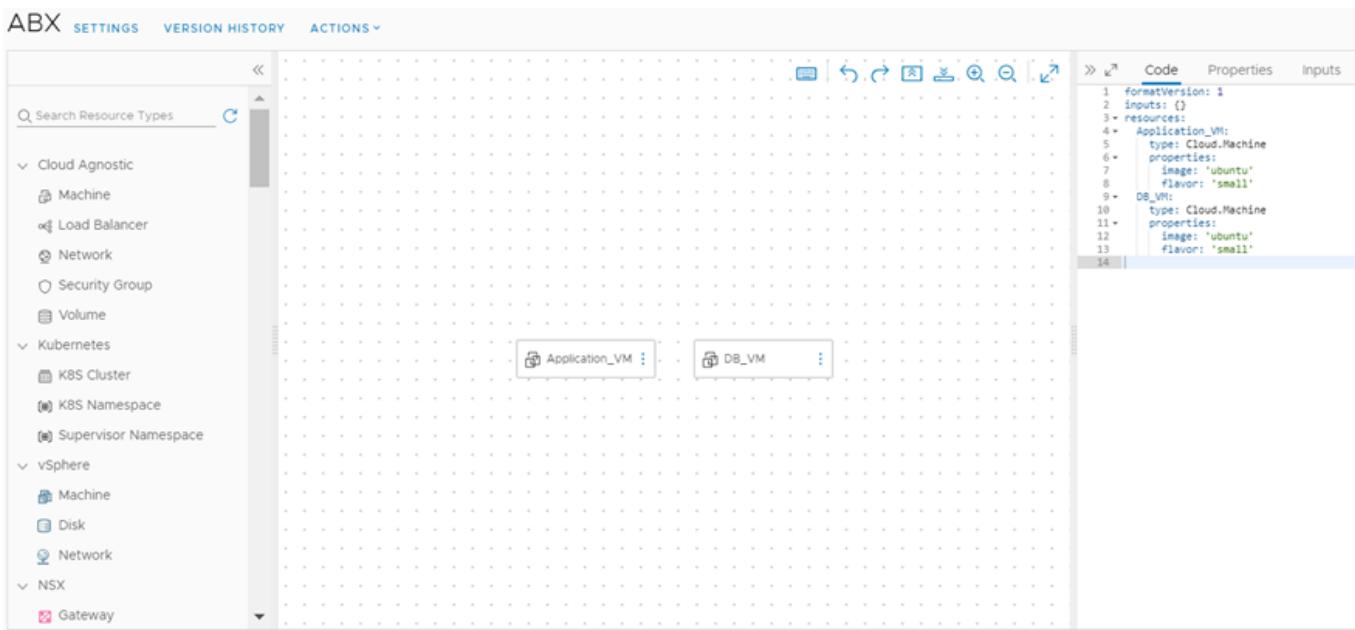

9. Enter the following subscription details.

| Detail          | Setting                                                                                                                                                                                     |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Event Topic     | Select an event topic related to the tagging phase of the VM. For example, Compute Allocation.<br><br><b>NOTE</b><br>Tags must be part of the event parameters of the selected event topic. |
| Blocking        | Set the timeout for the subscription to 1 minute.                                                                                                                                           |
| Action/Workflow | Select an extensibility action runnable type, and select your custom extensibility action.                                                                                                  |

10. To save your custom extensibility action subscription, click **Save**.

11. Navigate to **Design > Cloud Templates**, and create a cloud template from a blank canvas.

12. Add two virtual machines to the cloud template: Application\_VM and DB\_VM.

13. To deploy the VMs, click **Deploy**.
14. During deployment, verify that the event is initiated and the extensibility action is run.
15. To verify that the tags are applied correctly, navigate to **Resources > Resources > Virtual Machines**.

### How can I configure a network interface controller name by using extensibility actions

You can configure the interface name of a network interface controller (NIC) by using IaaS API calls applied through extensibility actions.

- You can only configure the NIC interface name prior to provisioning a compute resource. Therefore, only the **Compute Provision** event topic can be selected for relevant extensibility subscriptions.
- You can only configure NIC interface names for NICs that use Microsoft Azure as a provider.

To configure the interface name of a NIC, you must make **GET** and **PATCH** calls to the VMware Aria Automation IaaS API. By making a **GET** call to `https://your_vRA_fqdn/iaas/api/machines/{id}`, you can retrieve the NIC link for the compute resource you want to modify. Then you can make a **PATCH** call to `https://your_vRA_fqdn/iaas/api/machines/{id}/network-interfaces/{nicId}`, which includes the NIC interface name as a payload, to add the new name for your NIC. The following scenario uses a sample Python script that can be used for NIC interface name configuration. For your own use cases, you can use a different script and script language, such as Node.js.

1. Create the extensibility action.
  - a) Navigate to **Extensibility > Actions**.
  - b) Click **New Action**.
  - c) Enter a name and project for the extensibility action and **Next**.
  - d) Add the NIC configuration script.

The following is a sample Python script:

```
import json
```

```
def handler(context, inputs):
```

```

Get the machine info, which contains machine nic link
response = context.request('/iaas/api/machines/'+inputs["resourceIds"][0],
"GET", {})

Build PATCH machine nic payload here
name = "customized-nic-02";
data = {'name':name};

Convert machine data string to json object
response_json = json.loads(response["content"])

Patch machine nic
response_patch = context.request(response_json["links"]["network-
interfaces"]["hrefs"][0] + "?apiVersion=2021-07-15", 'PATCH', data)

return value is empty since we are not changing any compute provisioning
parameters

outputs = {}

return outputs

```

The preceding sample script performs two primary operations through the IaaS API. First, the script uses a GET call to retrieve the NIC link and then uses a PATCH call to apply the interface name. In this sample, the NIC interface name is hard-coded into the script as "customized-nic-02".

- e) To finish editing the extensibility action, click **Save**.
2. Create a extensibility subscription.
  - a) Navigate to **Extensibility > Subscriptions**.
  - b) Click **New Subscription**.
  - c) Enter a name for the extensibility subscription.
  - d) Under **Event Topic**, select **Compute Provision** as the event topic for the extensibility subscription.
  - e) Under **Action/workflow**, select the extensibility action you created for NIC configuration.
  - f) Enable event blocking.  
By enabling blocking, you make sure that the provisioning process is blocked until the extensibility action finishes its run.
- g) To finish editing the extensibility subscription, click **Save**.

The new extensibility subscription runs when a compute provision event is triggered and configures the NIC interface name for the compute resources to be provisioned.

## Learn more about extensibility actions

Action-based extensibility uses streamlined scripts of code within Automation Assembler to automate extensibility actions.

Action-based extensibility provides a lightweight and flexible run-time engine interface where you can define small scriptable actions and configure them to initiate when events specified in extensibility subscriptions occur.

You can create these extensibility action scripts of code within Automation Assembler, or on your local environment, and assign them to subscriptions. Extensibility action scripts are used for more lightweight and simple automation of tasks and steps. For more information on integrating Automation Assembler with a Automation Orchestrator server, see [Configure an integration in](#).

Action-based extensibility provides:

- An alternative to Automation Orchestrator workflows, using small and reusable scriptable actions, for lightweight integrations and customizations.
- A way to reuse action templates, which contain reusable parameterized actions.

You can create extensibility actions by either writing a user-defined action script code or importing a predefined script code as a ZIP package. Action-based extensibility supports Node.js, Python, and PowerShell run-time environments. The Node.js and Python run-times rely on Amazon Web Services Lambda. Therefore, you must have an active subscription with Amazon Web Services Identity and Access Management (IAM), and configure Amazon Web Services as an endpoint in Automation Assembler. For information on getting started with Amazon Web Services Lambda, see [ABX: Serverless Extensibility of Cloud Assembly Services](#).

### NOTE

Extensibility actions are project-specific.

## How do I create extensibility actions

With Automation Assembler, you can create extensibility actions for use in extensibility subscriptions.

- Membership in an active and valid project.
- Configured Amazon Web Services role for Lambda functions. For example, AWSLambdaBasicExecutionRole.
- Cloud administrator role or iam:PassRole permissions enabled.

Extensibility actions are highly customizable, lightweight, and flexible ways to extend application life cycles by using user-defined script code and action templates. Action templates contain predefined parameters that help set up the foundation of your extensibility action.

There are two methods of creating an extensibility action:

- Writing user-defined code for an extensibility action script.

### NOTE

Writing user-defined code in the extensibility action editor might require an active Internet connection.

- Importing a deployment package as a ZIP package for an extensibility action. For information on creating a ZIP package for extensibility actions, see [Create a ZIP package for Python runtime extensibility actions](#), [Create a ZIP package for Node.js runtime extensibility actions](#), or [Create a ZIP package for PowerShell runtime extensibility actions](#).

The following steps describe the procedure for creating an extensibility action that uses Amazon Web Services as a FaaS provider.

1. Select **Extensibility > Library > Actions**.
2. Click **New Action**.
3. Enter a name for your action and select a project.
4. Add a description for your action.

5. Click **Next**.
6. Search and select an action template.

**NOTE**

To create a custom action without using an action template, select **Custom script**.

- New configurable parameters appear.
7. Select **Write script or Import package**.
  8. Select the action runtime.
  9. Enter an **Main function** name for the action's entry point.
- NOTE**
- For actions imported from a ZIP package, the main function must also include the name of the script file that contains the entry point. For example, if your main script file is titled `main.py` and your entry point is `handler (context, inputs)`, the name of the main function must be `main.handler`.
10. Define the input and output parameters of the action.
  11. Add secrets or extensibility action constants to your default inputs.
- NOTE**
- For more information on secrets and extensibility action constants, see [How can I create secrets for use in extensibility actions](#) and [How can I create extensibility action constants](#).

12. Add application dependencies to the action.

**NOTE**

For PowerShell scripts, you can define your application dependencies so they are resolved against the PowerShell Gallery repository. To define your application dependencies so, they are resolvable from the public repository use the following format:

```
@{
 Name = 'Version'
}
```

e.g.

```
@{
 Pester = '4.3.1'
}
```

**NOTE**

For actions imported from a ZIP package, application dependencies are added automatically.

13. To define timeout and memory limits, enable the **Set custom timeout and limits** option.

The maximum timeout value for scripting type actions is 15 minutes. The maximum timeout value for flow type actions is five hours. For flow type actions, you can also leave the timeout text box blank in which case there is no timeout limit. If you do not set a timeout limit, the action run ends when all flow elements finish their tasks or an error occurs.

14. To test your action, click **Save** and then **Test**.

After your extensibility action is created and verified, you can assign it to a subscription.

**NOTE**

Extensibility subscriptions use the latest released version of an extensibility action. After creating a new version of an action, click **Versions** on the top-right of the editor window. To release the version of the action you want to use in your subscription, click **Release**.

## Create a ZIP package for Python runtime extensibility actions

You can create a ZIP package that contains the Python script and dependencies used by your Automation Assembler extensibility actions.

If you are using Python 3.3 or earlier, download and configure the PIP package installer. See [Python Package Index](#).

There are two methods of building the script for your extensibility actions:

- Writing your script directly in the extensibility action editor in Automation Assembler.
- Creating your script on your local environment and adding it, with any relevant dependencies, to a ZIP package.

By using a ZIP package, you can create a custom preconfigured template of action scripts and dependencies that you can import to Automation Assembler for use in extensibility actions.

Furthermore, you can use a ZIP package in scenarios where modules associated with dependencies in your action script cannot be resolved by the Automation Assembler service, such as when your environment lacks Internet access.

You can also use a ZIP package to create extensibility actions that contain multiple Python script files. Using multiple script files can be useful for organizing the structure of your extensibility action code.

1. On your local machine, create a folder for your action script and dependencies.  
For example, /home/user1/zip-action.
2. Add your main Python action script or scripts to the folder.  
For example, /home/user1/zip-action/main.py.
3. Add any dependencies for your Python script to the folder.
  - a) Create a requirements.txt file that contains your dependencies. See [Requirements Files](#).
  - b) Open a Linux shell.

**NOTE**

The runtime of action-based extensibility in Automation Assembler is Linux-based. Therefore, any Python dependencies compiled in a Windows environment might make the generated ZIP package unusable for the creation of extensibility actions. Therefore, you must use a Linux shell.

- c) Install your requirements.txt file in the script folder by running the following command:  
`pip install -r requirements.txt --target=/home/user1/zip-action`
4. In the assigned folder, select your script elements and, if applicable, your requirements.txt file and compress them to a ZIP package.

**NOTE**

Both your script and dependency elements must be stored at the root level of the ZIP package. When creating the ZIP package in a Linux environment, you might encounter a problem where the package content is not stored at the root level. If you encounter this problem, create the package by running the `zip -r` command in your command-line shell.

```
cd your_script_and_dependencies_folder
zip -r ../your_action_ZIP.zip *
```

Use the ZIP package to create an extensibility action script. See [How do I create extensibility actions](#).

## Create a ZIP package for Node.js runtime extensibility actions

You can create a ZIP package that contains the Node.js script and dependencies used by your Automation Assembler extensibility actions.

There are two methods of building the script for your extensibility actions:

- Writing your script directly in the extensibility action editor in Automation Assembler.
- Creating your script in your local environment and adding it, with any relevant dependencies, to a ZIP package.

By using a ZIP package, you can create a custom preconfigured template of action scripts and dependencies that you can import to Automation Assembler for use in extensibility actions.

Furthermore, you can use a ZIP package in scenarios where modules associated with dependencies in your action script cannot be resolved by the Automation Assembler service, such as when your environment lacks Internet access.

Also, you can use packages to create extensibility actions that contain multiple Node.js script files. Using multiple script files can be useful for organizing the structure of your extensibility action code.

1. On your local machine, create a folder for your action script and dependencies.  
For example, /home/user1/zip-action.
2. Add your main Node.js action script or scripts to the folder.  
For example, /home/user1/zip-action/main.js.
3. Add any dependencies for your Node.js script to the folder.
  - a) Create a `package.json` file with dependencies in your script folder. See [Creating a package.json file](#) and [Specifying dependencies and devDependencies in a package.json file](#).
  - b) Open a command-line shell.
  - c) Navigate to the folder that you created for the action script and dependencies.

```
cd /home/user1/zip-action
```

- d) Install your `package.json` file in the script folder by running the following command:

```
npm install --production
```

**NOTE**

This command creates a `node_modules` directory in your folder.

4. In the assigned folder, select your script elements and, if applicable, your `node_modules` directory and compress them to a ZIP package.

**NOTE**

Both your script and dependency elements must be stored at the root level of the ZIP package. When creating the ZIP package in a Linux environment, you might encounter a problem where the package content is not stored at the root level. If you encounter this problem, create the package by running the `zip -r` command in your command-line shell.

```
cd your_script_and_dependencies_folder
zip -r ../your_action_ZIP.zip *
```

Use the ZIP package to create an extensibility action script. See [How do I create extensibility actions](#).

## Create a ZIP package for PowerShell runtime extensibility actions

You can create a ZIP package that contains your PowerShell script and dependency modules for use in extensibility actions.

Verify that you are familiar with PowerShell and PowerCLI. You can find a Docker image with PowerShell Core, PowerCLI 10, PowerNSX, and several community modules and script examples at [Docker Hub](#).

There are two methods of building the script for your extensibility actions:

- Writing your script directly in the extensibility action editor in Automation Assembler.
- Creating your script on your local environment and adding it, with any relevant dependencies, to a ZIP package.

By using a ZIP package, you can create a custom preconfigured template of action scripts and dependencies that you can import to Automation Assembler for use in extensibility actions.

**NOTE**

You do not need to define PowerCLI cmdlets as dependencies or bundle them into a ZIP package. PowerCLI cmdlets come preconfigured with the PowerShell runtime of your Automation Assembler service.

Furthermore, you can use a ZIP package in scenarios where modules associated with dependencies in your action script cannot be resolved by the Automation Assembler service, such as when your environment lacks Internet access.

You can also use a ZIP package to create extensibility actions that contain multiple PowerShell script files. Using multiple script files can be useful for organizing the structure of your extensibility action code.

1. On your local machine, create a folder for your action script and dependencies.  
For example, `/home/user1/zip-action`.
2. Add your main PowerShell script with a `.psm1` extension to the folder.  
The following script presents a simple PowerShell function called `main.psm1`:

```
function handler($context, $payload) {
```

```
 Write-Host "Hello " $payload.target
```

```
return $payload
```

**NOTE**

The output of a PowerShell extensibility action is based on the last variable displayed in the body of the function. All other variables in the included function are discarded.

3. Add a proxy configuration to your main PowerShell script by using [context parameters](#). See [Using context parameters to add a proxy configuration in your PowerShell script](#).
4. Add any dependencies for your PowerShell script.

**NOTE**

Your PowerShell dependency script must use the `.psm1` extension. Use the same name for the script and the subfolder where the script is saved.

- a) Log in to a Linux PowerShell shell.

**NOTE**

The runtime of action-based extensibility in Automation Assembler is Linux-based. Any PowerShell dependencies compiled in a Windows environment might make the generated ZIP package unusable. Any installed third-party dependencies must be compatible with the VMware Photon OS as PowerShell scripts run on Photon OS.

- b) Navigate to the `/home/user1/zip-action` folder.
- c) Download and save the PowerShell module containing your dependencies, by running the **Save-Module** cmdlet.

```
Save-Module -Name <module name> -Path ./
```

- d) Repeat the previous substep for any additional dependency modules.

**IMPORTANT**

Verify that each dependency module is located in a separate subfolder. For more information on writing and managing PowerShell modules, see [How to Write a PowerShell Script Module](#).

5. In the assigned folder, select your script elements and, if applicable, your dependency module subfolders and compress them to a ZIP package.

**NOTE**

Both your script and dependency module subfolders must be stored at the root level of the ZIP package. When creating the ZIP package in a Linux environment, you might encounter a problem where the package content is not stored at the root level. If you encounter this problem, create the package by running the **zip -r** command in your command-line shell.

```
cd your_script_and_dependencies_folder
zip -r ../your_action_ZIP.zip *
```

Use the ZIP package to create an extensibility action script. See [How do I create extensibility actions](#).

## Using context parameters to add a proxy configuration in your PowerShell script

You can enable network proxy communication in your PowerShell script by using context parameters.

Certain PowerShell cmdlets might require that you set a network proxy as an environment variable in your PowerShell function. Proxy configurations are provided to the PowerShell function with the \$context.proxy.host and \$context.proxy.port parameters.

You can add these context parameters in the beginning of your PowerShell script.

```
$proxyString = "http://" + $context.proxy.host + ":" + $context.proxy.port
$Env:HTTP_PROXY = $proxyString
$Env:HTTPS_PROXY = $proxyString
```

If the cmdlets support the `-Proxy` parameter, you can also pass the proxy value directly to the specific PowerShell cmdlets.

## Configure cloud-specific extensibility actions

You can configure extensibility actions to work with your cloud accounts.

A valid cloud account is required.

When creating an extensibility action, you can configure and link it to various cloud-based accounts:

- Microsoft Azure
  - Amazon Web Services
1. Select **Extensibility > Library > Action**.
  2. Click **New Action**.
  3. Enter the action parameters as necessary.
  4. In the **FaaS provider** drop-down menu, select your cloud account provider or select **Auto Select**.

### NOTE

If you select **Auto**, the action automatically defines the FaaS provider.

5. Click **Save**.

Your extensibility action is linked for use with the configured cloud account.

## Configure on-premises extensibility actions

You can configure your extensibility actions to use an on-premises FaaS provider instead of an Amazon Web Services or Microsoft Azure cloud account.

By using an on-premises FaaS provider for your extensibility actions, you can use on-premises services like LDAP, CMDB, or vCenter data centers in your Automation Assembler extensibility subscriptions.

1. Select **Extensibility > Library > Actions**.
2. Click **New Action**.
3. Enter a name and project for the extensibility action.
4. Enter a description for the extensibility action.
5. Click **Next**.
6. Create or import your extensibility action script.
7. Click the **FaaS provider** drop-down menu and select **On Prem**.

8. To save the new extensibility action, click **Save**.

Use the created extensibility action in your Automation Assembler extensibility subscriptions.

## How can I create secrets for use in extensibility actions

You can add encrypted inputs to your extensibility action by using project level secrets.

- Create a secret to use with the extensibility action. See [Secret Automation Assembler properties](#).
- Verify that the extensibility action and the secret you want to use together are associated with the same project.

With secrets, you can add encrypted input values to your extensibility actions. Encryption is useful for use cases where your inputs are used to manage sensitive data, such as passwords and certificates. Secrets are available for all FaaS providers and runtimes.

### NOTE

You can also add encrypted input values by using action constants. See [How can I create extensibility action constants](#).

Access to secrets depends on the project that they are created in. Secrets created in Project A, for example, are accessible only to users included in Project A.

Secrets use the `context.getSecret()` function to decrypt the secret value when it is added to your script. This function uses the name of the secret as a parameter. For example, you might use an secret named `abxsecret` as an encrypted input parameter in your action. To add this input parameter to your action script, you must use `context.getSecret(inputs["abxsecret"])`.

1. On the **Extensibility > Actions** page, select an existing extensibility action or create a new extensibility action.
2. Under **Default Inputs**, select the type **Secret**.
3. Search for your secret and add it to the extensibility action inputs.
4. Add the secret to the script of the extensibility action by using the `context.getSecret()` function.
5. To test your secret, click **Test**.

## How can I create extensibility action constants

You can create and store constants for use in extensibility actions.

With extensibility action constants, you can add encrypted input values to your extensibility actions. Encryption is useful for use cases where your inputs are used to manage sensitive data, such as passwords and certificates. Constants are available for all FaaS providers and runtimes.

### NOTE

Unlike secrets, extensibility action constants can only be used for extensibility secrets. For more information on secrets, see [How can I create secrets for use in extensibility actions](#).

Extensibility action constants are accessible to all users included in your organization.

Constants use the `context.getSecret()` function to run as part of your script. This function uses the name of constant as a parameter. For example, you might use an extensibility action constant named `abxconstant` as an encrypted input parameter in your action. To add this input parameter to your action script, you must use `context.getSecret(inputs["abxconstant"])`.

1. Create a extensibility action constant.
  - a) Navigate to **Extensibility > Library > Actions**.
  - b) Select **Action Constants**.
  - c) To create a constant, click **New Action Constant**.
  - d) Enter a name and value for the constant, and click **Save**.
2. Add your constant to a extensibility action.

- a) Select an existing extensibility action or create a new extensibility action.
- b) Under **Default Inputs**, tick the **Secret** check box.
- c) Search for your constant and add it to the extensibility action inputs.
- d) Add the constant to the script of the extensibility action by using the `context.getSecret()` function.
- e) To test your extensibility action constant, click **Test**.

### Create shared extensibility actions

As an Automation Assembler administrator, you create extensibility actions that can be shared across projects without exporting and importing the action.

Create two or more projects in your Automation Assembler organization.

For information on exporting and importing extensibility actions, see [Export and import extensibility actions](#).

1. Select **Extensibility > Library > Actions**.
2. Click **New Action**.
3. Enter a name for your extensibility action.
4. Enter a description for your extensibility action.
5. Select a project in which your extensibility action is created.
6. Tick the **Share with all projects in this organization** checkbox.
7. Click **Next**.
8. Create or import your action script, and save your extensibility action.

#### NOTE

You can enable or disable sharing from **Settings**. If the extensibility action is used in subscriptions, you cannot disable sharing. To disable sharing, you must remove the extensibility action from your subscriptions.

9. Create an extensibility subscription, add the shared extensibility action, and set the subscription scope to **Any Project**.

#### NOTE

For more information on creating extensibility subscriptions, see [Create an extensibility subscription](#).

The extensibility subscription is triggered by matching events in any of your projects.

You can also import shared extensibility actions as a content source in the Automation Service Broker catalog. When you select the source project, enter the project that the extensibility action was created in. For more information on adding extensibility actions to Automation Service Broker, see [Add extensibility actions to the Service Broker catalog](#).

### Configuring the Log Analytics Workspace for Azure based extensibility actions

You can use the Log Analytics Workspace to gather useful logging data about your Azure based extensibility actions. Before using the Log Analytics Workspace, you must register the relevant resource provider.

Verify that your Microsoft Azure account has the **Contributor** or **Owner** role. These roles include the permission to use the `/register/action` operation required for registering a resource provider. You can view your active roles by navigating to your subscription and selecting **My permissions**.

Log Analytics enables you to edit and run log queries on data collected by Azure Monitor Logs, and then interactively analyze the results. You can use Log Analytics queries to retrieve records that match specific criteria to help identify trends and patterns and provide multiple data insights. Before using Log Analytics, you must register the **Microsoft.OperationalInsights** resource provider to your Azure subscription.

1. Log in to the Microsoft Azure portal.
2. In the search box, enter Subscriptions.
3. Select the **Subscriptions** service.
4. Select the subscription associated with your extensibility actions.
5. From the left-side navigation pane, select **Resource providers**.
6. In the **Filter by name** search box, enter **Microsoft.OperationalInsights**.
7. To finish registering the resource provider, click **Register**.  
The status of the **Microsoft.OperationalInsights** resource provider changes from **NotRegistered** to **Registered**.

## Azure logging for Python-based extensibility actions

You can now use Microsoft Azure 3.x logging functions in your extensibility action script.

Extensibility actions in Automation Assembler now use the Microsoft Azure 3.x Scripting API which replaces the previous 1.x version. Microsoft Azure 3.x Scripting API is Linux-based and runs in a container environment.

Because of this version change, logging functions inserted into the script of extensibility actions that use Microsoft Azure as a FaaS (Function as a Service) provider work differently. The next two script samples demonstrate the different logging functions used in the two API versions.

Microsoft Azure 1.x script sample.

```
def handler(context, inputs):
 greeting = "Hello, {0}!".format(inputs["target"])
 print(greeting)

 outputs = {
 "greeting": greeting
 }

 return outputs
```

Microsoft Azure 3.x script sample.

```
import logging

def handler(context, inputs):
 greeting = "Hello, {0}!".format(inputs["target"])
 logging.info(greeting)

 outputs = {
 "greeting": greeting
 }
```

```

 }
 return outputs
}

```

The preceding sample demonstrates that the 3.x version adds the `import logging` function at the beginning of the script while replacing the `print()` function with the `logging.info()` function. To continue using logging with extensibility actions created in the Microsoft Azure 1.x API, you must change the logging functions in your script so it matches the Microsoft Azure 3.x sample.

For more information on logging, see the [Azure Functions Python developer guide](#).

### **Export and import extensibility actions**

With Automation Assembler, you can export and import extensibility actions for use in different projects.

An existing extensibility action.

1. Export an extensibility action.
  - a) Navigate to **Extensibility > Library > Actions**.
  - b) Select an extensibility action and click **Export**.  
The action script and its dependencies are saved on your local environment as a ZIP file.
2. Import an extensibility action.
  - a) Navigate to **Extensibility > Library > Actions**.
  - b) Click **Import**.
  - c) Select the exported extensibility action and assign it to a project.
  - d) Click **Import**.

#### **NOTE**

If the imported extensibility action is already assigned to the specified project, you are prompted to select a conflict resolution policy.

## **What is an action flow**

Action flows are a set of extensibility action scripts that are used to extend life cycles and automation further.

All action flows begin with `flow_start` and end with `flow_end`. You can link several extensibility action scripts together, by using the following action flow elements:

- **Sequential** - Multiple extensibility action scripts running sequentially.
- **Fork** - Multiple extensibility action scripts or flows that split pathways to contribute to the same output.
- **Join** - Multiple extensibility action scripts or flows that join together and contribute to the same output.
- **Conditional** - Multiple extensibility action scripts or flows that run after a condition is satisfied.

### **Sequential action flows**

Multiple extensibility action scripts running sequentially.

```

version: "1"
flow:
 flow_start:
 next: action1
 action1:
 action: <action_name>
 next: action2
 action2:
 action: <action_name>
 next: flow_end

```

**NOTE**

You can loop back to a previous action by assigning it as the `next: action`. For instance, in this example, instead of `next: flow_end`, you can enter `next: action1` to rerun `action1` and restart the sequence of actions.

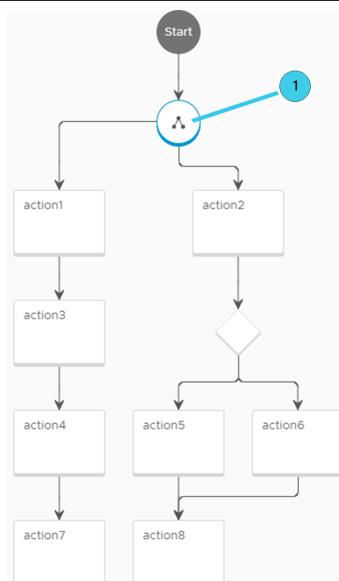

**Fork action flows**

Multiple extensibility action scripts or flows that split pathways to contribute to the same output.

```

version: "1"
flow:
 flow_start:
 next: forkAction
 forkAction:
 fork:
 next: [action1, action2]
 action1:
 action: <action_name>
 next: action3
 action3:
 action: <action_name>
 next: action4
 action4:
 action: <action_name>
 next: action7
 action7:
 action: <action_name>
 next: flow_end

```

*Table continued on next page*

*Continued from previous page*

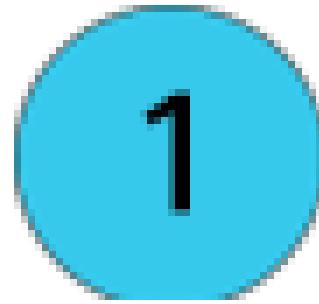

```
action4:
 action: <action_name>
 next: action7

action7:
 action: <action_name>

action2:
 action: <action_name>
```

#### NOTE

You can loop back to a previous action by assigning it as the `next: action`. For example, instead of `next: flow_end` to end your action flow, you can enter `next: action1` to rerun `action1` and restart the sequence of actions.

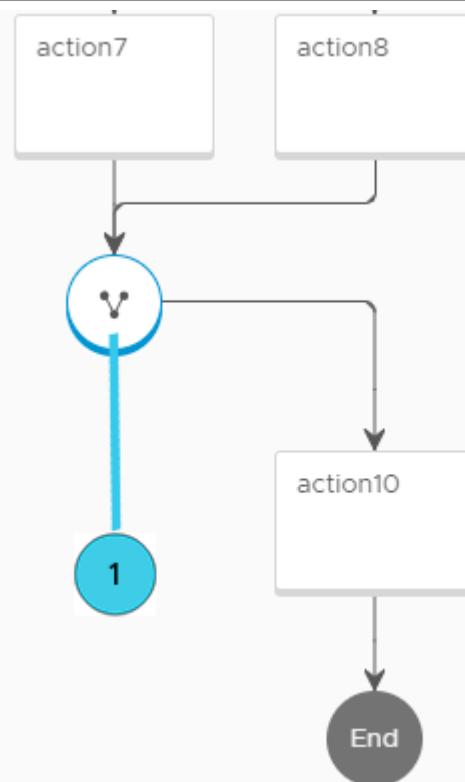

Fork Element

## Join action flows

Multiple extensibility action scripts or flows that join pathways together and contribute to the same output.

```
version: "1"
action7:
 action: <action_name>
 next: joinElement
action8:
 action: <action_name>
 next: joinElement
joinElement:
 join:
 type: all
 next: action10
action10:
 action: <action_name>
 next: flow_end
```

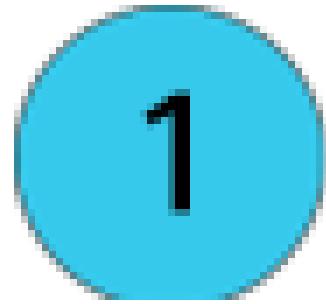

*Table continued on next page*

*Continued from previous page*

**NOTE**

You can loop back to a previous action by assigning it as the `next: action`. For instance, in this example, instead of `next: flow_end`, you can enter `next: action1` to rerun `action1` and restart the sequence of actions.

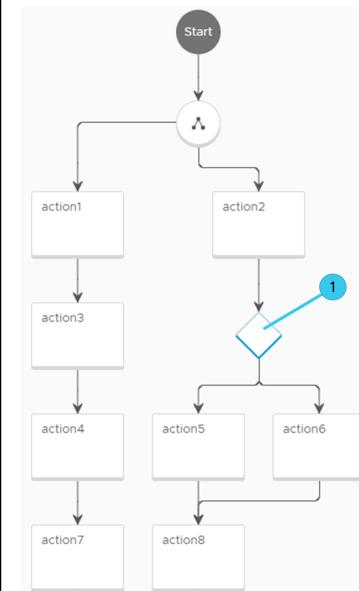

Join Element

## Conditional action flows

Multiple extensibility action scripts or flows that run when a condition is satisfied using a switch element.

In some cases, the condition must be equal to `true` in order for the action to run. Other cases, as seen in this example, require parameter values to be met before an action can run. If none of the conditions are met the action flow fails.

```
version: 1
id: 1234
name: Test
inputs: ...
outputs: ...
flow:
 flow_start:
 next: forkAction
 forkAction:
 fork:
 next: [action1, action2]
 action1:
 action: <action_name>
 next: action3
 action3:
 action: <action_name>
 next: action4
 action4:
 action: <action_name>
 next: action7
 action7:
```

Switch element

*Table continued on next page*

*Continued from previous page*

```

action: <action_name>
next: joinElement

action2:
action: <action_name>
next: switchAction

switchAction:
switch:
"${1 == 1}": action5
"${1 != 1}": action6

action5:
action: <action_name>
next: action8

action6:
action: <action_name>
next: action8

action8:
action: <action_name>
```

**NOTE**

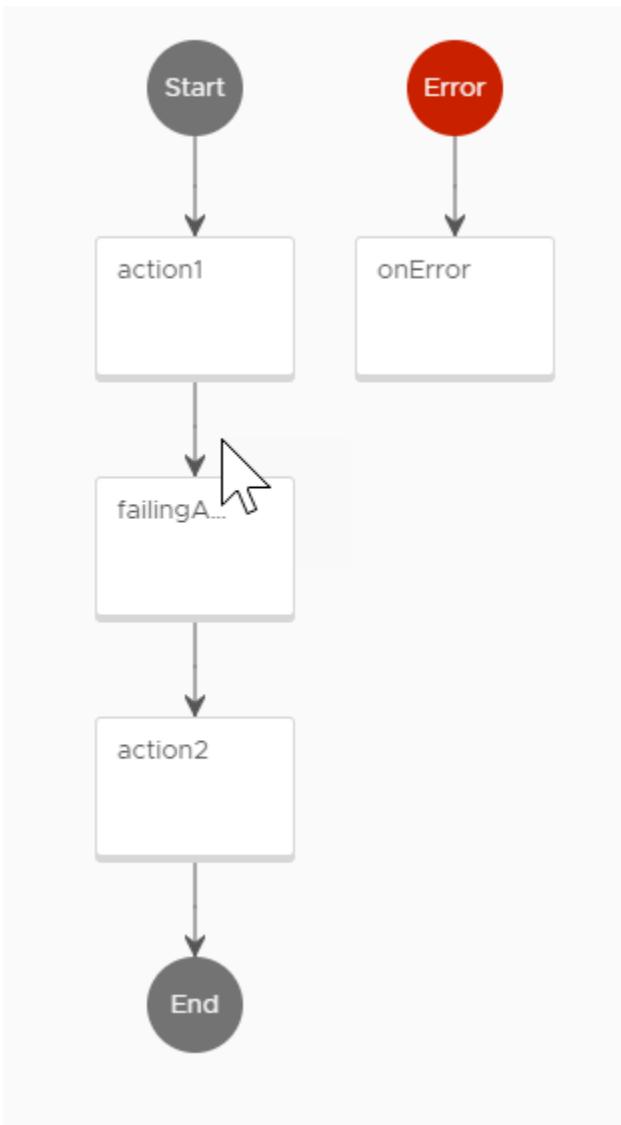

You can loop back to a previous action by assigning it as the `next: action`. For example, instead of `next: flow_end` to end your action flow, you can enter `next: action1` to rerun `action1` and restart the sequence of actions.

## How do I use an error handler with action flows

You can configure your action flow to issue an error at specified stages of the flow by using an error handler element.

An error handler element requires two inputs:

- Specified error message of the failed action.
- Action flow inputs.

If an action in your flow fails and the action flow contains an error handler element, an error message is issued alerting you of the action failure. The error handler is an action on its own. The following script is an example of an error handler that can be used in an action flow.

```
def handler(context, inputs):

 errorMsg = inputs["errorMsg"]
 flowInputs = inputs["flowInputs"]

 print("Flow execution failed with error {}".format(errorMsg))
 print("Flow inputs were: {}".format(flowInputs))
```

```

outputs = {

 "errorMsg": errorMsg,
 "flowInputs": flowInputs
}

return outputs

```

You can view the successful and failed runs on the Action Runs window.

The screenshot shows the VMware Aria Automation Cloud Assembly interface. The top navigation bar includes tabs for Deployments, Blueprints, Infrastructure, Extensibility (which is currently selected), and Marketplace. On the left, a sidebar menu lists Events, Subscriptions, Library (with Event Topics, Actions, Workflows), and Activity (with Action Runs selected). The main content area is titled 'Action Runs' and displays a table with 3943 items. The table has columns for a checkbox, Status (with icons for green checkmark or red exclamation mark), Run ID, and Action name (error-handler, failing-action, simple-hello, flow-with-handler). The table shows four rows: one completed run for 'error-handler', one failed run for 'failing-action', and two completed runs for 'simple-hello' and 'flow-with-handler' respectively.

|                          | Status    | Run ID                   | Action            |
|--------------------------|-----------|--------------------------|-------------------|
| <input type="checkbox"/> | Completed | 8a76996b6839fe3c01684... | error-handler     |
| <input type="checkbox"/> | Failed    | 8a76996b6839fe3c01684... | failing-action    |
| <input type="checkbox"/> | Completed | 8a76996b6839fe3c01684... | simple-hello      |
| <input type="checkbox"/> | Completed | 8a76996b6839fe3c01684... | flow-with-handler |

In this example, the flow-with-handler action flow, which contains an error handler element, was run successfully. However, one of the actions in the flow failed, which then initiated the error handler to issue an error.

## How do I track action runs

The action runs tab shows you a log of subscription triggered extensibility actions and their status.

You can view the log of action runs using **Extensibility > Activity > Action Runs**. You can also filter the list of action runs by one or more properties at once.

## Troubleshooting failed extensibility action runs

If your extensibility action run fails, you can perform troubleshooting steps to correct it.

When an action run fails you might receive an error message, a failed status, and a failed log. If your action run fails, it is either due to a deployment or code failure.

| Problem            | Solution                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Deployment Failure | These failures are a result of problems related to the cloud account configuration, action deployment, or other dependencies that can prevent the action from deploying. Ensure that the project you used is defined within the configured cloud account and granted permissions to run functions. Before initiating the action again, you can test the action against a specific project within the action's details page. |
| Code Failure       | These failures are a result of invalid scripts or code. Use the Action run logs to troubleshoot and correct the invalid scripts.                                                                                                                                                                                                                                                                                            |

## Extensibility workflow subscriptions

You can use your Automation Orchestrator hosted workflows with Automation Assembler to extend application lifecycle.

### How do I modify virtual machine properties using a Automation Orchestrator workflow subscription

You can use an existing Automation Orchestrator workflow to modify virtual machine properties and add virtual machines to the active directory.

- Cloud administrator user role
- Existing Automation Orchestrator on-premises workflows.
- Successful integration and connection to the Automation Orchestrator client server.

The event topic parameters define the format of the payload for Event Broker Service (EBS) messages. To receive and use EBS message payload inside a workflow, you must define the `inputProperties` workflow input parameters.

1. Select **Extensibility > Subscriptions**.
2. Click **New Subscription**.
3. Create a subscription with the following parameters:

| Parameter             | Value                                                                                                                |
|-----------------------|----------------------------------------------------------------------------------------------------------------------|
| Name                  | RenameVM                                                                                                             |
| Event topic           | Select an event topic suitable for the desired Automation Orchestrator integration. For example, compute allocation. |
| Blocking/Non-blocking | Non-blocking                                                                                                         |
| Action/workflow       | Select a Automation Orchestrator runnable type. Select the desired workflow. For example, Set VM name.               |

4. To save your subscription, click **Save**.
5. Assign and activate your subscription by creating a cloud template or deploying an existing cloud template.

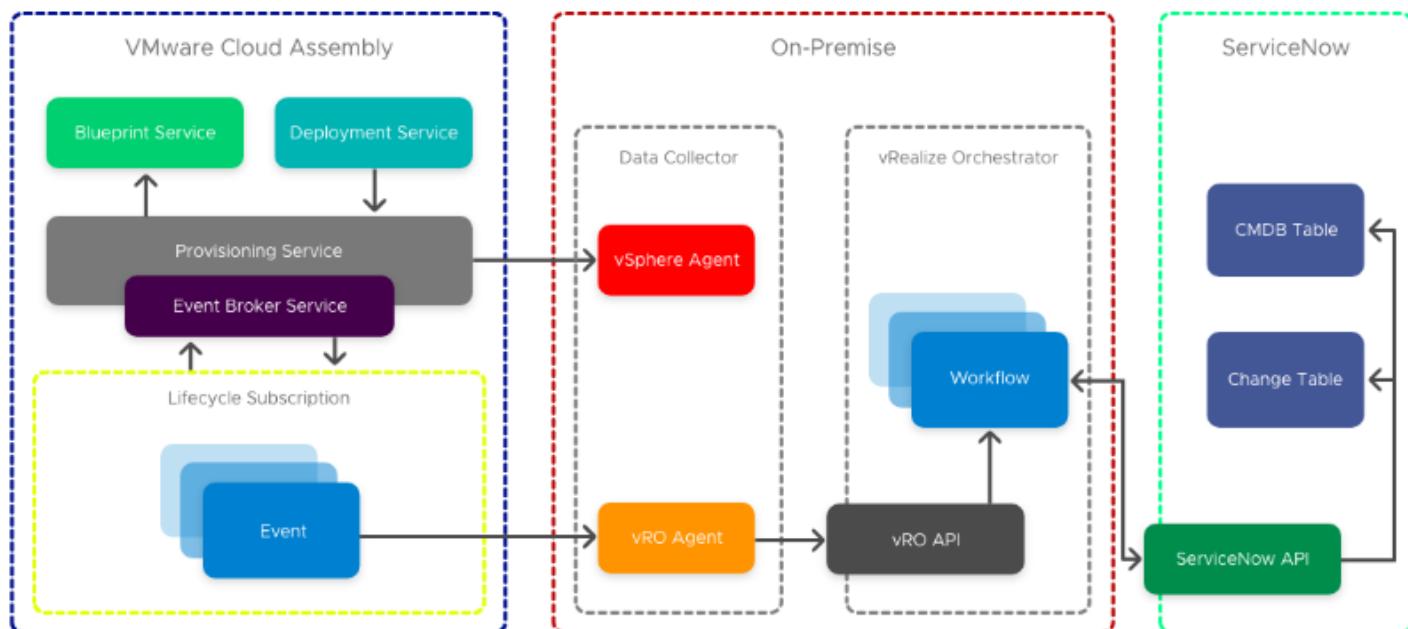

Verify that the workflow initiated successfully by one of the following methods:

- Verify the workflow runs log, **Extensibility > Activity > Workflow Runs**.
- Open the Automation Orchestrator client and check workflow status by navigating to the workflow and verifying the status or by opening the specific logs tab.

## How do I integrate Automation Assembler for ITSM with ServiceNow using Automation Orchestrator workflows

Using Automation Orchestrator hosted workflows, you can integrate Automation Assembler with ServiceNow for ITSM compliance.

- A standalone or clustered Automation Orchestrator environment.
- A Automation Orchestrator integration in Automation Assembler. For information on integrating a standalone Automation Orchestrator with Automation Assembler, see [Configure an integration in](#).

Enterprise users commonly integrate their Cloud Management Platform with an IT Service Management (ITSM) and Configuration Management Database (CMDB) platform for compliance. Following this example, you can integrate Automation Assembler with ServiceNow for CMDB and ITSM using Automation Orchestrator hosted workflows. When using Automation Orchestrator integrations and workflows, capability tags are especially useful if you have multiple instances for different environments. For more information on capability tags, See [Using capability tags in](#).

### NOTE

You can also integrate ServiceNow with Automation Assembler using extensibility action scripts. For information about integrating ServiceNow using extensibility action scripts, see [How do I integrate with ServiceNow using extensibility actions](#).

In this example, the ServiceNow integration is composed of three top-level workflows. Each workflow has their own subscriptions so that you can update and iterate each component individually.

- Event subscription entry point - Basic logging, identifies the requesting user and vCenter VM, if applicable.
- Integration workflow - Separates objects and feeds inputs into the technical workflow, handles logging, property, and output updates.
- Technical workflow - Downstream system integration for ServiceNow API to create the CMDB CI, CR, and Automation Assembler IaaS API with additional virtual machine properties outside of the payload.

1. Create and save a configuration file in Automation Orchestrator that contains common configuration used in multiple workflows.
2. Save your Automation Assembler API token in the same location, as the configuration file from Step 1.

**NOTE**

The Automation Assembler API token has an expiration.

3. Create a workflow in Automation Orchestrator with the provided script element. This script references and locates a REST Host. It also standardizes REST actions that use an optional parameter of a token, which is added as an extra authorization header.

```

var configPath = "CS"

var configName = "environmentConfig"

var attributeName = "CASRestHost"

//get REST Host from configuration element

var restHost =
System.getModule("au.com.cs.example").getRestHostFromConfig(configPath,configName,attributeName)

var ConfigurationElement =
System.getModule("au.com.cs.example").getConfigurationElementByName(configName,configPath);

System.debug("ConfigurationElement:" + ConfigurationElement);

var casToken = ConfigurationElement.getAttributeWithKey("CASToken") ["value"]

if(!casToken) {

 throw "no CAS Token";

}

//REST Template

var opName = "casLogin";

var opTemplate = "/iaas/login";

var opMethod = "POST";

// create the REST operation:

var opLogin =
System.getModule("au.com.cs.example").createOp(restHost,opName,opMethod,opTemplate);

//cas API Token

var contentObject = {"refreshToken":casToken}

```

```
postContent = JSON.stringify(contentObject);

var loginResponse =
System.getModule("au.com.cs.example").executeOp(opLogin,null,postContent,null) ;

try{
 var tokenResponse = JSON.parse(loginResponse) ['token']
 System.debug("token: " + tokenResponse);
} catch (ex) {
 throw ex + " No valid token";
}

//REST Template Machine Details

var opName = "machineDetails";
var opTemplate = "/iaas/machines/" + resourceId;
var opMethod = "GET";

var bearer = "Bearer " + tokenResponse;

var opMachine =
System.getModule("au.com.cs.example").createOp(restHost,opName,opMethod,opTemplate);

// (Rest Operation, Params, Content, Auth Token)

var vmResponse =
System.getModule("au.com.cs.example").executeOp(opMachine,null,"",bearer) ;

try{
 var vm = JSON.parse(vmResponse);
} catch (ex) {
 throw ex + " failed to parse vm details"
}

System.log("cpuCount: " + vm["customProperties"]["cpuCount"]);
System.log("memoryInMB: " + vm["customProperties"]["memoryInMB"]);
```

```
cpuCount = vm["customProperties"]["cpuCount"];
memoryMB = vm["customProperties"]["memoryInMB"];
```

This script sends the output `cpuCount` and `memoryMB` to the parent workflow and updates the existing `customProperties` properties. These values can be used in subsequent workflows when creating the CMDB.

4. Add the ServiceNow CMDB Create CI script element to your workflow. This element locates the ServiceNow REST Host using the configuration item, creates a REST operation for the `cmdb_ci_vmware_instance` table, creates a string of content object based on workflow inputs for post data, and outputs the returned `sys_id`.

```
var configPath = "CS"
var configName = "environmentConfig"
var attributeName = "serviceNowRestHost"
var tableName = "cmdb_ci_vmware_instance"

//get REST Host from configuration element
var restHost =
System.getModule("au.com.cs.example").getRestHostFromConfig(configPath,configName,attributeName)

//REST Template
var opName = "serviceNowCreateCI";
var opTemplate = "/api/now/table/" + tableName;
var opMethod = "POST";

// create the REST operation:
var opCI =
System.getModule("au.com.cs.example").createOp(restHost,opName,opMethod,opTemplate);

//cmdb_ci_vmware table content to post;
var contentObject = {};
contentObject["name"] = hostname;
contentObject["cpus"] = cpuTotalCount;
contentObject["memory"] = MemoryInMB;
contentObject["correlation_id"] = deploymentId
contentObject["disks_size"] = diskProvisionGB
```

```

contentObject["location"] = "Sydney";
contentObject["vcenter_uuid"] = vcUuid;
contentObject["state"] = "On";
contentObject["owned_by"] = owner;

postContent = JSON.stringify(contentObject);
System.log("JSON: " + postContent);

// (Rest Operation, Params, Content, Auth Token)
var ciResponse =
System.getModule("au.com.cs.example").executeOp(opCI,null,postContent,null) ;

try{
 var cmdbCI = JSON.parse(ciResponse);
} catch (ex) {
 throw ex + " failed to parse ServiceNow CMDB response";
}

serviceNowSysId = cmdbCI['result']['sys_id'];

```

- Using the output from the child workflow, create a properties object using the existing `customProperties` and overwrite the `serviceNowSysId` property with the value from ServiceNow. This unique id is used in the CMDB to mark an instance as retired on destroy.

Automation Assembler is successfully integrated with ITSM ServiceNow.

### **Learn more about workflow subscriptions**

By using an Automation Orchestrator integration with Automation Assembler, you can extend the life cycles of applications with workflows.

VMware Aria Automation includes an embedded Automation Orchestrator deployment. You can use the workflow library of the embedded Automation Orchestrator deployment in your subscriptions. You can create, modify, and delete workflows by using the Automation Orchestrator client.

You can also integrate an external Automation Orchestrator deployment in Automation Assembler. See [Configure an integration in](#).

## Best practices for creating Automation Orchestrator workflows

A workflow subscription is based on a specific event topic and the event parameters of that topic. To ensure that the subscriptions initiate the Automation Orchestrator workflows, you must configure them with the correct input parameters so that they work with the event data.

### Workflow Input Parameters

Your custom workflow can include all the parameters or a single parameter that consumes all the data in the payload.

To use a single parameter, configure one parameter with a type of `Properties` and name `inputProperties`.

### Workflow Output Parameters

Your custom workflow can include output parameters that are relevant to subsequent events necessary for a reply event topic type.

If an event topic expects a reply, the workflow output parameters must match the parameters of the reply schema.

## How do I track workflow runs

The **Workflow Runs** window displays the logs of the subscription triggered workflows and their status.

You can view the logs of your workflow runs by navigating to **Extensibility** > **Activity** > **Workflow Runs**.

## Troubleshooting failed workflow subscriptions

If your workflow subscription fails, you can perform troubleshooting steps to correct it.

Failed workflow runs can cause your workflow subscription not to start or complete successfully. Workflow run failure can result from several common problems.

| Problem                                                                                    | Cause                                                                                                                                                       | Solution                                                                                                                                                                                                                                                                                                                                                                |
|--------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Your Automation Orchestrator workflow subscription did not start or complete successfully. | You configured a workflow subscription to run a custom workflow when the event message is received, but the workflow does not run or complete successfully. | <ol style="list-style-type: none"> <li>Verify that the workflow subscription is saved correctly.</li> <li>Verify that the workflow subscription conditions are configured correctly.</li> <li>Verify that Automation Orchestrator contains the specified workflow.</li> <li>Verify that the workflow is configured correctly within Automation Orchestrator.</li> </ol> |
| Your approval request Automation                                                           | You configured a pre-approval or post-approval workflow subscription to run a Automation Orchestrator workflow. The workflow does not run.                  | To successfully run an approval workflow subscription, you must verify that all the components are configured correctly.                                                                                                                                                                                                                                                |

### Learn more about extensibility subscriptions

You can extend your application life cycles by using either extensibility actions or Automation Orchestrator workflows with extensibility subscriptions.

When a triggering event occurs in your environment, the subscription is initiated and the specified workflow or extensibility action is run. You can view system events on the event log, workflow runs in the workflow runs window, and action runs in the action run window. Subscriptions are project-specific, meaning they are linked to cloud templates and deployments through the specified project.

### Extensibility terminology

As you work with extensibility subscriptions within Automation Assembler, you might encounter some terminology that is specific to the subscriptions and event broker service.

**Table 31: Extensibility Terminology**

| Term        | Description                                                                                                                                                                                                                                                                  |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Event Topic | <p>Describes a set of events that have the same logical intent and the same structure. Every event is an instance of an event topic.</p> <p>You can assign blocking parameters to certain event topics. For more information, see <a href="#">Blocking event topics</a>.</p> |

| <b>Term</b>           | <b>Description</b>                                                                                                                                                                                                                                                                                             |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Event                 | Indicates a change in the state in the producer or any of the entities managed by it. The event is the entity that records information about the event occurrence.                                                                                                                                             |
| Event Broker Service  | The service that dispatches messages published by a producer to the subscribed consumers.                                                                                                                                                                                                                      |
| Payload               | The event data that contains all the relevant properties related to that Event Topic.                                                                                                                                                                                                                          |
| Subscription          | Indicates that a subscriber is interested in being notified about an event by subscribing to an event topic and defining the criteria that triggers the notification. Subscriptions link either extensibility actions or workflows to triggering events used to automate parts of the applications life cycle. |
| Subscriber            | The users notified by the events published to the event broker service based on the subscription definition. The subscriber can also be called a consumer.                                                                                                                                                     |
| System Administrator  | A user with privileges to create, read, update, and delete tenant workflow subscriptions and system workflow subscriptions using Automation Assembler.                                                                                                                                                         |
| Workflow Subscription | Specifies the event topic and conditions that trigger a Automation Orchestrator workflow.                                                                                                                                                                                                                      |
| Action Subscription   | Specifies the event topic and conditions that trigger an extensibility action to run.                                                                                                                                                                                                                          |
| Workflow              | A Automation Orchestrator workflow that is integrated within Automation Assembler. You can link these workflows to events within subscriptions.                                                                                                                                                                |
| Extensibility Action  | A streamlined script of code that can run after an event is triggered in a subscription. Extensibility actions are similar to workflows, but are more lightweight. Extensibility actions can be customized from within Automation Assembler.                                                                   |
| Action Runs           | Accessible through the <b>Action Runs</b> tab. An action run is a detailed log of extensibility actions that have run in response to triggering events.                                                                                                                                                        |

## Blocking event topics

Some event topics support blocking events. The behavior of an extensibility subscription depends on whether the topic supports these event types and how you configure the subscription.

Automation Assembler extensibility subscriptions can use two broad types of event topics: non-blocking and blocking event topics. The event topic type defines the behavior of the extensibility subscription.

### Non-Blocking Event Topics

Non-blocking event topics only allow you to create non-blocking subscriptions. Non-blocking subscriptions are triggered asynchronously and you cannot rely on the order that the subscriptions are triggered in.

#### Blocking Event Topics

Some event topics support blocking. If a subscription is marked as blocking, all messages that meet the set conditions are not received by any other subscriptions with matching conditions until the runnable item of the blocking subscription is run.

Blocking subscriptions run in priority order. The highest priority value is 0 (zero). If you have more than one blocking subscription for the same event topic with the same priority level, the subscriptions run in a reverse alphabetical order based on the name of the subscription. After all blocking subscriptions are processed, the message is sent to all the non-blocking subscriptions at the same time. Because the blocking subscriptions run synchronously, the changed event payload includes the updated event when the subsequent subscriptions are notified.

You can use blocking event topics to manage multiple subscriptions that are dependent on each other.

For example, you can have two provisioning workflow subscriptions where the second subscription depends on the results of the first subscription. The first subscription changes a property during provisioning, and the second subscription records the new property, such as a machine name, in a file system. The ChangeProperty subscription is prioritized as 0 and the RecordProperty is prioritized as 1 because the second subscription uses the results of the first subscription. When a machine is provisioned, the ChangeProperty subscription begins running. Because the RecordProperty subscription conditions are based on a post-provisioning condition, an event triggers the RecordProperty subscription. However, because the ChangeProperty workflow is a blocking workflow, the event is not received until it is finished. When the machine name is changed and the first workflow subscription is finished, the second workflow subscription runs and records the machine name in the file system.

#### Recovery Runnable Item

For blocking event topics, you can add a recovery runnable item to the subscription. The recovery runnable item in a subscription runs if the primary runnable item fails. For example, you can create a workflow subscription where the primary runnable item is a workflow that creates records in a CMDB system such as ServiceNow. Even if the workflow subscription fails, some records might be created in the CMDB system. In this scenario, a recovery runnable item can be used to clean up the records left in the CMDB system by the failed runnable item.

For use cases that include multiple subscriptions that are dependent on each other, you can add a `ebs.recover.continuation` property to the recovery runnable item. With this property, you can direct if the Extensibility service must continue with the next subscription in your chain, if the current subscription fails.

## **Event topics provided with Automation Assembler**

Automation Assembler includes predefined event topics.

#### Event Topics

Event topics are the categories that group similar events together. When assigned to a subscription, event topics define which event triggers the subscription. The following event topics are provided by default with Automation Assembler. All topics can be used to add or update custom properties or tags of the resource. If a Automation Orchestrator workflow or extensibility action fails, the corresponding task fails as well.

**Table 32: Automation Assembler Event Topics**

| Event Topic            | Blockable | Description                                                                                   |
|------------------------|-----------|-----------------------------------------------------------------------------------------------|
| Approval Events        | Yes       | Issued when an action that requires an approval is triggered.                                 |
| Template configuration | No        | Issued when a cloud template configuration event, such as the creation or deletion of a cloud |

| <b>Event Topic</b>                | <b>Blockable</b> | <b>Description</b>                                                                                                                                                                                                                  |
|-----------------------------------|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                   |                  | template, occurs. This event topic can be useful for notifying external systems of such events.                                                                                                                                     |
| Template version configuration    | No               | Issued when a new cloud template versioning event occurs, such as the creation, release, de-release, or restoration of a version. This event topic can be useful with integrations of third-party version control systems.          |
| Compute allocation                | Yes              | Issued before the allocation of <code>resourcenames</code> and <code>hostselections</code> . Both of these properties can be modified at this stage. Issued once for a cluster of machines.                                         |
| Compute gateway post provisioning | Yes              | Issued after a compute gateway resource is provisioned.                                                                                                                                                                             |
| Compute gateway post removal      | Yes              | Issued after a compute gateway is removed.                                                                                                                                                                                          |
| Compute gateway provisioning      | Yes              | Issued before a compute gateway is provisioned.                                                                                                                                                                                     |
| Compute gateway removal           | Yes              | Issued before a compute gateway is removed.                                                                                                                                                                                         |
| Compute initial power on          | Yes              | Issued after a resource is provisioned at the hypervisor layer, but before the resource is powered on for the first time. Currently, this event topic is only supported for vSphere. Events are sent for each machine in a cluster. |
| Compute nat post provisioning     | Yes              | Issued after a compute NAT resource is provisioned.                                                                                                                                                                                 |
| Compute nat post removal          | Yes              | Issued after a compute NAT resource is removed.                                                                                                                                                                                     |
| Compute nat provisioning          | Yes              | Issued before a compute NAT is provisioned.                                                                                                                                                                                         |
| Compute nat removal               | Yes              | Issued before a compute NAT is removed.                                                                                                                                                                                             |
| Compute post provision            | Yes              | Issued after a resource is provisioned. Events are sent for each machine in a cluster.                                                                                                                                              |
| Compute post removal              | Yes              | Issued after a compute resource is removed. Events are sent for each machine in a cluster.                                                                                                                                          |
| Compute provision                 | Yes              | Issued before the resource is provisioned at the hypervisor layer. Events are sent for each machine in a cluster.                                                                                                                   |

| Event Topic                             | Blockable | Description                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------------------------|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                         |           | <b>NOTE</b><br>You can change the allocated IP address.                                                                                                                                                                                                                                                                                                          |
| Compute removal                         | Yes       | Issued before the resource is removed. Events are sent for each machine in a cluster.                                                                                                                                                                                                                                                                            |
| Compute reservation                     | Yes       | Issued at the time of reservation.<br>Issued once for a cluster of machines.<br><b>NOTE</b><br>You can change the placement order.                                                                                                                                                                                                                               |
| Compute post migration reconcile status | No        | When a managed virtual machine is moved by using vMotion in vCenter or across vCenter instances, the VM is then reconciled in VMware Aria Automation. This event topic is issued to publish details of this virtual machine. The event topic contains the status of the VM reconciliation in VMware Aria Automation and the destination details of the moved VM. |
| Custom resource post provision          | Yes       | Issued for post provisioning events triggered by custom resource operations.<br><b>NOTE</b><br>This event topic is usable only for Automation<br>Orchestrator-based custom resources.                                                                                                                                                                            |
| Custom resource pre provision           | Yes       | Issued for pre provisioning events triggered by custom resource operations.<br><b>NOTE</b><br>This event topic is usable only for Automation<br>Orchestrator-based custom resources.                                                                                                                                                                             |
| Deployment action completed             | Yes       | Issued after a deployment action is finished.                                                                                                                                                                                                                                                                                                                    |

| Deployment action requested          | Yes              | Issued before a deployment action is finished.                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Deployment completed                 | Yes              | Issued after the deployment of a cloud template or catalog request.                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Deployment onboarded                 | No               | Issued when a new deployment is onboarded.                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Deployment requested                 | Yes              | Issued before the deployment of a cloud template or catalog request.                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Deployment resource action completed | Yes              | Issued after the deployment of a resource action.                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Deployment resource action requested | Yes              | Issued before the deployment of a resource action.                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Deployment resource completed        | Yes              | Issued after the provisioning of a deployment resource.                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Deployment resource requested        | Yes              | Issued before the provisioning of a deployment resource.                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Disk allocation                      | Yes              | Issued for the preallocation of disk resources.                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Disk attach                          | Yes              | <p>Issued before a disk is attached to a machine. <code>Disk attach</code> is a read and write event. Disk properties supported for write-back are:</p> <ul style="list-style-type: none"> <li>• <code>diskFullPaths</code></li> <li>• <code>diskDatastoreNames</code></li> <li>• <code>diskParentDirs</code></li> </ul> <p>All three vSphere specific disk properties are required for updates. All other properties are read-only.</p> <p><b>NOTE</b><br/>Write-back is optional for vSphere First Class Disks.</p> |
| Disk detach                          | Yes              | Issued after a disk is detached from a machine. <code>Disk detach</code> is a read-only event.                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Disk post removal                    | Yes              | Issued after a disk resource is deleted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Disk post resize                     | Yes              | Issued after a disk resource is resized.                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Idem Service post event              | No               | Issued when an idem task is completed or failed                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Kubernetes cluster allocation        | Yes              | Issued for the preallocation of resources for a Kubernetes cluster.                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Kubernetes cluster post provision    | Yes              | Issued after a Kubernetes cluster is provisioned.                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Kubernetes cluster post removal      | Yes              | Issued after a Kubernetes cluster is deleted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

|------------------------------------------------|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Kubernetes cluster provision                   | Yes       | Issued before a Kubernetes cluster is provisioned.                                                                                                                                                                                                                                                                              |
| Kubernetes cluster removal                     | Yes       | Issued before the process of deleting a Kubernetes cluster is initiated.                                                                                                                                                                                                                                                        |
| Kubernetes namespace allocation                | Yes       | Issued during the preallocation for Kubernetes namespace resources.                                                                                                                                                                                                                                                             |
| Kubernetes namespace post provision            | Yes       | Issued after a Kubernetes namespace resource is provisioned.                                                                                                                                                                                                                                                                    |
| Kubernetes namespace post removal              | Yes       | Issued after a Kubernetes namespace resource is removed.                                                                                                                                                                                                                                                                        |
| Kubernetes namespace provision                 | Yes       | Issued before a Kubernetes namespace is provisioned.                                                                                                                                                                                                                                                                            |
| Kubernetes namespace removal                   | Yes       | Issued before a namespace cluster resource is removed.                                                                                                                                                                                                                                                                          |
| Kubernetes supervisor namespace allocation     | Yes       | Issued during the preallocation for Kubernetes supervisor namespace resources.                                                                                                                                                                                                                                                  |
| Kubernetes supervisor namespace post provision | Yes       | Issued after a supervisor namespace is provisioned.                                                                                                                                                                                                                                                                             |
| Kubernetes supervisor namespace post removal   | Yes       | Issued after a supervisor namespace resource is removed.                                                                                                                                                                                                                                                                        |
| Kubernetes supervisor namespace provision      | Yes       | Issued before a supervisor namespace is provisioned.                                                                                                                                                                                                                                                                            |
| Kubernetes supervisor namespace removal        | Yes       | Issued before a supervisor namespace resource is removed.                                                                                                                                                                                                                                                                       |
| Load balancer post provision                   | Yes       | Issued after the provisioning of a load balancer.                                                                                                                                                                                                                                                                               |
| Load balancer post removal                     | Yes       | Issued after the removal of a load balancer.                                                                                                                                                                                                                                                                                    |
| Load balancer provision                        | Yes       | Issued before provisioning a load balancer.                                                                                                                                                                                                                                                                                     |
| Load balancer removal                          | Yes       | Issued before removing a load balancer.                                                                                                                                                                                                                                                                                         |
| Network Configure                              | Yes       | <p>Issued when the network is configured during compute allocation.</p> <p><b>NOTE</b><br/>The Network Configure event topic supports multiple IP addresses/NICs.</p> <p>Using a static IP assignment (<code>assignment:static</code>) is not supported within a cloud template when using a Network Configure event topic.</p> |

| Event Topic                            | Blockable | Description                                                                                                                                                                                                                                                                                            |
|----------------------------------------|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Network post provisioning              | Yes       | Issued after a network resource is provisioned.                                                                                                                                                                                                                                                        |
| Network post removal                   | Yes       | Issued after a network resource is removed.                                                                                                                                                                                                                                                            |
| Network provisioning                   | Yes       | Issued before a network resource is provisioned.                                                                                                                                                                                                                                                       |
| Network removal                        | Yes       | Issued before a network resource is removed.                                                                                                                                                                                                                                                           |
| Post unregistered provisioned approval | Yes       | Issued after a provisioned machine is unregistered.                                                                                                                                                                                                                                                    |
| Pre unregistered provisioned approval  | Yes       | Issued before a provisioned machine is unregistered.                                                                                                                                                                                                                                                   |
| Project Lifecycle Event Topic          | No        | Issued when a project is created, updated, or deleted.                                                                                                                                                                                                                                                 |
| Provider resource action cud           | No        | Issued when a resource action is created, updated, or deleted.                                                                                                                                                                                                                                         |
| Provisioning request                   | Yes       | Issued when a request is sent to the provisioning service. This can be an allocation request, provisioning request, or a day 2 operation, such as removal. Allocation requests are issued once for each cluster of machines. Provisioning and day 2 requests are issued for each machine in a cluster. |
| Security group post provision          | Yes       | Issued after a security group is provisioned.                                                                                                                                                                                                                                                          |
| Security group post removal            | Yes       | Issued after a security group is removed.                                                                                                                                                                                                                                                              |
| Security group provisioning            | Yes       | Issued before a security group is provisioned.                                                                                                                                                                                                                                                         |
| Security group removal                 | Yes       | Issued before a security group is removed.                                                                                                                                                                                                                                                             |

## **Event Parameters**

After you add an event topic, you can view the parameters of that event topic. These event parameters define the structure of the event's payload, or `inputProperties`. Certain event parameters cannot be modified and are marked as read-only. You can identify these read-only parameters by clicking the info icon to the right of the parameter.

## **Extensibility event log**

The extensibility events page displays a list of all events that have occurred within your environment.

You can view the extensibility event logs by navigating to **Extensibility > Events**. You can also filter the list of events by one or more properties. To view additional details of an individual event, select the event's ID.

| ID                                    | Timestamp          | Event Topic | User Name | Target ID | Description |

## Create an extensibility subscription

By using a Automation Orchestrator integration, or extensibility actions with Automation Assembler, you can create subscriptions to extend your applications.

- Verify that you have the cloud administrator user role.
- If you are using Automation Orchestrator workflows:
  - The library of the embedded Automation Orchestrator Client or the library of any integrated external Automation Orchestrator instance.
- If you are using extensibility actions:
  - Existing extensibility action scripts. For more information, see [How do I create extensibility actions](#).

Extensibility subscriptions allow you to extend your applications by triggering workflows or actions at specific life-cycle events. You can also apply filters to your subscriptions to set Boolean conditions for the specified event. For example, the event and workflow or action only triggers if the Boolean expression is '`true`'. This is helpful for scenarios where you want to control when events, actions, or workflows are triggered.

1. Select **Extensibility > Subscriptions**.
2. Click **New Subscription**.
3. Enter the details of your subscription.
4. Set the **Organization scope** for the subscription.

### NOTE

For more information on creating extensibility subscriptions for organization providers and tenants, see [Create extensibility subscriptions for providers or tenants](#).

5. Select an **Event Topic**.
6. Set conditions for the event topic.

### NOTE

Conditions can be created by using a JavaScript syntax expression. This expression can include Boolean operators, such as "`&&`" (AND), "`||`" (OR), "`^`" (XOR), and "`!"` (NOT). You can also use arithmetic operators, such as "`==`" (equal to), "`!=`" (not equal to), "`>=`" (greater than or equal), "`<=`" (less than or equal), "`>`" (greater than), and "`<`" (lesser than). More complex Boolean expressions can be built out of simpler expressions. To access the event payload according to the specified topic parameters, use '`event.data`' or any of the event header properties:

`sourceType, sourceIdentity, timeStamp, eventType, eventTopicId, correlationType, correlationId, description, targetType, targetId, userName, and orgId.`

7. Under **Action/workflow**, select a runnable item for your extensibility subscription.
8. If applicable, configure the blocking behavior for the event topic.

- To define the project scope of the extensibility subscription, deselect **Any Project** and click **Add Projects**.

**NOTE**

If the organization scope of the subscription is set to **Any tenant organization**, the project scope is always set to **Any Project** and the project scope cannot be changed. You can only change the project scope if the organization scope is set to the provider organization.

- To save your subscription, click **Save**.

Your subscription is created. When an event, categorized by the selected event topic occurs, the linked Automation Orchestrator workflow or extensibility action is initiated and all subscribers are notified.

After creating your subscription, you can create or deploy a cloud template to link and use the subscription. You can also verify the status of the workflow or extensibility action run in the **Extensibility** tab in Automation Assembler. For subscriptions containing Automation Orchestrator workflows, you can also monitor runs and workflow status from the Automation Orchestrator Client.

### Using extensibility subscriptions to manage deployment expiry

You can manage expired deployments and their resources by using the `Expire` action alongside existing event topics.

After a deployment lease in your environment expires, you can use extensibility event topics to perform tasks, such as stopping the back up or monitoring of any deployment resources. To perform these day 2 operations, the VMware Aria Automation API uses a system-level `Expire` action. This action is triggered automatically by the system whenever a deployment lease in your organization expires. The `Expire` action trigger precedes the power off event for any resources associated with that deployment.

**NOTE**

In previous product releases, the power off event was triggered at the deployment level after lease expiry. Now the power off event is triggered at the resource level for each deployment resource that is in the powered on state.

The `Expire` action is included in the payload of existing event topics, such as **Deployment action requested** and **Deployment action completed**, and uses the `deploymentId` parameter to perform pre-expiry and post-expiry tasks associated with the deployment resources.

**NOTE**

The `Expire` action is triggered approximately 10 to 15 minutes after your deployment lease expires. The system does not trigger lease expiry events prior to the actual lease expiry. The `Expire` action is a system-level action and users cannot trigger the events associated with it manually.

For the current use case, you are using the **Deployment action requested** event topic along with the `Expire` action to back up a virtual machine in your deployment as a template. For this case, the back up is performed by using a Automation Orchestrator workflow but the same task can also be performed by using an extensibility action as the runnable item of the subscription.

- Navigate to **Extensibility > Subscriptions** and click **New Subscription**.
- Enter a name for the subscription.
- Under **Status**, verify that the subscription is enabled.
- Under **Event Topic**, select the **Deployment action requested** event topic.
- Toggle on the **Condition** option and add a filter for the expiry action:

```
event.data.actionName == 'Expire'
```

**NOTE**

The **Deployment action requested** event topic can be triggered by different deployment day 2 operations, such as changing the deployment lease duration. Adding the lease expiry action filter guarantees that the subscription is triggered only for expiry events.

6. Under **Action/workflow**, add the Automation Orchestrator workflow.

The schema of this sample workflow includes a scriptable task and a workflow element which includes the **Clone virtual machine, no customization** workflow which comes preconfigured with Automation Orchestrator. The scriptable task element includes the following sample script:

```
System.log("Lease expiry action triggered to clone a VM...")
```

```
System.log("Deployment Id is: " + inputProperties.deploymentId);
inputHeaders = new Properties();
deploymentId = inputProperties.deploymentId;
pathUriVariable = "/deployment/api/deployments/" +deploymentId +"/resources";
var restClient = vRAHost.createRestClient();
var request = restClient.createRequest("GET", pathUriVariable, null);
var keys = inputHeaders.keys;
for(var key in keys) {
 request.setHeader(keys[key], inputHeaders.get(keys[key]));
}
var response = restClient.execute(request);
System.log("Content as string: " + response.contentAsString);
var content = response.contentAsString;
var obj = JSON.parse(content);

var object = new Properties(obj);
var contentJson = object.content;
for (var i = 0; i < contentJson.length; i++) {
 var resources = contentJson[i];

 var resourceProperties = resources.properties;
 System.log("Resource name is: " + resourceProperties.resourceName)
 resourceName = resourceProperties.resourceName;
}
```

```

var query = "xpath:name='" + resourceName + "'";
var vms=Server.findAllForType("VC:VirtualMachine", query);
vcVM=vms[0];

System.log("VM input is: " + vcVM);
dataStoreOutput = datastore
template= true;
name="test-vm-name"

```

7. Decide whether to set the subscription as blocking or non-blocking.

**NOTE**

Making the subscription blocking means that the power off event for the deployment resources is triggered only after the runnable item, in this case the lease expiry workflow, finishes its run successfully. Making the subscription non-blocking means that power off event is triggered for the deployment resources regardless of the status of the workflow run.

8. To finish editing the subscription, click **Save**.

After the extensibility subscription is triggered by the lease expiry event and the workflow run is successful, navigate to the vSphere Web Client and validate that your virtual machine is converted to a template.

### Troubleshooting an extensibility subscription

Troubleshoot extensibility subscription failures.

When your subscription fails, it is commonly a result of errors with your workflow or extensibility action script.

### View topic parameters and payload

You can use a dump subscription topic parameters script to view the specific parameters and payload of your virtual machine at any given event stage.

Primarily, this script is useful for debugging and verifying available inputs for your Automation Orchestrator workflow. To view all parameters of your virtual machine, use the following script with your workflow:

```

function dumpProperties(props,lvl) {
 var keys = props.keys;
 var prefix = ""
 for (var i=0; i<lvl; i++) {
 prefix = prefix + "";

```

```

 }

 for (k in keys) {

 var key = keys[k];
 var value = props.get(keys[k])
 if ("Properties" == System.getObjectType(value)) {
 System.log(prefix + key + "[")
 dumpProperties(value, (lvl+2));
 System.log(prefix+ "]")
 } else{
 System.log(prefix + key + ":" + value)
 }
 }

}

dumpProperties(inputProperties, 0)

customProps = inputProperties.get("customProperties")

```

## Subscription version history

If your subscription fails, you can view the version history.

### Viewing Subscription Version History

The **Version History** tab of the subscription editor can show you the change history of your subscription, including the user and date of the change. You can also compare different subscription versions by clicking **Compare to**. If your subscription fails or is running incorrectly, the version history can help identify the cause.

## Managing deployments and resources in Automation Assembler

### Managing deployments and resources

As a cloud administrator or cloud template developer, you use the Resources tab to manage your resources. The resources can be those that you deployed, but they can also be those that are discovered for your cloud accounts, discovered resources that you onboarded, or otherwise available for management using Automation Assembler

## Managing Automation Assembler deployments

### Managing deployments

As an Automation Assembler cloud administrator or cloud template developer, you use the Deployments node to manage your deployments and the associated resources. You can troubleshoot failed provisioning processes, make changes to resources or, and destroy unused deployments.

The deployments include deployed cloud templates and onboarded resources. It is also possible for resources that are created using the IaaS API to appear as deployments.

If you manage a small number of deployments, the deployment cards provide a graphical view for managing them. If you manage a large number of deployments, the deployment list and the resource list provide more a more robust management view.

To view your deployments, select **Resources > Deployments > Deployments**.

### **Working with deployment cards and the deployment list**

You can locate and manage your deployments using the card list. You can filter or search for specific deployments, and then run actions on those deployments.

**Figure 7: Deployments page card view**

| Deployment ID              | Description    | Project Owner   | Resources                                                           | Created                              | Expires                                              |

1. Filter your requests based on attributes.

For example, you can filter based on owner, projects, lease expiration date, or other filtering options. Or you might want to find all the deployments for two projects with a particular tag. When you construct the filter for the projects and tag example, the results conform to the following criteria: (Project1 OR Project2) AND Tag1.

The values that you see in the filter pane depend on the current deployments that you have permission to view or manage.

Most of the filters and how to use them are relatively obvious. Additional information about some of these filters is provided below.

2. Search for deployments based on keywords or requester.
3. Sort the list to order by time or name.
4. Switch between the deployment card and the deployment grid views.
5. Run deployment-level actions on the deployment, including deleting unused deployments to reclaim resources.

You can also see deployment costs, expiration dates, scheduled deletion dates, and status.

To adjust what information you see for your deployments, click **Manage Columns** in the bottom left of the deployment grid and select your preferred columns.

You can switch between the card and grid view in the upper right of the page, to the right of the **Sort** text box. You can use the grid view to manage a large number of deployments on fewer pages.

**Figure 8: Deployment page grid view**

### Working with selected deployment filters

The following table is not a definitive list of filter options. Most of them are self-evident. However, some of the filters require a little extra knowledge.

**Table 33: Selected filter information**

| Filter name                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Optimizable Resources Only  | If you integrated VMware Aria Operations and are using the integration to identify reclaimable resources, you can toggle on the filter to limit the list of qualifying deployments.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Deployment Lifecycle Status | <p>The Deployment Lifecycle Status and Last Request Status filters can be used individually or in combination, particularly if you manage a large number of deployments. Examples are included at the end of the Last Request Status section below.</p> <p>Deployment Lifecycle Status filters on the current state of the deployment based on the management operations.</p> <p>This filter is not available for deleted deployments.</p> <p>The values that you see in the filter pane depend on the current state of the listed deployments. You might not see all possible values. The following list includes all the possible values. Day 2 actions are included in the Update status.</p> <ul style="list-style-type: none"> <li>• Create - Successful</li> <li>• Create - In Progress</li> <li>• Create - Failed</li> <li>• Update - Successful</li> <li>• Update - In Progress</li> <li>• Update - Failed</li> </ul> |

| Last Request Status filters | <p>Last Request Status filters on the last operation or action that ran on the deployment.</p> <p>This filter is not available for deleted deployments.</p> <p>The values that you see in the filter pane depend on the last operations that ran on the listed deployments. You might not see all possible values. The following list is all of the possible values.</p> <ul style="list-style-type: none"> <li>• Pending. The first stage of a request where the action is submitted but the deployment process has not yet started.</li> <li>• Failed. The request experienced a failure during any stage of the deployment process.</li> <li>• Cancelled. The request was cancelled by a user while the deployment process was processing and not yet completed.</li> <li>• Successful. The request successfully created, updated, or deleted a deployment.</li> <li>• In Progress. The deployment process is currently running. Additional deployment states, for example, Initialization and Completion that you see in the deployment History tab are not provided as filters, but you can use the In Progress filter to locate deployments in those states.</li> <li>• Approval Pending. The request triggered one or more approval policies. The process is waiting for a response to the approval request.</li> <li>• Approval Rejected. The request was denied by the approvers in the triggered approval policies. The request does not continue.</li> </ul> <p>The following examples illustrate how to use the Deployment Lifecycle Status and Last Request Status filters individually or together.</p> <ul style="list-style-type: none"> <li>• To find all delete requests that failed, select <b>Delete - Failed</b> in the Deployment Lifecycle Status filter.</li> <li>• To find all the requests waiting for approval, select <b>Approval Pending</b> in the Last Request Status filter.</li> <li>• To find the delete requests where the approval request is still pending, select <b>Delete - In Progress</b> in the Deployment Lifecycle Status filter and <b>Approval Pending</b> in the Last Request Status filter.</li> </ul> |

## How do I monitor deployments in Automation Assembler

How do I monitor deployments

After you deploy an Automation Assembler cloud template, you can monitor your request to ensure that the resources are provisioned and running. Beginning with the deployment card, you can verify the provisioning of your resources. Next, you can examine the deployment details. Finally, you can view and filter deleted deployments for up to 90 days after deletion.

1. Select **Resources > Deployments > Deployments** and locate your deployment using the filter and search, if needed.
2. Review the card status.

If the deployment is in progress, the process bar indicates the number of tasks remaining. If the deployment completed successfully, the card displays the basic details about the deployment.

If an approval policy is triggered for your request, you might see the request in an in progress state with the name of at least one approver. Approval policies are defined in Automation Service Broker by your administrator. The approvers are defined in the policy. The approvers approve requests in Automation Service Broker. You might also encounter approvals on day 2 actions.

3. To determine where your resources were deployed, click the deployment name and review the details on the Topology page.

You will likely need the IP address for the primary component. As you click on each component, notice the information provided that is specific to the component. In this example, the IP address is highlighted.

| Requestor      | apalnitkari                               | Expires on   | Never                    |
|----------------|-------------------------------------------|--------------|--------------------------|
| Project        | <a href="#">blueprint-default-project</a> | Last updated | Aug 24, 2020, 2:37:41 PM |
| Cloud Template | <a href="#">simple-bp</a>                 | Created on   | Aug 24, 2020, 2:27:20 PM |

The availability of the external link depends on the cloud provider. Where it is available, you must have the credential on that provider to access the component.

- You can make changes to your deployment. See [How do I manage the life cycle of a completed Automation Assembler deployment](#).

- If your deployment fails, see [What can I do if an Automation Assembler deployment fails](#).

## What can I do if an Automation Assembler deployment fails

Your deployment request might fail for many reasons. It might be due to network traffic, a lack of resources on the target cloud provider, or a flawed deployment specification. Or, the deployment succeeded, but it does not appear to be working. You can use Automation Assembler to examine your deployment, review any error messages, and determine whether the problem is the environment, the requested workload specification, or something else.

You use this workflow to begin your investigation. The process might reveal that the failure was due to a transient environmental problem. Redeploying the request after verifying the conditions have improved resolves this type of problem. In other cases, your investigation might require you to examine other areas in detail. As a project member, you can review the request details in Automation Assembler.

- To determine if a request failed, select **Deployments** > **Deployments** and locate the deployment card.

Failed deployments are indicated on the card.

- Review the error message.
  - For more information, click the deployment name for the deployment details.
- On the deployment details page, click the **History** tab.

| Timestamp               | Status                 | Resource type | Resource name | Details                                                                                                                                                           |
|-------------------------|------------------------|---------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Mar 21, 2022, 12:53:... | REQUEST_FAILED         |               |               | No placement exists that satisfies all of the request requirements. Please check if suitable placements and cloud zones exist and they have been properly tagged. |
| Mar 21, 2022, 12:53:... | COMPLETION_FINISHED    |               |               |                                                                                                                                                                   |
| Mar 21, 2022, 12:53:... | COMPLETION_IN_PROGRESS |               |               |                                                                                                                                                                   |

- Review the event tree to see where the provisioning process failed. This tree is useful when you modify a deployment, but the change fails.

The tree also shows when you run deployment actions. You can use the tree troubleshoot failed changes.

- The **Details** provides a more verbose version of the error message.
- The request ID specifically identifies each request in the tree. You can use the ID to locate a request in the **Infrastructure** > **Activity** > **Requests** page. You might also use it for billing purposes.

- d) If the requested item was an Automation Assembler cloud template, the link to the right of the message opens Automation Assembler so that you can see the **Request Details**.
3. The **Request Details** provides the provisioning workflow for failed components so that you can research the problem.

The request history is retained for 48 hours.

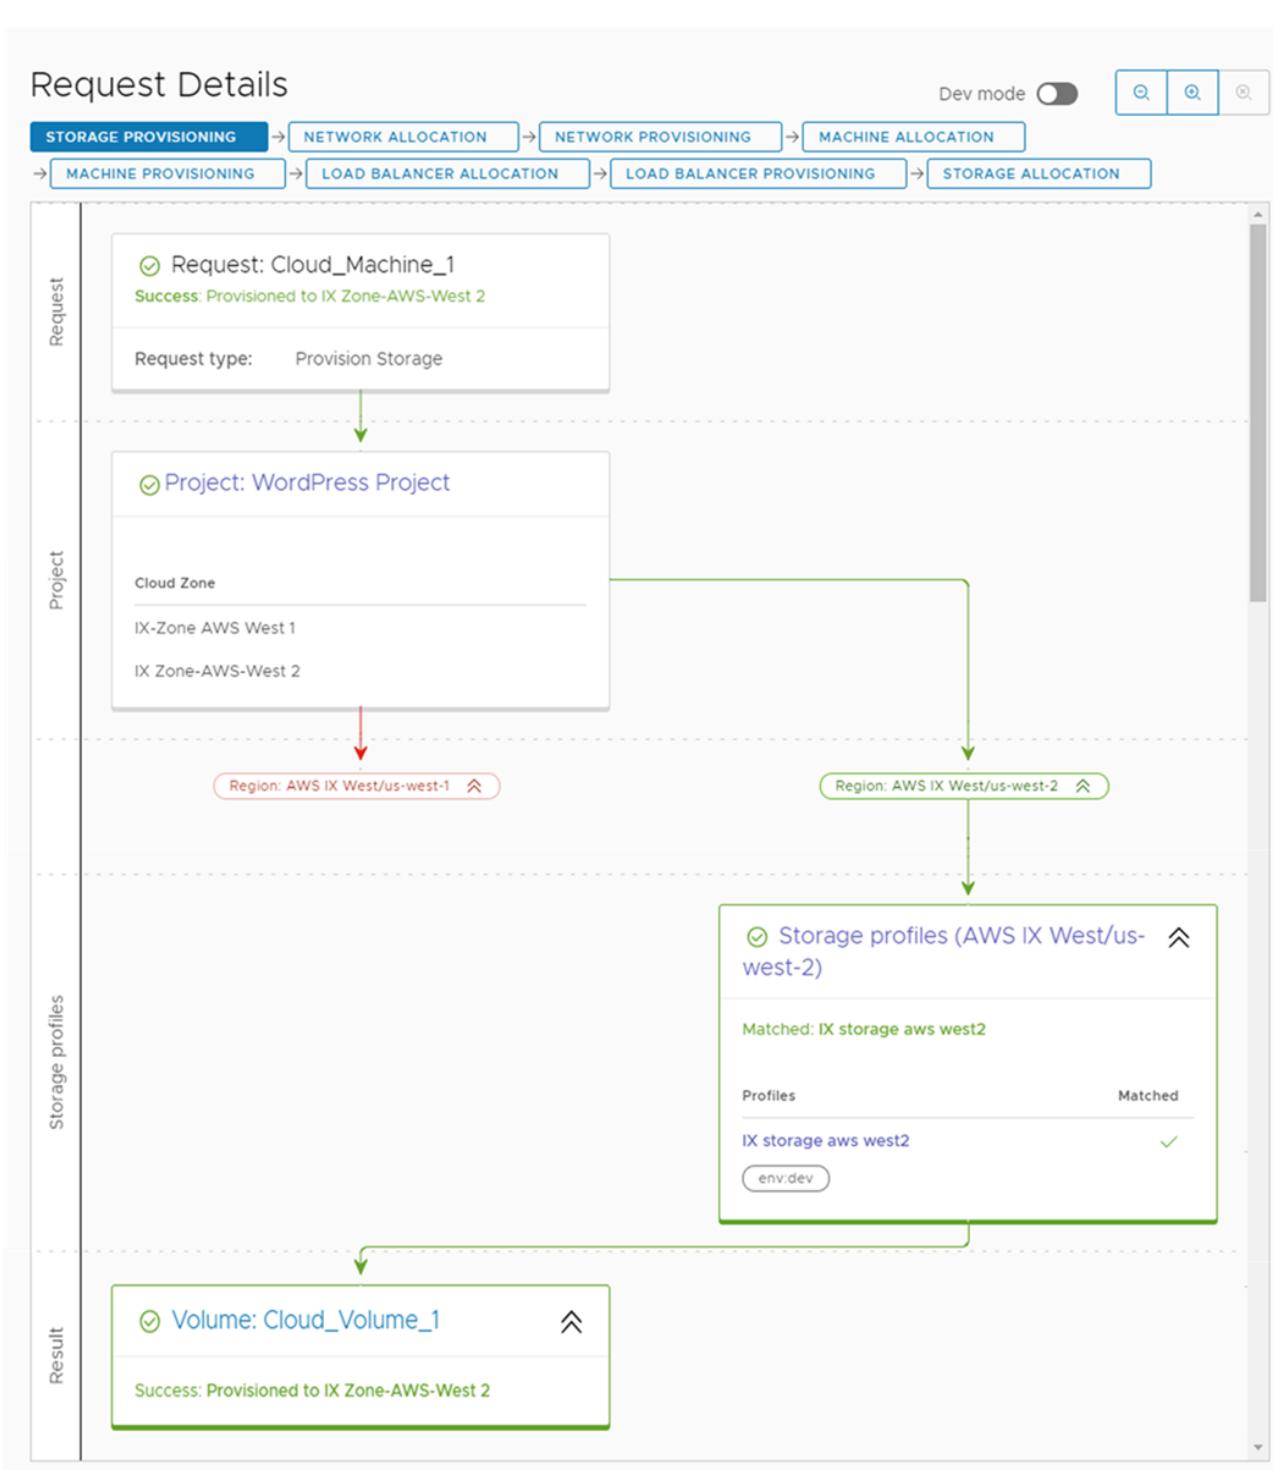

View and filter deleted deployment history for up to 90 days after deletion

The screenshot shows the 'Request Details' interface. On the left, there's a sidebar with 'Request' and 'Project' sections. Under 'Request', a card for 'Request: myapp-lb' is shown with an error message: 'Error: java.lang.IllegalArgumentException: com.vmware.xenon.common.LocalizableValidationException: [Cloud\_Network\_2-mcm112748-99510009947] of type [PRIVATE] that would match endpoint [AWS IX West] selected for load balancer [myapp-lb]' (marked with 3.a). Below it, a 'Request type' card shows 'Allocation', 'Network: Cloud\_Network\_2', 'Internet facing: false', and 'Constraints: none'. Under 'Project', a card for 'Project: WordPress Project' is listed. At the top, navigation tabs are shown: NETWORK ALLOCATION → MACHINE ALLOCATION → LOAD BALANCER ALLOCATION → STORAGE ALLOCATION. A 'Dev mode' toggle switch is at the top right, along with search and refresh icons. The main area is titled 'Request Details' and contains a flowchart of tasks. Task 1: Request (10:40:31 AM) has three arrows pointing down to three separate 'Error Occurred' boxes (each 10:40:31 AM), which are highlighted in red (marked with 3.c). To the right of the flowchart is a 'Task stage info' panel listing various configuration details like resourceDescriptionLink, endpointLink, regionId, and service.default.svc.cluster.local:8283/provisioning/aws/load-balancer-adapter.

- a) Review the error message.  
 b) You can turn on the **Dev mode** to switch between the simple provisioning workflow and a more detailed flowchart.  
 c) Click the card to review the deployment script.
4. Resolve the errors and redeploy the cloud template.

The errors might be in the template construction or they might be related to how your infrastructure is configured.

When the errors are resolved and the cloud template is deployed, you can see information similar to the following example in the Request Details. To see the request details, select **Infrastructure > Activity > Requests**.

## How do I manage the life cycle of a completed Automation Assembler deployment

How do I manage the life cycle of a completed deployment

After a deployment is provisioned and running, you have several actions that you can run to manage the deployment. The life cycle management can include powering on or off, resizing, and deleting a deployment. You can also run various actions on individual components to manage them.

1. Select **Resources > Deployments > Deployments** and locate your deployment.

2. To access the deployment details, click the deployment name.

You use the deployment details to understand how the resources are deployed and what changes have been made. You can also see pricing information, the current health of the deployment, if the deployment expires and when it's scheduled for deletion, and if you have any resources that need to be modified.

The screenshot displays the VMware Aria Automation 8.18 interface with the following sections:

- Deployment Details:** Shows deployment information for "sb-demo-03" including owner (sbhandari@vmware.com), requestor (sbhandari@vmware.com), project (demo-vcenter-project), and cloud template (sb-demo). It also shows expiration details: Expires on Never, Last updated Mar 17, 2021, 11:31:09 AM, and Created on Mar 2, 2021, 8:47:06 AM.
- Topology Tab:** Shows the deployment structure with "Cloud\_vSphere" as the root node.
- History Tab:** Shows deployment history with entries for "CREATE" (Mar 2, 2021, 8:48:58 AM) and "REQUEST\_FINISHED" (Mar 2, 2021, 8:48:58 AM).
- User Events Tab:** Shows deployment events with entries for "RECONFIGURE" (Aug 15, 2022, 6:58:14 AM), "USER\_INTERAC..." (Aug 15, 2022, 6:47:22 AM), "USER\_INTERAC..." (Aug 15, 2022, 6:46:02 AM), and "RECONFIGURE" (Aug 15, 2022, 6:46:02 AM).
- Price Analysis:** Shows price month-to-date at \$0.38 and last month at \$0.38. It includes a bar chart comparing resource usage across categories like Topology, History, User Events, Price, Monitor, Alerts, and Optimize.
- Monitor Tab:** Shows CPU usage over time (12 PM to 09 AM) for two VMs: "Cloud\_vSphere\_Machine\_1-mcm854702-208949240548" and "Cloud\_vSphere\_Machine\_1-mcm854702-208949240548". The CPU usage fluctuates between 0.12 and 0.14%.
- Alerts Tab:** Shows active alerts:
  - Definition\_Deployment\_VM:** Deployment in sb-demo-03 (Status: Active)
  - AlertDefinition\_Deployment\_has\_cost:** Severity: Immediate, Status: Active, Impact: Efficiency, Type: Infrastructure, Subtype: Capacity
- Optimize Tab:** Shows Underutilized VMs (2 Idle VMs) and Underutilized VMs (2 Idle VMs) with detailed resource allocation tables.

- **Topology tab.** You can use the Topology tab to understand the deployment structure and resources.

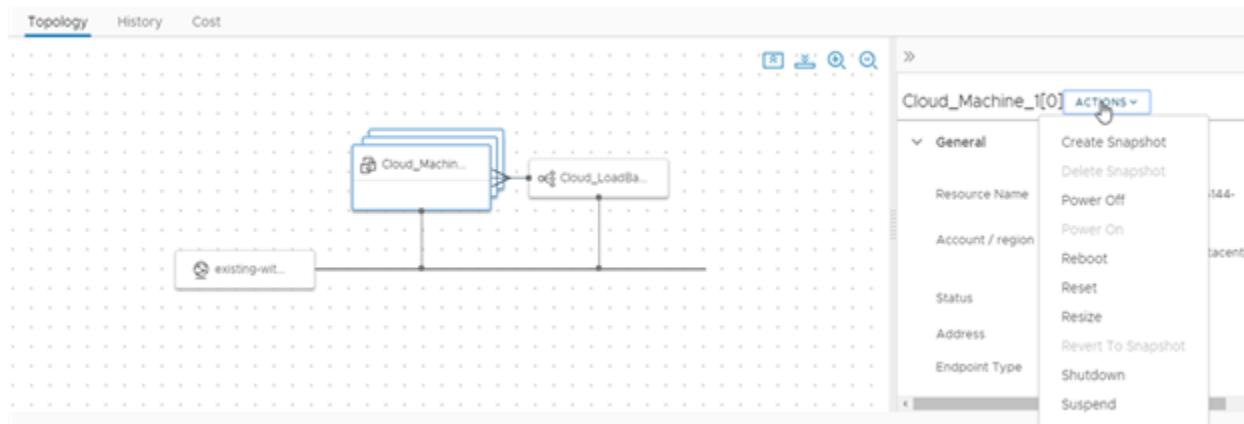

- **History tab.** The History tab includes all the provisioning events and any events related to actions that you run after deploying the requested item. If there are any problems with the provisioning process, the History tab events helps you with troubleshoot the failures.
- **User Events tab.** You can use the User Events tab to provide and track the user interactions for your deployment. The events include any initial input values, any required approvals, input values for day 2 changes, and any values that you must provide as part of a deployment or for a day 2 action workflow. Where the request requires input values, you can also enter the values on the Inputs tab in Automation Service Broker.

For deployments that include VMware Aria Automation Orchestrator workflow user events, where you enter values during the deployment process, there are some situations where the tab does not display the form or where the workflow is canceled. If you have multiple VMware Aria Automation Orchestrator instances that do not have tags or where they all have the same tag, the form does not load. Ensure that you correctly tag the instances so that the form displays on the tab. If there are not assignees in the workflow form, the workflow is canceled and the deployment or action fails. Ensure that your workflow form includes assignees.

- **Price tab.** You can use the pricing tab for insights about how much your deployment is costing your organization. Pricing information is provided by your VMware Aria Operations or CloudHealth integrations.
- **Monitor tab.** The Monitor tab data provides information about the health of your deployment based on data from VMware Aria Operations.
- **Alerts tab.** The Alerts tab provides active alerts on the deployment resources. You can dismiss the alert or add reference notes. The alerts are based on data from VMware Aria Operations.
- **Optimize tab.** The Optimize tab provides utilization information about your deployment and offers suggestions for reclaiming or otherwise modifying the resources to optimize resource consumption. The optimization information is based on data from VMware Aria Operations.

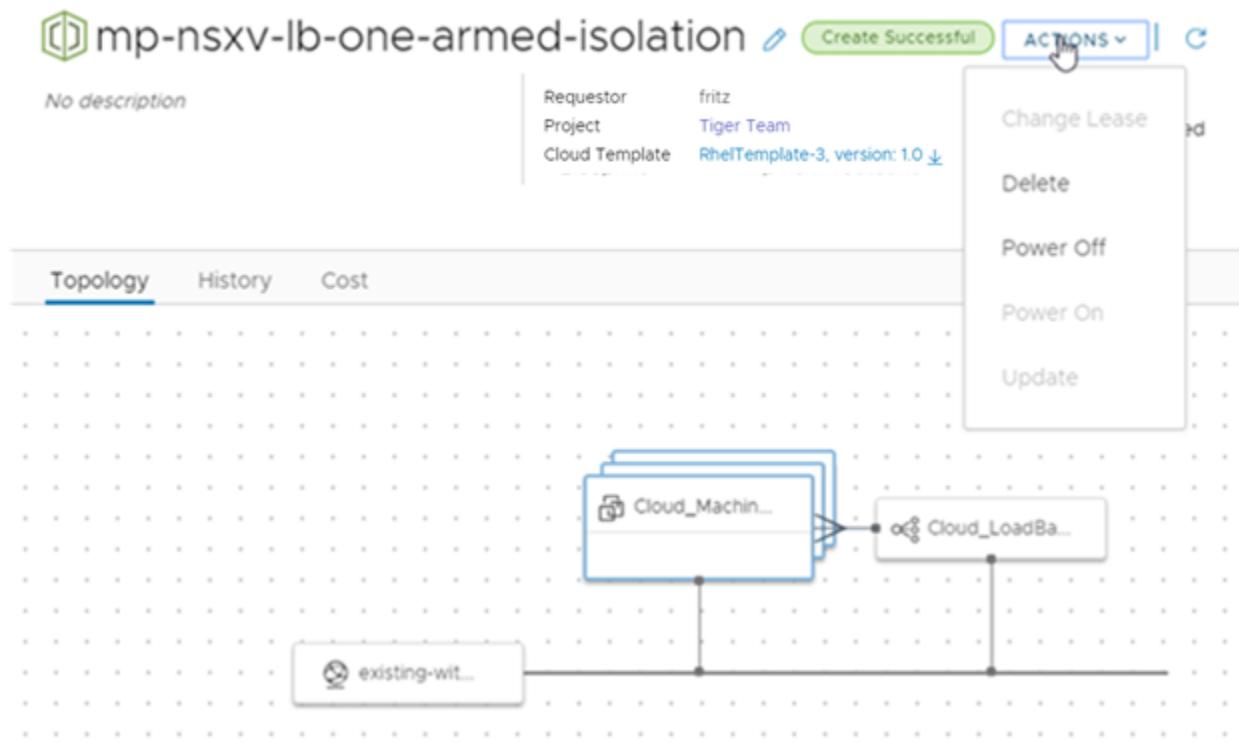

3. If you determine that a deployment is too costly in its current configuration and you want to resize a component, select the component on the topology page and then select **Actions > Resize** on the component page.

The available actions depend on the component, the cloud account, and your permissions.

4. As part of your development life cycle, one of your deployments is no longer needed. To remove the deployment and reclaim resources, select **Actions > Delete**.

The available actions depend on the state of the deployment.

- To view your deleted deployments, click the filter on the **Deployments** page, and then turn on **Deleted Deployments Only**.

The list of deployments is now limited to those that are deleted. You might want to review the history of a particular deployment. For example, to retrieve the name of a deleted machine.

The deleted deployments are listed for 90 days.

| Deployments                                                                                                                                                                                                                                   |                                       |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------|
| 10 Items of 37                                                                                                                                                                                                                                | <input type="button" value="Filter"/> |
| <input type="text" value="Search deployments"/> <input type="button" value="Sort: Created on"/> <input type="button" value="Filter"/>                                                                                                         |                                       |
| <div style="border: 1px solid #ccc; padding: 5px;"> <b>AR-DP11</b><br/>           No description<br/>           Project Requestor<br/> <small>Deleted by abhimannr on Apr 30, 2020, 4:19:23 AM</small><br/> <small>0 Resources</small> </div> |                                       |
| <div style="border: 1px solid #ccc; padding: 5px;"> <b>AR-DP10</b><br/>           No description<br/>           Project Requestor<br/> <small>Deleted by abhimannr on Apr 30, 2020, 1:57:57 AM</small><br/> <small>0 Resources</small> </div> |                                       |

To learn more about possible actions, see [What actions can I run on Automation Assembler deployments or supported resources](#).

## Managing resources in Automation Assembler

### Managing resources

As an Automation Assembler cloud administrator or cloud template developer, you use the Resources tab to manage your cloud resources. The Resources tab acts as a resource center where you can monitor resources across clouds, make changes to them, and even destroying or deleting them.

You can locate and manage your resources using the different views. You can filter the lists, view resource details, and then run actions on the individual items. The available actions depend on the resource state and the day 2 policies.

If you are an Automation Assembler administrator, you can also view and manage discovered machines.

To view your resources, select **Resources > Deployments > All Resources**.

### Viewing billable objects

As an Automation Assembler or an Automation Service Broker administrator, you can monitor what billable objects are used in your organization. Counted objects include billable virtual machines, CPUs, and cores that are in use at view time. It might take up to ten minutes for the object count data to refresh.

When viewing resource lists, you can use the Billable Resources Only filter in combination with other available filters.

| Name                                    | Power State | Address        | Origin   | Billable | Created On  |
|-----------------------------------------|-------------|----------------|----------|----------|-------------|
| Cloud_Machine_1-mcm1296120-245022878950 | On          | 44.211.218.190 | Deployed | ✓        | 8 days ago  |
| test-mcm1296541-244851762495            | Off         |                | Deployed | ✓        | 10 days ago |
| Cloud_Machine_1-mcm1295930-244833967033 | On          | 3.86.155.152   | Deployed | ✓        | 10 days ago |
| Cloud_Machine_1-mcm1293768-244245329772 | On          | 44.203.126.56  | Deployed | ✓        | 17 days ago |

If you force delete a deployment, the resource count might not match what is displayed in the resource list. You must delete the virtual machine from the corresponding IaaS layer, such as vCenter.

What is actually counted towards the bill depends on your VMware Aria Automation subscription commit contract and entitlement type.

To learn more about billing in VMware Aria Automation, see this [article](#).

## Working with the resource lists

You can use the resource lists to manage the following resource types: machines, storage volumes, networks, load balancers, and security groups that make up your deployments. In the resource list you can manage them in resource type groups rather than by deployments.

- All Resources

Includes all the discovered, deployed, migrated, and onboarded resources described in the following sections.

- Virtual Machines

Individual virtual machines. The machines might be part of larger deployments.

Only administrators have permission to use the **Create New VM** option. Administrators can turn the option on in Automation Service Broker by selecting **Infrastructure > Administration > Settings** and turning on **Create new resource**. To control the amount of resources that Automation Service Broker users might deploy, it is likely that your administrator added approval policies to reject or approve any deployment requests based on the image used or the flavor or size requested.

- Volumes

Administrators should know that by activating the option, Automation Service Broker users can create VMs based on any image and any flavor even though they are not administrators themselves. To avoid the potential overconsumption of resources, administrators can create approval policies to reject or approve any deployment requests based on the image used or the flavor or size requested.

Storage volumes that were discovered or associated with deployments.

- Networking and Security

Includes networks, load balancers, and security groups.

Similar to the deployment list view, you can filter the list, select a resource type, search , sort, and run actions.

If you click the resource name, you can work with the resource in the context of the resource details.

**Figure 9: Virtual Machines page list**

| Name                                            | Power State | Account / Region          | Address       |
|-------------------------------------------------|-------------|---------------------------|---------------|
| Cloud_AWS_EC2_Instance_1-mcm875742-209927226509 | On          | aws-us-east-1 / us-east-1 | 54.146.171.35 |
| cloudgcpmachine1-mcm1562-ncm852756-62           | Off         | GCP / asia-east1          | 10.140.0.17   |
| ne_1-mcm852756-62                               | On          | aws-us-east-1 / us-east-1 | 54.173.72.224 |
| ne_1-mcm1069383-25                              | On          | blueprint-aws / us-east-1 | 54.147.36.132 |
| Cloud_Machine_1-mcm1069384-222049773325         | On          | blueprint-aws / us-east-1 | 3.239.9.191   |

1. Filter your list based on resource attributes.

For example, you can filter based on project, cloud types, origin, or other attributes.

2. Search for resources based on name, account regions, or other values.

3. Run available day 2 actions that are specific to the resources type and the resource state.

For example, you might power on a discovered machine if it is off. Or you might resize an onboarded machine.

In addition to the search and filter options on each page, the All Resource page includes a Resource Type selector where you can construct a filter for all the resources.

The screenshot shows the 'All Resources' page with a list of resources on the left and a detailed view on the right. A green box highlights the 'RESOURCE TYPE' dropdown menu, which is open to show a hierarchical list of resource types. The top level has 'All' selected. Below it, 'Machines (4)' is expanded, showing 'AWS Machines', 'vSphere Machines', 'Azure Machines', and 'GCP Machines'. Other collapsed categories include 'Volumes (4)', 'Networks (3)', 'Gateways (1)', and 'Load Balancers (2)'. To the right of the dropdown, there's a table listing resources by 'Created On' (all entries are '3 minutes ago'). At the bottom, there are pagination controls and a 'Manage Columns' button.

### List of managed resources by origin

You can use the Resources tab to manage the following types of resources.

**Table 34: Resource origins**

| Managed Resource | Description                                                                                                                                                                                                                                                                                                                       |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Deployed         | <p>Deployments are fully managed workloads that are deployed from cloud templates or onboarded resources. The workload resources can include machines, storage volumes, networks, load balancers, and security groups.</p> <p>You can manage your deployments in the Deployments section.</p>                                     |
| Discovered       | <p>Discovered resources are the machines, storage volumes, networks, load balancers, and security groups that the discovery process identified for each cloud account region that you added.</p> <p>Only Automation Assembler Administrators can see and manage discovered resources in the Resources section.</p>                |
| Migrated         | <p>Migrated resources are the 7.x deployments that you migrated to VMware Aria Automation. The migrated resources can include machines, storage volumes, networks, load balancers, and security groups. Migrated resources are managed like deployments.</p> <p>You can manage migrated resources in the Deployments section.</p> |
| Onboarded        | Onboarded resources are discovered resources that you bring under more robust VMware Aria                                                                                                                                                                                                                                         |

*Table continued on next page*

*Continued from previous page*

Automation management. Onboarded resources are managed like deployments.

You can manage onboarded resources in the Deployments section.

## **What is the resource details view**

You can use the resource details view to get a deeper look at the selected resource. Depending on the resource, the details can include networks, ports, and other information collected about the machine. The depth of the information varies depending on cloud account type and origin.

To open the details pane, click the resource name or the double arrows.

**Figure 10: Resources details pane**

## **What day 2 actions can I run on resources**

The available day 2 actions depend on the resource origin, cloud account, resource type, and state.

**Table 35: List of actions by origin**

| Resource Origin | Day 2 Actions                                                                                                                                                                                                                              |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Deployed        | The actions that are available to run on the resources depend on the resource type, cloud account, and state. For a detailed list, see <a href="#">What actions can I run on Automation Assembler deployments or supported resources</a> . |
| Discovered      | The available actions for discovered resources are limited to virtual machines. Depending on the status, you can perform the following actions. <ul style="list-style-type: none"> <li>• Power Off</li> <li>• Power On</li> </ul>          |

*Table continued on next page*

*Continued from previous page*

|           |                                                                                                                                                                                                                                                                                                                                                       |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|           | <p>Additional vSphere virtual machine action.</p> <ul style="list-style-type: none"> <li>• Connect to Remote Console</li> </ul>                                                                                                                                                                                                                       |
| Migrated  | Migrated resources have the same day 2 action management options as deployments. The actions that are available to run on the migrated resources depend on the resource type, cloud account, status, and day 2 policies. For a detailed list, see <a href="#">What actions can I run on Automation Assembler deployments or supported resources</a> . |
| Onboarded | Onboarded resources have the same day 2 action management options as deployments. The actions that are available to run on the onboarded resources depend on the resource type, cloud account, and state. For a detailed list, see <a href="#">What actions can I run on Automation Assembler deployments or supported resources</a> .                |

## How do I work with individual resources in Automation Assembler

### Working with individual resources

As a cloud administrator or a project member with resources for your project, you can use the Deployments section of the Resources tab to manage your deployed, onboarded, and migrated resources as individual resources by resource type. This workflow, which focuses on managing virtual machines, provides a guide for high-level resource life cycle management that you can apply to the other resource types.

### Locate virtual machine resources

Deployed, onboarded, and migrated virtual machines are available on the All Resources page and the Managed tab on the Virtual Machines page. This example focuses on virtual machines, but you can apply the same workflow to the other resource types.

1. Select **Resources > Virtual Machines > Managed**.
2. Locate your virtual machine.  
You can use the filters or the search to locate particular resources.

| Name                     | Deployment                   | VM State | Account / Region                                   | Address         | Project |
|--------------------------|------------------------------|----------|----------------------------------------------------|-----------------|---------|
| vm-administrator-VLDX... |                              | ► On     | https://cmbu-w01-vc08.eng.vmware.com / w01-vc08... |                 |         |
| vm-administrator-N6CE... |                              | ► On     | https://cmbu-w01-vc08.eng.vmware.com / w01-vc08... | 192.167.211.142 |         |
| mcm-20211203215331-O...  | Google Cloud Create VM_6f... | ► On     | yingzhi-GCP / us-east1                             | 34.74.168.22    | Crea    |

## **Review the virtual machine details**

The resource details provide a quick view of the machine information, including networks, custom properties, and other collected information.

1. Locate the machine in the Virtual Machines list.
  2. Click the double arrows next to the resource name in the left column of the table.
- The details pane opens on the right side of the list.

The screenshot shows the VMware Aria Automation interface. On the left, there is a list of virtual machines under the 'Managed' tab. One specific VM, 'mcm-20211203215331-000020', is selected and its details are displayed on the right side of the screen. The details pane includes sections for VM State (On), Address (34.74.168.22), Account / region (yingzhi-GCP / us-east1), Origin (Deployed), Deployment (Google Cloud Create VM\_6f6d0315-ddc8-4f5d-9e1e-563cf49a836d), Tags, Volumes, Networks, and Custom Properties. The 'Volumes' section lists two volumes: 'create-vm-new-disk-1-524598563851' (4 GB, HDD) and 'mcm-20211203215331-000020' (10 GB, HDD). The 'Networks' section shows one network interface 'default' assigned to address 10.142.0.56 with an 'Assignment Type' of 'dynamic'. The 'Custom Properties' section lists several key-value pairs.

| Name                      | Value                                                   |
|---------------------------|---------------------------------------------------------|
| resourceId                | 3b43b1a6-105c-4d68-8562-f84d545d07a0                    |
| zone_overlapping_migrated | true                                                    |
| project                   | d952119a-7354-4dc2-af5-718755917230                     |
| zone                      | us-east1-b                                              |
| environmentName           | Google Cloud Platform                                   |
| providerId                | 1393403671676923083                                     |
| id                        | /resources/compute/3b43b1a6-105c-4d68-8562-f84d545d07a0 |

3. To close the pane, click the double arrows or the resource name.

## **Run day 2 actions on the virtual machine**

You use the day 2 actions to manage your resources. The available actions depend on the resource type, the state of the resource, and the day 2 action policies that are enforced.

1. Locate the machine in the Virtual Machines list.
2. Click the vertical ellipsis to see the available actions.
3. Click the action.

## Virtual Machines ▾

Discovered   Managed

Managed machines are those under full VMware Aria Automation management so that you can run day 2 actions. The managed machines included onboarded or deployed machines. Click New VM if you want to deploy a VM based on your current cloud provider OS image and size flavors.

| Name                     | Deployment                   | VM State | Account / Region                                                                                                | Address         |

### How do I work with discovered resources in Automation Assembler

#### Working with discovered machines

As an Automation Assembler Administrator, you use the Deployments section of the Resources tab to manage your discovered machines. Only administrators will see discovered resources on the various pages.

This workflow focuses on managing discovered virtual machines.

#### What to do first

- Add a cloud account for the resources that you want to discover. In this workflow, an Amazon Web Services machine is used as the example. To add a cloud account, see [Adding cloud accounts to Automation Assembler](#).

#### Locate discovered virtual machines

Discovered resources are collected from the cloud account region and added to the resources on the Resource tab. This example focuses on virtual machines, but other resource types are collected, including storage and network information.

1. Select **Resources** > **Virtual Machines** > **Discovered**.

| Name                              | Power State | Account / Region          | Address        | Tags                                    | Created On     |
|-----------------------------------|-------------|---------------------------|----------------|-----------------------------------------|----------------|
| e2e-a8n-mysql-mcm14-245597735739  | On          | aws-hnguyen11 / us-east-1 | 34.239.113.202 | e2e-a8n-custom-key:e2e-a8n-custom-value | 11 minutes ago |
| e2e-a8n-mysql-mcm498-245597386669 | On          | aws-hnguyen11 / us-east-1 | 44.211.193.217 | e2e-a8n-custom-key:e2e-a8n-custom-value | 12 minutes ago |

2. To locate the AWS virtual machines, click the **Filter** icon near the page label.
3. In the filter list, expand **Cloud Types** and select **AWS**.  
The list is now limited to discovered AWS virtual machines. You can see deployed, discovered, and other origin types on the **Managed** tab.
4. To locate a particular machine, you can use the **Search resources** option to search by name, IP address, tags, or values.  
In this example, `mysql` is the search term.

## **Review virtual machine details**

The resource details include all the collected information for the resource. You can use this information to understand the resource and any associations with other resources.

1. Locate the virtual machine in the Virtual Machine list.
2. To view the resource details, click the machine name or click the double arrows in the left column.  
The details pane opens on the right side of the list.

3. Review the details, including storage, networks, custom properties, and other collected information.
4. To close the pane, click the double arrows or click the resource name.

### Run day 2 actions on the virtual machine

You use the day 2 actions to manage the resources. The current actions for discovered virtual machines includes Power On and Power Off. If you are managing a vSphere virtual machine, you can also run Connect with Remote Console.

1. Locate the machine in the Virtual Machines list.
  2. Click the vertical ellipsis to see the available actions.
- The possible actions for an AWS virtual machine are Power Off and Power On. Power On is not active because the machine is already on.
3. Click **Power Off** and submit the request.

When the process is completed, the machine is powered off. You can now power it back on.

### Onboarding virtual machines

You can quickly onboard discovered machines from the Virtual Machines page. Onboarding gets you full day 2 management capabilities for the onboarded resources. See [What actions can I run on Automation Service Broker deployments or supported resources](#).

- On the **Discovered** tab, select the machines that you want to onboard and then click **Onboard**. You can onboard up to 50 virtual machines at a time.

**Virtual Machines**

Discovered   Managed

Discovered machines are identified when you add cloud accounts. You can run simple day 2 actions on the machines or click Onboard to bring the selected machines under full management, including robust day 2 management actions. You can only include 50 machines each time you run an onboarding action.

| Name                                                                | Power State | Account / Region                                                                            | Created On  |
|---------------------------------------------------------------------|-------------|---------------------------------------------------------------------------------------------|-------------|

ONBOARD   **2**

Search resources   **1**

Manage Columns   Machines per page: 20   41 - 60 of 784 machines   3 / 40

- Follow the prompts in the onboarding wizard.

- Select a project for the machines.
- Select if you want to group the machines into a single deployment or if you want to create a separate deployment for each machine.
- Click **Next**.
- Review the deployment summary. You can update the deployment name and owner by clicking the deployment name.
- When you're done, click **Onboard**.

The screenshot shows the 'Onboard Machines' interface. At the top, it says 'Onboard Machines' and 'Each onboarded machine is applied to your resource count'. Below this is a search bar for 'Project' with the value 'vmware-system-ccs'. A note states: 'Cloud account resources are organized into projects so that you can later add users, apply governance, and delegate the project management to others.' Step 2a shows a dropdown for 'Project' with 'vmware-system-ccs' selected. Step 2b shows a radio button for 'Create single deployment for all machines' selected. Step 2c shows 'NEXT' and 'CANCEL' buttons. Step 2d shows the 'Deployment Summary' step with a table titled 'Machine Details' containing three items:

| Name                                           | Type                  |
|------------------------------------------------|-----------------------|
| Cloud_vSphere_Machine_1-mcm198927-177909572476 | Cloud.vSphere.Machine |
| Cloud_vSphere_Machine_1-mcm199226-177909706836 | Cloud.vSphere.Machine |
| Cloud_vSphere_Machine_1-mcm199228-177910167328 | Cloud.vSphere.Machine |

Step 2e shows 'ONBOARD' and 'CANCEL' buttons.

The selected machines are onboarded.

3. To view the deployment, go to **Resources > Deployments** and then click the deployment name.
4. You manage your onboarded machines, go to **Virtual Machines > Managed**.

If you need to onboard more than 50 machines, you create an onboarding plan. See [What are onboarding plans](#).

## What actions can I run on Automation Assembler deployments or supported resources

### What actions can I run on deployments or resources

After you deploy cloud templates, you can run actions in Automation Assembler to manage the resources. The available actions depend on the resource type and whether the actions are supported on a particular cloud account or integration platform.

The available actions also depend on what your administrator entitled you to run.

As an administrator or project administrator, you can set up Day 2 Actions policies in Automation Service Broker. See [How do I entitle consumers to Automation Service Broker day 2 action policies](#)

You might also see actions that are not included in the list. These are likely custom actions added by your administrator. For example, a [vMotion](#) action.

### CAUTION

To change a deployment, you can edit its cloud template and reapply it, or you can use day 2 actions. However, in most cases you should avoid mixing the two approaches.

Lifecycle day 2 changes such as power on/off are usually safe, but others require caution, such as when adding disks.

For example, if you add disks with a day 2 action, and then take a mixed approach by reapplying the cloud template, the cloud template could overwrite the day 2 change, which might remove disks and cause data loss.

**Table 36: List of possible actions**

| Action                    | Applies to these resource types | Available for these cloud types                                                                                                                       | Resource origin                                                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------------------|---------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Add Disk                  | Machines                        | <ul style="list-style-type: none"> <li>Amazon Web Service</li> <li>Google Cloud Platform</li> <li>Microsoft Azure</li> <li>VMware vSphere</li> </ul>  | <ul style="list-style-type: none"> <li>Deployed</li> <li>Onboarded</li> </ul> | <p>Add additional disks to existing virtual machines.</p> <p>If you add a disk to an Azure machine, the persistent disk or non-persistent disk is deployed in the resource group that includes the machine.</p> <p>When you add a disk to an Azure machines, you can also encrypt the new disk using the Azure disk encryption set configured in the storage profile.</p> <p>You cannot add a disk to an Azure machine with an unmanaged disk.</p> <p>When you add a disk to vSphere machines, you can select the SCSI controller, the order of which was set in the cloud template and deployed. You can also specify the unit number for the new disk. You cannot specify a unit number without a selected controller. If you do not select a controller or provide a unit number, the new disk is deployed to first available controller and assigned then next available unit number on that controller.</p> <p><b>NOTE</b><br/>Any virtual device that Automation Assembler processes must be configured with the SCSI controller.</p> <p>If you add a disk to a vSphere machine for a project with defined storage limits, the added disk must not exceed the storage limits. Storage limits consider the actual capacity for thick and thin resource provisioning so that you cannot over-provision using thin provisioning.</p> <p>If you use VMware Storage DRS (SDRS) and the datastore cluster is configured in the storage profile, you can add disks on SDRS to vSphere machines.</p> |
| Attach SaltStack Resource | Machines                        | <ul style="list-style-type: none"> <li>Amazon Web Services</li> <li>Google Cloud Platform</li> <li>Microsoft Azure</li> <li>VMware vSphere</li> </ul> | <ul style="list-style-type: none"> <li>Deployed</li> <li>Onboarded</li> </ul> | <p>Attach a SaltStack Resource to a deployment resource so that you can install a Salt minion and update the Salt configuration on the virtual machine. You can use this action to update a configuration on a resource or attach the resource and install the minion on another resource in the deployment.</p> <p>The Attach Salt Resource action is available if you configured the SaltStack Config integration.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Action | Applies to these resource types | Available for these cloud types | Resource origin | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------|---------------------------------|---------------------------------|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|        |                                 |                                 |                 | <ul style="list-style-type: none"> <li>To change the project of a deployment with deployed or migrated resources, the initiating user must have the following role:           <ul style="list-style-type: none"> <li>Cloud administrator.</li> </ul> </li> <li>You can only change the project when the target project contains all the cloud zones where the deployment's machines and disks are deployed. The moved deployment is then subject to the configured limits of the target project, including instance count, memory, CPU, and storage. After the move, the current usage is released from the source project.</li> <li>After you move a deployment to the target project, it is subject to the policies of target project. For example, lease, day 2 actions, resource quota, and other polices. To move a deployment, the deployment lease defined by the lease policy of the target project cannot expire in the next 24 hours.</li> <li>The Change Project action is available for deployments where the custom resources are scoped to be available to any project. The lifecycle and day 2 actions for each custom resource in the deployment must be shared with all projects to ensure that you can continue to manage the custom resource using lifecycle actions or day 2 actions after you move the deployment to the new project.</li> <li>The extensibility constraints of the target project must match the VRO integration or the same ABX FaaS provider as the source project. The integrations and providers must match so that you can manage the custom resource using lifecycle actions or day 2 actions after you move the deployment to the new project.</li> <li>The Change Project action is available for deployments with Terraform configurations where all the content sources are shared. If any content sources used in the deployment are not shared, the Change Project action fails validation and does not run.</li> <li>If a Change Project action fails because a Terraform GitHub repository content source was not shared, you can note the corresponding ID that you must share and then share the source. To share the source repository, select <b>Infrastructure &gt; Integrations</b> and select the GitHub integration. In the open integration page, click the Projects tab,</li> </ul> |

## Deployment properties that you cannot update using day 2 actions in VMware Aria Automation

Properties excluded from day 2 action changes

Day 2 actions are changes that you can make to deployed resources. There are limits to the changes that you can make using the actions. There are some properties that you cannot change using certain actions. Review the list of excluded properties if you expected a change but nothing was modified.

### **Storage Properties**

The following storage properties cannot be modified using the **Update** deployment action.

**Table 37: List of excluded properties**

| Deployment Component | Property                       |
|----------------------|--------------------------------|
| Cloud.Machine        | storage - bootDiskCapacityInGB |
| Cloud.Machine        | storage - maxDiskCapacityInGB  |
| Cloud.Machine        | storage - constraints          |
| Cloud.Volume         | encrypted                      |
| Cloud.Volume         | name                           |
| Cloud.Volume         | constraints                    |
| Cloud.Volume         | maxDiskCapacityInGB            |
| Cloud.Volume         | persistent                     |
| Cloud.Volume         | tags                           |
| Cloud.Vsphere.Disk   | datastore                      |
| Cloud.Vsphere.Disk   | storagePolicy                  |
| Cloud.Vsphere.Disk   | provisioningType               |
| Cloud.Vsphere.Disk   | SCSIController                 |
| Cloud.Vsphere.Disk   | UnitNumber                     |
| Cloud.AWS.Volume     | volumeType                     |
| Cloud.AWS.Volume     | iops                           |
| Cloud.Azure.Disk     | resourceGroup                  |
| Cloud.Azure.Disk     | storageAccountName             |
| Cloud.Azure.Disk     | managedDiskType                |
| Cloud.Azure.Disk     | diskCaching                    |
| Cloud.GCP.Disk       | persistentDiskType             |

# Using Automation Service Broker

The VMware Aria Automation Service Broker provides a single point where you can request and manage catalog items.

As a cloud administrator, you create catalog items by importing released VMware Aria Automation Assembler cloud templates and Amazon Web Services CloudFormation templates that your users can deploy to your cloud vendor regions or datastores.

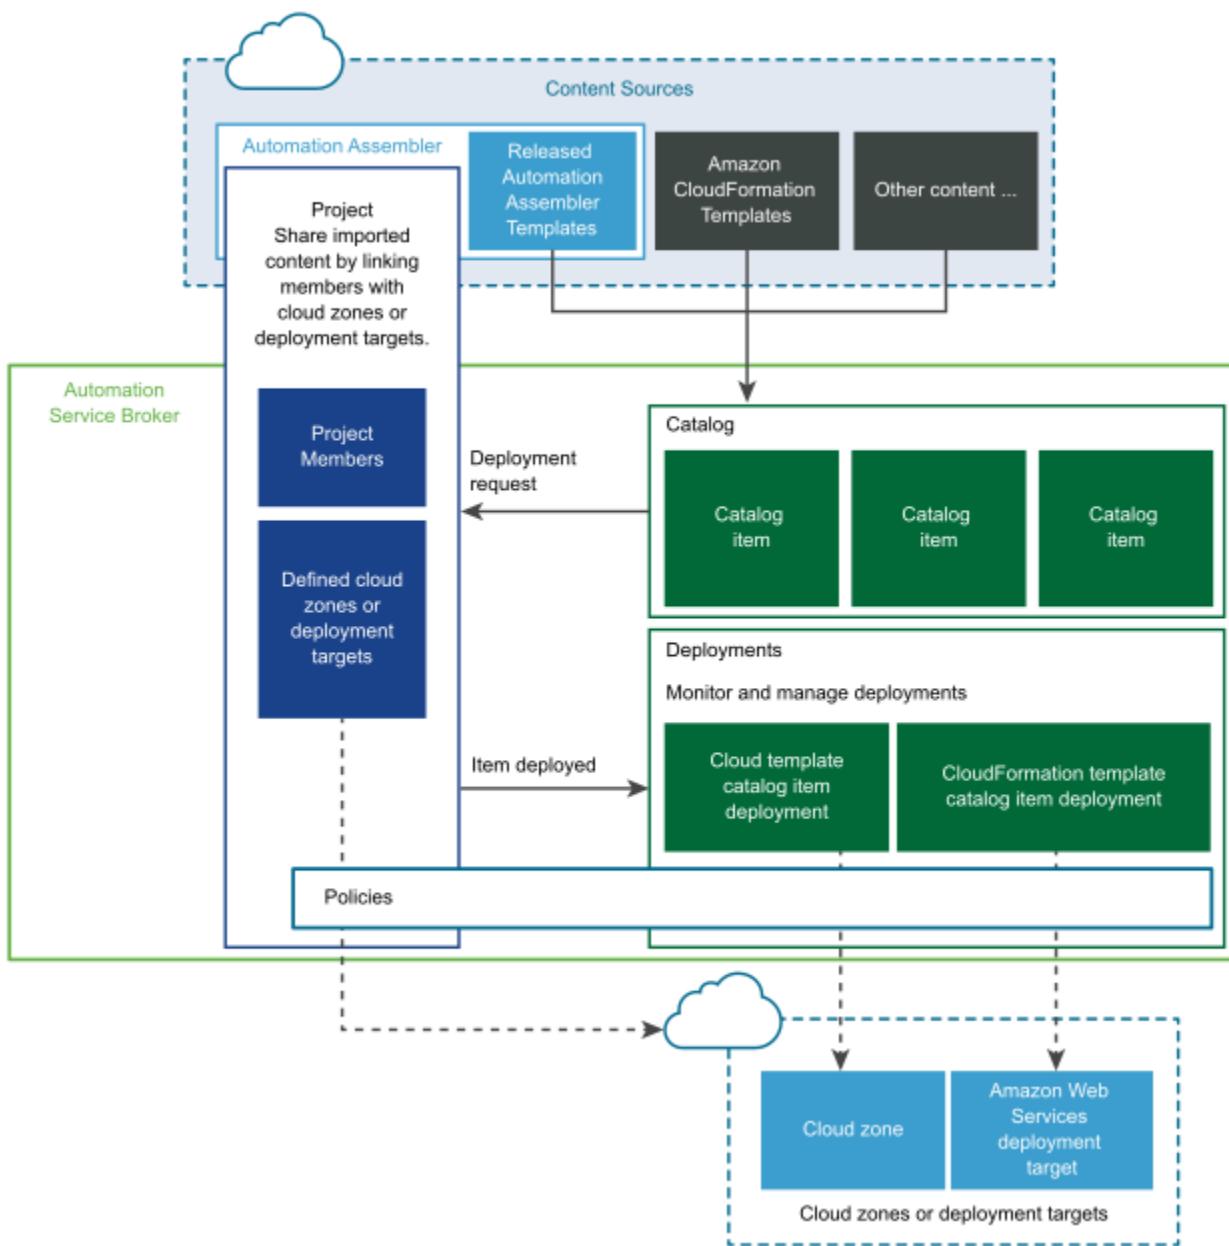

As a user, you can request and monitor the provisioning process. After deployment, you manage the deployed catalog items throughout the deployment lifecycle.

The screenshot shows the VMware Aria Automation Service Broker interface. The top navigation bar includes the VMware logo, the title "VMware Aria Automation", and various icons for search, help, and navigation. Below the header, a secondary navigation bar has tabs for "Service Broker" (selected), "CHANGE", "Consume", "Content & Policies", "Infrastructure", and "Inbox". On the left, a sidebar menu lists "Projects", "Catalog" (which is selected and highlighted in blue), "Deployments", "Resources", "Virtual Machines", "Volumes", and "Networking & Security". The main content area is titled "Catalog" with a sub-label "(20 items of many)". It displays three catalog items: "catalog-bp-1" (VMware Aria Automatio...), "catalog-bp-2" (VMware Aria Automatio...), and another "catalog-bp-2" (VMware Aria Automatio...). Each item card shows its name, provider, project association ("catalog-1" or "catalog-2"), and a "REQUEST" button at the bottom. The interface uses a clean, modern design with a light gray background and blue highlights for active sections.

## How does Automation Service Broker work

The Automation Service Broker is the simplified user interface that cloud administrators make available to users when the administrator's teams do not need full access to developing and building the templates.

You use Automation Service Broker to deploy templates to cloud regions or datastores associated with projects.

To provide the templates, the cloud administrator configures content sources. The content sources can include Automation Assembler templates and Amazon CloudFormation templates. Once developed and released to the catalog, the templates become catalog items.

- The content sources are entitled to projects. Projects link a set of users with one or more target cloud zone regions or datastores.
- For example, UserA is a member of ProjectA and ProjectB, but not ProjectC. UserA sees only the imported templates that were entitled to ProjectA and ProjectB.

When users request a catalog item, where it is deployed depends on the project selected. Projects might have one or more cloud zones.

- If UserA and UserB are members of ProjectA, they see the imported templates as catalog items. At deployment time they can deploy to ProjectA, which determines which cloud regions or datastores the catalog item is deployed to.

The availability of the catalog items is determined by project membership. Projects link users, catalog items, and cloud resources where the items are deployed. The Consume tab provides a single point for Automation Service Broker consumers to access their catalog, deployments, and available resources.

- The Overview page provides users with details about VMware Aria Automation components and lists the projects to which they belong.
- By selecting a project in the Projects drop-down menu, users can filter the catalog items, deployments, and resources that are available for that project. The project filter is applied globally. If no project is selected, then all available items are displayed.

After a successful request, your users can then manage their deployments by running actions, including dismiss or delete.

## Setting up Automation Service Broker for your organization

To fully configure Automation Service Broker, you need to determine your catalog sources and apply governance using projects. As a cloud administrator, you can also apply policies and customize the catalog request form.

As a cloud administrator, you can also apply policies and customize the catalog request form.

## What are the Automation Service Broker user roles

Your user role in Automation Service Broker determines what you can see and do. Some roles are defined at the service organization level, and some are specific to Automation Assembler.

### **User Roles**

User roles are defined for the organization in the VMware Aria Automation console. There are two types of roles, organization roles and service roles.

The organization roles are global and apply to all services in the organization. A user is assigned an Organization owner or Organization Member role.

For more information about the organization, service, and custom roles, start with the [cloud user roles](#).

The Automation Service Broker service roles, which are service-specific permissions, are also assigned at the organization level in the console.

### **Service Broker Service Roles**

The Automation Service Broker service roles determine what you can see and do in Automation Service Broker. These service roles are defined in the console by an organization owner.

**Table 38: Service Broker Service Role Descriptions**

| Role                         | Description                                                                                                                                                                                                                                                               |
|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Service Broker Administrator | Must have read and write access to the entire user interface and API resources. This is the only user role that can perform all tasks, including creating a new project and assigning a project administrator.                                                            |
| Service Broker User          | Any user who does not have the Automation Service Broker Administrator role.<br>In an Automation Service Broker project, the administrator adds users to projects as project members, administrators, or viewers. The administrator can also add a project administrator. |

*Table continued on next page*

| <b>Role</b>           | <b>Description</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Service Broker Viewer | <p>A user who has read access to see information but cannot create, update, or delete values. This is a read-only role across all projects in all the services.</p> <p>Users with the viewer role can see all the information that is available to the administrator. They cannot take any action unless you make them a project administrator or a project member. If the user is affiliated with a project, they have the permissions related to the role. The project viewer would not extend their permissions the way that the administrator or member role does.</p> |

In addition to the service roles, Automation Service Broker has project roles. Any project is available in all of the services.

The project roles are defined in Automation Service Broker and can vary between projects.

In the following tables, which tells you what the different service and project roles can see and do, remember that the service administrators have full permission on all areas of the user interface.

Use the following descriptions of project roles will help you as you decide what permissions to give your users.

- Project administrators leverage the infrastructure that is created by the service administrator to ensure that their project members have the resources they need for their development work.
- Project members work within their projects to design and deploy cloud templates. In the following table, Your projects can include only resources that you own or resources that are shared with other project members.
- Project viewers are restricted to read-only access.
- Project supervisors are approvers in Automation Service Broker for their projects where an approval policy is defined with a project supervisor approver. To provide the supervisor with context for approvals, consider also granting them the project member or viewer role.

## Adding Content to the Automation Service Broker Catalog

### Adding Content to the Catalog

The requirements and process for setting up your Automation Service Broker catalog depends on the content that you are providing to your users.

Each process is provided as an end-to-end procedure. Identify the content that you are providing and add each relevant type. Ensure that the imported content is working properly outside of Automation Service Broker before you add it to the catalog.
