After you add the content sources, the templates are refreshed every six hours. Any changes to the templates in your external sources are reflected in the catalog after a refresh.

### Add Automation Assembler templates to the Automation Service Broker catalog

#### Add Automation Assembler cloud templates to the catalog

As a cloud administrator, you can make Automation Assembler templates available in the Automation Service Broker catalog by adding an Automation Assembler content source and sharing the templates. The templates are the specifications for services or applications that you can deploy to your cloud providers.

- Verify that the cloud templates that you are importing are deployable and released in Automation Assembler before you import them. See [How to save different versions of a cloud template](#).

After you import the Automation Assembler templates, you share them with project members so that they can deploy the templates. At the request time, the template is deployed to cloud zone account region or datastore that supports the template requirements.

- Import templates from Automation Assembler.
  - Select **Content and Policies > Content Sources**.
  - Click **New**, and then click **Template**.
  - Enter the **Name** for this content source.
  - Select the **Source project** and then click **Validate**.  
The validation process tests the connection and provides the number of released templates that are associated with the project in Automation Assembler.
  - Click **Create and Import**.

The Content Sources page lists your new source and the number of discovered and imported items.

- Share the imported items with a project.

If you want to share the template with more than one project, you must create a separate content sharing policy for each project.

- Select **Content and Policies > Policies > Definitions**, and create a new content sharing policy.
- Enter a name for the content sharing policy.
- In the **Scope** list, select the target project.
- In the **Content sharing** section, click **Add Items**, and then select one or more cloud templates to share with the project.

The list of possible templates includes the templates associated with the current project in Automation Assembler and any templates for other projects where sharing is enabled.

You can select all the items imported from a content sources or you can select individual items. To select only particular templates, select **All Content** in the Content Sources drop-down menu.

- e) In the **Users** section, select the users and user groups that you want to have access to the content.

You can share the content with all users and groups in the project, or you can select individual users and groups.

- f) Click **Create**.

The Automation Assembler templates are added to the catalog where the project members can request them.

3. Verify that the template is available in the catalog to the members of the selected projects with whom you shared the content.

- a) Click the **Consume** tab.

- b) In the **Projects** drop-down menu, select the project with which you shared the cloud template.

You can select multiple projects.

- c) On the **Catalog** page, locate the imported template, and review the projects to ensure that the project you configured is included.

- d) Click **Request** and provide any required information.

If the template has more than one released version, select the version that you want to deploy.

- e) Click **Submit**.

The provisioning process begins and the Deployments page opens with your current request at the top.

4. Monitor the provisioning process to ensure successful deployment.

- a) Select **Deployments** > **Deployments** and locate your deployed catalog item.

- b) Monitor the card status until it is successful.

The released Automation Assembler templates are imported into Automation Service Broker, shared in the catalog, and deployable.

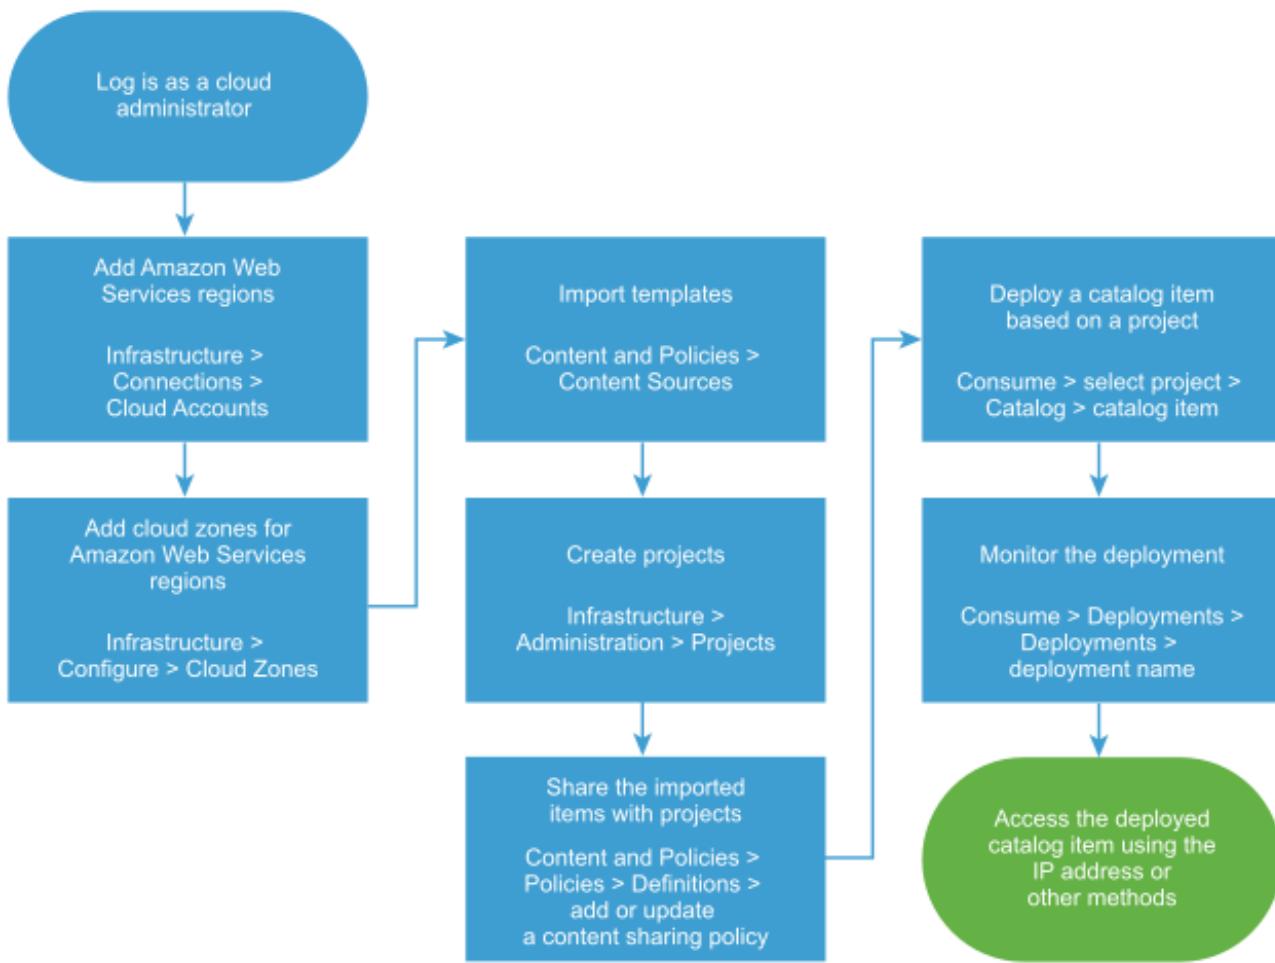

- If the deployment fails, click the deployment name and begin troubleshooting. See [What can I do if an Automation Service Broker deployment fails](#). If you are an Automation Assembler cloud administrator, you can also do more extensive troubleshooting in Automation Assembler[What can I do if an Automation Assembler deployment fails](#).
- If you want to control how long a deployment can exist, create a lease. See [Setting up Automation Service Broker policies](#).
- To provide more or fewer user inputs at request time, you can create a custom form. See [Customize an Automation Service Broker icon and request form](#).

## Add CloudFormation templates to the Automation Service Broker catalog

Add CloudFormation templates to the catalog

As a cloud administrator, you can populate the Automation Service Broker catalog with Amazon CloudFormation templates by adding one or more Amazon S3 buckets as content sources and sharing them with project members. The templates are the specifications for the services or applications that you can deploy to Amazon Web Services.

- Ensure that you know the name of the S3 bucket that contains your CloudFormation templates.
- If you are adding a private bucket, you must know the access key and the secret key.
- Ensure that the CloudFormation template you want to import meets the size limit. The maximum allowed size is 150KB.

You can only add one bucket as a content source. To add multiple buckets, you create a content source for each bucket. After you add the templates, you entitle project members to deploy the cloud templates. At the request time, the cloud template is deployed to the cloud account region that you define when you add the content source.

1. To deploy your CloudFormation templates, you must have at least one Amazon Web Services cloud account and select the regions.
  - a) Select **Infrastructure > Connections > Cloud Accounts**.
  - b) Click **Add Cloud Account** and then click **Amazon Web Services**.
  - c) Enter the 20-digit **Access Key ID** and corresponding **Secret Access Key**.
  - d) To verify the credentials, click **Validate**.
  - e) Enter an account name.

Provide a name that you can identify when you share templates with projects.

  - f) Select one or more regions in this account that you want to deploy templates to.
  - g) Click **Create**.
2. Define cloud zones for the Amazon Web Services cloud account regions.
  - a) Select **Infrastructure > Configure > Cloud Zones**, and then click **New Cloud Zone**.
  - b) Select the **Account/region**, the **Name**, and the **Placement policy**.
  - c) Click the **Compute** tab and verify or modify the resources that are included in the cloud zone.
  - d) Click **Create**.
3. Import the templates.

- a) Select **Content and Policies** > **Content Sources**.
  - b) Click **New**, and then click **AWS CloudFormation Template**.
  - c) Enter the **Name** for this content source.
  - d) Add the S3 bucket information.
  - e) Click **Validate**.  
If the bucket is public, the validation process verifies the name and the number of templates. If the bucket is private, the validation process verifies the name, the keys, and the number of templates.
  - f) Select the **Deployment Target** Amazon Web Services cloud account and a region.
  - g) Click **Create and Import**.
4. Add a project so that you can share the templates with project members.
- a) In Automation Service Broker, select **Infrastructure** > **Administration** > **Projects**, and then click **New Project**.
  - b) Enter the project information on the **Summary** tab.
  - c) Click the **Users** tab and then click **Add Users**.  
To add project users, the individuals or the groups must already be active service organization users.
  - d) If this project supports only CloudFormation templates, ignore the Provisioning tab.  
CloudFormation templates are deployed to the target account and region that you defined when you imported the templates. If the project members can deploy other templates or content, you must add the target cloud zones for the content to the project.
  - e) Click **Create**.  
The new project is added to your projects. It is also added to your associated Automation Assembler instance. If the project is for VMware Cloud Templates, you can add cloud zones in Automation Assembler. If the project is for templates, you do not need to add cloud zones.
5. Share the imported templates with a project.
- If you want to share the templates with more than one project, you must create a separate content sharing policy for each project.
- a) Select **Content and Policies** > **Policies** > **Definitions**, and create a new content sharing policy.
  - b) Enter a name for the content sharing policy.
  - c) In the **Scope** list, select the project that includes the users who should be able to deploy the templates.
  - d) In the **Content sharing** section, click **Add Items**, and then select one or more Amazon Web Services content sources to share with the project.
  - e) In the **Users** section, select the users and user groups that you want to have access to the content.
  - f) Click **Create**.  
The templates are added to the catalog where the project members can request them.
6. Verify that the template is available in the catalog to the members of the selected projects.
- a) Click the **Consume** tab.
  - b) In the **Projects** drop-down menu, select the project with which you shared the CloudFormation template.  
You can select multiple projects.
  - c) On the **Catalog** page, locate the imported CloudFormation template, and review the projects to ensure that the project you configured is included.
  - d) Click **Request** and provide any required information.
  - e) Click **Submit**.  
The provisioning process begins and the Deployments page opens with your current request at the top.
7. Monitor the provisioning process to ensure successful deployment.
- a) Select **Deployments** > **Deployments** and locate your deployed catalog item.

- b) Monitor the card status until it is successful.

The templates are imported into Automation Service Broker and shared in the catalog.

- If the deployment fails, click the deployment name and begin troubleshooting. See [What can I do if an Automation Service Broker deployment fails](#). If you are an Automation Assembler cloud administrator, you can also do more extensive troubleshooting in Automation Assembler[What can I do if an Automation Assembler deployment fails](#).
- If you want to control how long a deployment can exist, create a lease. See [Setting up Automation Service Broker policies](#).
- To provide more or fewer user inputs at request time, you can create a custom form. See [Customize an Automation Service Broker icon and request form](#).

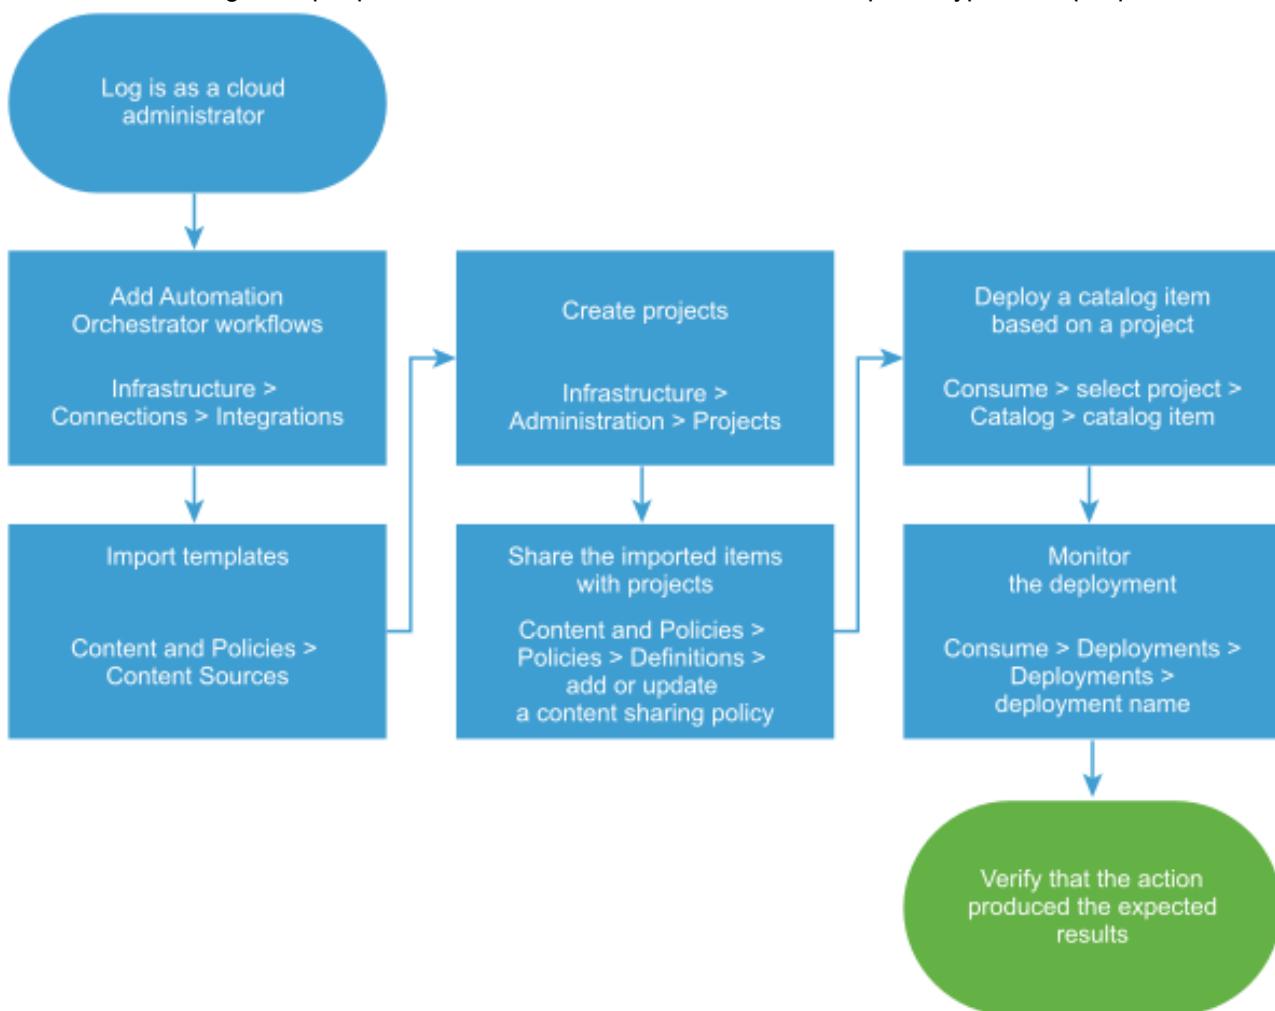

### Add Automation Orchestrator workflows to the Automation Service Broker catalog

Add Automation Orchestrator workflows to the catalog

As a cloud administrator, you can add VMware Aria Automation Orchestrator workflows to the catalog. The workflows are created in Automation Orchestrator to accomplish a simple or complex task.

- Verify that you have Automation Orchestrator workflows that can perform required tasks. See [Managing Workflows](#).

In addition to the regular input parameters, the workflows can include composite types as input parameters.

1. If you do not have a VMware Aria Automation Orchestrator integration configured in Automation Assembler, you can add the integration in Automation Service Broker.
  - a) Select **Infrastructure > Connections > Integrations**.
  - b) Click **Add Integration** and then click **Orchestrator**.
  - c) Enter a name that identifies this instance when you create the content source.
  - d) Enter the URL for your Automation Orchestrator instance.
  - e) Click **Validate**.
  - f) Click **Add**.
2. Import the workflow.
  - a) Select **Content and Policies > Content Sources**.
  - b) Click **New**, and then click **Orchestrator**.
  - c) Enter the **Name** for this content source so that you can identify it when you share the content.
  - d) Click **Add** and select the workflows that you want to make available in Automation Service Broker.
  - e) Click **Create and Import**.
3. Share the imported workflow with a project.
  - a) Select **Content and Policies > Policies > Definitions**, and create a new content sharing policy.
  - b) Enter a name for the content sharing policy.
  - c) In the **Scope** list, select the project that includes the users who should be able to deploy the workflows.
  - d) In the **Content sharing** section, click **Add Items** and then select one or more workflows to share with the project members.

You can select all the items imported from a content source or you can select individual items. To select only particular workflows, select **All Content** in the Content Sources drop-down menu.

  - e) In the **Users** section, select the users and user groups that you want to have access to the content.
  - f) Click **Create**.
4. Verify that the workflow is available in the catalog to members of the selected project.
  - a) Click the **Consume** tab.
  - b) In the **Projects** drop-down menu, select the project with which you shared the workflow.

You can select multiple projects.

  - c) On the **Catalog** page, locate the imported workflow, and review the projects to ensure that the project you configured is included.
  - d) Click **Request** and provide any required information.
  - e) Click **Submit**.

The provisioning process begins and the Deployments page opens with your current request at the top.
5. Monitor the provisioning process to ensure that the workflow runs successfully.
  - a) Select **Deployments > Deployments** and locate your deployed request.
  - b) Monitor the card status until it is successful.

The Automation Orchestrator workflows are imported into Automation Service Broker and shared in the catalog.

- If the deployment fails, click the deployment name and begin troubleshooting. See [What can I do if an Automation Service Broker deployment fails](#). If you are an Automation Assembler cloud administrator, you can also do more extensive troubleshooting in Automation Assembler[What can I do if an Automation Assembler deployment fails](#).
- If you want to control how long a deployment can exist, create a lease. See [Setting up Automation Service Broker policies](#).

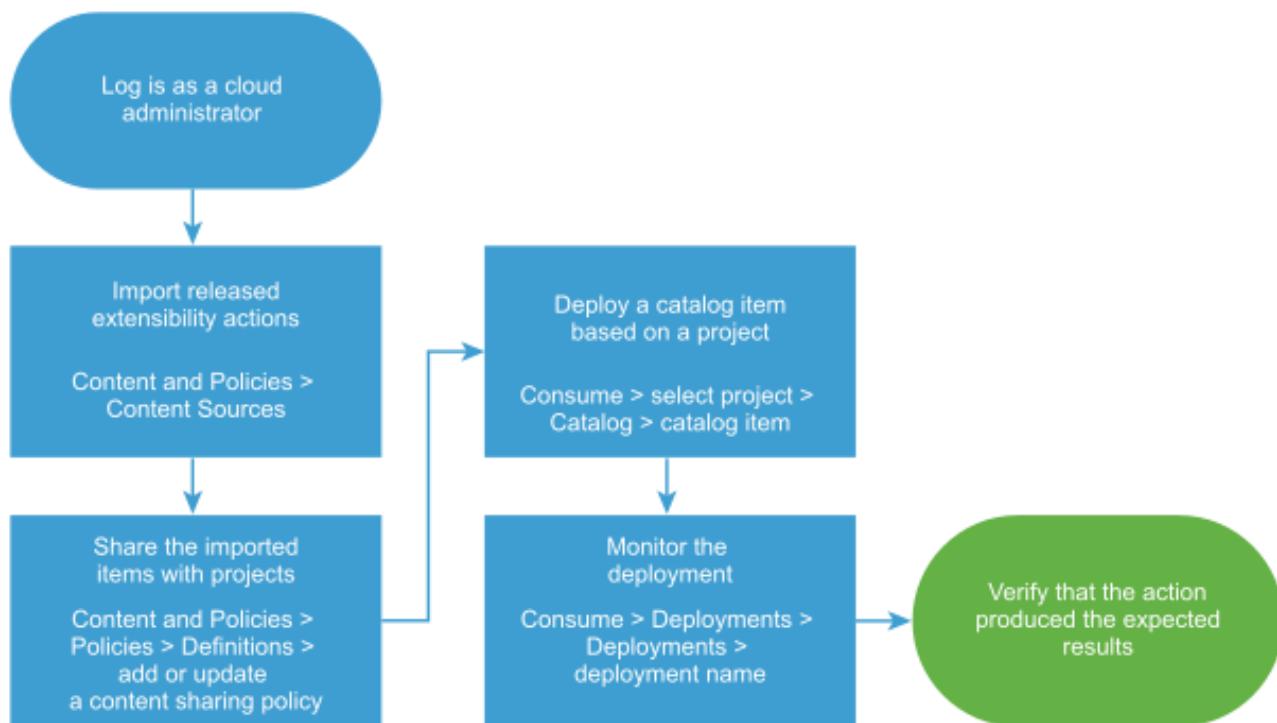

- To provide more or fewer user inputs at request time, you can create a custom form. See [Customize an Automation Service Broker icon and request form](#). If a workflow includes data grids, do not change the column IDs in the custom form. Use the IDs provided in the workflow.
- To learn more about working with workflows from more than one Automation Orchestrator instance, consider [this blog post](#) from a VMware solution architect.

## Add extensibility actions to the Automation Service Broker catalog

Add extensibility actions to the catalog

As a cloud administrator, you can add Automation Assembler extensibility actions to Automation Service Broker as a content source. The extensibility actions are created and managed in Automation Assembler.

- Verify that the actions you are adding are associated with a project, and that they are released. See [How do I create extensibility actions](#).

The actions are small scripts that perform lightweight tasks or steps. For example, rename a virtual machine or assign an IP address.

1. Import the released extensibility actions.
  - a) Select **Content and Policies** > **Content Sources**, and click **New**.
  - b) Click **New**, and then click **Extensibility actions**.
  - c) Enter the **Name** for this content source.
  - d) Select the **Source project** and then click **Validate**.  
The validation process verifies the number of released extensibility actions that are associated with the project in Automation Assembler.
  - e) Click **Create and Import**.
2. Share the imported actions with a project.
  - a) Select **Content and Policies** > **Policies** > **Definitions**, and create a new content sharing policy.
  - b) Enter a name for the content sharing policy.

- c) In the **Scope** list, select the project that includes the users who should be able to deploy the extensibility actions.
- d) In the **Content sharing** section, click **Add Items** and then select one or more actions to share with the project.

You can select all the items imported from a content source or you can select individual items. To select only particular extensibility actions, select **All Content** in the Content Sources drop-down menu.

- e) In the **Users** section, select the users and user groups that you want to have access to the content.
- You can share the content with all users and groups in the project, or you can select individual users and groups.

- f) Click **Create**.

The actions are added to the catalog where the project members can request them.

3. Verify that the action is available in the catalog to the members of the selected projects.
  - a) Click the **Consume** tab.
  - b) In the **Projects** drop-down menu, select the project with which you shared the extensibility action.

You can select multiple projects.
- c) On the **Catalog** page, locate the imported extensibility action, and review the projects to ensure that the project you configured is included.
- d) Click **Request** and provide any required information.
- e) Click **Submit**.

The provisioning process begins and the Deployments page opens with your current request at the top.

4. Monitor the provisioning process to ensure that the action runs successfully.
  - a) Select **Deployments > Deployments** and locate your deployed request.
  - b) Monitor the card status until it is successful.

The extensibility actions are imported into Automation Service Broker and shared in the catalog.

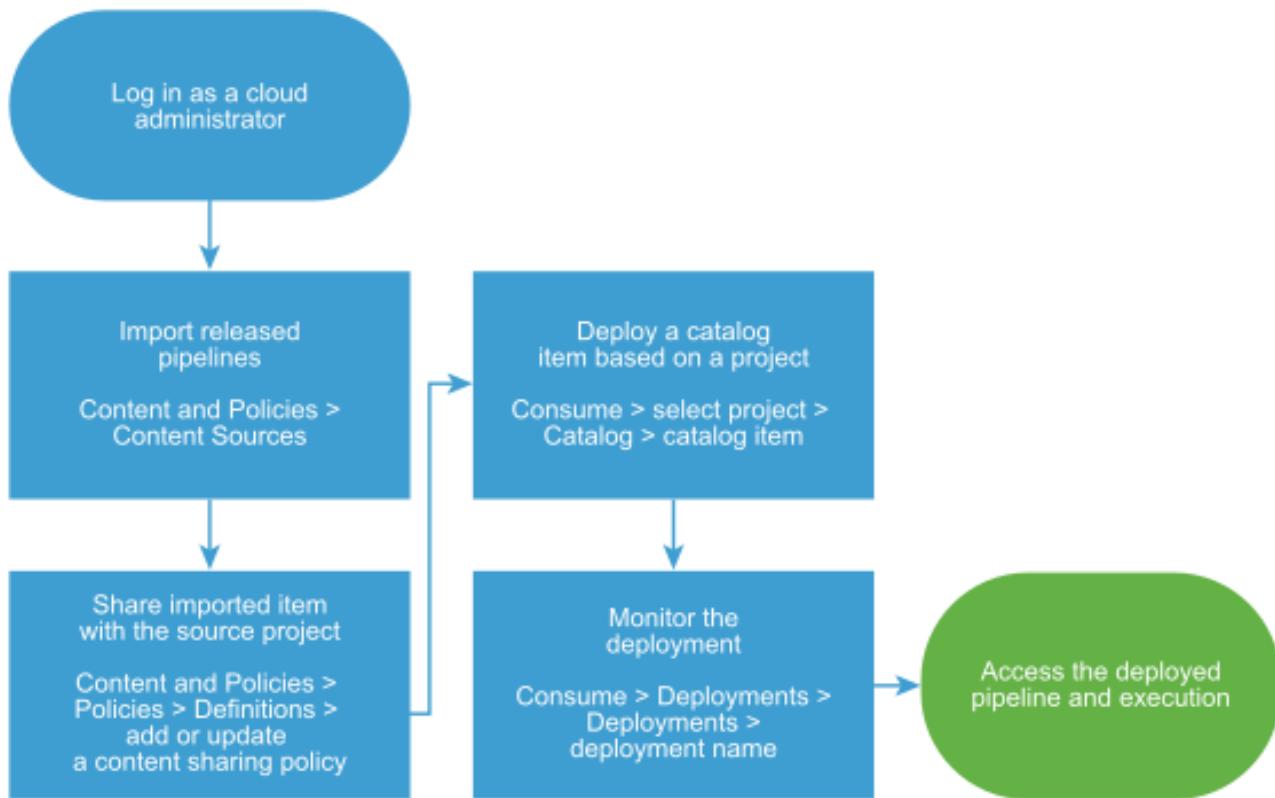

- If the deployment fails, click the deployment name and begin troubleshooting. See [What can I do if an Automation Service Broker deployment fails](#). If you are an Automation Assembler cloud administrator, you can also do more extensive troubleshooting in Automation Assembler[What can I do if an Automation Assembler deployment fails](#).
- If you want to control how long a deployment can exist, create a lease. See [Setting up Automation Service Broker policies](#).
- To provide more or fewer user inputs at request time, you can create a custom form. See [Customize an Automation Service Broker icon and request form](#).

## Add Automation Pipelines pipelines to the Automation Service Broker catalog

### Add pipelines to the catalog

As a service administrator, you can make Automation Pipelines pipelines available in the Automation Service Broker catalog by adding a Automation Pipelines content source and sharing the pipelines. The pipelines are the continuous integration and delivery model of your software release process.

- Verify that the pipelines that you are importing are enabled and released in Automation Pipelines before you import it. See [How do I run a pipeline and see results](#).

After you import the pipelines, you share them with project members so that they can deploy the pipelines from the catalog. After the pipeline deployment execution completes, the users can access review the inputs and outputs, and use the output, pipeline, and execution links.

1. Import pipelines from Automation Pipelines.
  - a) Select **Content and Policies** > **Content Sources**.
  - b) Click **New**, and then click **Code Stream Pipelines**.
  - c) Enter the **Name** for this content source.
  - d) Select the **Source project** and then click **Validate**.  
The validation process tests the connection and provides the number of released pipelines that are associated with the project in Automation Pipelines.
  - e) Click **Create and Import**.  
The Content Sources page lists your new source and the number of discovered and imported items.
2. Share the imported items with the source project so that they appear in the catalog.
  - a) Select **Content and Policies** > **Policies** > **Definitions**, and create a new content sharing policy.
  - b) Enter a name for the content sharing policy.
  - c) In the **Scope** list, select the source project that includes the users who have permission to request the pipelines.
  - d) In the **Content sharing** section, click **Add Items** and then select one or more pipelines to share with the project.  
You can select all the items imported from a content source or you can select individual items. To select only particular pipelines, select **All Content** in the Content Sources drop-down menu.
  - e) In the **Users** section, select the users and user groups that you want to have access to the content.

You can share the content with all users and groups in the project, or you can select individual users and groups.

- f) Click **Create**.

The pipelines are added to the catalog where the project members can request them.

3. Verify that the pipeline is available in the catalog to the members of the selected projects.

- a) Click the **Consume** tab.

- b) In the **Projects** drop-down menu, select the project with which you shared the pipeline.

You can select multiple projects.

- c) On the **Catalog** page, locate the imported pipeline.

- d) Click **Request** and provide any required information.

- e) Click **Submit**.

The provisioning process begins and the Deployments page opens with your current request at the top.

4. Monitor the provisioning process to ensure successful deployment.

- a) Select **Deployments** > **Deployments** and locate your deployed catalog item.

- b) Monitor the card status until it is successful.

You can open the deployment, review the inputs and outputs, use the links to access the output URL, and use the links to the pipeline and execution in Automation Pipelines.

The released pipelines are imported into Automation Service Broker, shared in the catalog, and deployable.

- If the deployment fails, click the deployment name and begin troubleshooting. See [What can I do if an Automation Service Broker deployment fails](#). If you are an Automation Assembler cloud administrator, you can also do more extensive troubleshooting in Automation Assembler[What can I do if an Automation Assembler deployment fails](#).
- If the deployment fails, review the failed execution in Automation Pipelines.
- If you want to control who must approve a pipeline request before it provisions, create an approval policy. See [How do I configure approval policies](#). The lease and day 2 policies do not apply to pipelines.
- To provide more or fewer user inputs at request time, you can create a custom form. See [Customize an Automation Service Broker icon and request form](#).

## Setting up Automation Service Broker policies

### Setting up policies

To provide the background management of your deployments, you set up policies. Each Automation Service Broker policy is a set of rules or parameters that are applied to deployments, freeing the cloud administrator for other tasks.

Any policies that you create in Automation Service Broker are applied to the deployments in Automation Service Broker and in Automation Assembler.

### Getting started with policies

To begin creating policies, select **Content and Policies** > **Policies** > **Definitions**. Any policy that you add is applied to current deployments and any new deployments.

To get you started, use the full use cases that are provided for each policy type. The use cases guide you through the process of creating more than one policy. The use case provides contextual explanations of the choices and the desired behavior.

The use cases are followed by more in-depth information about how multiple policies are processed.

## How do I configure Automation Service Broker approval policies

How do I configure approval policies

Approval policies are a level of governance that you add to exercise control over deployment and day 2 action requests before they are run. You define approval policies in Automation Service Broker so that you, or others that you designate, review requests before resources are consumed or destroyed. The approval policy use cases in this procedure are an introduction that you can use as you explore your governance options.

If you have only a small team adding and deploying catalog items, then approval policies might be less useful. But as you make the catalog available to a larger group of developers and general consumers, you can use the approval policies to ensure that someone reviews a request before the resources are consumed or changes are made to the provisioned items.

For example, you have a catalog item that is important, but it consumes a significant amount of resources. You want one of your IT administrators to review any deployment requests to ensure that the request is needed. Another example applies to day 2 actions. Making changes to a deployment that is used by many might be devastating. You want the project administrator who manages the deployment for that team to review all changes to the deployed catalog item.

### **Who works with or is affected by approval policies**

- Automation Service Broker administrator. Configures the policies.
- Catalog consumers. Users who request catalog items or day 2 actions to which one or more policies apply.
- Users deploying cloud templates in Automation Assembler. Users who request templates or day 2 actions in Automation Assembler to which one or more policies apply.
- Designated approvers. Users who must review and then approve or reject a request. You can grant approver rights to selected users and user groups, or you can choose from the following approver roles.
  - AD Manager. Active Directory user with manager attributes. See [Configure Active Directory attributes for the AD Manager approver role](#)
  - Project Administrators. Administrators of projects within the policy scope are automatically assigned as approvers. If a project does not have a dedicated administrator, the approval policy is not applied to that project.
  - Project Supervisors. Members of projects within the policy scope who are assigned the Supervisor role. Supervisor access rights are limited to approving and rejecting deployment requests for a project. If a project does not have a dedicated supervisor, the approval policy is not applied to that project.

### **What happens when approval policies are enforced**

Multiple approval policies might be enforceable. The approval policies are evaluated, and an enforced policy is applied to the request. When there are multiple valid policies, where the approvers are different people, all the approvers are added. When you have multiple policies, it is important to understand this process. For more information, see [Approval policy goals and enforcement examples](#).

1. Approval policies are defined.
2. A user requests a catalog item or day 2 action. At request time, Automation Service Broker evaluates the catalog item to see if any policies apply.
3. An approval policy is enforced.
  - a. The deploy card displays the status. For example, Create - Approval Pending.
  - b. An email notification is sent to the requester. See [How do I track my requests that require approval](#).
  - c. An email notification is sent to the approvers. See [How do I respond to an approval request](#).

The deployment does not begin deploying and consuming infrastructure resources, or make changes to a deployed system, until the request is approved. The requesting user is notified by email that the request is waiting for approval.

- d. The approvers respond to the request using the Approvals page in Automation Service Broker.

4. The approval process is completed.
  - a. If the request is rejected, the requesting user is notified and the deployment request is canceled.
  - b. If the request is approved, the deployment proceeds.
  - c. It is possible that the enforced policy is configured to automatically approve or reject a request if the approver does not take any action.

### **How can I use the deployment criteria**

To limit what items or activities the policy applies to, you can define the deployment criteria. For more about the criteria, see [How do I configure deployment criteria in Automation Service Broker policies](#).

### **Approval policy constraints**

- The change lease action is not available to include in an approval policy.
- Using custom resources as resource type in the policy criteria is not supported.

### **Prerequisites**

- An approver, who might not be a regular Automation Service Broker or Automation Assembler user, must have one of the following combination of roles:
  - Organization member and Automation Service Broker user
  - Organization member and the Manage Approvals custom role
 These roles provide the minimum level of permissions and still allow them to approve or reject a request.
- Verify that the email notification server is defined. See [Add an email server in to send notifications](#).
- If you plan to use the Active Directory manager as the role-based approval type, you must use the Workspace ONE Access VMware Identity Manager integration configured for VMware Aria Automation. You must also include the Active Directory manager attributes in the user attributes. See [Configure Active Directory attributes for the AD Manager approver role](#).

### **Procedure**

As you review the approval policies use case and create your own policy, consult the signpost help on the key text boxes for more information.

1. Select **Content and Policies > Policies > Definitions > New Policy > Approval Policy**.
2. Configure Approval Policy 1.

As an administrator, you have an important catalog item that also consumes a significant amount of your cloud resources. You want several managers to review any deployment requests to ensure that the request is really needed and that the resources exist to support it.

1. Define when the policy is valid.

| Setting  | Sample Value                                                                 |
|----------|------------------------------------------------------------------------------|
| Scope    | Organization<br>This policy is applied to all projects in your organization. |
| Criteria | Catalog Item equals CompanyApplication                                       |

2. Define the approval behavior.

| Setting              | Sample Value                                                                                                                                                                                                |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Approval type        | Select <b>User based</b> .<br>You select the users and user groups who are the request approvers.                                                                                                           |
| Approver mode        | All<br>You want all your IT managers to agree that the deployment request does not waste resources.                                                                                                         |
| Approvers            | {GroupName1}@YourCompany, {ApproverName1}@YourCompany, {ApproverName2}@YourCompany<br>The approval request is sent to all members of the user group. Only one member of the group must approve the request. |
| Auto expiry decision | Reject<br>The possible load on your cloud resources means that you do not want to inadvertently deploy the item without approval.                                                                           |
| Auto expiry trigger  | 3<br>This value should carry you over a long weekend when the managers might not be available.                                                                                                              |
| Actions              | Deployment.Create                                                                                                                                                                                           |

In this scenario, if any catalog consumer requests this catalog item, Approver 1, Approver 2, and any one member of User Group 1 must approve the request within 3 days or the request is rejected.

### 3. Configure Approval Policy 2.

As an administrator, you have several projects where you want the project administrators to approve any changes to deployments that might have catastrophic consequences. For example, deleting the deployment.

#### a. Define when the approval policy is valid.

| Setting  | Sample Value                                                                                                                                            |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| Scope    | Multiple Projects<br>Project name contains Prod<br><br>The policy is applied to deployments associated with all projects that match the scope criteria. |
| Criteria | None                                                                                                                                                    |

#### b. Define the approval behavior.

| Setting              | Sample Value                                                                                                                                                 |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Approval type        | Select <b>Role based</b> .                                                                                                                                   |
| Approver role        | Project Administrators<br>If a project does not have a dedicated administrator, the approval policy is not applied to requests associated with that project. |
| Approver mode        | Any                                                                                                                                                          |
| Auto expiry decision | Reject                                                                                                                                                       |
| Auto expiry trigger  | 7                                                                                                                                                            |

*Table continued on next page*

*Continued from previous page*

| Setting | Sample Value                                                                                                                    |
|---------|---------------------------------------------------------------------------------------------------------------------------------|
| Actions | Deployment.Delete, Deployment.PowerOff, Deployment.Update, and any of the component-specific power, reboot, and delete actions. |

In this scenario, when a member of one of the scoped projects submits a request to run the listed actions on a deployment, the request is rejected after seven days if the project administrator does not respond.

#### 4. Configure Approval Policy 3.

As an administrator, you want to maintain a little control over resource consumption. For example, when a user requests a catalog item where the size is large, you want to evaluate and approve the request. Size is defined by the flavor mappings.

- a. Define when the approval policy is valid.

| Setting  | Sample Value                             |
|----------|------------------------------------------|
| Scope    | Organization                             |
| Criteria | Resources has any<br>Flavor equals large |

- b. Define the approval behavior.

| Setting              | Sample Value                                                                                                                             |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| Approval type        | Select <b>User based</b> .                                                                                                               |
| Approver mode        | Any                                                                                                                                      |
| Approvers            | {AdminName}@YourCompany                                                                                                                  |
| Auto expiry decision | Reject<br>The possible consumption of your cloud resources means that you do not want to inadvertently deploy the item without approval. |
| Auto expiry trigger  | 5                                                                                                                                        |
| Actions              | Deployment.Create and any applicable *.Machine.Resize actions. For example, Cloud.vSphere.Machine.Resize.                                |

In this scenario, when any user submits a request for a large deployment or to resize a deployment to large, the request is rejected after 5 days if the cloud administrator does not respond.

#### What to do next

- For more information about how approval policies are processed, see [Approval policy goals and enforcement examples](#).
- For more about the consumer and approver experience, see [How do I track my requests that require approval](#) and [How do I respond to an approval request](#).

## Configure Active Directory attributes for the AD Manager approver role

You must have the manager Active Directory attributes configured in Workspace ONE Access VMware Identity Manager if you plan to use role-based approvers for approval policies in Automation Service Broker. To do this you must have permission to configure the VMware Identity Manager instance that you use with VMware Aria Automation.

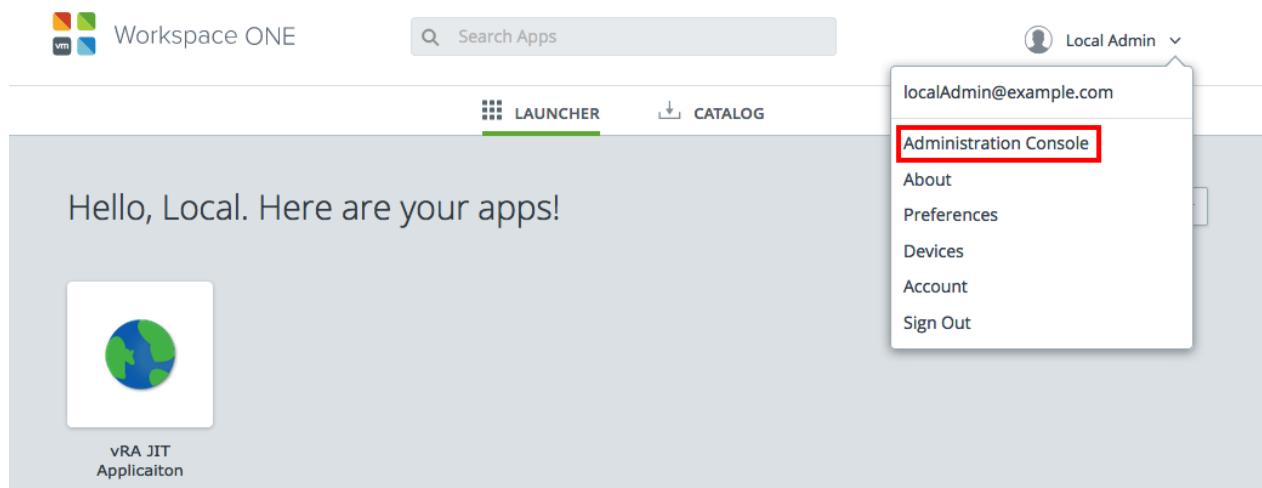

- Verify that you have administrator credentials in Workspace ONE Access and VMware Identity Manager.

This procedure primarily covers work that you perform outside of VMware Aria Automation. Links to relevant procedure are provided.

- In the VMware Identity Manager instance that you use with VMware Aria Automation, verify that you are integrating Active Directory with Identity Manager.
- Configure the user attributes.

The basic steps are provided below.

- In Identity Manager, click your local administrator login and click **Administration Console**.

- Select the **Identity and Access Management** tab and click **Setup**.
- Click **User Attributes**.

**User Attributes**

**Default Attributes** Select the attributes to use when users sync to the directory or when local users are created. These attributes can be viewed from the Directory pages.

|                   | Required                            |
|-------------------|-------------------------------------|
| userName          | <input checked="" type="checkbox"/> |
| email             | <input type="checkbox"/>            |
| firstName         | <input type="checkbox"/>            |
| lastName          | <input type="checkbox"/>            |
| phone             | <input type="checkbox"/>            |
| disabled          | <input type="checkbox"/>            |
| employeeID        | <input type="checkbox"/>            |
| distinguishedName | <input type="checkbox"/>            |
| userPrincipalName | <input type="checkbox"/>            |
| domain            | <input type="checkbox"/>            |

---

**Add other attributes to use** Add other attributes to sync to the directory. Go to the directory's attributes page to map these attributes.

| Attributes  | +                                                                       |
|-------------|-------------------------------------------------------------------------|
| manager     | <span style="color: red;">x</span> <span style="color: green;">+</span> |
| displayName | <span style="color: red;">x</span> <span style="color: green;">+</span> |
| memberOf    | <span style="color: red;">x</span> <span style="color: green;">+</span> |

**Save**

d) Verify that the following attributes exist in the **Default Attributes** section.

- userName
- email
- firstName
- LastName
- phone
- disabled
- employeeID
- distinguishedName
- userPrincipalName

- domain

e) In the **Add other attributes to use** section add the following attribute.

  - manager

f) Click **Save**.

3. After you make any changes, you must synchronize the affected directories.

  - a) Click **Manage**.
  - b) Select the **Directories** tab.
  - c) Open the directory by clicking the directory name and click **Sync Settings**.

| Sync Frequency    | Domains | Mapped Attributes     | Groups | Users | Safeguards |
|-------------------|---------|-----------------------|--------|-------|------------|
| userPrincipalName |         | userPrincipalName     |        |       | Required   |
| disabled          |         | userAccountControl    |        |       |            |
| displayName       |         | Enter Custom Input... |        |       |            |
|                   |         | Enter Custom Input... |        |       |            |
| distinguishedName |         | distinguishedName     |        |       |            |
| domain            |         | canonicalName         |        |       |            |
| email             |         | mail                  |        |       |            |
| employeeID        |         | employeeID            |        |       |            |
| firstName         |         | givenName             |        |       |            |
| lastName          |         | sn                    |        |       |            |
| manager           |         | manager               |        |       |            |
| phone             |         | telephoneNumber       |        |       |            |
| userPrincipalName |         | userPrincipalName     |        |       |            |

- d) Click **Mapped Attributes** and verify that the manager attribute is defined as `manager`.
  - e) Click **Save and Sync**.
  - f) Click **Sync Directory**.

You can now use the AD Manager role in your approval policies.

### Configure multi-level approval policies in Automation Service Broker

#### Configure multi-level approvals

You use multi-level approvals to maintain technical constraints and capabilities for resources within the organization. In this use case, there are two approval policy definitions that illustrate how you can construct multi-level approvals and the results when they are enforced.

To manage virtual infrastructure resources and to control prices, you add two policies at different approval levels, where one approval is for machine resources and the other is for price of machine per day.

1. Select **Content and Policies > Policies > Definitions > New Policy > Approval Policy**.

2. Configure Approval Policy 1.

You want an administrator to approve the deployment request first.

- a) Define when the policy is valid.

| Setting  | Sample Value                                                                                               |
|----------|------------------------------------------------------------------------------------------------------------|
| Scope    | Organization                                                                                               |
| Criteria | <p>Resources has any</p> <p>CPU Count greater than 6</p> <p>OR</p> <p>Total Memory (MB) greater than 8</p> |

- b) Define the approval behavior.

| Setting              | Sample Value                                                                                                                                                                                                                              |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Approval level       | <p>1</p> <p>Enter a value between 1 and 99.</p> <p>You prioritize levels based on the order that you want them processed. When the approval policy is triggered, if the first level of approval is rejected, the request is rejected.</p> |
| Approval type        | Select <b>Role based</b> .                                                                                                                                                                                                                |
| Approver role        | Select <b>Project Administrators</b> .                                                                                                                                                                                                    |
| Approver mode        | <p>Any</p> <p>You want a project administrator to ensure that the deployment request does not waste resources.</p>                                                                                                                        |
| Auto expiry decision | Approve                                                                                                                                                                                                                                   |
| Auto expiry trigger  | 3                                                                                                                                                                                                                                         |

*Table continued on next page*

*Continued from previous page*

| Setting | Sample Value      |
|---------|-------------------|
| Actions | Deployment.Create |

If a deployment request exceeds at least one of the level 1 deployment criteria, then an administrator must approve the request. Only level 1 approvers are notified of the request. When an approver approves the request at this level, the request is routed to the next level. If an approver rejects the request, it is not routed to any higher levels and the request is denied.

### 3. Configure Approval Policy 2.

To ensure that a provisioning request is within budget, create a second policy.

- a) Define when the approval policy is valid.

| Setting  | Sample Value                             |
|----------|------------------------------------------|
| Scope    | Organization                             |
| Criteria | Deployment Creation Cost greater than 15 |

- b) Define the approval behavior.

| Setting              | Sample Value                                                                                                                              |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| Approval level       | 2<br>Because you want this policy to be executed after Policy 1, enter a number that is larger than the number you specified in Policy 1. |
| Approval type        | Select <b>User based</b> .                                                                                                                |
| Approver mode        | Any                                                                                                                                       |
| Approvers            | Add user groups<br>Select the finance user group.                                                                                         |
| Auto expiry decision | Reject                                                                                                                                    |
| Auto expiry trigger  | 7                                                                                                                                         |
| Actions              | Deployment.Create                                                                                                                         |

In this scenario, when a user requests a virtual machine, the request is evaluated to determine whether the requested CPU and memory amounts are over the amounts specified in level 1. If they are not and the request is approved at level 1, then the level 2 condition is evaluated.

- For more information about how approval policies are processed, see [Approval policy goals and enforcement examples](#).
- For more about the consumer and approver experience, see [How do I track my requests that require approval](#) and [How do I respond to an approval request](#).

## **How do I entitle deployment users to Automation Service Broker day 2 actions using policies**

How do I configure day 2 actions using policies

You define day 2 action policies so that you can control what changes your users can make to deployments and their component resources. By creating a list of permitted actions that all or some users can run on deployments, you ensure that the users cannot initiate any destructive or costly changes. The use cases related to day 2 actions policies are an introduction to the procedure.

When you entitle users to run day 2 actions, you select the individual actions that they can run. You are creating an inclusion list, not an exclusion list.

### **When does a day 2 actions policy go into effect**

- If you do not have any Day 2 Action policies defined, then no governance is applied and all users have access to all the actions. This initial lack of governance as you are starting out ensures that you and your users can exercise the day two actions in Automation Service Broker and Automation Assembler without the need to understand day 2 policies.
- After you determine that you are ready to control who has access to what actions, you add governance in the form of a single Day 2 Action policy. When the first policy goes into effect, the Day 2 Action policies are enforced for all users in Automation Service Broker and Automation Assembler. As a result, only the users for whom the first policy is true can run the selected actions. All others are excluded. They are excluded because the actions policies include the trusted users. By excluding all others, you are able to craft the policies to match your governance goals.
- To entitle other users, you must create policies that entitle them to run the actions you select.

### **How does deployment sharing affect day 2 actions policies**

Deployment sharing in projects affects how you configure the day 2 actions entitlements. If the project is not set to share, then only the requesting user can see a deployment. If the project shares deployments, then all the members of the project can see the deployment, and run any actions that they are entitled to run by a Day 2 Action policy. Deployment sharing is configured in a project. Select **Infrastructure > Administration > Projects**, then select the project and click the **Users** tab.

As you create your policies, the way that you define Day 2 Actions policies must take sharing status into consideration.

### **When are day 2 actions policies applied**

To focus when the Day 2 Actions policies are applied, you can configure scope, role, and criteria. These configurations control what deployments the policy is applied to and who can run the actions when the policy is enforced.

- What deployments the policy is applied to.
  - Scope determines whether the policy is applied to deployments at the organization or project level.
  - Criteria narrow the scope of the policy to particular aspects of deployments.
- Who can run what actions on those deployments.
  - Role entitles the members of the selected role, within the selected scope and criteria, to run the selected actions. The role can be project administrator, project member, or a named custom role.

Day 2 policies are enforced when a user tries to manage a deployment using the Actions menu on the deployment or on the component resources.

In this use case, which is used to illustrate a collection of day 2 action policies, the assumption is that you enabled deployment sharing in the project.

### **Selecting day 2 actions**

As you review the day 2 actions policies use case, you must also select the actions. You must select the actions that support your cloud accounts.

- Actions are cloud specific. When you are entitling the users to make changes, consider what cloud accounts the entitled users are deploying to and ensure that you select all the cloud-specific versions of the actions. For example,

add Cloud.AWS.EC2.Instance.Resize, Cloud.GCP.Machine.Resize, and Cloud.Azure.Machine.Resize to entitle users to resize those machines.

- Cloud agnostic actions, for example, Cloud.Machine.Resize, exist to accommodate resources where the on-boarding or migration process cannot identify the machine type. If you entitle users to the cloud agnostic actions, you have not entitled them to run the cloud-specific action that will make the changes to the deployed resources. The agnostic actions might appear in the action menu, but running the actions has no effect. Avoid entitling the agnostic actions and only entitle cloud-specific actions to ensure that actions are available to the users for your various cloud platforms.

### **Prerequisites**

- For a list of possible actions, see [What actions can I run on Automation Service Broker deployments or supported resources](#).
- For more information about constructing deployment criteria, see [How do I configure deployment criteria in Automation Service Broker policies](#).
- Custom roles are used in Day 2 Policy 4. Create a Deployment Troubleshooter role, but with the Manage Deployment role in the custom Deployment Troubleshooting role does not limit the members by project. The Manage Deployment role allows the assignees to see all deployments and run all actions. If the Troubleshooting Deployments role does not include Manage Deployments, then the assignees see deployments based on their project membership. For more information about custom roles, see [custom role use case](#).

### **Procedure**

- Select **Content and Policies > Policies > Definitions > New Policy > Day 2 Actions Policy**.

- Configure Day 2 Policy 1.

As an administrator, you want to control storage costs by restricting the ability of users to request snapshots.

- Define when the policy is valid.

| Setting          | Sample Value                                                                                                                 |
|------------------|------------------------------------------------------------------------------------------------------------------------------|
| Scope            | Organization<br>This policy applied to all deployments in your organization.                                                 |
| Criteria         | None                                                                                                                         |
| Enforcement type | Soft<br>This enforcement type allows you to create other policies related to the snapshot actions that override this policy. |
| Entitlement type | Role based                                                                                                                   |
| Role             | Member<br>This role applies the policy to all project members.                                                               |

- Select the actions that the users can run, but do not select any snapshot actions.

You explicitly entitle users to run actions. To exclude users from running snapshot actions, ensure that the actions are not selected.

In this scenario, none of the project members in your organization are entitled to create snapshots. Nor can your project administrators. Your next step is to create a policy that entitles the project administrators to create and manage snapshots.

- Configure Day 2 Policy 2.

As an administrator, you want to give the project administrators the ability to create and manage snapshots.

- Define when the policy is valid.

| Setting          | Sample Value                                                                                                                 |
|------------------|------------------------------------------------------------------------------------------------------------------------------|
| Scope            | Organization<br>This policy is applied to all deployments in your organization.                                              |
| Criteria         | None                                                                                                                         |
| Enforcement type | Soft<br>This enforcement type allows you to create other policies related to the snapshot actions that override this policy. |
| Entitlement type | Role based                                                                                                                   |
| Role             | Administrator<br>This role applies the policy to the project administrators.                                                 |

- b. Select the snapshot actions that you want the administrators to run.

Project administrators are also entitled to run any actions that the members of their projects are entitled to run. You do not need to give them permission to member actions.

In this scenario, the project administrators are entitled to run the snapshot-related actions and all the actions that their project members are entitled to run.

#### 4. Configure Day 2 Policy 3.

As a project administrator, you have two developers who are doing work that potentially makes a deployment unusable. You want to entitle them to snapshot and revert without your intervention. You entitle the two project members to use the snapshot actions.

- a. Define when the policy is valid.

| Setting          | Sample Value                                                                                                                                                                                                       |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Scope            | Project MT5<br>This policy is applied to deployments associated with this project.                                                                                                                                 |
| Criteria         | Catalog Item equals Multi-tier five machine with LB<br><br>Based on this criteria expression, only the deployments for a catalog item named Multi-tier five machine with LB are considered for policy enforcement. |
| Enforcement type | Hard<br>This enforcement type ensures that the policy is enforced based on the definition.                                                                                                                         |
| Entitlement type | User based                                                                                                                                                                                                         |
| Users            | Add users.<br>jan@mycompany.com, kris@mycompany.com<br><br>Only the deployments where Jan or Kris deployed a catalog item are considered for policy enforcement.                                                   |

- b. Select the snapshot actions that you want the specified users to run.

Project administrators are also entitled to run any actions that the members of their projects are entitled to run.

In this scenario, Jan and Kris can use the snapshot actions on the Multi-tier 5 Machines with LB catalog item that either of them deploy. Although other members of the project can see the deployment, only Jan, Kris, and the project administrator can use the snapshot actions.

## 5. Configure Day 2 Policy 4.

As an administrator, you want to assign the permissions to run most of the day 2 actions to the users who are assigned to a Deployment Troubleshooter custom role. While most custom role permissions go across projects, what users can see in the Deployments page is based on their project membership. To see the deployments, the users who are assigned the custom roles must be members of the projects that deployed them.

- Define when the policy is valid.

| Setting          | Sample Value                                                                                                               |
|------------------|----------------------------------------------------------------------------------------------------------------------------|
| Scope            | Organization                                                                                                               |
| Criteria         | None                                                                                                                       |
| Enforcement type | Soft<br>This enforcement type allows you to create other policies related to the extended day 2 that override this policy. |
| Entitlement type | Role based                                                                                                                 |
| Role             | Select the <b>Deployment Troubleshooter</b> role.                                                                          |

- Select all the actions that you want the members of this custom role to be able to run.

In this scenario, all the users with the Deployment Troubleshooting role can manage all deployments and run all selected day 2 actions across projects. The Manage Deployments role grants service administrator privileges on deployments so that they can run any action that a service administrator can run. If the Deployment Troubleshooting custom role does not include the Manage Deployments role, the users can run all the selected day 2 actions for the deployments belonging to their projects.

## What to do next

- For more examples of how the policies are processed and enforced, see [How are policies processed](#).
- Configure policies that are relevant to your organizations and projects.

## **How do I configure Automation Service Broker deployment leases using policies**

### How do I configure deployment leases using policies

By using policy-based leases, you reduce the need to intervene manually to reclaim resources. You define lease policies so that you can control the amount of time that a deployment is available to your users. The lease policy use cases in this procedure provide a beginning point for learning about and implementing policies for your organization.

If you do not have any lease policies defined, then the deployments never expire. To reclaim the resources, you must manually destroy the deployments.

### When does a lease policy go into effect

- If the policy scope is Organization, then all the deployments in your organization are managed based on the defined policies.
- If the policy scope is a project, then the deployments that are associated with that project are managed based on the defined lease. Other projects are not affected.

### When are lease policies applied

Lease policies are applied when you:

- Create or update a lease policy. After lease policies are applied, they continuously evaluate the deployments in the background to ensure that they are in compliance with the defined leases.
- Request a catalog item in Automation Service Broker or a cloud template in Automation Assembler. The maximum lease and maximum total lease values go into effect when the deployment is created.
- Onboard workloads or resources in Automation Assembler so that you can manage them using Automation Service Broker, Automation Assembler, or Automation Pipelines.

### **Lease-specific options**

As you review the lease policies use case, you must also configure lease-specific options. The following descriptions provide a brief summary. Consult the signpost help for more information.

- Maximum Lease (days). The number of days that the deployment resources are active without being renewed. If they are not renewed, the lease expires and the deployment is destroyed. If a grace period is specified, the user can renew the lease for up to the same number of days that the lease has been active.
- Maximum Total Lease (days). The combined total number of days that the deployment can be active, including lease renewals. Each renewal cannot exceed the maximum lease, and the cumulative renewal value cannot exceed the maximum total lease. After the total lease is reached, the deployment is destroyed and the resources within that deployment are reclaimed.
- Grace period (days). The number of days the user has to renew an expired lease before the deployment is destroyed. The grace period is not included in the total lease days. If you don't define a grace period, it defaults to 1 day.

### **What happens when I update an existing lease policy**

You can increase the maximum lease, the maximum total lease, and the grace period of your lease policies. The updated policy is applied to new deployments only.

Note that increasing the policy parameters does not extend the expiry date of existing deployments. Existing deployments expire on the same date as originally scheduled.

If you decrease the lease values, however, the deployment expiry date is affected and existing deployments expire earlier than originally scheduled.

### **What happens when a deployment expires**

When a deployment is about to expire, the deploying user receives an email notification. If the user doesn't extend the lease, the deployment expires and is scheduled for deletion. The deployment owner can see the scheduled deletion date in the deployment details. If the deletion date is set to Soon, then the deployment is already queued for deletion.

Expired virtual machines are powered off within several minutes after expiry. Unless the lease is extended, a powered-off machine can't be powered back on in VMware Aria Automation. The machine can be powered back on manually in the original environment, in which case VMware Aria Automation registers the machine as powered on. Even though the deployment is already expired, the machine is not automatically powered off for a second time until the grace period of the lease policy is elapsed and the deployment is deleted.

### **Procedure**

In this use case, there are three policy definitions that illustrate how you can construct policies and the results when they are enforced. The last policy is not enforced, but the reasons are provided in the scenario results.

1. Select **Content and Policies > Policies > Definitions > New Policy > Lease Policy**.
2. Configure Lease Policy 1.

As an administrator, you want to control costs by limiting the starting lease time for all deployments to 30 days, with the option to renew the lease for a total of 90 days.

- a. Define when the policy is valid.

| Setting          | Sample Value                                                                                                       |
|------------------|--------------------------------------------------------------------------------------------------------------------|
| Scope            | Organization<br>This policy is applied to everyone in your organization.                                           |
| Criteria         | None                                                                                                               |
| Enforcement type | Soft<br>This enforcement type allows you to create other policies related to this lease that override this policy. |

- b. Define the lease.

| Setting                    | Sample Value |
|----------------------------|--------------|
| Maximum lease (days)       | 30           |
| Maximum total lease (days) | 90           |
| Grace period (days)        | 10           |

In this scenario, the deployment is shut down after 30 days and an email is sent to the user. During the grace period, the user extends the lease by 30 days. After the lease expires again, the user renews it for another 30 days. At the end of the third extension, the lease reaches the maximum total lease period of 90 active days and the user cannot extend it anymore. The deployment is shut down and destroyed 10 days later.

3. Configure Lease Policy 2.

As an administrator, you want to control costs by limiting the lease time on an expensive template to two weeks. For this example, the template name is Multi-tier 5 machine with LB.

- a. Define when the policy is valid.

| Setting          | Sample Value                                                                                                                                                                 |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Scope            | Project MT5<br>This policy applied to deployments associated with this project.                                                                                              |
| Criteria         | Cloud Template equals Multi-tier 5 machine with LB<br>Based on this criteria expression, only deployments for the referenced template are considered for policy enforcement. |
| Enforcement type | Soft<br>This soft enforcement still overrides the organization policy of 90 days in Policy 1 because the values are more meaningful at the project level.                    |

- b. Define the lease policy.

| Setting                    | Sample Value |
|----------------------------|--------------|
| Maximum lease (days)       | 14           |
| Maximum total lease (days) | 28           |
| Grace period (days)        | 3            |

In this scenario, both policies are applied, but Policy 2 takes precedence over Policy 1 because it is more specific. When applied, the deployment is shut down after 14 days. If the user does not extend the lease, it is destroyed

three days later. If the user extends the lease for up to another 14 days, the deployment is shut down at the end of the second extension and it is destroyed three days later.

#### 4. Review the configuration of Lease Policy 3.

As a project manager, you realize that one of your developers is working on a complex application. The developer requires the Multi-tier 5 Machines with LB template and another template, Distributed Database Across Clouds, but for a longer lease than defined in Policy 2.

Unless you understand how the policies are processed based on how they are defined, you might encounter unexpected results. Policy 3 is an example of how processing and precedence affect the result.

This policy, as provided, will not be enforced. This example provides an opportunity for you to see how leases are applied and enforced when there is more than one that applies.

##### a. Define when the policy is valid.

| Setting          | Sample Value                                                                                                                                                                                                                                                         |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Scope            | Project MT5<br>This policy is applied to deployments in this project.                                                                                                                                                                                                |
| Criteria         | (Cloud Template equals Multi-tier five machine with LB<br><br>OR<br><br>Catalog Item equals Distributed Database Across Clouds)<br><br>AND<br><br>Created By equals jan@mycompany.com<br><br>You use Catalog Item because it is a non-Automation Assembler template. |
| Enforcement type | Soft<br>This soft enforcement still overrides the organization policy of 90 days in policy 1 because the values are more meaningful at the project level.                                                                                                            |

##### b. Define the lease policy.

| Setting                    | Sample Value |
|----------------------------|--------------|
| Maximum lease (days)       | 21           |
| Maximum total lease (days) | 50           |
| Grace period (days)        | 3            |

In this scenario, Lease Policy 2 is applied, not Lease Policy 3.

- Lease 3 has a lease time that is less than or equal to 21 days, and the policy is applied. Lease 2 has a lease time that is less than or equal to 14 days, and the policy is applied.
- Lease 2 is applicable and it does not violate the lease 3 policy. But, lease 2 is more restrictive, so it takes precedence. Lease policy 2 is more restrictive because it is for a shorter period of time.
- When both lease definitions are true and applicable, the more restrictive policy is the one that is enforced.

#### 5. To resolve the unexpected behavior in Lease Policy 3, you can implement one of the following solutions.

- To ensure that you can provide Jan with the needed policy, change the enforcement type to hard.
- Alternatively, you could create a new project with access to the same resources, and then create Lease Policy 3 for that project. While this solution isolates the working policy, you must maintain a parallel project. The effort needed to set up and maintain the content sources, content sharing, and so on, are time consuming and subject to error.

## **What to do next**

- For more examples of how the lease policies are processed and enforced, see [How are policies processed](#).
- Configure policies that are relevant to your organizations and projects. If you are just getting started with lease policies, begin with one lease policy at the organization level.
- To send an email to the deploying user, configure the email server for notifications. See [Add an email server in to send notifications](#).
- If you use Automation Orchestrator, you can manage expired deployments and their resources by using extensibility subscriptions. See [Using extensibility subscriptions to manage deployment expiry](#).
- Review more examples of how lease policies work in this blog article: [Demystifying Lease Policies](#).

## **How do I configure Automation Service Broker resource quotas using policies**

### How do I configure resource quotas using policies

Resource quota policies control the amount of resources that are available to your users. You define resource quota policies so that you limit the resources that can be consumed by each user, project, or the organization. The use cases in this procedure are an introduction to resource quota policies.

If you do not have any resource quota policies defined, then no governance is applied and users can consume resources until all available resources are used up.

As a cloud administrator, you can create one or more resource quota policies and apply them, for example, at the organization level. As users across the organization request deploy resources, resource quota policies track the consumption of resources to ensure that new deployment requests do not exceed the resource limits defined in the policies.

### **Defining the policy scope**

As you create your policies, you must configure policy scope. The scope determines whether the policy is applied to resources at the organization or project level. For more information about policy scope, see [How do I configure scope in Automation Service Broker policies](#).

- If the policy scope is organization, then all resources in your organization are managed based on the defined policies.
- If the policy scope is multiple projects, then the resources that are associated with the specified projects are managed based on the defined policy.
- If the policy scope is a single project, then the resources that are associated with that project are managed based on the defined policy. Other projects are not affected.

### **Defining scope level limits**

When defining resource quotas, you must specify scope level limits for each resource. Level limits provide additional resource governance. For example, if you want to apply a resource quota policy to the whole organization, you can set the scope level to organization limits, or you can define limits for a smaller segment, such as projects or users within that organization.

You can set only one limit for a resource type per scope level in the same policy. For example, you can set a resource quota for storage consumption at the organization level and per user in the same policy. You cannot define two storage quotas at the organization level in the same policy.

Resource quota limits are dependent on the broad policy scope. If you change the scope after you define the resource quota limits, the resource quota settings are deleted and you must start over.

The scope level drop-down menu includes the following options.

| Option                   | Description                                                                                                                                                                                                                                                                                                                                  | Available at these policy scope levels                                                                           |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| Organization Limits      | <p>Limits the amount of resources that are available for consumption at the organization level.</p> <p>Resource quotas with organization limits are distributed among all users or all projects in the organization.</p>                                                                                                                     | <ul style="list-style-type: none"> <li>• Organization</li> </ul>                                                 |
| Organization User Limits | <p>Limits the total amount of resources that each user can consume within the organization.</p>                                                                                                                                                                                                                                              | <ul style="list-style-type: none"> <li>• Organization</li> </ul>                                                 |
| Projects Limits          | <p>Limits the amount of resources that are available for consumption at the project level.</p> <p>Resource quotas with project limits are distributed among all users in the specified projects.</p> <p>Project limits are not cumulative. If the policy scope is set to multiple projects, the resource limits are applied per project.</p> | <ul style="list-style-type: none"> <li>• Organization</li> <li>• Multiple projects</li> <li>• Project</li> </ul> |
| Projects User Limits     | <p>Limits the total amount of resources that each user who belongs to the specified projects can consume at the project level.</p>                                                                                                                                                                                                           | <ul style="list-style-type: none"> <li>• Organization</li> <li>• Multiple projects</li> <li>• Project</li> </ul> |

### **How are resource quota policies enforced**

- Multiple resource quota policies might be enforceable. The resource quota policies are evaluated, and an enforced policy is applied to the deployment request. When there are multiple policies defined for a resource at the same scope level, the resource quota with the lowest limit value is enforced. The use case in this procedure provides more information about how resource quotas are processed.
- When a resource quota policy is enforced, all existing deployment resources are evaluated against the resource quota, except for deployment requests that are in-progress. Resource use is updated after the deployment request is completed, so in-progress requests are not included in the evaluation.
- When deploying cloud templates, resource quota policies allow over-provisioning of storage because the system does not know the actual storage size of the deployment before the machine is provisioned in the endpoint. After the resource use is updated and the system recognizes that the provisioning resources exceed the resource quota limit, the policy does not allow any subsequent requests.
- Resource quota policies are enforced on the following day 2 actions: Add Disk, Change Owner, Change Project, Resize Machine, Resize Boot Disk, Resize Disk, Update Deployment.
- Resource quota policies support only VMware vSphere, Amazon Web Services, Microsoft Azure and Google Cloud Platform resources created from cloud templates.

### **When are resource quota policies applied**

Resource quota policies are applied when:

- A user requests a catalog item in Automation Service Broker or a cloud template in Automation Assembler.
- A user changes a deployment or its component resources.
- When you create a new policy or update an existing policy, the system can take up to two minutes to apply the changes. For example, if you create a new deployment within two minutes of updating a policy, the policy updates might not apply to the deployment request.

## **Procedure**

In this use case, there are three policy definitions that illustrate how you can construct resource quota policies and the results when they are enforced.

1. Select **Content and Policies > Policies > Definitions > New Policy > Resource Quota Policy**.

2. Configure Resource Quota Policy 1.

As a cloud administrator, you want to control how resources are distributed among users and projects in the organization that you administer.

- a. Define when the policy is valid.

| Setting | Sample Value                                                      |
|---------|-------------------------------------------------------------------|
| Scope   | Organization<br>This policy is applied to the whole organization. |

- b. Define the resource quotas.

| Scope Level              | Resource and Limit |
|--------------------------|--------------------|
| Organization Limits      | CPU = 2000         |
| Organization User Limits | CPU = 10           |
| Project Limits           | CPU = 200          |
| Project User Limits      | CPU = 5            |

In this scenario, the total amount that is available for consumption among all users in the organization is 2000 CPU and the total amount that is available per project is 200 CPU. Each user can use up to 5 CPU in each project that they belong to, but no more than 10 CPU, combined across all their deployments. Once a scope level limits is reached, any new deployment request that exceeds this limit fails.

3. Configure Resource Quota Policy 2.

As a project administrator, you want to control how resources are distributed among developers in several projects that you administer.

- a. Define when the policy is valid.

| Setting | Sample Value                                                                                                                                                                                   |
|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Scope   | Multiple Projects<br><br>Define the project criteria. For example,<br><br>Project name contains dev<br><br>This policy is applied only to projects whose name contains the phrase <i>dev</i> . |

- b. Define the resource quotas.

| Scope Level         | Resource and Limit |
|---------------------|--------------------|
| Project Limits      | CPU = 100          |
| Project User Limits | CPU = 10           |

In this scenario, the resources that are available at each scope level are evaluated and both Policy 1 and Policy 2 are enforced. Between the two policies, the lowest limits are applied.

- Projects user limits in Policy 1 are applied because the defined value is lower than in Policy 2.
- Project limits in Policy 2 are applied because the defined value is lower than in Policy 1.
- Organization level limits defined in Policy 1 also apply to the projects specified in the scope of Policy 2.

#### 4. Configure Resource Quota Policy 3.

As a cloud administrator, you want to distribute resources at the project and organization level evenly among users.

1. Define when the policy is valid.

| Setting | Sample Value                                                          |
|---------|-----------------------------------------------------------------------|
| Scope   | Organization<br><br>This policy is applied to the whole organization. |

2. Define the resource quotas.

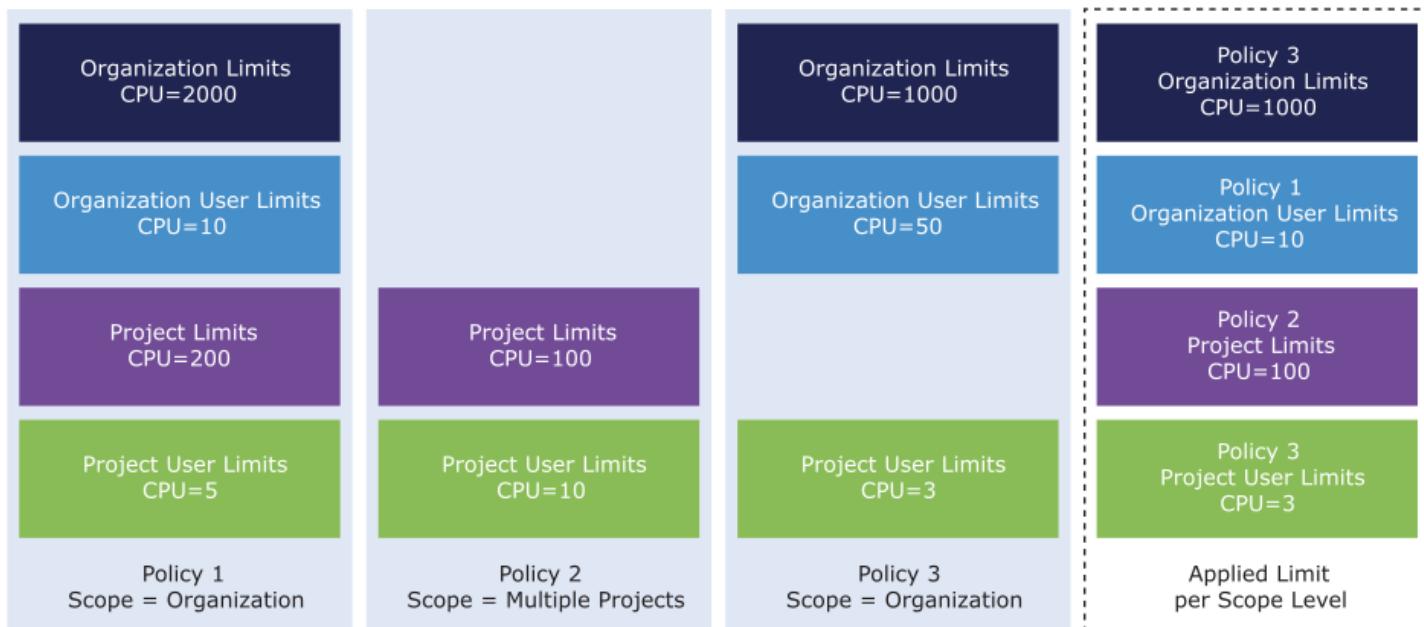

| Scope Level              | Resource and Limit |
|--------------------------|--------------------|
| Organization Limits      | CPU = 1000         |
| Organization User Limits | CPU = 50           |
| Project User Limits      | CPU = 3            |

In this scenario, the resources that are available at each scope level are evaluated and all three policies are enforced. Again, the lowest scope level limits between the three policies are applied.

- Projects User Limits in Policy 3 are applied because the defined value is lower than in Policy 1 and Policy 2.
- Organization User Limits in Policy 3 are not applied. Instead, the limit defined in Policy 1 is applied because the value is lower.
- Organization level limits defined in Policy 3 are applied because the value is lower than in Policy 1.

#### Summary

Based on the configuration examples above, the following diagram summarizes how resource quotas across multiple policies are applied.

## What to do next

- For more examples of how other policies are processed and enforced, see [How are policies processed](#).
- Configure policies that are relevant to your organizations and projects.
- Monitor provisioned resources on the My Resource Usage dashboard. See [Learn more about the catalog items](#).

## How do I limit deployment resources using Automation Service Broker policies

### How do I limit deployment resources

You define deployment limit policies to control the amount of resources that deployments can consume when users deploy templates in Automation Assembler and request catalog items in Automation Service Broker. The use cases in this procedure are an introduction to configuring deployment limit policies.

Deployment limits are applied to individual deployments for cloud templates or catalog items. If you want to limit resources at the user, project, or organization level, see [How do I configure resource quotas using policies](#).

As a cloud administrator, you can limit the total memory, CPU count, storage, and number of virtual machines that can be used per deployment. You can also limit memory, CPU count, and storage for specific resources in the deployment, for example, machines within a cloud template.

The limits apply to all deployments within the policy scope. You can use the policy criteria to narrow the scope to a specific deployment, in which case the policy applies to that deployment only.

### How are deployment limit policies enforced

- When the policy is enforced, users can provision deployment resources within the specified limits.
- Multiple deployment limit policies can be enforceable. If there are multiple policies defined for a deployment, the lowest limit value is enforced for each resource.
- If there are resource quota policies and approval policies defined that affect the deployments within the policy scope, deployment limits are enforced before the other policy types.
- If a deployment requests no resources, such as a workflow deployment, the policy is not enforced on that deployment.

## **When are deployment limit policies applied**

- A user requests a catalog item in Automation Service Broker or a cloud template in Automation Assembler.
- A user changes a deployment or its component resources.

## **Deployment limit policy constraints**

The storage value for some images is not calculated during allocation because the images do not contain any storage-related information. A default boot disk size of 8 GB is allocated for storage for such images. The following table provides more information about what images contain boot disk capacity information for each cloud type.

| Cloud Type | Boot disk capacity unavailable                                                                                                                        | Boot disk capacity available                                                                                             |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------|
| Azure      | <ul style="list-style-type: none"> <li>• Default images</li> <li>• Standard images</li> </ul> <p>The default boot disk size is 8 GB.</p>              | <ul style="list-style-type: none"> <li>• Private images</li> <li>• Custom images</li> </ul>                              |
| AWS        | <p>Instance store image disk sizes, including boot disk, are not counted.</p> <p>The default boot disk size is 8 GB.</p>                              | <ul style="list-style-type: none"> <li>• Public images</li> <li>• Private images</li> </ul>                              |
| GCP        |                                                                                                                                                       | Public images                                                                                                            |
| vSphere    | <ul style="list-style-type: none"> <li>• ova</li> <li>• ovf</li> </ul> <p>The default boot disk size is 8 GB.</p> <p>Image disks are not counted.</p> | <ul style="list-style-type: none"> <li>• VM templates</li> <li>• Library item ova</li> <li>• Library item ovf</li> </ul> |

## **Procedure**

In this use case, there are three policy definitions that illustrate how you can construct deployment limit policies and the results when they are enforced.

1. Select **Content and Policies** > **Policies** > **Definitions** > **New Policy** > **Deployment Limit Policy**.
2. Configure Deployment Limit Policy 1.

As a cloud administrator, you want to limit the amount of resources that deployments across the organization can use.

- a. Define when the policy is valid.

| Setting  | Sample Value                                                                  |
|----------|-------------------------------------------------------------------------------|
| Scope    | Organization<br>The policy is applied to all deployments in the organization. |
| Criteria | None                                                                          |

- b. Define the deployment limits.

| Resource | Sample Limit Value |
|----------|--------------------|
| CPU      | 200                |
| VM Count | 3                  |
| Memory   | 100 GB             |
| Storage  | 240 GB             |

In this scenario, any deployment across the organization can use up to 200 CPUs, 3 virtual machines, 100GB of memory, and 240GB of storage in total.

**3. Configure Deployment Limit Policy 2.**

As a project administrator, you want to apply granular control over resources that are provisioned at the deployment level in a project that you manage.

- Define when the policy is valid.

| Setting  | Sample Value                                                                               |
|----------|--------------------------------------------------------------------------------------------|
| Scope    | Project = TestProj1<br>This policy is applied to all deployments in the specified project. |
| Criteria | None                                                                                       |

- Define the deployment limits.

| Resource | Sample Limit Value |
|----------|--------------------|
| CPU      | 15                 |
| Memory   | 10 GB              |

In this scenario, the resources that are available for deployments within the scoped project are evaluated and both Policy 1 and Policy 2 are applied. In this case, the CPU and memory values are lower in Policy 2, so Policy 2 is enforced.

**4. Configure Deployment Limit Policy 3.**

As a cloud administrator, you want to control the amount of resources that are consumed when a specific cloud template is deployed by anyone in your organization. Additionally, you want to define limits for specific deployment resources within the cloud template.

- Define when the policy is valid.

| Setting  | Sample Value                                                                                                                                               |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Scope    | Organization                                                                                                                                               |
| Criteria | Cloud template equals Proj1Templ1<br>This policy is applied to all deployments in the organization that are provisioned from the specified cloud template. |

- Define the deployment limits.

| Resource | Sample Limit Value |
|----------|--------------------|
| CPU      | 15                 |
| VM Count | 10                 |
| Memory   | 20 GB              |

- Define the deployment resource limits.

- Define a limit for all deployments provisioned by developers in the organization.

| Setting  | Sample Value                                              |
|----------|-----------------------------------------------------------|
| Name     | Depl Resource Limit 1                                     |
| Criteria | Tags has any<br>Key equals env<br>AND<br>Value equals dev |
| Limits   | CPU = 5<br>Memory = 10 GB<br>Storage = 40 GB              |

- b. Define limits for a machine in the cloud template.

| Setting  | Sample Value                               |
|----------|--------------------------------------------|
| Name     | Depl Resource Limit 2                      |
| Criteria | Resource Type equals Cloud.vSphere.Machine |
| Limits   | CPU = 4<br>Memory = 8 GB                   |

In this scenario, you apply two levels of governance.

- When a user in your organization deploys the Proj1Templ1 cloud template, the resources that are available for the whole deployment are evaluated and all three existing policies are applied. The lowest deployment limits between the three policies are enforced.
  - The CPU limit value defined in Policy 3 is applied.
  - The VM Count limit value defined in Policy 1 is applied.
  - The Memory limit value defined in Policy 2 is applied.
- The requested deployment resources are evaluated against Depl Resource Limit 1 and Depl Resource Limit 2 and the deployment resource limits are applied. In this case, there are no other policies that limit these specific deployment resources.

### What to do next

- For more examples of how other policies are processed and enforced, see [How are policies processed](#).
- Configure policies that are relevant to your organizations and projects.
- Monitor provisioned resources on the My Resource Usage dashboard. See [Learn more about the catalog items](#).

### **How do I configure Automation Service Broker content sharing policies**

#### How do I share content using policies

Content sharing policies control what items and actions are available in the Automation Service Broker catalog for users and user groups. If you have catalog items that require additional governance, you can apply content sharing policies to those items.

You can share content at the project level or at the organization level. When you add a content source or a catalog item to a content sharing policy, you allow the users and user groups specified in the policy to request the items in the Automation Service Broker catalog.

### **How are content sharing policies enforced**

- You can create content sharing policies that apply to the whole organization, to selected projects, or to a single project. You can also provide additional governance at the content source or at the catalog item level for all content that is associated with a specific project.
- For the organization scope, all users can request shared catalog items. For items that are not shared, users with the Viewer and User roles can view or request catalog items only if they are members of the project that the item is associated with, based on their project role.
- Multiple content sharing policies can be created per project and per organization.
- If you upgrade to vRealize Automation 8.8.2, all of your shared content is migrated. A content sharing policy is automatically created for every project with entitlements that were added through the Content Sharing tab.

### **Content sharing policy constraints**

- Users who are not members of the organization or the project, specified in the policy scope, can still be added to the content sharing policy when the policy is created through an API request. Such users, however, still don't have access to the catalog items associated with the project. You can limit the policy scope to adding users who belong to the selected project.

### **Procedure**

In this use case, there are three policy definitions that illustrate how you can construct content sharing policies and the results when they are enforced.

1. Select **Content and Policies > Policies > Definitions > New Policy > Content Sharing Policy**.

2. Configure Content Sharing Policy 1.

As an administrator, you want to grant two new users in your project access to all cloud templates that are associated with the project.

- a. Select a project to which to apply the policy.

| Setting | Sample Value                                                                                                          |
|---------|-----------------------------------------------------------------------------------------------------------------------|
| Scope   | Select <b>Project</b> and search for your project.<br>This policy is applied to content associated with this project. |

- b. Select what content you want to share with members of the project.

| Setting         | Sample Value                                                                                                                                                                                |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Content sharing | Click <b>Add Items &gt; Content Sources</b> , then select the <i>cs-project1</i> content source to share with users.<br>In this scenario, <i>cs-project1</i> contains four cloud templates. |

- c. Select the users you want to share the content with.

| Setting          | Sample Value                                                                                                                                                                                          |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Entitlement type | User based                                                                                                                                                                                            |
| Users            | <p>Click <b>Add Users</b> and enter the emails of the two new users.<br/><i>User1@company.com, User2@company.com</i></p> <p>You can only select users who are associated with the scoped project.</p> |

In this scenario, all four cloud templates associated with the content source you specified become available for User 1 and User 2.

### 3. Configure Content Sharing Policy 2.

You want to share a new cloud template with developers in several projects.

- Select the projects to which to apply the policy.

| Setting | Sample Value                                                                                                                                                                                             |
|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Scope   | <p>Select <b>Multiple Projects</b> and define project criteria. For example,<br/>Project name contains dev</p> <p>This policy is applied only to projects whose name contains the phrase <i>dev</i>.</p> |

- Select the content that you want to share.

| Setting         | Sample Value                                                                                            |
|-----------------|---------------------------------------------------------------------------------------------------------|
| Content sharing | Click <b>Add Items &gt; All Content</b> , then select an individual cloud template to share with users. |

- Select the users you want to share the content with.

| Setting          | Sample Value                                                                    |
|------------------|---------------------------------------------------------------------------------|
| Entitlement type | User based                                                                      |
| Users            | Select the <b>Share content with all users/groups in the project</b> check box. |

In this scenario, the cloud template becomes available to all users and user groups in the developer projects that are included in the policy scope.

### 4. Configure Content Sharing Policy 3.

You want to grant administrators access to multiple content sources across your organization.

- Select a project to which to apply the policy.

| Setting | Sample Value |
|---------|--------------|
| Scope   | Organization |

- Select the content that you want to share with members of the project.

| Setting         | Sample Value                                                                                                                        |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------|
| Content sharing | Click <b>Add Items &gt; Content Sources</b> , then select the content sources you want to share.<br><i>cs-project3, cs-project4</i> |

- c. Select the users you want to share the content with.

| Setting          | Sample Value                                                                                                                                                            |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Entitlement type | Role based                                                                                                                                                              |
| Users            | Select <b>Administrator</b> .<br>You can grant content sharing rights only to users with the Project Administrator or Project Member role as well as custom user roles. |

In this scenario, all content from the selected content sources becomes available to users with the Project Administrator role across your organization.

### **What to do next**

- For more examples of how other policies are processed and enforced, see [How are policies processed](#).
- Configure policies that are relevant to your organizations and projects.
- Provide content to your users. See [Adding Content to the Catalog](#).

### **How do I configure deployment criteria in Automation Service Broker policies**

#### **How do I configure deployment criteria in policies**

The deployment criteria narrows the scope of a policy so that it is applied only to the deployments where the criteria is true. For example, you can use the deployment criteria to create a policy that is applied only to a particular catalog item or template.

#### **Constructing deployment criteria**

You use the graphical interface to construct the deployment criteria expression. To construct complex expressions, you can use AND and OR. You can also group expressions as parenthetical operators. For more about how the expressions are processed, see the *Order of operations for the expression section* below.

Here is an example of an expression.

Deployment equals Multi-tier five machine with LB AND (Owned By equals jan@mycompany.com OR Owned By kris@mycompany.com)

Using the deployment criteria components, it looks like the following example.

Criteria

```

 graph TD
 Root[Deployment equals Multi-tier five machine with LB] --- AND1[AND]
 AND1 --- OwnedBy1[Owned By equals jan@mycompany.com]
 AND1 --- OR1[OR]
 OR1 --- OwnedBy2[Owned By equals kris@mycompany.com]

 OwnedBy1 --- X1[X]
 OR1 --- X2[X]
 OwnedBy2 --- X3[X]

 OwnedBy1 --- Plus1[+]
 OwnedBy1 --- PlusGroup1[+ (GROUP)]

 OwnedBy2 --- Plus2[+]
 OwnedBy2 --- PlusGroup2[+ (GROUP)]

```

## Deployment criteria properties

To create a functional deployment criteria, you must understand the syntax.

The criteria text box has various drop-down menus that provide the available properties and operators. How you construct your expression depends on the available values and on the order of operations.

The drop-down menus include the following properties. Some properties vary between policy types.

| Property     | Description                                                                                                                                                                                                                                                                                                                                                                | Available in these policy types                                                                                     | Supports these operators                                                       |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------|
| Template     | <p>Identifier for the Automation Assembler template that was used to create the deployment.</p> <p>Use <b>Template</b> rather than <b>Catalog Item</b> when your policy is specific to Automation Assembler templates. For example, an Amazon Web Services template does not have a Template.</p>                                                                          | <ul style="list-style-type: none"> <li>Approvals</li> <li>Day 2</li> <li>Lease</li> <li>Deployment Limit</li> </ul> | <ul style="list-style-type: none"> <li>equals</li> <li>not equal to</li> </ul> |
| Catalog Item | <p>Identifier for the Automation Service Broker catalog item that was used to request the deployment.</p> <p>Use <b>Catalog Item</b> rather than <b>Template</b> when your policy can include Automation Service Broker catalog items based on any template, extensibility workflow, or other content type. For example, Automation Assembler templates and Amazon Web</p> | <ul style="list-style-type: none"> <li>Approvals</li> <li>Day 2</li> <li>Lease</li> <li>Deployment Limit</li> </ul> | <ul style="list-style-type: none"> <li>equals</li> <li>not equal to</li> </ul> |

### Criteria formats for resource tags

Resource tags are key value pairs. When you define deployment criteria based on the tags, you must define the key. Defining the value is optional. The criteria are based on user-defined tags and system tags.

For example, to create criteria for one tag pair, the expression is similar to the following example.

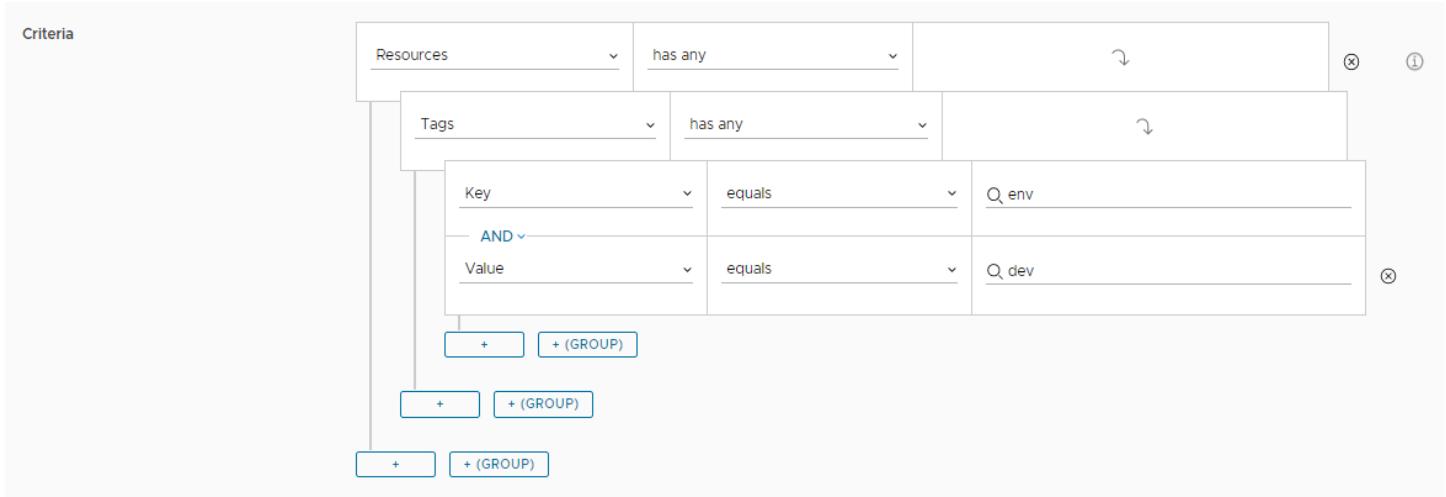

Resources has any

Tags has any

Key equals env

AND

Value equals dev

To create criteria based on one key but multiple values, the expression is similar to the following example.

Resources has any

Tags has any

Key equals env

AND

Value equals dev

OR

Value equals prod

Criteria

|                                  |                                          |                                  |                                  |                                  |
|----------------------------------|------------------------------------------|----------------------------------|----------------------------------|----------------------------------|
| Resources                        | has any                                  | <input type="button" value="X"/> | <input type="button" value="i"/> |                                  |
| Tags                             | has any                                  | <input type="button" value="X"/> | <input type="button" value="i"/> |                                  |
| Key                              | equals                                   | Q_env                            |                                  |                                  |
| AND                              |                                          |                                  |                                  |                                  |
| Value                            | equals                                   | Q_dev                            | <input type="button" value="X"/> |                                  |
| OR                               | Value                                    | equals                           | Q_prod                           | <input type="button" value="X"/> |
| <input type="button" value="+"/> | <input type="button" value="+ (GROUP)"/> |                                  |                                  |                                  |
| <input type="button" value="+"/> | <input type="button" value="+ (GROUP)"/> |                                  |                                  |                                  |
| <input type="button" value="+"/> | <input type="button" value="+ (GROUP)"/> |                                  |                                  |                                  |
| <input type="button" value="+"/> | <input type="button" value="+ (GROUP)"/> |                                  |                                  |                                  |

To create criteria based on multiple keys but no values, the expression is similar to the following example.

Resources has any

Tags has any

Key equals env1

OR

Key equals env2

Criteria

|                                  |                                          |                                  |                                  |                                  |
|----------------------------------|------------------------------------------|----------------------------------|----------------------------------|----------------------------------|
| Resources                        | has any                                  | <input type="button" value="X"/> | <input type="button" value="i"/> |                                  |
| Tags                             | has any                                  | <input type="button" value="X"/> | <input type="button" value="i"/> |                                  |
| Key                              | equals                                   | Q_env1                           |                                  |                                  |
| OR                               | Key                                      | equals                           | Q_env2                           | <input type="button" value="X"/> |
| <input type="button" value="+"/> | <input type="button" value="+ (GROUP)"/> |                                  |                                  |                                  |
| <input type="button" value="+"/> | <input type="button" value="+ (GROUP)"/> |                                  |                                  |                                  |
| <input type="button" value="+"/> | <input type="button" value="+ (GROUP)"/> |                                  |                                  |                                  |

If you want to create criteria that evaluate two different key value pairs, then you must add them as individual resource tags. For example,

Resources has any

Tags has any

Key equals env

AND

Value equals envprod

AND

Tags has any

Key equals vc\_65\_network

AND

Value equals vc

The screenshot shows the search criteria builder interface with the following structure:

- Criteria:** Resources has any
- Sub-criteria 1:** Tags has any
  - Sub-criteria 1.1:** Key equals env
  - Sub-criteria 1.2:** Value equals envprod
- Sub-criteria 2:** Tags has any
  - Sub-criteria 2.1:** Key equals vc\_65\_network
  - Sub-criteria 2.2:** Value equals vc

Each row in the criteria builder contains fields for the property name, operator, and value, along with a delete icon (X) and a help icon (i). There are also '+', '+ (GROUP)', and 'AND' buttons.

### Using the `contains` and `matches` Regex operators

The `contains` and `matches` Regex operators define a search for a specified set of characters within a property. You can apply these operators to string based properties that do not support a drop-down, such as `createdBy`, `name`, and `ownedBy`.

The `contains` operator searches for all instances of the value you specify in any context. The value input text box is case sensitive and space sensitive. If you want to account for context variation, you must set a value for each additional variant. Use the `contains` operator for simple searches for a limited number of values.

The `matches Regex` operator provides great flexibility when you use it for complex searches that must account for a lot of context variation. The regular expressions must follow ECMAScript syntax. When defining regular expressions, do not enter the forward slashes (/) at the beginning and at the end of the value.

The following table provides examples of expressions using the two operators and compares how they might be used to achieve the same goal.

| Example with the <code>contains</code> operator                                                                                                                                                                                                                                   | Example with the <code>matches Regex</code> operator                                                                 | Field value matches                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Name contains test                                                                                                                                                                                                                                                                | Name matches Regex <code>test*</code>                                                                                | All deployment names that contain <code>test</code> in lowercase. For example, <code>test deployment</code> , <code>mytest</code> , <code>test-123</code> , and so on.                                                                                                                                                                                                           |
| Name contains test<br>OR<br>Name contains Test                                                                                                                                                                                                                                    | Name matches Regex <code>(t T)est.*</code>                                                                           | All deployment names that contain <code>test</code> or <code>Test</code> .                                                                                                                                                                                                                                                                                                       |

For example, <code>test deployment</code> , <code>testdeployment</code> , <code>Test-Deployment</code> , and so on. |

*Table continued on next page*

*Continued from previous page*

| Example with the contains operator | Example with the matches Regex operator | Field value matches |
|------------------------------------|-----------------------------------------|---------------------|
| OR<br>Name contains Deploy         |                                         |                     |

### **Order of operations for the expression**

An expression is processed in the following order. Groups are illustrated as parentheses.

1. Expressions in groups
2. AND
3. OR

Use the following examples to understand the order.

- X OR Y AND Z. In this example, Y AND Z is evaluated before X OR Y. Next, the X OR is evaluated against the results of Y AND Z.
- (X OR Y) AND Z. In this example, X OR Y is evaluated before AND because the expression in the group is always evaluated first. Next the AND Z is evaluated against the results of X OR Y.

### **How are Automation Service Broker policies processed**

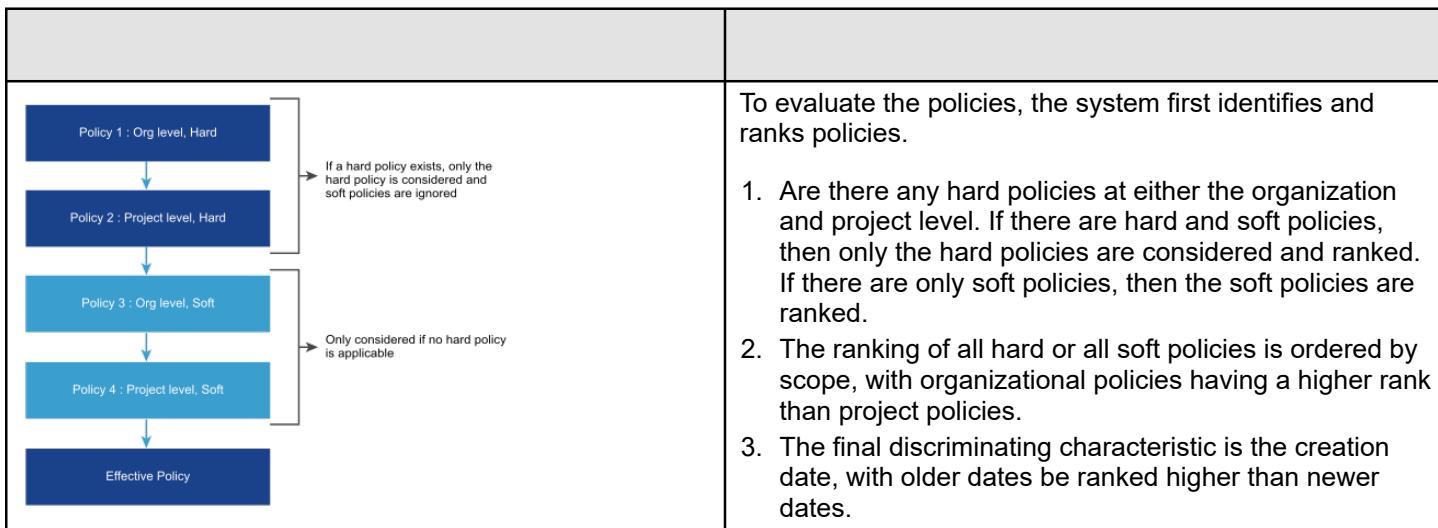

#### How policies are processed

Policies are processed based on the policy definition. In particular, the scope and the enforcement level determine which policy is valid when you have multiple policies that might apply to a single deployment.

This article provides general information about policy processing, but it also includes more details for the different types of policies.

### **How policies are ranked based on organization level and enforcement type**

When a user, who is a member of a project, creates a deployment, there might be more than one policy that applies to that deployment.

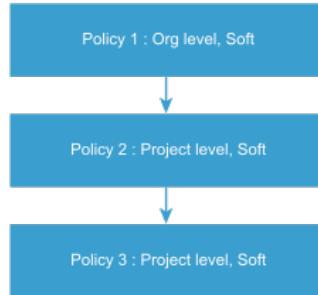

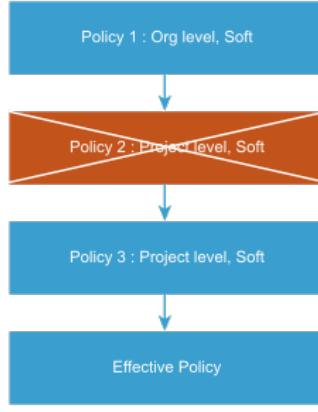

## **How policies are processed based on organization level and enforcement type**

The policies are evaluated, ranked, and, where applicable, merged to produce an effective policy. An effective policy produces the intended results but is not always a specific named policy.

This section includes the following examples:

- Lease policies
- Day 2 actions policies

Review the following lease policy examples.

|                                                                                                                                                                                                                                                                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|  <pre> graph TD     P1[Policy 1 : Org level, Soft] --&gt; P2[Policy 2 : Project level, Soft]     P2 --&gt; P3[Policy 3 : Project level, Soft]   </pre>                                        | <p>After identifying the policies to be considered and ranking them, the policies are then evaluated to identify the merge order.</p> <ul style="list-style-type: none"> <li>• The highest ranking policy becomes the baseline. The second-level policy is applied on top of it, and so on.</li> <li>• If a policy is incompatible with the preceding policies, then it is discarded from consideration. For example, the values are higher than the preceding policies.</li> <li>• Any policy that is discarded is ignored. To see which policy is applied, select <b>Content and Policies</b> &gt; <b>Policies</b> &gt; <b>Enforcement</b>, locate the deployment, and review the decision notes.</li> </ul> |
|  <pre> graph TD     P1[Policy 1 : Org level, Soft] --&gt; P2X[Policy 2 : Project level, Soft]     P2X --&gt; P3[Policy 3 : Project level, Soft]     P3 --&gt; EP[Effective Policy]   </pre> | <p>Rather than applying one policy and excluding all the others above, the policies are merged and might include values from more than one individual policy.</p> <p>In this example, the merging process excludes Policy 2 from consideration because the values are higher than Policy 1.</p> <p>Next, Policy 3 is evaluated against Policy 1. The Lease and Total Lease values in Policy 3 are lower than Policy 1, so those values, in addition to the Grace period, become part of the effective policy.</p>                                                                                                                                                                                              |

Review the following day 2 actions policy examples.

|                                                                                                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

To see which policy is applied, select <b>Content and Policies &gt; Policies &gt; Enforcement</b>, locate the deployment, and review the decision notes.</li> </ul> |

### Lease policy management goal considerations

Now that you know how lease policies are processed, identify your policy management goals. By understanding how the policies are processed, you can meet your management goals without creating an excessive and unmanageable number of policies.

When deciding how to implement your policies, consider the following scenarios.

- Lease policy goals and enforcement examples
- Day 2 policy goals and enforcement examples

**Table 40: Lease policy goals and enforcement examples**

| Management goal                                                                                                                 | Configuration Example                                                                                                                                                                                                                                                                                                                                                                        | Behavior                                                                                                                                                                                                                                                                                                                     |
|---------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Meaningful default organization-level policy that still allows the project-level policy values to influence the applied values. | <p>Organization policy = Soft</p> <ul style="list-style-type: none"> <li>Grace period: 10</li> <li>Lease: 100</li> <li>Total Lease: 100</li> </ul> <p>Project 1 policy 1= Soft</p> <ul style="list-style-type: none"> <li>Lease: 20</li> <li>Total Lease: 50</li> </ul> <p>Project 2 policy 1= Soft</p> <ul style="list-style-type: none"> <li>Lease: 10</li> <li>Total Lease: 30</li> </ul> | <p>A member of project 1 requests a catalog item.</p> <p>Project 2 is not considered because it is not applicable to project 1 deployments.</p> <p>The merged effective policy is:</p> <ul style="list-style-type: none"> <li>Grace period: 10</li> <li>Lease: 20</li> <li>Total Lease: 50</li> </ul>                        |
| Always default to the organization-level policy.                                                                                | <p>Organization policy = Hard</p> <ul style="list-style-type: none"> <li>Grace period: 10</li> <li>Lease: 100</li> <li>Total Lease: 100</li> </ul> <p>Project 1 policy 1= Soft</p> <ul style="list-style-type: none"> <li>Lease: 20</li> <li>Total Lease: 50</li> </ul>                                                                                                                      | <p>A member of project 1 requests a catalog item.</p> <p>Project 1 policy 1 is not considered because the hard organization level project is a higher rank and the soft policy is not considered.</p> <p>The effective policy is:</p> <ul style="list-style-type: none"> <li>Grace period: 10</li> <li>Lease: 100</li> </ul> |

## **Approval policy goals and enforcement examples**

The approval policy evaluation follows this process.

1. A request for a deployment or day 2 action is submitted.
2. The approval service queries for policies that apply to the project that is requesting a catalog item or changing a deployed item.
3. All the applicable project- and organization-level scope policies are returned.
4. The approval policies are filtered based on the deployment criteria. Deployment criteria apply to deployments and day 2 actions.
5. If no matching policies are found, no approval is required and the deployment process proceeds.
6. If there are matching policies, for example, AP1, AP2, APn, then an approval item is created as:
  - Enforced policies = AP1, AP2, APn.
  - Approvers = A union of all the approvers in all the enforced policies.
  - Auto expiry = Reject, if any policy has a reject value; otherwise, approve.
  - Expiry = Minimum number of days of any of the enforced policies.

The following table provides a sample of multiple policies. The description of how they are processed is below the table.

| Policy | Configuration example                                            |
|--------|------------------------------------------------------------------|
| AP1    | Scope = Organization<br>Auto expiry = Approve<br>Expiry = 7 days |
| AP2    | Scope = Project 1<br>Auto expiry - Approve<br>Expiry = 3 days    |
| AP3    | Scope = Project 1<br>Auto expiry = Reject<br>Expiry = 4 days     |
| AP4    | Scope = Project 2<br>Auto expiry = Approve<br>Expiry = 5 days    |

Based on the policies and configuration examples above, the following information explains how a Project 1 request is processed.

1. The scope evaluation returns AP1, AP2, and AP3. AP4 is not included because it is a Project 2 policy.
2. Assuming that AP1, AP2, and AP3 satisfy the deployment and action criteria, then the approval item includes the following values:
  - Approvers = Any or all the approvers from AP1, AP2, and AP3 are added as approvers.
  - Auto expiry = Reject. AP3 provides the more restrictive behavior.
  - Expiry = 3 days. AP2 provides the lowest value.

## **Customize an Automation Service Broker icon and request form**

Customize an icon and request form

In Automation Service Broker, you can customize the icon that represents the content in the catalog, limit the number of deployed instances for a catalog item, and customize the request form for imported templates. When customizing the request form, you can also design the input parameters that allow the user requesting a catalog item to provide the values. You can customize how the custom options are presented in the form.

- To add an icon, verify that you have an image that does not exceed 100 KB. The optimal size is no larger than 100x100 pixels.
- This use case assumes that you imported the WordPress use case cloud template from Automation Assembler, or that you have a cloud template or template that includes input parameters.

The icon that you provide helps you and your catalog consumers use visual queues to identify specific items. You are not required to customize a form if all you want is a custom icon. Nor are you required to customize the icon when you create a custom form.

When creating the custom form, the WordPress cloud template is used as the example in this use case. If you don't customize the request form, it is a simple list of parameters. See the following example.

**New Request**

**WordPress** Version 2

Deployment Name \*

Description

Project \* WordPress Project

Environment env:dev

Tier Machine Size \*

WordPress Cluster Size 2

Image \*

In this use case, you customize the following options:

- Reduce the maximum number of WordPress Cluster Size from 5 to 3.
- Specify operating system based on Node Size. For example, if size is small, then the operating system is coreos. If it medium, then the operating system is ubuntu.
- Set the MySQL Data Disk Size value to 5 and hide the option from the requesting users.

1. Select **Content and Policies** > **Content**.
2. Locate the WordPress cloud template, click the menu to the left of the name, and select **Configure item**.
  - a) Set the maximum number of deployment instances for this catalog item.  
If you select a value greater than one, the **Deployment count** field is added to the request form. This option allows the requesting user to do bulk deployments.
  - b) Add a custom icon.

If all you want is a custom icon, you can stop here.

3. Locate the WordPress template, click the arrow to the left of the name, locate the version you want to edit, and select **Customize form**.

If the template has input properties, they are listed in the Request Inputs pane on the left, and are added to the canvas.

4. Edit the form using the values provided in the following table.

| For this field in the screenshot | Appearance | Values                                                                                                                                                                         | Constraints                                                                                                       |
|----------------------------------|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------|
| WordPress Cluster Size           |            |                                                                                                                                                                                | Maximum value<br><ul style="list-style-type: none"> <li>Value source = Constant</li> <li>Max value = 3</li> </ul> |
| Select Image/OS                  |            | Default value<br><ul style="list-style-type: none"> <li>Value source = Conditional value</li> <li>Expression = Set value = coreos</li> </ul> If Tier Machine Size Equals small |                                                                                                                   |

*Table continued on next page*

*Continued from previous page*

| For this field in the screenshot | Appearance                                                                                                 | Values                                                                                                                         | Constraints |
|----------------------------------|------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------|-------------|
|                                  |                                                                                                            | <ul style="list-style-type: none"> <li>Expression = Set value = ubuntu</li> <li>If Tier Machine Sieze Equals medium</li> </ul> |             |
| MySQL Data Disk Size             | Visibility <ul style="list-style-type: none"> <li>Value source = Constant</li> <li>Visible = No</li> </ul> | Default value <ul style="list-style-type: none"> <li>Value source = Constant</li> <li>Default value = 5</li> </ul>             |             |

5. Click and drag the fields to rearrange them on the form.
6. To create a new version of the form, click **Version**.
7. To turn on the custom form, click **Enable**.

8. Click **Save**.

The request form is now similar to the following example.

| Project *         | PersonnelAppDev |
|-------------------|-----------------|
| Tier Machine Size | small           |
| Integer           | 4               |
| Select Image/OS   | coreos          |
| Environment       | env:dev         |

Notice that the Wordpress Cluster Size field indicates an error. The limit is 3, but the user entered a value of 4.

Request the item in the catalog and verify that the presentation and behavior is what you expected.

## Learn more about Service Broker custom forms

### Using the data grid element in the Automation Service Broker custom form designer

If you use a data grid element in a custom form, the data that is presented in the table might be manually provided.

#### Provided CSV data example

In this use case, you have a table of values that you provide in the custom request form. You provide the information in the table as a constant value source. The source is based on a CSV data structure where the first row defines the grid headers. The headers are the column IDs separated by a comma. Each additional row is the data that appears in each row in the table.

1. Add the Data Grid generic element to the design canvas.
2. Select the data grid and define the values in the properties pane.

## Data Grid

Field ID: datagrid\_0694ecef

Appearance    **Values**    Constraints

 Columns

[ADD COLUMN](#)

Label                      Username

ID                         username

Type                       String

Label                      Employee ID

ID                         employeeld

Type                       Integer

Label                      Manager

ID                         manager

Type                       String

 Default value

Constant

Value source

Constant

CSV

```
username,employeeld,manager
leonardo,95621,Farah
vindhya,15496,Farah
martina,52648,Nikolai
```

| Label       | ID         | Type    |
|-------------|------------|---------|
| Username    | username   | String  |
| Employee ID | employeeld | Integer |
| Manger      | manager    | String  |

Define the CSV values.

```
username,employeeId,manager
leonardo,95621,Farah
vindhya,15496,Farah
martina,52648,Nikolai
```

- Verify that the data grid displays the expected data in the request form.

|                                | Username | Employee ID | Manager    |
|--------------------------------|----------|-------------|------------|
| <input type="checkbox"/>       | leonardo | 95621       | Farah      |
| <input type="checkbox"/>       | vindhya  | 15496       | Farah      |
| <input type="checkbox"/>       | martina  | 52648       | Nikolai    |
| <a href="#">Manage Columns</a> |          |             | 1 - 3 of 3 |

## External Source Example

This example uses the previous example but the values are based on a VMware Aria Automation Orchestrator action. Although this is a simple action example, you can use a more complex action where you retrieve this information from another database or system.

- In VMware Aria Automation Orchestrator, configure an action, `getUserDetails`, with an array similar to the following example.

The screenshot shows the 'getUserDetails' action configuration in the VMware Aria Automation Orchestrator. The 'Script' tab is selected, showing the following JavaScript code:

```
1 return [{"username": "Fritz", "employeeId": 6096, "manager": "Tom"}]
```

The right side of the screen displays the API Explorer interface, which includes:

- API Explorer** sidebar with sections for System, Plugins (AD), and Properties.
- Return type**: `CompositeType(username:string,employeeId:number,manager:string)` (with Array checked).
- Inputs** section with a 'ADD NEW INPUT' button.

At the bottom left are buttons for **CREATE**, **VERSION**, and **CLOSE**.

- On the General tab, enter the name `getUserDetails` and provide a Module name.

- b. On the Script tab, use the following script example.

```
return [{"username": "Fritz", "employeeId": 6096, "manager": "Tom"}]
```

- c. In the Return type area, clear the initial selection and click **New Composite Type**.

- d. Define a new composite type named `UserDetails` and add the following fields, then click **Create**.

| Field      | Type   |
|------------|--------|
| username   | string |
| employeeId | number |
| manager    | string |

- e. In the Return type area, click **Array**.

- f. Version and save the action.

2. In Automation Service Broker, add the data grid and use the Values tab to configure the data grid columns with the following values.

| Label       | ID         | Type    |
|-------------|------------|---------|
| Username    | username   | String  |
| Employee ID | employeeId | Integer |
| Manager     | manager    | String  |

3. In the Default value, Value source list, select **External source**.

4. In Select action, enter `getUserDetails` and select the action you created in VMware Aria Automation Orchestrator.

5. Save the form.

6. In the catalog, verify the table in the request form.

|                                | Username | Employee ID | Manager |
|--------------------------------|----------|-------------|---------|
| <input type="checkbox"/>       | Fritz    | 6096        | Tom     |
| <a href="#">Manage Columns</a> |          | 1 - 1 of 1  |         |

### Inspecting complex values in data grids

You can examine data grid rows in a separate modal, where complex values are displayed as expandable tree nodes.

The values in the first column of the data grid are links. Click the link to view detailed information about the value in the row you want to examine.

The following table provides information about how different value types are displayed in the table.

| Value type        | Displayed as      |
|-------------------|-------------------|
| Boolean           | true/false string |
| Non-complex value | label:value pair  |

*Table continued on next page*

*Continued from previous page*

| Value type              | Displayed as                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Complex value           | <ol style="list-style-type: none"> <li>1. If the value is an array of objects, <code>{objects.count}</code> objects is displayed. If the array has only 1 element, object is displayed in the cell.</li> <li>2. If the object has 2 or fewer properties, none of which is complex, the <code>label:value</code> pairs are separated by a comma and displayed in the cell as Object, object.</li> <li>3. If the object has more than 2 properties, or has a complex property, object is displayed in the cell.</li> </ol> |
| Array of complex values | <code>{length of array} objects</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Empty value             | hyphen (-)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

If the data grid contains only one column, the hide/show control in the footer is not displayed.

## Using VMware Aria Automation Orchestrator actions in the custom form designer in Automation Service Broker

### Using VMware Aria Automation Orchestrator actions in the custom form designer

When you customize a Automation Service Broker request form, you can base the behavior of some fields on the results of a VMware Aria Automation Orchestrator action.

There are several ways that you can use VMware Aria Automation Orchestrator actions. You might have an action that pulls the data from a third source, or you can use a script that defines the size and cost.

The first example is based on manually added fields so that you understand the underlying process. The second example uses the same premise, but instead relies on a template field.

The third example is based on a custom option that is added to the catalog request form, where the user selects a folder based on the results from a custom VMware Aria Automation Orchestrator action.

The fourth example uses VMware Aria Automation Orchestrator workflow attributes to customize a field in the request form.

In addition to the following examples, other examples are available in the [VMware Cloud Management blog](#).

### Size and cost as manually added fields example

In this use case, you want the catalog user to select a virtual machine size, and then display the cost of that machine per day. To do this example, you have a VMware Aria Automation Orchestrator script that correlates the size and cost. You then add a size field and a cost field to the template custom form. The size field determines the value that appears in the cost field.

1. In VMware Aria Automation Orchestrator, configure an action named `getWindows10Cost`.

```

1 var cost = "Unknown";
2
3 switch(deploymentSize) {
4 case 'small' : cost = "$15";break;
5 case 'medium' : cost = "$25";break;
6 case 'large' : cost = "$45";break ;
7
8 default : break ;
9 }
10
11 return cost;

```

**Inputs:**

deploymentSize : string

**Properties**

Return type: string

Inputs: deploymentSize string

## 2. Add a script.

You can use the following example script.

```

var cost = "Unknown";

switch(deploymentSize) {

 case 'small' : cost = "$15";break;
 case 'medium' : cost = "$25";break;
 case 'large' : cost = "$45";break ;

 default : break ;

}

return cost;

```

## 3. Add deploymentSize as an input string.

## 4. In Automation Service Broker, add and configure a Size field to a template custom form. Configure the size field as a drop-down element with Small, Medium, and Large values.

## Size ②

Field ID: dropDown\_1e4ad8b9

| Appearance                            | Values   | Constraints |
|---------------------------------------|----------|-------------|
| Default value                         | large    |             |
| Value source                          | Constant |             |
| Value options                         | Constant |             |
| Value source                          | Constant |             |
| small Small,medium Medium,large Large |          |             |

On the **Values** tab, configure the following property values.

- Default value = Large
- Value options
  - Value source = Constant
  - Value definition = small|Small,medium|Medium,large|Large

5. Add the cost field as a text field to display the cost as defined in the VMware Aria Automation Orchestrator action based on the value selected in the size field.

| Cost ②         |                                             |             |
|----------------|---------------------------------------------|-------------|
| Field ID: cost |                                             |             |
| Appearance     | Values                                      | Constraints |
| Default value  | External source                             |             |
| Value source   | External source                             |             |
| Select action  | com.vmware.vra.customforms/getWindows10Cost |             |
| Action inputs  |                                             |             |
| deploymentSize | Field                                       | Size        |

On the **Values** tab, configure the following property values.

- Default value = External source
- Select action = <your VMware Aria Automation Orchestrator actions folder>/getWindows10Cost
- Action inputs
  - deploymentSize. This value was configured in the action as the input.
  - Field
  - Size. This is the field that you previously created.

6. Enable the custom form and save it.

7. To verify that it is working, request the item in the catalog. You should see the Cost field populated based on the selected Size value.

|      |        |                                  |
|------|--------|----------------------------------|
| Size | Medium | <input type="button" value="X"/> |
| Cost | \$25   |                                  |

### Cost based on schema element example

In this use case, you want the catalog user to see the cost of that machine per day based on the flavor property in the template. To do this example, you use the VMware Aria Automation Orchestrator script from the previous example. But in this use case the cost is based on the flavor size that your user selected in the custom form when they request the Automation Service Broker catalog item.

The simple example template includes a size input field where the user selects the flavor property.

```

1 formatVersion: 1
2 inputs:
3 size:
4 type: string
5 enum:
6 - small
7 - medium
8 - large
9 description: Size of Nodes
10 title: Select machine size
11 image:
12 type: string
13 enum:
14 - ubuntu
15 - centos
16 - windows
17 description: OS image
18 title: Select OS
19 resources:
20 Cloud_vSphere_Machine_1:
21 type: Cloud.vSphere.Machine
22 properties:
23 image: '${input.image}'
24 flavor: '${input.size}'
25

```

The custom form uses the field, named `Select machine size` in this example.

The screenshot shows the VMware Aria Automation custom form editor. On the left, there's a sidebar with 'Request Inputs' and 'Generic Elements' sections. The main area has a 'General' tab selected, showing fields for 'Deployment Name', 'Description', 'Project', 'Select machine size', 'Cost', and 'Select OS'. To the right, a specific field configuration for 'Cost' is detailed: it uses an 'External source' (com.vmware.vra.customforms/getWindows10Cost) and is linked to the 'Select machine size' input.

The cost deploymentSize input is based on the Select machine size field.

This screenshot shows a catalog request form with three inputs:

- Select machine size \***: The value is set to "large".
- Cost**: The value is "\$45".
- Select OS \***: The value is "windows".

### Destination folder based on a custom action example

In this use case, you want the catalog user to select from the folders that are available to them when they move a machine from one folder to another. To do this example, you create a custom action in VMware Aria Automation Orchestrator that returns folders available to the user requesting the action from the catalog. You then customize the **Destination folder** field in the catalog request form.

In the catalog, the **Move virtual machines to folder** workflow that is used in this example is exposed as a custom resource action created in Automation Assembler.

1. In VMware Aria Automation Orchestrator, create an action named `getFolderForUser`.

- a. On the **Script** tab, add action inputs, select the return type of the output, and add a script. You can use the following example script.

```

var parentTargetDirName = "users";

var sdkConnection = VcPlugin.findSdkConnectionForUUID(vcUuid);

var rootFolder = sdkConnection.getAllVmFolders(null, "xpath:matches(name, '" +
parentTargetDirName + "')") [0];

var result = new Array();

for each(var folder in rootFolder.childEntity) {

```

```

if (folder instanceof VcFolder && folder.permission.length > 0) {

 var entityPrivilege =
 sdkConnection.authorizationManager.hasUserPrivilegeOnEntities([folder],
 username, ["System.Read"])[0];

 if (entityPrivilege.privAvailability[0].isGranted) {

 result.push(folder);

 }

}

return result;
}

```

- b. When you finish editing the action, click **Save**.
2. In Automation Assembler, create a custom resource action named `ChangeFolder`.
  - a. Select the **Cloud.vSphere.Machine** resource type.
  - b. Select the **Move virtual machines to folder** workflow.
3. Customize the request form that users see when they request the action.
  - a. Open the `ChangeFolder` action.
  - b. Click **Edit Request Parameters**.
  - c. Customize how the **Destination folder** field is presented to users.

| Value options                                | Sample value                                                                                                                          |
|----------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| Value source                                 | External source                                                                                                                       |
| Select action                                | <code>getFolderForUser</code>                                                                                                         |
| Action inputs<br><code>username</code> Field | Click <b>Select string</b> > <b>Request info fields</b> > <b>Requested by</b> .<br>Click <b>Select</b> .                              |
| Action inputs<br><code>vcUuid</code>         | Click <b>Select string</b> > <b>Request info fields</b> > <b>Resource properties</b> > <b>vCenter UUID</b> .<br>Click <b>Select</b> . |

- d. Click **Save**.

When a user requests the action in the catalog, they can select a destination folder for the virtual machine from the folders that are available to them.

### Hostname based on workflow attributes example

In this use case, you want to customize the URL field in the request form using VMware Aria Automation Orchestrator workflow attributes. To do this example, you need a VMware Aria Automation Orchestrator workflow with an attribute or variable that has either a constant value or is bound to a configuration element. The attribute or variable must have an initial value set because the binding is done before you run the workflow.

1. In VMware Aria Automation Orchestrator, create or clone an existing workflow. For example, clone the **Add a REST Host** workflow.

- a. On the **Variables** tab, add a variable and bind it to a configuration element.

| Value options | Sample value                                                                                                                                                                                                                           |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Name          | <i>hostname</i>                                                                                                                                                                                                                        |
| Type          | <i>string</i>                                                                                                                                                                                                                          |
| Configuration | Enable the <b>Bind to configuration</b> option.<br>In the <b>Configuration</b> text box, select the configuration that you want to bind the variable to.<br>For example, select the custom <b>vRO Configuration: hostname</b> element. |

- b. Save the workflow.
2. Import the workflow in Automation Service Broker.
3. Customize the request form.
  - a. Click the **URL** element in the form designer.
  - b. On the **Values** tab, set the value source to **Bind field**.
  - c. Click **Value Field > Request info fields**.
  - d. Select the *hostname* variable or any of the available workflow attributes.
4. Save and enable the form.

When a user requests the workflow from the catalog, the URL field is populated based on the *hostname* variable.

If you switch to a different project, the workflow attributes are recalculated because the workflow might come from a different VMware Aria Automation Orchestrator integration.

## Using value picker and multi value picker elements in the Automation Service Broker custom form designer

Using value picker and multi value picker elements in the custom form designer

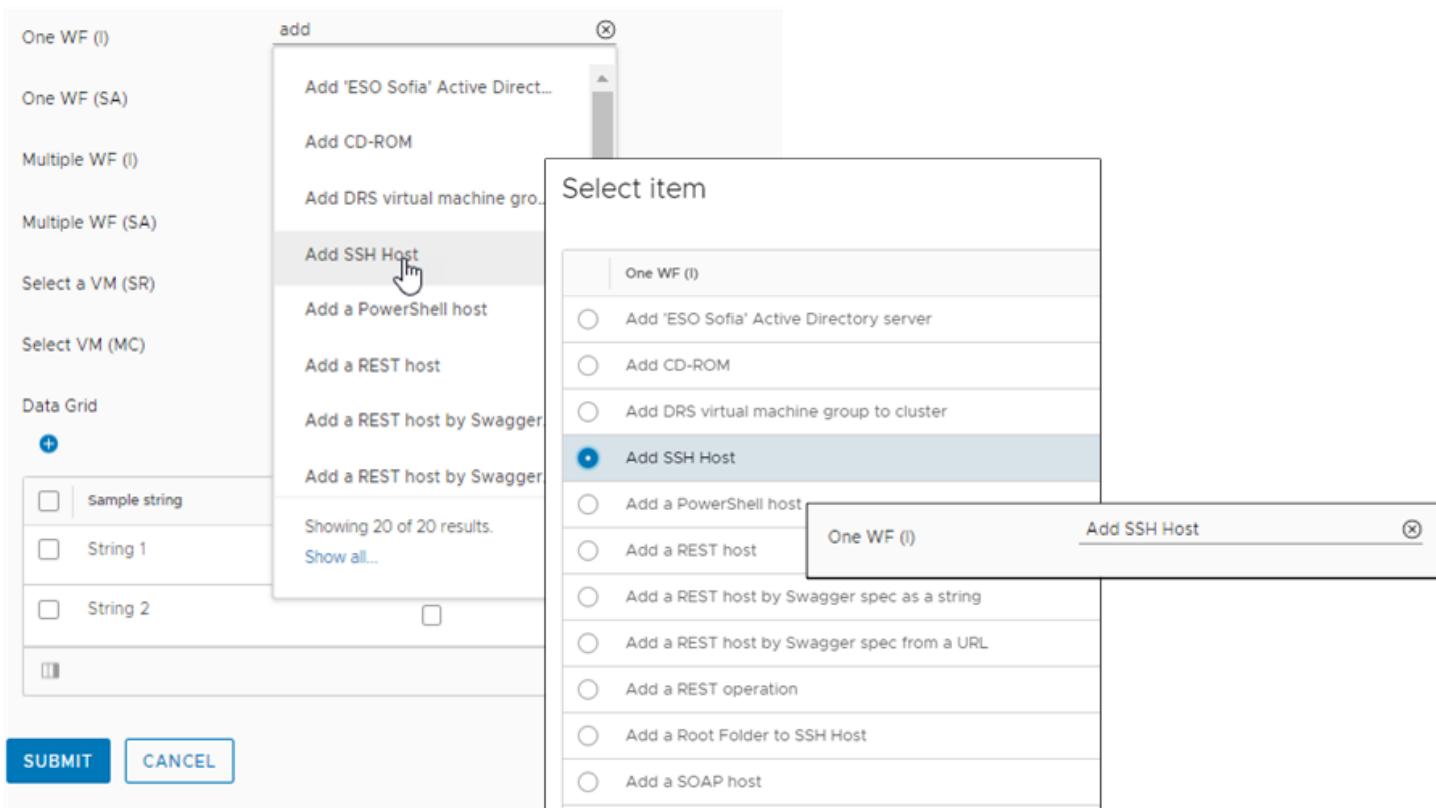

When you create a custom form, you can add elements where the user selects a value from a search results list. Using the value picker, the user selects a single value. Using the multi value picker, the user selects one or more values.

The value picker and multi value picker work with the Reference Type that is defined on the custom form Appearance tab. The Reference type is a VMware Aria Automation Orchestrator resource. For example, AD:UserGroup or VC:Datastore. By defining the reference type, when the user enters a search string, the results are limited to the resources that have the matching parameter.

For the pickers, you can then further limit the possible values by configuring an external source.

### Working with the Value Picker

The value picker appears in the form as a search option when users request the item in the catalog. The user enters a string and the picker provides list based on how you configured it.

You can use the picker based on the following use cases. The most valuable use of the value picker is pairing it with an external source value.

- **Value picker with a constant value source.**

Use this method when you want the requesting user to select from a predefined static list of values. Similar to the combobox, drop down, multiselect, and radio group elements, this method provides search results in a list based on the defined constant values and labels.

- **Value picker with no defined value source.**

Use this method when you want the requesting user to search the VMware Aria Automation Orchestrator inventory for a specific object with the configured reference type. For example, the reference type is VC:Datastore and you want the users to select the datastore from the retrieved list.

- **Value picker with an external value source.**

Use this method when you want the requesting user to select from results that are based on a VMware Aria Automation Orchestrator action. The following script provides an example of a basic VMware Aria Automation Orchestrator action that works with the value picker. In this example, the reference type is Properties.

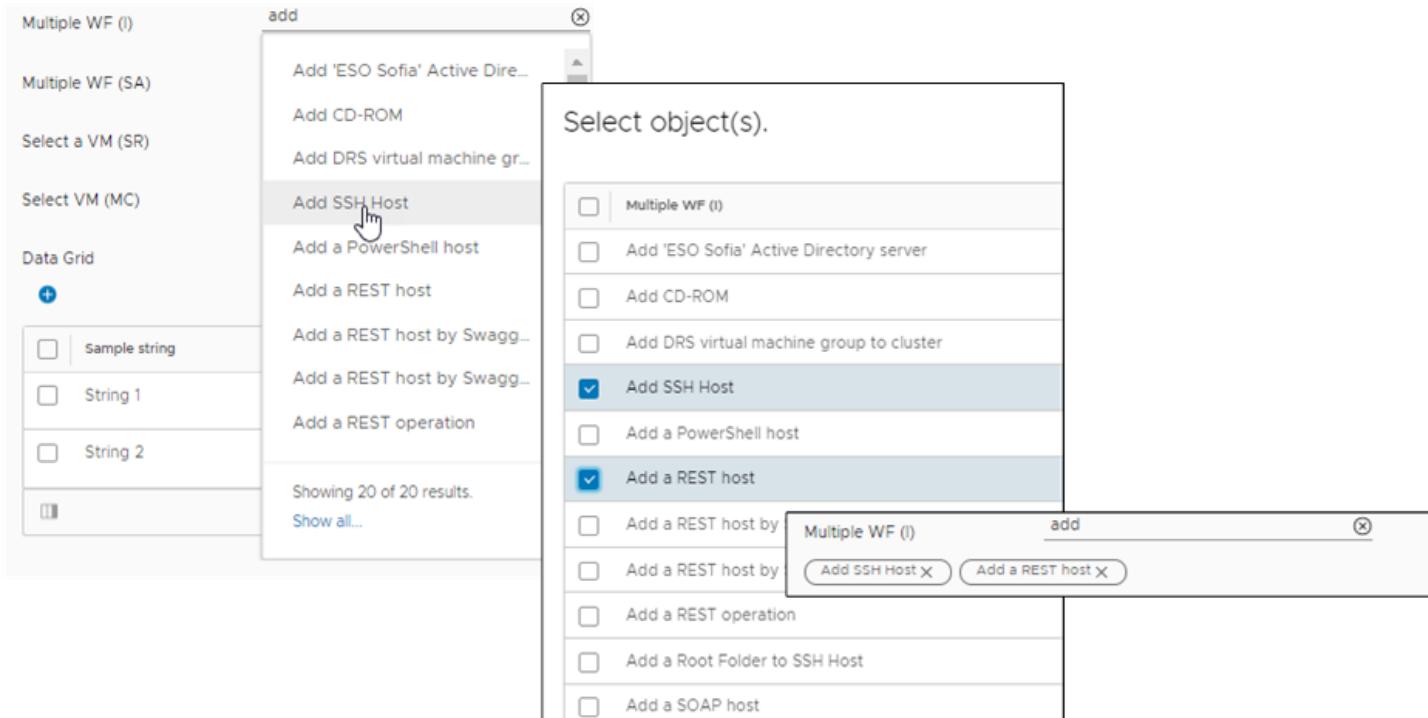

```
var res = [];
res.push(new Properties({label: 'label1', value: 'value1'}));
res.push(new Properties({label: 'label2', value: 'value2'}));
res.push(new Properties({label: 'label3', value: 'value3'}));
return res;
```

**NOTE**

The Properties input cannot be input to a workflow, only an intermediate value in the custom form.

## **Working with the Multi Value Picker**

The multi value picker appears in the request form as a search option, similar to the value picker, but where you can select one or more values. The user enters a string and the picker provides list based on how you configured the element properties.

You can use the multi value picker based on the following use cases in addition to the use cases described for the value picker. The most valuable use of the multi value picker is using it with a reference data type and a VMware Aria Automation Orchestrator reference.

- Multi value picker with a complex data type and constant value source.  
Use this method when you want the requesting user to select one or more values from a predefined static list of values. Similar to the data grid, this method provides search results in a list based on the defined constant values and labels.
- Multi value picker with a complex data type and an external source.  
Use this method when you want the requesting user to select one or more values from a list of values based on a VMware Aria Automation Orchestrator action. You can use this method with VMware Aria Automation Orchestrator composite types.
- Multi value picker with a reference data type and a VMware Aria Automation Orchestrator reference type. Use this method when you want the requesting user to search the VMware Aria Automation Orchestrator inventory for a specific object with the configured reference type. For example, the reference type is VC:Datastore and you want the users to select the datastore from the retrieved list. Or, if you have a workflow filter configured, you can use Workflow as the reference. To be retrieved, the filter must return values in a property array, not a string array. An example of a workflow filter is provided in the next section. In this example, the filtering is done in the UI when the user enters a search term.
- Multi value picker with a reference data type, a VMware Aria Automation Orchestrator reference type, and an external source.  
Use this method when you want the requesting user to select from results that are first filtered by the reference type and then based on a VMware Aria Automation Orchestrator action. This combination more thoroughly refines the results and populates the request form more quickly. Just as the reference type results must return a property array, so must the external source action. In this example, the filtering is done in VMware Aria Automation Orchestrator and

might improve the speed with which the list is populated, particularly if you have a large number of VMware Aria Automation Orchestrator actions.

### **Limit the VMware Aria Automation Orchestrator results for a multi value picker element results list**

To limit the number of actions returned when the user searches for an action, you can create a filter action and bind the filter results to the search term.

1. In VMware Aria Automation Orchestrator, create an action named filterWorkflow.

- a. Select **Library > Actions**, and click **New Action**.
- b. On the **General** tab, enter or select the following values.

| Option | Value                       |
|--------|-----------------------------|
| Name   | filterWorkflow              |
| Module | com.vmware.library.workflow |

- c. Click the **Script** tab and add the following script.

```
var workflows =
System.getModule("com.vmware.library.workflow").getAllWorkflows();
```

```
var result = [];

for(var i = 0; i < workflows.length; i++) {
 if(workflows[i].name.indexOf(searchTerm) != -1) {
 result.push(workflows[i]);
 }
}
```

```
return result;
```

- d. Configure the following properties.

```

1 var workflows = System.getModule("com.vmware.library.workflow").getAllWorkflows();
2
3 var result = [];
4
5 for(var i = 0; i < workflows.length; i++) {
6 if(workflows[i].name.indexOf(searchTerm) !== -1) {
7 result.push(workflows[i]);
8 }
9 }
10
11 return result;
12

```

**Properties**

**Return type**

Type: Workflow (Array)

**Inputs**

ADD NEW INPUT

|            |        |       |             |
|------------|--------|-------|-------------|
| searchTerm | string | Array | Description |
|------------|--------|-------|-------------|

| Properties Option | Value                                                                                                                                                                                                                |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Return type       | Enter Workflow and select Array.<br>You can use any of the returned types when you run the search. The selected reference type in the custom form must match it.<br><br>If this procedure, continue to use Workflow. |
| Inputs            | Enter searchTerm.<br>Notice that the input searchTerm matches the string used in the script.                                                                                                                         |

- e. Click **Create**.
2. Configure the multi value picker properties in the custom form designer in Automation Service Broker.

The screenshot shows the VMware Aria Automation Properties pane for a field named "Multiple WF (SA)". The "Appearance" tab is selected, displaying properties like Label, Data type (Reference), Reference type (Workflow), and Display type (Multi Value Picker). The "Values" tab is also visible, showing configuration for Value options, Value source (External source, com.vmware.bdimov/filterWorkflows), Select action, Action inputs, and searchTerm.

- In Automation Service Broker, select **Content and Policies** > **Content** and click the vertical dots to the left of the template that you are modifying and click **Customize form**.
- Add or select the multi value picker element in the design canvas.
- In the Properties pane, click **Appearance** and configure the following values.

| Property       | Value                                                                                                                                                              |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Data type      | Reference                                                                                                                                                          |
| Reference type | Enter Workflow.<br>Remember, this value is the return type selected for the filterWorkflow action in VMware Aria Automation Orchestrator, and it must be an array. |
| Display type   | Multi Value Picker                                                                                                                                                 |

- Click the **Values** tab and configure the following values.

| Property                     | Value                                                              |
|------------------------------|--------------------------------------------------------------------|
| Value options > Value source | External source                                                    |
| Select action                | Select the filter action. In this example, select filterWorkflows. |
| Action inputs searchTerm     | Select Field and Search term.                                      |

- Test the filter by requesting the catalog item.

You must ensure that the filter returns the expected values in the multi value picker list, and that the catalog item deploys correctly.

## How do I version custom forms in Automation Service Broker

### Versioning custom forms

The Automation Service Broker custom forms maintain a version history record for custom forms that you create for VMware Aria Automation templates. You can create snapshots of your custom forms, compare different form versions, and revert to a previous version.

In addition to the version-specific form configuration, the catalog item keeps a base, or root, version of the form, which provides a reference to the basic form design. You can update just the base form, just the version-specific form, or both, depending on your use case.

Once you have versions of your base custom form, you must edit the version-specific form for the changes to appear for your catalog users. Updating the base only doesn't affect the actual request form in the catalog. You can choose to keep the base up-to-date with the latest version-specific form or not.

Versioning the template itself removes the version-specific custom forms. You can recreate old form versions from the base form or from saved copies of the YAML.

To view what versions are available for your custom forms, locate your imported template at **Content and Policies > Content**. To update the base form, click the vertical ellipsis next to the custom form and click Customize form. To update a form version, click the arrow button to the left of the template name to expand the details view, and then click the version that you want to edit.

The screenshot shows the VMware Aria Automation Content interface. On the left, there's a sidebar with a list of imported templates. One template, 'catalog-bp-1', is selected and expanded. The main pane displays the details for 'catalog-bp-1', including its description, source (VMware Aria Automation Templates), entitlements, and content item status (Disabled). Below this, under 'Custom Forms', is a table showing four versions of the custom form:

| Content Item Version | Status   | Version-specific Form | Creation Time            |
|----------------------|----------|-----------------------|--------------------------|
| 4                    | Enabled  | ✓                     | Dec 22, 2022, 4:16:49 AM |
| 3                    | Enabled  | ✓                     | Dec 22, 2022, 4:16:14 AM |
| 2                    | Enabled  | ✓                     | Dec 21, 2022, 2:28:13 AM |
| 1                    | Disabled |                       | Nov 16, 2022, 1:30:54 AM |

A green box highlights the '4' in the first row of the table, indicating the current active version.

### Versioning a custom form

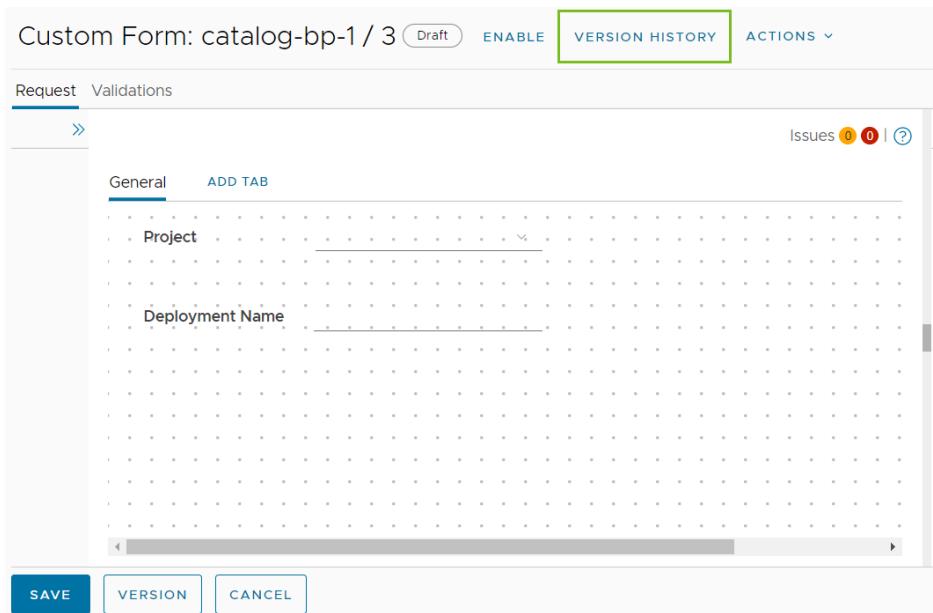

When editing a custom form for the first time, you notice that the **Version** button is dimmed at first. To version the custom form you are editing, you must create the form or save your changes first. Then, you click **Version** and provide a name. When you are done editing the form, save your changes again.

When you version custom forms, the system validates your changes and prevents you from creating a new version that is identical to the previous version.

## Comparing form versions

When you have multiple versions for a custom form, you can inspect the differences between them.

From the custom form editor, click **Version History**.

On the versioning timeline on the left, select a version and click **Diff**. From the **Compare to** dropdown select another version. You can view the comparison between the two versions side-by-side or inline.

The screenshot shows the 'catalog-bp-1 / 1.0 - version 2' page. On the left, there's a sidebar with a timeline showing 'Current ver: VERSION' and 'version 2' (Created by at Apr 3, 2023, 1:23:14 PM). There are 'View' and 'Diff' tabs, with 'Diff' selected. A 'Compare to:' dropdown is set to 'Current version'. Under 'View mode', 'Side-by-side' is selected. The main area displays a 'Form Definition (version 2 → Current version)' with a diff view. The code shows changes from line 15 to 23, where line 19 is marked with a plus sign (+) and indicates the addition of a new section definition.

```

@@ -15,8 +15,36 @@

 "id": "description",
 "display": "textArea",

```

Use the **View** tab on the **Version History** page to preview the custom form versions.

## Restoring an earlier version

When you develop a custom form, you might have to restore an earlier working version of your form.

From the versioning timeline on the **Version History** page, select your desired version and click **Restore**.

The snapshot you selected is applied to the current custom form.

## Cloning a custom form

You can create a custom form that is based on another existing custom form or custom form version.

1. On the **Content** page, locate the template for which you want to create a new form version.
2. Click **New Form From** in the action menu to the left of the version name.
3. Select the catalog item whose form you want to copy.  
If the item has multiple custom form versions, you can select which version to copy.
4. Click **Create**.

The screenshot shows the VMware Aria Automation Content page. On the left, there's a list of imported templates. In the center, a modal window is open for a catalog item named "catalog-bp-1". The modal includes fields for Description (empty), Source (VMware Aria Automation Templates), and Entitled to (disabled). Below these are sections for "Custom Forms" and "Create New Custom Form". The "Custom Forms" section lists three versions (4, 3, 2) of the catalog item, with version 4 currently selected. A button labeled "New Form From" is highlighted with a green box. The "Create New Custom Form" modal at the bottom has a note about selecting a starting point for version 1, a search bar for "Select item", and "CANCEL" and "CREATE" buttons.

## What to do next

For more information about versioning custom forms, see [this article](#).

## Troubleshooting Automation Service Broker custom forms

### Troubleshooting

If you encounter problems when using custom forms in Automation Service Broker, you can refer to this troubleshooting topic to understand the problem or solve it, if there is a workaround.

These issues affect VMware Aria Automation version 8.16.0.

### **External actions are not executed correctly**

**Problem:** External actions in your custom forms are not executed correctly, for example, a field might not autopopulate with the default value or a dropdown menu might appear without options.

**Cause:** External actions used in a custom form field are only executed when all dependency fields with constraints are properly populated with valid values. When a field breaks some of its constraints, such as required, min/max value, or length, and pattern constraints, any directly dependent input field with an external action is evaluated only after the field is within the valid requirements. Transitively dependent fields with an external action are not evaluated unless the field is valid. If a valid field is updated and becomes invalid, then all dependent actions are not run.

**Solution:** Ensure that all dependency fields with constraints are populated with valid values. For example, ensure that all required dependencies are filled and all constraints on the dependencies are satisfied.

### **Form requests fail**

**Problem:** You get form errors, for example, Some data cannot be retrieved. If the problem persists, contact your system administrator. Failed request: <action name>.

**Cause:** Your form might include one or more fields that contain a regex constraint that doesn't comply with Java and JavaScript.

**Solution:** Ensure that the regex in your fields is both Java and JavaScript compliant.

### **Unable to import Automation Orchestrator workflows**

**Problem:** When you import an Automation Orchestrator workflow into the Automation Service Broker catalog content sources, you get an error message, for example, Error downloading catalog item '/workflow/<workflowId>' (Error: Content provider error).

**Solution:** Verify that the workflow does not contain any inputs or fields with the id project, which is a system property.

## **Send email notifications to Automation Service Broker users**

### Send email notifications to users

As a cloud administrator, you can configure VMware Aria Automation to send users notifications when specific events in Automation Service Broker and Automation Assembler occur.

- Verify that you configured an outbound email server. See [Add an email server in vRealize Automation Service Broker to send notifications](#).

You can send notifications for several types of events, called scenarios, such as the successful completion of a catalog request or a required approval.

Email messages are sent to users in the following scenarios.

| Scenario                                                                 | Description                                                                                                                                                            |
|--------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Deployment Lease Deletion                                                | A deployment lease expired and the deployment is scheduled for deletion. The message is sent to the deployment owner 15–30 minutes before the deployment is destroyed. |
| Deployment Lease Expired                                                 | A deployment lease expired and the deployment is about to be deleted.                                                                                                  |
| Deployment Lease Expiring                                                | A deployment lease expires soon. The message is sent to the deployment owner three days before the lease expires.                                                      |
| Deployment Request Approved                                              | A request is approved. The message is sent to the user who requested the deployment.                                                                                   |
| Deployment Request Rejected                                              | A request is rejected. The message is sent to the user who requested the deployment.                                                                                   |
| Deployment Request Waiting for Approval (Notification sent to requester) | A request awaits approval. The message is sent to the user who requested the deployment.                                                                               |
| Pending Approval Request (Notification sent to approver)                 | A request requires approval. The message is sent to the user who must approve the request.                                                                             |
| Pending Work Item (Notification sent to assignees)                       | A request requires user input to proceed. The message is sent to the user who must provide input.                                                                      |
| Pending Work Item (Notification sent to requester)                       | A request requires user input to proceed. The message is sent to the user who requested the deployment.                                                                |
| Work Item Answered                                                       | A request that required user input was answered and the deployment proceeded.                                                                                          |
| Work Item Rejected                                                       | A request that required user input was rejected and the deployment did not proceed.                                                                                    |

1. Log in to VMware Aria Automation as an administrator.
2. Select **Content and Policies** > **Notifications** > **Scenarios**.
3. Select one or more events to trigger user notifications.

Users are subscribed to the notifications that you enabled.

When configuring notifications in Automation Service Broker, consider:

- If a user email is changed in Active Directory, it might take at least 15 minutes before the email address is updated in VMware Aria Automation. In the meantime, notifications might be sent to the old email address.
- Notification recipients are limited to 100 users per notification. For Active Directory groups, the limit is 10 groups per notification, where each group consists of a maximum of 500 users. If a group consists of more than 500 users, the notification is only sent to 500 users, and not to the rest of the users.

## Add an email server in Automation Service Broker to send notifications

Add an email server to send notifications

As a cloud administrator, you configure an email server if you want to send messages to users about events in Automation Service Broker and Automation Assembler. The messages are a courtesy that improves the experience of your consumers.

- Verify that you know the credentials required to configure the email server. You must provide the server name and an email account that you want to be the message sender. If your email server requires authentication, you must also provide the user name and password.

This email server is for outbound messages only.

Email messages are sent to users in the following scenarios.

- A deployment lease expires soon. The message is sent to the deployment owner three days before the lease expires.

The lease for deployment <Deployment Name> expires in 3 days.

When the lease expires, the deployment will be deleted.

The content and links in this email contain information intended solely for its named recipients and are not to be shared with third parties unless otherwise specified. Any information that you provide to VMware will be treated in accordance with our [Privacy Policy](#).

1. Select **Content and Policies** > **Notifications** > **Email Server**.

2. Enter the information for each setting.

If you need assistance on a particular setting, consult the signpost help.

3. To verify the configured settings, click **Test Connection**.

4. To save, click **Create**.

As the administrator, monitor the leases to ensure that the messages are sent to the deployment owners at the correct time.

## Working with the Infrastructure options in Automation Service Broker

### Working with the Infrastructure options

The Infrastructure tab that is provided in Automation Service Broker is available to administrators. As an administrator who is setting up the service catalog for your users, you use the options to create and manage configuration and connection information that is shared with Automation Assembler.

For more information about the various connection options, see [Setting up Automation Assembler for your organization](#).

To better understand projects, and how it associates users with resources, see [Adding and managing Automation Assembler projects](#).

When working with cloud zones, see [Learn more about Automation Assembler cloud zones](#)

## How do I deploy an Automation Service Broker catalog item

How do I deploy a catalog item

As an Automation Service Broker consumer, you deploy a catalog item that was imported from Automation Assembler, Amazon CloudFormation, and other sources so that you can deploy it as part of your work processes.

The catalog items are provided to you by your cloud administrator. The items that are available to you depend on your project membership.

- If you are a member of one project, you can see only the catalog items for that project.
- If you are a member of several projects, you can see the catalog items for those projects. You can use the Projects section to filter catalog items by a specific project.
- If your project does not have any configured catalog items, the Catalog section does not appear.

Projects also determine your options at deployment time.

The information provided in this article is general because each catalog item is unique. The variation depends on how the template and other items were constructed, including what variables are made available to you at request time.

1. Click the **Consume** tab in Automation Service Broker.

2. In the **Projects** drop-down menu, select the project for which you want to view the available catalog items.

If multiple projects appear in the drop-down menu, you can select more than one project. You can see a list of your projects on the Overview page.

If you have access to a single project, you can skip this step. All catalog items for that project appear in the catalog.

3. Click **Catalog**.

The available catalog items are available to you based on the project you selected. If you didn't select a project, all catalog items that are available to you appear in the Catalog.

4. Locate the catalog item you plan to deploy.

You can use the filter, search, or sorting options to find the catalog item.

5. Click **Request**.

6. Provide any required information.

If the template has more than one released version, select the version that you want to deploy.

A deployment name is required, as is a project. The project list includes those that you are a member of.

The form might have other options that you must configure, depending on how the template was designed.

7. Click **Submit**.

The provisioning process begins and the Deployments page opens with your current request at the top.

Monitor your request. See [How do I monitor deployments](#).

## Learn more about the Automation Service Broker catalog items

[Learn more about catalog items](#)

Catalog items are imported templates that you can request for deployment. At request time, the information that you must provide or configure depends on how the template was designed by your administrator. When you deploy an item, it is provisioned to based on the cloud regions or datastores that are associated with the selected project.

For a general review of how to deploy, see [How do I deploy an catalog item](#).

### **Using the filter and search to locate a catalog item**

Depending on your company goals and project members, the catalog available to you can be extensive. In addition to filtering available items based on project in the Projects drop-down menu, you can use the following tools to locate a catalog item.

1. Search. Enter a search term.
2. Filter. Opens the left panel where you can filter by content type and projects.
3. Sort. If the list is still too long, you can sort in ascending or descending order.

My Resource Usage

2 VMs Count 16 CPU Count 346 Storage (GB) 58 Memory (GB)

Catalog Items (20 items of many)

1. Content Type filter dropdown.

2. Filter button.

3. Sort dropdown menu.

| Icon                       | Name              | Description                | Projects | Status  |
|----------------------------|-------------------|----------------------------|----------|---------|
| Active Directory host icon | Add an Active ... | vRealize Orchestrator W... | TMM Auto | REQUEST |
| Custom attribute icon      | Add custom att... | vRealize Orchestrator W... | TMM Auto | REQUEST |
| Autoscale icon             | Autoscale Ope...  | VMware Cloud Templates     | TMM Auto | REQUEST |
| Deployment actions icon    | Deployment A...   | Extensibility actions      |          |         |
| Deployment library icon    | Deployment Li...  | VMware Cloud Templates     |          |         |
| Terraform icon             | Deploy Terrafo... | Extensibility actions      |          |         |

1 - 20 of 52 items

### **My Resource Usage dashboard**

The My Resource Usage dashboard provides the current number of VMs, CPUs, storage, and memory that your deployments consume. This information is provided so that you can understand how much you are consuming before you deploy another catalog item. If the numbers seem large, you might consider destroying some of your unused deployments.

The calculated resource usage is for all the deployments where you are the owner, including across projects.

The usage is calculated for resources provisioned by cloud templates for the following resource types:

- VMware vSphere
- VMware Cloud on AWS
- Amazon Web Services
- Microsoft Azure
- Google Cloud Platform

The usage is calculated when any of the following occurs:

- You deploy a catalog item that is provisioned on vSphere, AWS, Azure, or GCP.
- Your administrator onboards deployments where you are the owner. VMs, CPUs, storage, and memory are available for onboarded vSphere deployments. However, CPU and memory are not available for all the endpoints.
- You change a deployment by running a day 2 action. For example, if you add two CPUs to a machine in a deployment, the calculated number of CPUs increases by two.

Automation Service Broker listens for events, such as deployment, onboarding, or day 2 actions, make the calculations, and then updates your resource usage. This usually takes one to two minutes after the change is finished.

The change might include you assigning the deployment to another user. When the change owner action is finished, the resources are subtracted from your resource usage board and added to the new owner's board.

## How do I deploy VMware Private AI Foundation catalog items in the Automation Service Broker

### How do I deploy Private AI catalog items

If your cloud administrator has set up Private AI Automation Services in VMware Aria Automation, you can access and request AI workloads using the Automation Service Broker catalog.

#### NOTE

This documentation is based on VMware Aria Automation 8.18. For information about the VMware Private AI Foundation functionality in VMware Aria Automation 8.18.1, see the [VMware Private AI Foundation with NVIDIA](#) documentation.

As a data scientists or a DevOps engineer, you can request the following Private AI Automation Services catalog items:

- **AI Workstation** – a GPU-enabled virtual machine that can be configured with desired vCPU, vGPU, memory, and the option to pre-install AI/ML frameworks like PyTorch, CUDA Samples, and TensorFlow.
- **AI RAG Workstation** – a GPU-enabled virtual machine with Retrieval Augmented Generation (RAG) reference solution.
- **Triton Inference Server** – a GPU-enabled virtual machine with NVIDIA Triton Inference Server.
- **AI Kubernetes Cluster** – a VMware Tanzu Kubernetes Grid Cluster with GPU-capable worker nodes to run AI/ML cloud-native workloads.
- **AI Kubernetes RAG Cluster** – a VMware Tanzu Kubernetes Grid Cluster with GPU-capable worker nodes to run a reference RAG solution.

The screenshot shows the VMware Aria Automation Service Broker interface. The top navigation bar includes 'Service Broker' and 'CHANGE'. Below it, tabs for 'Consume', 'Content & Policies', 'Infrastructure', and 'Inbox' are visible. The 'Consume' tab is selected. On the left, a sidebar lists various service categories: Projects, Catalog (which is currently selected), Deployments, Resources, Virtual Machines, Volumes, Networking & Security, and Supervisor Namespaces. The main content area is titled 'Catalog' and shows '5 items'. It includes filters for 'My resource usage' (0 VMs, 0 CPUs, 0 GB storage, 0 GB memory) and a search bar. The catalog items are:

- AI Kubernetes Cluster**: Deploy a VMware Tanzu Kubernetes Cluster with customizable, GPU capable worker nodes to run AI/ML cloud-native workloads. The cluster will run Kubernetes version 1.26.5 with Ubuntu nodes.
- AI Kubernetes RAG Cluster**: Deploy a VMware Tanzu Kubernetes Cluster with customizable, GPU capable worker nodes to run AI/ML cloud-native workloads. The cluster will run Kubernetes version 1.26.5 with Ubuntu nodes.
- AI RAG Workstation**: This reference solution demonstrates how to find business value in generative AI by augmenting an existing foundational LLM to fit your business use case. This is done using retrieval augmented generation (RAG) which...
- AI Workstation**: Workstation (VM) with preconfigured GPU capabilities, and options to pre-install selectable customizations during deployment.
- Triton Inferencing Server**: Triton Inference Server provides a cloud and edge inferencing solution optimized for both CPUs and GPUs. Triton supports an HTTP/REST and GRPC protocol that allows remote clients to request inferencing for any...

Each item card includes a 'Projects' section showing 'vpaif-quickstart-1' and a 'REQUEST' button.

## **Before you begin**

- Verify that your cloud administrator has configured Private AI Automation Services for your project.
- Verify that you have permissions to request AI catalog items.

## **How do I access the Private AI Automation Services catalog items**

In Automation Service Broker, open the Consume tab and then click Catalog. The catalog items that are available to you are based on the project you selected. If you didn't select a project, all catalog items that are available to you appear in the catalog.

Remember that all values shown in the procedures described in this section are use case samples. Your account values depend on your environment.

## **How do I monitor my Private AI deployments**

You use the Deployments page in Automation Service Broker to manage your deployments and the associated resources, making changes to deployments, troubleshooting failed deployments, making changes to the resources, and destroying unused deployments.

To manage your deployments, select **Consume > Deployments > Deployments**.

For more information, see [How do I manage my Automation Service Broker deployments](#).

### **Deploy a GPU-accelerated Tanzu Kubernetes Grid cluster**

Deploy a TKG cluster

As a DevOps engineer, you can request a GPU-accelerated Tanzu Kubernetes Grid (TKG) cluster, where worker nodes can run AI/ML workloads, from the self-service Automation Service Broker catalog.

**NOTE**

This documentation is based on VMware Aria Automation 8.18. For information about the VMware Private AI Foundation functionality in VMware Aria Automation 8.18.1, see [Deploy a GPU-Accelerated TKG Cluster by Using a Self-Service Catalog Item in VMware Aria Automation](#) in the VMware Private AI Foundation with NVIDIA documentation.

The TKG cluster contains an NVIDIA GPU operator, which is a Kubernetes operator that is responsible for setting up the proper NVIDIA driver for the NVIDIA GPU hardware on the TKG cluster nodes. The deployed cluster is ready to use for AI/ML workloads without needing additional GPU-related setup.

The deployment contains a supervisor namespace, a TKG cluster with three work nodes, multiple resources inside the TKG cluster, and a Carvel application which deploys the GPU Operator application.

1. On the **Catalog** page in Automation Service Broker, locate the **AI Kubernetes Cluster** card and click **Request**.
2. Select a project.
3. Enter a name and description for your deployment.
4. Select the number of control pane nodes.

| Setting    | Sample value                                                                                                                                         |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| Node count | 1                                                                                                                                                    |
| VM class   | <p><i>best-effort-4xlarge - 16 CPUs and 128 GB Memory</i></p> <p>The class selection defines the resources available within the virtual machine.</p> |

5. Select the number of work nodes.

| Setting               | Description                                                                                        |
|-----------------------|----------------------------------------------------------------------------------------------------|
| Node count            | 3                                                                                                  |
| VM class              | <i>best-effort-4xlarge-a100-40c - 1 vGPU (40 GB), 16 CPUS and 120 GB Memory</i>                    |
| Time-slicing replicas | <p>1</p> <p>Time-slicing defines a set of replicas for a GPU that is shared between workloads.</p> |

6. Provide the NVIDIA AI enterprise API key.
7. Click **Submit**.

## Managing deployments and resources in Automation Service Broker

### Managing deployments and resources

As a cloud administrator or a catalog consumer with the necessary permissions, you use the Resources tab to manage your resources. The resources can be deployed catalog items, but they can also be those that were discovered for your project cloud accounts.

## How do I manage my Automation Service Broker deployments

### How do I manage my deployments

As an Automation Service Broker consumer, you use the Deployments page to manage your deployments and the associated resources, making changes to deployments, troubleshooting failed deployments, making changes to the resources, and destroying unused deployments.

The deployments are the provisioned instances of catalog items, cloud templates, and onboarded resources. If you manage a small number of deployments, the deployment cards provide a graphical view for managing them. If you manage a large number of deployments, the deployment list and the resource list provide more a more robust management view.

To manage your deployments, select **Consume** > **Deployments** > **Deployments**.

You can use the **Projects** drop-down on the Consume tab to view only the deployments for a specific project.

### **Working with deployment cards and the deployment list**

You can locate and manage your deployments using the card list. You can filter or search for specific deployments, and then run actions on those deployments.

**Figure 11: Deployments page card view**

| Deployment ID             | Description    | Project       | Owner           | Resources   | Created           | Expires           |
|---------------------------|----------------|---------------|-----------------|-------------|-------------------|-------------------|
| Deployment-76ba0e5a-9a... | No description | Project Owner | CA IX Project 1 | 6 Resources | Created a day ago | Expires in 9 days |
| Deployment-1e4bebb4-59... | No description | Project Owner | CA IX Project 1 | 2 Resources | Created a day ago | Expires in 9 days |
| Deployment-88dde269-55... | No description | Project Owner | CA IX Project 1 | 1 Resource  | Created a day ago | Expires in 9 days |
| Deployment-cf382420-ad... | No description | Project       | CA IX Project 1 | 1 Resource  | Created a day ago | Expires in 9 days |

1. Filter your requests based on attributes.

For example, you can filter based on owner, projects, lease expiration date, or other filtering options. Or you might want to find all the deployments for two projects with a particular tag. When you construct the filter for the projects and tag example, the results conform to the following criteria: (Project1 OR Project2) AND Tag1.

The values that you see in the filter pane depend on the current deployments that you have permission to view or manage.

Most of the filters and how to use them are relatively obvious. Additional information about some of these filters is provided below.

2. Search for deployments based on keywords or requester.
3. Sort the list to order by time or name.
4. Switch between the deployment card and the deployment grid views.
5. Run deployment-level actions on the deployment, including deleting unused deployments to reclaim resources.

You can also see deployment costs, expiration dates, scheduled deletion dates, and status.

To adjust what information you see for your deployments, click **Manage Columns** in the bottom left of the deployment grid and select your preferred columns.

You can switch between the card and grid view in the upper right of the page, to the right of the Sort text box. You can use the grid view to manage a large number of deployments on fewer pages.

**Figure 12: Deployment page grid view**

| Deployments <span style="border: 1px solid #ccc; padding: 2px;">40 items of 208</span> |         |                       |                       |                 |                   |            |
|----------------------------------------------------------------------------------------|---------|-----------------------|-----------------------|-----------------|-------------------|------------|
|                                                                                        | Actions | Address               | Owner                 | Project         | Status            | Expires on |
| ...                                                                                    | ...     | shared-ip-ranges-d... | bratanov@vmware.com   | bratanov-ipa... | On                | Never      |
| ...                                                                                    | ...     | nikola-ipam-test-O... | 192.168.0.6           |                 | On                |            |
| ...                                                                                    | ...     | net.90                |                       |                 |                   |            |
| >                                                                                      | ...     | shared-ip-ranges-d... | bratanov@vmware.com   | bratanov-ipa... | On                | Never      |

### Working with selected deployment filters

The following table is not a definitive list of filter options. Most of them are self-evident. However, some of the filters require a little extra knowledge.

**Table 42: Selected filter information**

| Filter name                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Optimizable Resources Only  | If you integrated VMware Aria Operations and are using the integration to identify reclaimable resources, you can toggle on the filter to limit the list of qualifying deployments.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Deployment Lifecycle Status | <p>The Deployment Lifecycle Status and Last Request Status filters can be used individually or in combination, particularly if you manage a large number of deployments. Examples are included at the end of the Last Request Status section below.</p> <p>Deployment Lifecycle Status filters on the current state of the deployment based on the management operations.</p> <p>This filter is not available for deleted deployments.</p> <p>The values that you see in the filter pane depend on the current state of the listed deployments. You might not see all possible values. The following list includes all the possible values. Day 2 actions are included in the Update status.</p> <ul style="list-style-type: none"> <li>• Create - Successful</li> <li>• Create - In Progress</li> <li>• Create - Failed</li> <li>• Update - Successful</li> </ul> |

| Last Request Status filters | <p>Last Request Status filters on the last operation or action that ran on the deployment.</p> <p>This filter is not available for deleted deployments.</p> <p>The values that you see in the filter pane depend on the last operations that ran on the listed deployments. You might not see all possible values. The following list is all of the possible values.</p> <ul style="list-style-type: none"> <li>• Pending. The first stage of a request where the action is submitted but the deployment process has not yet started.</li> <li>• Failed. The request experienced a failure during any stage of the deployment process.</li> <li>• Cancelled. The request was cancelled by a user while the deployment process was processing and not yet completed.</li> <li>• Successful. The request successfully created, updated, or deleted a deployment.</li> <li>• In Progress. The deployment process is currently running. Additional deployment states, for example, Initialization and Completion that you see in the deployment History tab are not provided as filters, but you can use the In Progress filter to locate deployments in those states.</li> <li>• Approval Pending. The request triggered one or more approval policies. The process is waiting for a response to the approval request.</li> <li>• Approval Rejected. The request was denied by the approvers in the triggered approval policies. The request does not continue.</li> </ul> <p>The following examples illustrate how to use the Deployment Lifecycle Status and Last Request Status filters individually or together.</p> <ul style="list-style-type: none"> <li>• To find all delete requests that failed, select <b>Delete - Failed</b> in the Deployment Lifecycle Status filter.</li> <li>• To find all the requests waiting for approval, select <b>Approval Pending</b> in the Last Request Status filter.</li> <li>• To find the delete requests where the approval request is still pending, select <b>Delete - In Progress</b> in the Deployment Lifecycle Status filter and <b>Approval Pending</b> in the Last Request Status filter.</li> </ul> |

## Working with deployment details

You use the deployment details to understand how the resources are deployed and what changes have been made. You can also see pricing information, the current health of the deployment, if the deployment expires and when it's scheduled for deletion, and if you have any resources that need to be modified.

The screenshot displays the VMware Aria Automation interface with the following sections:

- Topology:** Shows a summary of the deployment with "sb-demo-03" as the name, "Good" health, and "Create Successful" status. It lists the owner (sbandari@vmware.com), requestor (sbandari@vmware.com), project (demo-vcenter-project), and cloud template (sb-demo). It also shows deployment details like "Expires on Never", "Last updated Mar 17, 2021, 11:31:09 AM", and "Created on Mar 2, 2021, 8:47:06 AM".
- History:** Shows a timeline of events for the deployment, including "CREATE" (Mar 2, 2021, 8:45:58 AM) and "REQUEST\_FINISHED" (Mar 2, 2021, 8:4:44 PM).
- User Events:** Displays configuration changes and interactions. For example, on Aug 15, 2022, at 6:58:14 AM, there was a "RECONFIGURE" event for a vSphere machine with CPU 4 and RAM 4GB. On Aug 15, 2022, at 6:47:22 AM, there were "USER\_INTERAC." events for the same machine.
- Price:** Shows price analysis from Mar 2, 2021, to Mar 17, 2021. The total price for the month is \$0.38. A bar chart shows price fluctuations over time.
- Monitor:** Includes a real-time monitoring section for CPU usage. A graph shows CPU (%) from 12 PM to 9 AM, with a specific point highlighted for Mar 17, 2021, at 7:36:58 AM (CPU (%): 0.123).
- Alerts:** Lists active alerts, such as "Definition\_Deployment\_VM" (Created: Mar 8, 2021, 3:20:27 AM) and "AlertDefinition\_Deployment\_has\_cost" (Created: Mar 8, 2021, 4:59:59 PM).
- Optimize:** Provides insights into VM utilization. It shows "Underutilized VMs" (2 Idle VMs) and "Underutilized VMs" (Idle since Mar 09, 2021, for Cloud\_vSphere\_Machine\_1-mcm306191-163093649552).

- **Topology tab.** You can use the Topology tab to understand the deployment structure and resources.

- **History tab.** The History tab includes all the provisioning events and any events related to actions that you run after deploying the requested item. If there are any problems with the provisioning process, the History tab events helps you with troubleshoot the failures.
- **User Events tab.** You can use the User Events tab to provide and track the user interactions for your deployment. The events include any initial input values, any required approvals, input values for day 2 changes, and any values that you must provide as part of a deployment or for a day 2 action workflow. Where the request requires input values, you can also enter the values on the Inputs tab in Automation Service Broker. For deployments that include VMware Aria Automation Orchestrator workflow user events, where you enter values during the deployment process, there are some situations where the tab does not display the form or where the workflow is canceled. If you have multiple VMware Aria Automation Orchestrator instances that do not have tags or where they all have the same tag, the form does not load. Ensure that you correctly tag the instances so that the form displays on the tab. If there are not assignees in the workflow form, the workflow is canceled and the deployment or action fails. Ensure that you workflow form includes assignees.
- **Price tab.** You can use the pricing tab for insights about how much your deployment is costing your organization. Pricing information is provided by your VMware Aria Operations or CloudHealth integrations.
- **Monitor tab.** The Monitor tab data provides information about the health of your deployment based on data from VMware Aria Operations.
- **Alerts tab.** The Alerts tab provides active alerts on the deployment resources. You can dismiss the alert or add reference notes. The alerts are based on data from VMware Aria Operations.
- **Optimize tab.** The Optimize tab provides utilization information about your deployment and offers suggestions for reclaiming or otherwise modifying the resources to optimize resource consumption. The optimization information is based on data from VMware Aria Operations.

## How do I monitor Automation Service Broker deployments

### How do I monitor deployments

You monitor Automation Service Broker deployment requests to ensure that the resources are provisioned, that the provisioned resources are running, and to resize or destroy the resources as needed.

The Deployments page provides information about the current state of the deployment and where the resources are deployed in your provider clouds.

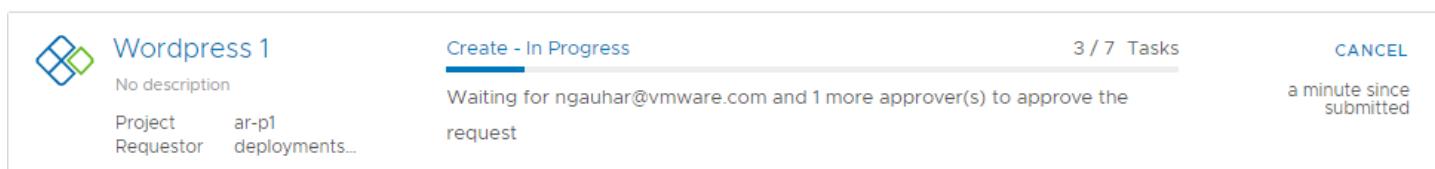

### How do I know that my deployment request succeeded

The deployment cards that appear on the Deployments page show the state of the deployment, including in-progress (top) and completed (below). The card includes the number of deployed resources, how long it has been deployed, and the lease expiration date.

The cards also provide the IP addresses and the actions that you can run on the deployment.

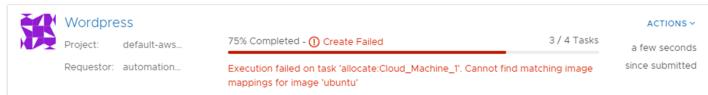

If an approval policy is triggered for your request, you might see the request in an in progress state with the name of at least one approver. [Approval policies](#) are defined in Automation Service Broker by your administrator. The approvers are defined in the policy. The approvers approve requests using an Approvals tab. You might also encounter approvals on day 2 actions.

If a deployment fails, the cards show the error message for the point of failure and the process progress. To learn more about the failure, click the deployment name at review the History tab.

For more information about troubleshooting failed deployments, see [What can I do if a Automation Service Broker deployment fails](#).

## Where are my resources deployed

To access your successfully provisioned deployments, you might need more than the IP address provided on the card. Click the deployment name and review the deployment details on the Topology tab.

The screenshot shows the deployment details for 'Test dep1'. The 'Topology' tab is selected, displaying a network diagram with components like 'r1', 'disk2', and 'mydisk'. The 'History' tab is also visible. On the right, detailed resource information is shown:

|                   |                          |
|-------------------|--------------------------|
| Resource name     | r1-mcm40494-146694441921 |
| Account / Region  | aws/us-east-1            |
| Status            | On                       |
| Address           | 54.237.108.168           |
| Availability zone | us-east-1e               |

You most likely need the IP address for the primary component. As you click on each component, notice the information that is provided is specific to that component.

The availability of the external link depends on the cloud provider. Where it is available, you must have the credential on that provider to access the component.

## How do I track deleted deployments

After you delete a deployment, you might want to see a list or review the history of a particular deployment.

To view your deleted deployments, click the filter on the **Deployments** page, and then turn on **Deleted Deployments Only** toggle. The list of deployments is now limited to those that are deleted.

If you need the name of delete machines, you can look at the history to retrieve the information.

The deleted deployments are available for 90 days.

**Deployments** 10 Items of 37

### What can I do if a Automation Service Broker deployment fails

Your deployment request might fail for many reasons. It might be due to network traffic, a lack of resources on the target cloud provider, or a flawed deployment specification. Or, the deployment succeeded, but it does not appear to be working. You can use Automation Service Broker to examine your deployment, review any error messages, and determine whether the problem is the environment, the requested workload specification, or something else.

You use this workflow to begin your investigation. The process might reveal that the failure was due to a transient environmental problem. Redeploying the request after verifying the conditions have improved resolves this type of problem. In other cases, your investigation might require you to examine other areas in detail.

1. To determine if a request failed, select **Deployments** > **Deployments** and locate the deployment card.

WP-ROR1.0  
No description  
Project Owner: github-proj, cnugent@vmware.com

0 Resources      Created 29 minutes ago      Never expires      ACTIONS  
29 minutes since submitted

Create - Failed 3 / 9 Tasks  
No placement exists that satisfies all of the request requirements. Please check if suitable placements and cloud zones exist and they have been properly tagged.

Failed deployments are indicated on the card.

- a) Review the error message.
- b) For more information, click the deployment name for the deployment details.
2. On the deployment details page, click the **History** tab.

The screenshot shows a deployment card for 'WP - ROR1'. The card includes details such as Requestor (fritz), Project (PersonnelAppDev), Cloud Template (Web App dev), and status information (Expires on Never, Last updated Sep 10, 2020, 2:32:24 PM, Created on Sep 10, 2020, 2:10:53 PM). Below the card is a table of events for all requests, with columns for Timestamp, Status, Resource Type, Resource Name, and Details. The table contains four rows of data, each with a timestamp from Feb 22, 2019, and a status like REQUEST\_FAILED or ALLOCATE\_FAILED. The 'Details' column provides a detailed error message for each event.

| Timestamp                | Status               | Resource Type  | Resource Name | Details                                                                                                                                                                                   |
|--------------------------|----------------------|----------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Feb 22, 2019, 1:55:09 PM | REQUEST_FAILED       |                |               | No placement exists that satisfies all of the request requirements. Please check if suitable placements and cloud zones exist for the current project and they have been properly tagged. |
| Feb 22, 2019, 1:55:08 PM | ALLOCATE_FAILED      | Cloud.Mac hine | DBTier        | No placement exists that satisfies all of the request requirements. Please check if suitable placements and cloud zones exist for the current project and they have been properly tagged. |
| Feb 22, 2019, 1:55:02 PM | ALLOCATE_IN_PROGRESS | Cloud.Mac hine | DBTier        |                                                                                                                                                                                           |
| Feb 22, 2019             | ALLOCATE             | Cloud.Net      | WP-Netwo      |                                                                                                                                                                                           |

- Review the event tree to see where the provisioning process failed. This tree is useful when you modify a deployment, but the change fails.
- The **Details** provides a more verbose version of the error message.

If you are unable to resolve your problem, contact your cloud administrator for additional assistance.

## How do I track and respond to requests that require approval in Automation Service Broker

### How do I manage approval requests

As an Automation Service Broker consumer or an Automation Assembler user, you received an email notification about a deployment or day 2 action request that you made. Your request must be approved by a designated approver before it proceeds. If you are an assigned approver, you received an email notification about a deployment request that someone made. In either case, you can use these procedures to understand the approval policy workflow related to deployment requests and how to respond to approval requests if you are an assigned approver.

### How do I track my requests that require approval

This procedure assumes that you received an email notification about your deployment request is pending approval, or that you noticed that your deployment did not progress.

- To learn more about how approval policies are configured, see [How do I configure approval policies](#).

You receive an email with the name of your deployment and the name of the first approver on the list. The message includes a link to the deployment details where you can track the approvals in the deployment details.

If you received an email about the pending request, you can see the name of your deployment and the name of the first approver on the list. The message includes a link to the deployment details where you can track the approvals in the deployment details.

- Select **Consume > Deployments > Deployments**.
- You requested a deployment or a day 2 action on an existing deployment, but you now see message on your deployment card.  
For example, your card displays **Create - Approval Pending** and lists the names of the approvers.

Your request triggered one or more approval policies.

3. For information that helps you track the progress of your request, click the deployment name, and then click the **Details** tab.

When the deployment is first awaiting approval, you only see APPROVAL\_IN\_PROGRESS. After a few minutes the list of approver names are added in the Details column. If the request requires multiple approvers, the approver list updates as an approver responds. With each update, only the pending approver names remain.

4. When your request is approved or rejected, you receive another email message appropriate to the outcome.

If the request is rejected, the deployment details **History** tab displays REQUEST\_FAILED and the details column provides the name of the approver and the reason for rejecting the request.

## How do I respond to an approval request

As a designated approver for deployment or day 2 action requests made in Automation Service Broker or Automation Assembler, you are tasked with approving requests. If you are an assigned approver in the policy, you received an email notification about a deployment request that someone made. If you are a user with the Manage Approvals custom role who monitors and responds to approval requests, you do not receive a notification.

- To learn more about how approval policies are configured, see [How do I configure approval policies](#).

Some policies might require only your approval, while others require multiple people to approve a request.

If the policy that you are responding to has multiple approvers but only requires one approver, you might see an already approved request in the Approvals page. You do not need to take further action.

If you are managing many requests, you can limit the number of approval requests by using the filter option. For example, rather than all the requests, you can use the Pending for me filter to see only pending approval requests from all levels where you are an assigned approver.

1. If you are an assigned approver, you receive an email that provides the name of the requesting user, the catalog item, and a link to the request in the **Approvals** page in Automation Service Broker.

If you are someone who manages approvals, you can select **Inbox > Approvals** and continue with the following steps.

2. Locate the approval card for the notification.
3. Review the deployment details and the approval details, and approve or reject the request.

Required approvals are grouped into sequential levels. For example, if you are an assigned approver for deployment requests where level 1 and level 4 policies apply, then the approval details page shows the required approvals from the level 1 policies grouped under the Level 1 category, and the level 4 policies grouped under the Level 2 category.

If you are a user with administrative rights, you have the following options.

- Approve full request. You approve the request at all levels where you are an assigned approver. No other approvals are required so the request is approved.
- Approve current level. You approve the request at all levels where you are an assigned approver. The request is routed to the next level that is pending approval.
- Approve as an assigned approver. You approve the request at all levels where you are an assigned approver. If there are other approvers who have not responded, the request remains pending and is not routed to the next level until others approve the request.

If you reject the request, you must provide a reason that is included in the email message sent to the requester.

4. The system sends an email to the requester indicating that the request was approved or rejected.

## How do I track and respond to requests that require user input in Automation Service Broker

### How do I manage user input requests

As an Automation Service Broker consumer or an Automation Assembler user, you received an email notification about a deployment request for an Automation Orchestrator workflow that requires user input before it proceeds. The deployment might request you or another user to provide input. You can use these procedures to understand how your request is processed and how to respond to user input requests.

### How do I track my requests that require user input

You receive an email with the name of your deployment and the name of the first assignee on the list. The message includes a link to the deployment details where you can track responses to your request on the **User Events** tab.

- A VMware Aria Automation Orchestrator workflow that contains a manual user interaction element is added to the catalog. See [Add workflows to the catalog](#).
- To learn more about user interactions in VMware Aria Automation Orchestrator workflows, see [Requesting User Interactions While a Workflow Runs](#).

This procedure assumes that you received an email notification about the user input request, or that you noticed that your deployment did not progress.

1. Select **Consume > Deployments > Deployments**.

2. Locate your deployment request for the VMware Aria Automation Orchestrator workflow.

You notice a message on your deployment card. For example, your card displays `User Interaction Pending`.

3. To view a summary of your request, click the deployment name.

4. Click the **User Events** tab.

Until the user input request is answered, you see `USER_INTERACTION_IN_PROGRESS` and the list of users who must provide input.

5. If you are one of the response assignees, you see an input form.

Provide the information required for the workflow to proceed, and click **Submit**.

6. When your request is answered or rejected, you receive another email message.

If the user input request is rejected, your deployment request is cancelled.

The deployment details **History** tab displays `REQUEST_FAILED`.

### How do I respond to a user input request

When a VMware Aria Automation Orchestrator workflow that contains a user interaction element is requested in the Automation Service Broker catalog, the deployment remains in progress until the assigned users provide the required input.

- A VMware Aria Automation Orchestrator workflow that contains a manual user interaction element is added to the catalog. See [Add workflows to the catalog](#).
- To learn more about user interactions in VMware Aria Automation Orchestrator workflows, see [Requesting User Interactions While a Workflow Runs](#).

A VMware Aria Automation Orchestrator workflow can sometimes require additional input parameters while it runs. For example, if a certain event occurs while a workflow runs, the workflow can request user interaction to decide what course of action to take. The workflow waits before continuing, either until the assigned user responds to the request for information, or until the waiting time exceeds a possible timeout period.

If multiple users are listed as assignees that can respond to the input request, only one of them must answer or reject the request.

You can use the filter option to limit the number of the user input requests that you manage. For example, rather than all the requests that are waiting for input, you can use the Answered filter to see only requests that were answered by you or other assignees.

1. If a workflow requires your input, you receive an email that provides the name of the requesting user, the name of the requested workflow, and a link to the request in the **User Input Requests** page in Automation Service Broker. You can also select **Inbox > User Input Requests** in Automation Service Broker and continue with the following steps.
  2. Locate the card for the user input request.
  3. Review the request summary and input fields, and answer or reject the request.
    - Answer. Provide the required input, and click **Submit**.
    - Reject. If you reject a user input request, the deployment request for the workflow is cancelled.
  4. The system sends an email to the requester indicating that the user input request was answered or rejected.

## How do I manage resources in Automation Service Broker

### How do I manage resources

As an Automation Service Broker cloud administrator or catalog consumer, you can use the Deployments node on the Consume tab to manage your cloud resources.

You can locate and manage your resources using the different views. You can filter the lists, view resource details, and then run actions on the individual items. The available actions depend on the resource origin, for example, discovered compared to deployed, and the state of the resources.

If you are an Automation Assembler administrator, you can also view and manage discovered machines.

To view your resources, select **Consume > Deployments > Resources**.

You can use the **Projects** drop-down on the Consume tab to view only the resources that are available for a specific project.

### Viewing billable objects

As an Automation Assembler or an Automation Service Broker administrator, you can monitor what billable objects are used in your organization. Counted objects include billable virtual machines, CPUs, and cores that are in use at view time. It might take up to ten minutes for the object count data to refresh.

When viewing resource lists, you can use the Billable Resources Only filter in combination with other available filters.

| Name                                    | Power State | Address        | Origin   | Billable | Created On  |
|-----------------------------------------|-------------|----------------|----------|----------|-------------|
| Cloud_Machine_1-mcm1296120-245022878950 | On          | 44.211.218.190 | Deployed | ✓        | 8 days ago  |
| test-mcm1296541-244851762495            | Off         |                | Deployed | ✓        | 10 days ago |
| Cloud_Machine_1-mcm1295930-244833967033 | On          | 3.86.155.152   | Deployed | ✓        | 10 days ago |
| Cloud_Machine_1-mcm1293768-244245329772 | On          | 44.203.126.56  | Deployed | ✓        | 17 days ago |

If you force delete a deployment, the resource count might not match what is displayed in the resource list. You must delete the virtual machine from the corresponding IaaS layer, such as vCenter.

What is actually counted towards the bill depends on your VMware Aria Automation subscription commit contract and entitlement type.

To learn more about billing in VMware Aria Automation, see this [article](#).

### **Working with the resource lists**

You can use the resource list to manage the machines, storage volumes, and networks that make up your deployments. In the resource list you can manage them in resource type groups rather than by deployments.

Similar to the deployment list view, you can filter the list, select a resource type, search, sort, and run actions.

If you click the resource name, you can work with the resource in the context of the deployment details.

If your administrator turned on the Create new resource setting, Automation Service Broker viewers and administrators, and project members have the option to **Create New VM**. Administrators can turn on the setting by selecting **Infrastructure > Administration > Settings**. To control the amount of resources that Automation Service Broker users might deploy, it is likely that your administrator added approval policies to reject or approve any deployment requests based on the image used or the flavor or size requested.

**Figure 13: Resources page list**

| Name                                            | Power State | Account / Region          | Address       |
|-------------------------------------------------|-------------|---------------------------|---------------|
| Cloud_AWS_EC2_Instance_1-mcm875742-209927226509 | On          | aws-us-east-1 / us-east-1 | 54.146.171.35 |
| cloudgcpmachinet1-mcm1562-62                    | Off         | GCP / asia-east1          | 10.140.0.17   |
| ne_18-mcm852756-62                              | On          | aws-us-east-1 / us-east-1 | 54.173.72.224 |
| ne_1-mcm1069383-25                              | On          | blueprint-aws / us-east-1 | 54.147.36.132 |
| Cloud_Machine_1-mcm1069384-                     | On          | blueprint-aws / us-       | 3.239.9.191   |

1. Filter your list based on resource attributes.  
For example, you can filter based on project, cloud types, origin, or other attributes.
2. Search for resources based on name, account regions, or other values.
3. Run available day 2 actions that are specific to the resources type and the resource state.  
For example, you might power on a discovered machine if it is off. Or you might resize an onboarded machine.

### List of managed resources by origin

You can use the Resources tab to manage the following types of resources.

**Table 43: Resource origins**

| Managed Resource | Description                                                                                                                                                                                                                                                                                                        |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Deployed         | <p>Deployments are fully manage workloads that are deployed cloud templates or onboarded resources. The workload resources can include machines, storage volumes, networks, load balancers, and security groups.</p> <p>You can manage your deployments in the Deployments section.</p>                            |
| Discovered       | <p>Discovered resources are the machines, storage volumes, networks, load balancers, and security groups that the discovery process identified for each cloud account region that you added.</p> <p>Only Automation Assembler Administrators can see and manage discovered resources in the Resources section.</p> |
| Migrated         | <p>Migrated resources are the 7.x deployments that you migrated to VMware Aria Automation. The migrated resources can include machines, storage volumes, networks, load balancers, and security groups. Migrated resources are managed like deployments.</p>                                                       |

*Table continued on next page*

*Continued from previous page*

|           |                                                                                                                                                                                                                                                        |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|           | You can manage migrated resources in the Deployments section.                                                                                                                                                                                          |
| Onboarded | <p>Onboarded resources are discovered resources that you bring under more robust VMware Aria</p> <p>Automation management. Onboarded resources are managed like deployments.</p> <p>You can manage onboarded resources in the Deployments section.</p> |

### **What is the resource details view**

You can use the resource details view to get a deeper look at the selected resource. Depending on the resource, the details can include networks, ports, and other information collected about the machine. The depth of the information varies depending on cloud account type and origin.

To open the details pane, click the resource name or the double arrows.

**Figure 14: Resources details pane**

### **What day 2 actions can I run on resources**

The available day 2 actions depend on the resource origin, cloud account, resource type, and state.

**Table 44: List of actions by origin**

| Resource Origin | Day 2 Actions                                                                                                                                                                                                                                   |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Deployed        | The actions that are available to run on the resources depend on the resource type, cloud account, and state. For a detailed list, see <a href="#">What actions can I run on Automation Service Broker deployments or supported resources</a> . |

## How do I work with individual resources in Automation Service Broker

### Working with individual resources

As a cloud administrator or a project member with resources for your project, you can use the Resources page on the Consume tab to manage your deployed, onboarded, and migrated resources as individual resources by resource type. This workflow, which focuses on managing virtual machines, provides a guide for high-level resource life cycle management that you can apply to the other resource types.

### Locate virtual machine resources

Deployed, onboarded, and migrated virtual machines are available on the Resources page and the Managed tab on the Virtual Machines page. This example focuses on virtual machines, but you can apply the same workflow to the other resource types.

1. Select **Consume > Deployments > Virtual Machines > Managed**.
2. Locate your virtual machine.  
You can use the filters or the search to locate particular resources.

**Virtual Machines ▾**

Discovered Managed

Managed machines are those under full VMware Aria Automation management so that you can run day 2 actions. The managed machines included onboarded or deployed machines. Click New VM if you want to deploy a VM based on your current cloud provider OS image and size flavors.

+ NEW VM

Search resources

| Name                     | Deployment                   | VM State | Account / Region                                    | Address         | Project |

### Review the virtual machine details

The resource details provide a quick view of the machine information, including networks, custom properties, and other collected information.

1. Locate the machine in the Virtual Machines list.
2. Click the double arrows next to the resource name in the left column of the table.  
The details pane opens on the right side of the list.

## Virtual Machines ▾

Discovered Managed

Managed machines are those under full VMware Aria Automation management so that you can run day 2 actions. The managed machines included onboarded or deployed machines. Click New VM if you want to deploy a VM based on your current cloud provider OS image and size flavors.

The screenshot shows the VMware Aria Automation interface for managing virtual machines. On the left, there is a list of managed VMs with their names and icons. One specific VM, "mcm-20211203215331-000020", is selected and shown in a detailed view on the right. The detailed view includes sections for VM State (On), Address (34.74.168.22), Account / region (yingzhi-GCP / us-east1), Origin (Deployed), Deployment (Google Cloud Create VM\_6f6d0315-ddc8-4f5d-9ete-563cf49a836d), Tags, Volumes, Networks, and Custom Properties. The Volumes section lists two volumes: "create-vm-new-disk-1-524598563851" (4 GB, HDD) and "mcm-20211203215331-000020" (10 GB, HDD). The Networks section shows a single network interface "default" assigned to address 10.142.0.56 with a dynamic assignment type. The Custom Properties section lists several key-value pairs related to the VM's configuration.

| Name                      | Value                                                   |
|---------------------------|---------------------------------------------------------|
| resourceId                | 3b43b1a6-105c-4d68-8562-f84d545d07a0                    |
| zone_overlapping_migrated | true                                                    |
| project                   | 0952119a-7354-4dc2-af5-718755917230                     |
| zone                      | us-east1-b                                              |
| environmentName           | Google Cloud Platform                                   |
| providerId                | 1393403671676923083                                     |
| id                        | /resources/compute/3b43b1a6-105c-4d68-8562-f84d545d07a0 |

- To close the pane, click the double arrows or the resource name.

### **Run day 2 actions on the virtual machine**

You use the day 2 actions to manage your resources. The available actions depend on the resource type, the state of the resource, and the day 2 action policies that are enforced.

- Locate the machine in the Virtual Machines list.
- Click the vertical ellipsis to see the available actions.
- Click the action.

## Virtual Machines ▾

Discovered    Managed

Managed machines are those under full VMware Aria Automation management so that you can run day 2 actions. The managed machines included onboarded or deployed machines. Click New VM if you want to deploy a VM based on your current cloud provider OS image and size flavors.

|                          | Power Off                    |          |                                                    |                 |
|                          | Resize                       |          |                                                    |                 |
|                          | Resize Boot Disk             |          |                                                    |                 |
|                          | Resize Disk                  |          |                                                    |                 |
|                          | Update Tags                  |          |                                                    |                 |

### How do I work with discovered resources in Automation Service Broker

#### Working with discovered machines

If you are a Automation Service Broker administrator, you use the Resources page on the Consume tab to manage your discovered machines. Only administrators will see discovered resources on the various pages.

This workflow focuses on managing discovered virtual machines.

#### Locate discovered virtual machines

Discovered resources are collected from the cloud account region and added to the resources on the Deployments node on the Consume tab. This example focuses on virtual machines, but other resource types are collected, including storage and network information.

**1. Select **Consume > Deployments > Virtual Machines > Discovered.****

The screenshot shows the VMware Aria Automation interface. On the left, there's a navigation sidebar with sections like Projects, Catalog, Deployments, and Virtual Machines. Under Virtual Machines, 'Discovered' is selected. The main area is titled 'Virtual Machines' with a dropdown menu. Below it, tabs for 'Discovered' and 'Managed' are shown, with 'Discovered' being active. A note says: 'Discovered machines are identified when you add cloud accounts. You can run simple day 2 actions on the machines or click Onboard to bring the selected machines under full management, including robust day 2 management actions. You can only include 50 machines each time you run an onboarding action.' There's a search bar labeled 'Search resources'. The main table lists several AWS virtual machines:

|                          | Name                                            | Power State | Account / Region          | Address        |
|--------------------------|-------------------------------------------------|-------------|---------------------------|----------------|
| <input type="checkbox"/> | Cloud_AWS_EC2_Instance_1-mcm875742-209927226509 | On          | aws-us-east-1 / us-east-1 | 54.146.171.35  |
| <input type="checkbox"/> | Cloud_Machine_1.8-mcm852756-208729629562        | On          | aws-us-east-1 / us-east-1 | 54.173.72.224  |
| <input type="checkbox"/> | Cloud_Machine_1-mcm1069383-222049773325         | On          | blueprint-aws / us-east-1 | 54.147.36.132  |
| <input type="checkbox"/> | Cloud_Machine_1-mcm1069384-222049773325         | On          | blueprint-aws / us-east-1 | 3.239.9.191    |
| <input type="checkbox"/> | Cloud_Machine_1-mcm1069385-                     | On          | blueprint-aws / us-east-1 | 54.164.181.108 |

At the bottom, there are buttons for 'Manage Columns', 'Machines per page' (set to 20), and a page navigation section showing '1 - 20 of 143 machines'.

2. To locate the AWS virtual machines, click the **Filter** icon near the page label.

3. In the filter list, expand **Cloud Types** and select **AWS**.

The list is now limited to discovered AWS virtual machines. You can see deployed, discovered, and other origin types on the Managed tab.

4. To locate a particular machine, you can use the **Search resources** option to search by name, IP address, tags, or values.

In this example, `mysql` is the search term.

### **Review virtual machine details**

The resource details include all the collected information for the resource. You can use this information to understand the resource and any associations with other resources.

1. Locate the virtual machine in the Virtual Machine list.

2. To view the resource details, click the machine name or click the double arrows in the left column.

The details pane opens on the right side of the list.

3. Review the details, including storage, networks, custom properties, and other collected information.
4. To close the pane, click the double arrows or click the resource name.

### Run day 2 actions on the virtual machine

You use the day 2 actions to manage the resources. The current actions for discovered virtual machines includes Power On and Power Off. If you are managing a vSphere virtual machine, you can also run Connect with Remote Console.

1. Locate the machine in the Virtual Machines list.
  2. Click the vertical ellipsis to see the available actions.
- The possible actions for an AWS virtual machine are Power Off and Power On. Power On is not active because the machine is already on.
3. Click **Power Off** and submit the request.

When the process is completed, the machine is powered off. You can now power it back on.

### Onboarding virtual machines

You can quickly onboard discovered machines from the Virtual Machines page. Onboarding gets you full day 2 management capabilities for the onboarded resources. See [What actions can I run on Automation Service Broker deployments or supported resources](#).

- On the **Discovered** tab, select the machines that you want to onboard and then click **Onboard**. You can onboard up to 50 virtual machines at a time.

**Virtual Machines**

Discovered   Managed

Discovered machines are identified when you add cloud accounts. You can run simple day 2 actions on the machines or click Onboard to bring the selected machines under full management, including robust day 2 management actions. You can only include 50 machines each time you run an onboarding action.

| Name                                                                | Power State | Account / Region                                                                            | Created On  |

ONBOARD   **2**

Search resources   **1**

Manage Columns   Machines per page: 20   41 - 60 of 784 machines   3 / 40

- Follow the prompts in the onboarding wizard.

- Select a project for the machines.
- Select if you want to group the machines into a single deployment or if you want to create a separate deployment for each machine.
- Click **Next**.
- Review the deployment summary. You can update the deployment name and owner by clicking the deployment name.
- When you're done, click **Onboard**.

## Onboard Machines

Each onboarded machine is applied to your resource count

The screenshot shows the 'Onboard Machines' process in VMware Aria Automation. It consists of two main steps:

- Step 1: Onboard Settings** (Top Panel): A title bar with '1. Onboard Settings' and 'Choose a project or deployment plan for your machines'. Below it, a note says 'Cloud account resources are organized into projects so that you can later add users, apply governance, and delegate the project management to others.' A 'Project' dropdown is set to 'vmware-system-ccs'. Buttons for 'NEXT' and 'CANCEL' are at the bottom.
- Step 2: Deployment Summary** (Bottom Panel): A title bar with '2. Deployment Summary' and 'Review deployment structure and details'. It shows a table titled 'Machine Details' with three items:
 

| Name                                           | Type                  |
|------------------------------------------------|-----------------------|
| Cloud_vSphere_Machine_1-mcm198927-177909572476 | Cloud.vSphere.Machine |
| Cloud_vSphere_Machine_1-mcm199226-177909706836 | Cloud.vSphere.Machine |
| Cloud_vSphere_Machine_1-mcm199228-177910167328 | Cloud.vSphere.Machine |

 A note says 'Click the deployment name to modify the name and owner.' Buttons for 'ONBOARD' and 'CANCEL' are at the bottom.

The selected machines are onboarded.

3. To view the deployment, go to **Resources > Deployments** and then click the deployment name.
4. You manage your onboarded machines, go to **Virtual Machines > Managed**.

If you need to onboard more than 50 machines, you create an onboarding plan. See [What are onboarding plans](#).

## What actions can I run on Automation Service Broker deployments or supported resources

### What actions can I run on deployments or resources

After you deploy catalog items, you can run actions in Automation Service Broker to modify and manage the resources. The available actions depend on the resource type and whether the action is supported on a particular cloud account or integrated platform.

The available actions also depend on what your administrator entitled you to run.

As an administrator or project administrator, you can set up Day 2 Actions policies. See [How do I entitle deployment users to day 2 actions using policies](#).

You might also see actions that are not included in the list. These are likely custom actions that your administrator configured in Automation Assembler.

**CAUTION**

To change a deployment, you can edit its cloud template and reapply it, or you can use day 2 actions. However, in most cases you should avoid mixing the two approaches.

Lifecycle day 2 changes such as power on/off are usually safe, but others require caution, such as when adding disks.

For example, if you add disks with a day 2 action, and then take a mixed approach by reapplying the cloud template, the cloud template could overwrite the day 2 change, which might remove disks and cause data loss.

**Table 45: List of possible actions**

| Action   | Applies to these resource types | Available for these cloud types                                                                                                                              | Resource origin                                                                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|----------|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Add Disk | Machines                        | <ul style="list-style-type: none"> <li>• Amazon Web Service</li> <li>• Google Cloud Platform</li> <li>• Microsoft Azure</li> <li>• VMware vSphere</li> </ul> | <ul style="list-style-type: none"> <li>• Deployed</li> <li>• Onboarded</li> </ul> | <p>Add additional disks to existing virtual machines.</p> <p>If you add a disk to an Azure machine, the persistent disk or non-persistent disk is deployed in the resource group that includes the machine.</p> <p>When you add a disk to an Azure machines, you can also encrypt the new disk using the Azure disk encryption set configured in the storage profile.</p> <p>You cannot add a disk to an Azure machine with an unmanaged disk.</p> <p>When you add a disk to vSphere machines, you can select the SCSI controller, the order of which was set in the cloud template and deployed. You can also specify the unit number for the new disk. You cannot specify a unit number without a selected controller. If you do not select a controller or provide a unit number, the new disk is deployed to first available controller and assigned then next available unit number on that controller.</p> <p><b>NOTE</b><br/>Any virtual device that Automation Assembler processes must be configured with the SCSI controller.</p> <p>If you add a disk to a vSphere machine for a project with defined storage limits, the added disk must not exceed the storage limits. Storage limits consider the actual capacity for thick and thin resource provisioning so that you cannot over-provision using thin provisioning.</p> |

|                           |                                                                                                                  |                                                                                                                                                               |                                                                                   | If you use VMware Storage DRS (SDRS) and the datastore cluster is configured in the storage profile, you can add disks on SDRS to vSphere machines.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Attach SaltStack Resource | Machines                                                                                                         | <ul style="list-style-type: none"> <li>• Amazon Web Services</li> <li>• Google Cloud Platform</li> <li>• Microsoft Azure</li> <li>• VMware vSphere</li> </ul> | <ul style="list-style-type: none"> <li>• Deployed</li> <li>• Onboarded</li> </ul> | <p>Attach a SaltStack Resource to a deployment resource so that you can install a Salt minion and update the Salt configuration on the virtual machine. You can use this action to update a configuration on a resource or attach the resource and install the minion on another resource in the deployment.</p> <p>The Attach Salt Resource action is available if you configured the SaltStack Config integration.</p> <p>To apply a configuration, you must select an authentication method. The <b>Remote access with existing credentials</b> uses the remote access credentials that are included in the deployment. If you changed the credentials on the machine after deployment, the action can fail. If you know the new credentials, use the <b>Password</b> authentication method.</p> <p>The <b>Password</b> and <b>Private key</b> use the user name and the password or key to validate your credentials and then connect to the virtual machine using SSH.</p> <p>If you do not provide a value for the Master ID and Minion ID, Salt creates the values for you.</p> |
| Cancel                    | <ul style="list-style-type: none"> <li>• Deployments</li> <li>• Various resource types in deployments</li> </ul> | <ul style="list-style-type: none"> <li>• Amazon Web Service</li> <li>• Google Cloud Platform</li> <li>• Microsoft Azure</li> <li>• VMware vSphere</li> </ul>  | <ul style="list-style-type: none"> <li>• Deployed</li> <li>• Onboarded</li> </ul> | <p>Cancel a deployment or a day 2 action on a deployment or a resource while the request is being processed.</p> <p>You can cancel the request on the deployment card or in the deployment details. After you cancel the request, it appears as a failed request on the <b>Deployments</b> page. Use the <b>Delete</b> action to release any deployed resources and clean up your deployment list.</p> <p>Canceling a request that you think has been running too long is one method for managing deployment time. However, it is more efficient to set the <b>Request Timeout</b> in the projects. The default timeout is two hours. You can set it for a longer period of time if the workload deployment for a project requires more time.</p>                                                                                                                                                                                                                                                                                                                                      |
| Change Display Name       | Disk                                                                                                             | <ul style="list-style-type: none"> <li>• Amazon Web Service</li> <li>• Microsoft Azure</li> <li>• VMware vSphere</li> </ul>                                   | <ul style="list-style-type: none"> <li>• Deployed</li> <li>• Onboarded</li> </ul> | <p>Change the name of a disk to a meaningful display name.</p> <p>This action changes the display name in:</p> <ul style="list-style-type: none"> <li>• Topology (Node view)</li> <li>• Topology (Tree view)</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## How to move a deployed machine to another network

While maintaining deployments and networks, you might need the ability to relocate machines that you deployed with Automation Assembler.

- The Automation Assembler network profile must include all subnets that the machine will connect to. In Automation Assembler, you can check networks by going to **Infrastructure > Configure > Network Profiles**. The network profile must be in an account and region that are part of the appropriate Automation Assembler project for your users.
- Tag the two subnets with different tags. The example that follows assumes that `test` and `prod` are the tag names.
- The deployed machine must keep the same IP assignment type. It can't change from static to DHCP, or vice versa, while moving to another network.

For example, you might deploy to a test network first, then move to a production network. The technique described here lets you design a cloud template in advance to prepare for such day 2 actions. Note that the machine is moved. It isn't deleted and redeployed.

This procedure only applies to `Cloud.vSphere.Machine` resources. It won't work for cloud agnostic machines deployed to vSphere.

1. In Automation Assembler, go to **Design**, and create a cloud template for the deployment.
2. In the inputs section of the code, add an entry that lets the user select a network.

```
inputs:
 net-tagging:
 type: string
 enum:
 - test
 - prod
 title: Select a network
```

3. In the resources section of the code, add the `Cloud.Network` and connect the vSphere machine to it.
4. Under the `Cloud.Network`, create a constraint that references the selection from the inputs.

```
resources:
 ABCServer:
 type: Cloud.vSphere.Machine
```

```

properties:
 name: abc-server
 ...
networks:
 - network: '${resource["ABCNet"].id}'

ABCNet:
 type: Cloud.Network
 properties:
 name: abc-network
 ...
constraints:
 - tag: '${input.net-tagging}'

```

5. Continue with your design, and deploy it as you normally would. At deployment, the interface prompts you to select the `test` or `prod` network.
6. When you need to make a day 2 change, go to **Resources > Deployments > Deployments**, and locate the deployment associated with the cloud template.
7. To the right of the deployment, click **Actions > Update**.
8. In the Update panel, the interface prompts you the same way, to select the `test` or `prod` network.
9. To change networks, make your selection, click **Next**, and click **Submit**.

### **Deployment properties that you cannot update using day 2 actions in VMware Aria Automation**

#### Properties excluded from day 2 action changes

Day 2 actions are changes that you can make to deployed resources. There are limits to the changes that you can make using the actions. There are some properties that you cannot change using certain actions. Review the list of excluded properties if you expected a change but nothing was modified.

#### **Storage Properties**

The following storage properties cannot be modified using the **Update** deployment action.

**Table 46: List of excluded properties**

| Deployment Component | Property                       |
|----------------------|--------------------------------|
| Cloud.Machine        | storage - bootDiskCapacityInGB |
| Cloud.Machine        | storage - maxDiskCapacityInGB  |
| Cloud.Machine        | storage - constraints          |
| Cloud.Volume         | encrypted                      |

## Working with the Cloud Consumption Interface

With a flexible VMware Aria Automation-based feature set, the Cloud Consumption Interface (CCI) enables DevOps users to work with vSphere namespaces and associated services to deliver simple, self-service consumption of Kubernetes and cloud infrastructure resources for VMware Cloud environments.

CCI exposes Supervisor IaaS services across the vSphere infrastructure and aggregates them into a common endpoint that can be accessed through a graphical web console, the CCI plug-in CLI, or the IaaS API for self-service access across

vSphere-based cloud.

As a user, you can create Supervisor Namespaces that consume supervisor IaaS services such as the VM service and the Tanzu Kubernetes Grid Service.

After creating the namespace, UI workflows guide you through the process of creating virtual machines, TKG clusters, and other resources. As you work through the creation wizards, CCI automatically generates corresponding Kubernetes YAML files that you can download locally. These Kubernetes YAML files can also be used to provision similar IaaS resources using the kubectl CCI plug-in command line.

#### **NOTE**

You can also create namespaces and resources such as VMs and TKG clusters after an Automation Assembler administrator creates a VMware cloud template backed catalog item that contains CCI resources. See [Automating Kubernetes-based workloads in Automation Assembler](#).

For information about Deploying the Opencart Application using CCI, see the video <http://bit.ly/3fttsiS>.

## **Getting Started with the Cloud Consumption Interface in Automation Service Broker**

### Getting started with CCI in Automation Service Broker

The Cloud Consumption Interface (CCI) enables Automation Service Broker DevOps users to provision Supervisor namespaces and use its associated services to create Kubernetes workloads using mainly the VM Service and the Tanzu Kubernetes Grid Service within vSphere namespaces.

The Cloud Consumption Interface uses VMware Aria Automation projects and infrastructure and vSphere Kubernetes resources as the foundation on which CCI users can work with namespaces and associated services to create virtual

machines and other resources. Services are pluggable UIs that follow SDK guidelines. They are built and tested as separate applications that have been incorporated into CCI.

CCI provides wizards that guide you through the process of using services to create virtual machines, and other resources. When working with services, CCI automatically generates YAML code that users can download to use as the basis of deployments or IaaS resources.

To configure virtual machines or other resources for deployment using CCI, you log in to Automation Service Broker, click the **Consume** tab and select **Supervisor Namespaces**. A **Welcome** page displays projects containing the namespace classes that are available to you.

Namespace classes are defined by administrators and function as templates that reserve resources for the namespaces that users create. After you select a namespace class, you can create a new namespace. The namespace is your personal workspace with a set of resources and services.

If you dismiss the **Welcome** page, you can also start working from the CCI **Home** page. This page lists the namespaces and projects available to you on separate tabs. In addition, the tree view on the left shows a list of available projects, and you can expand it to view the namespace classes within each project. By default, neither of these pages are displayed for administrative users.

Project membership determines access to either cloud zones, Kubernetes zones, or both, and each of the following scenarios describes what you will see depending on your level of project access.

- Users who are members of a project that is only configured with Kubernetes zones will see the Supervisor Namespaces node for CCI on the left menu for the Consume tab, but they will not see or have access to the Catalog or Deployments nodes on the Automation Service Broker left menu pane.
- Users who are members of a project that is only configured with cloud zones will see the Catalog and Deployments nodes on the left menu, but they will not see or have access to CCI through the Supervisor Namespaces node.
- Users who are members of a project that is configured with both cloud zones and Kubernetes zones have access to the Supervisor Namespaces node and to the Catalog and Deployments nodes on the Automation Service Broker left menu.

#### **NOTE**

Namespaces and other resources created in CCI are unique to that environment. Because they are managed by VMware Aria Automation, users should not attempt to manage them in other applications and products such as vCenter.

### **Create a Supervisor Namespace**

The Automation Service Broker Cloud Consumption Interface (CCI) enables users to create supervisor namespaces and then provision virtual machines and other deployable workloads.

A cloud administrator must configure CCI for VMware Aria Automation users. See [Cloud Consumption Interface setup and configuration](#).

Supervisor Namespaces are vSphere-based Kubernetes entities that enable you to provision vSphere workloads, such as vSphere pods, TKGs, and VMs. Different projects can have access to different supervisor namespaces classes that users can use to provision new supervisor namespaces. Administrators can configure each of the assigned supervisor namespace classes with different configurations based on the project needs.

#### **NOTE**

A VMware Aria Automation administrator might have already created a Supervisor Namespace by deploying a catalog item that is backed by a template with CCI resources in Automation Assembler. See [Using the CCI elements in VMware Aria Automation templates](#).

1. Log in to Automation Service Broker, click the **Consume** tab and select **Supervisor Namespaces**.

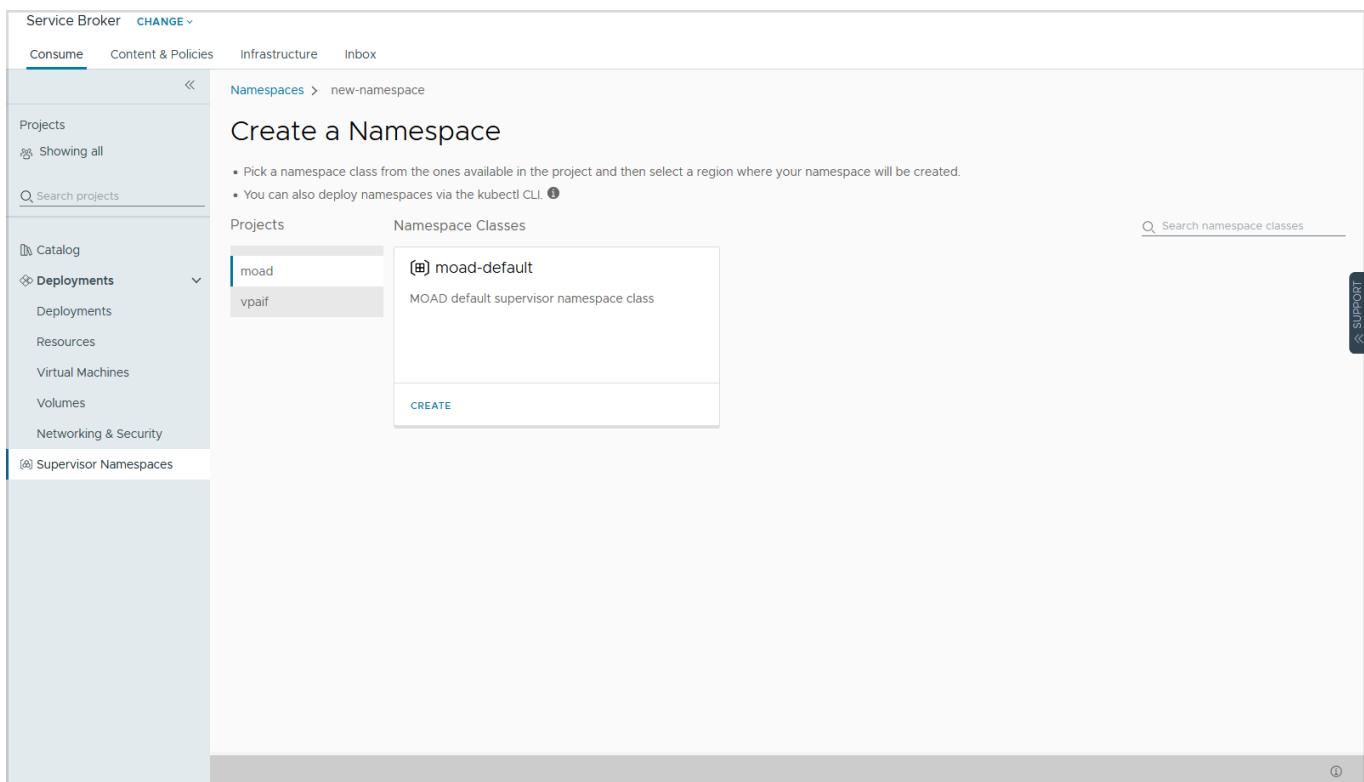

To create a new namespace, you start on the Getting Started with supervisor namespaces of the Supervisor namespace home page. Both pages provide access to components based on user profiles. Each project configured for you provides access to one or more namespace classes that you can use to provision a supervisor namespace.

- If there are no existing Supervisor namespaces that you can access the **Getting Started with supervisor namespaces** page appears. Click **New Namespace**.

The screenshot shows the Service Broker interface with the 'CHANGE' tab selected. The left sidebar shows 'Supervisor Namespaces' is currently selected. The main content area is titled 'Getting started with supervisor namespaces'. It contains several sections with instructions:

- Key concepts:**
  - Projects are groups of users that have access to parts of regions. Namespaces are created within projects.
  - Every resource here is deployed within a supervisor namespace that is part of a project.
  - Resources in the namespaces are deployed by vSphere Services that act as standard Kubernetes operators.
- Get access to a (supervisor) namespace:**
  - A supervisor namespace behaves like a regular Kubernetes namespace, but can contain custom resources like pod VMs and TKG Kubernetes clusters.
  - Projects you have been added to are available in the project selector. Namespaces you can access are listed under each project.
  - You can create your own namespace in a project depending on the project settings.
- + NEW NAMESPACE**
- Deploy Infrastructure:**
  - Select a namespace you have access to in the project's list of namespaces.
  - Resources you can deploy are displayed as cards. Different namespaces might be able to deploy different resources.
  - Click "Open" on the card to provision a resource.
- Download CLI plugin:**
  - You can use the familiar syntax of Kubectl CLI to perform all supervisor namespace tasks.
  - Download & extract our kubectl plugin to your \$PATH.
  - Login using your company SSO credentials by performing kubectl cci login.
  - Try accessing your resources: kubectl cci get namespace.

- If there are existing Supervisor namespaces that you can access, the Supervisor namespace home page appears. Click **New Supervisor Namespace**.
- On one of the available Namespace classes, click **Create** to begin creating a namespace based on that class. Namespace classes function as templates for namespaces.

### 3. Create a namespace.

- For **Name** and **Description**, enter basic identifying information for the project.
- For **Region**, select a regions based on your project region entitlement set by the cloud administrator. Regions are grouping mechanisms created by administrators that group Supervisor clusters across one or more vCenters.

New Namespace

|                                                        |                                                       |
|--------------------------------------------------------|-------------------------------------------------------|
| Project                                                | moad                                                  |
| Namespace class                                        | moad-default                                          |
| Sharing                                                | This namespace is accessible to all project users.    |
| Name                                                   | <u>name-must-be-lowercase-and-only-allows-hyphens</u> |
| May contain lowercase alphanumeric characters and "-". |                                                       |
| Description                                            | (Empty text area)                                     |
| Region                                                 | tmm-us-west                                           |
| <small>The TMM US West region</small>                  |                                                       |
| <span>CANCEL</span> <span>CREATE</span>                |                                                       |

4. Click **Create**.

The namespace appears on the list of namespaces for the applicable project. The Cloud Consumption Interface will select the appropriate supervisor within the specified region to create the namespace for the infrastructure resources specified.

After you create a namespace, click it to view the options for creating and working with workloads within that namespace. The namespace includes services that help you to create workloads. For example, you can click the Virtual Machine service to view existing virtual machines and initiate a wizard to help you create a new virtual machine.

Users with the appropriate privileges can view more details about a supervisor namespace by clicking the **Supervisor Namespaces** tab on the **Infrastructure > Resources > Supervisors** page.

### Working with the Virtual Machine service

Services in CCI are pluggable modules that help users create resources, such as virtual machines. These services can be incorporated into CCI to create a seamless experience for DevOps users working with services in a Kubernetes context.

#### Create a Virtual Machine

The following procedure shows how to use the Virtual Machine service to deploy a VM in your Supervisor namespace.cluster wizard.

1. On the **Supervisor Namespaces** page, click your namespace.
2. Under Services, click **Open** on the Virtual Machine service tile.
3. On the **Virtual Machine service** page, click **Create VM**.  
A wizard guides you through the process of creating a new virtual machine.

- a. Type a VM name.
- b. Select a VM image.
- c. Select a VM class. The class selection defines the resources available within the virtual machine.
- d. If you want to specify additional resources that are available within the virtual machine, click **Go to Advanced Settings**, add your information, then click **Next**.
- e. If you do not want to specify advanced settings, click **Review and Confirm**.  
The YAML code that defines the machine is displayed in the YAML section at the right side of the page. To download a zipped copy of the YAML file generated by the wizard, click the **Download .Zip** button.
- f. After confirming the VM configuration as shown in the YAML code, click **Deploy VM**.

You can copy and paste the virtual machine YAML code into a command line, incorporate it into a GIT repository as a GitOps style workflow, or use it in some other capacity as an IaaS object.

### **View and edit a Virtual Machine**

For example, to manage a virtual machine that you deployed on a namespace, you can use the Virtual Machine service.

1. On the **Supervisor Namespaces** page, click your namespace.
2. Under Services, click **Open** on the Virtual Machine service tile.
3. Click the virtual machine name. On the details page that appears, you can:
  - Use the **Power State** button to switch the machine from powered on to powered off.
  - Click the **Attach Volume** button to add disk volumes in specified sizes to the virtual machine.

If you want to see other objects associated with virtual machines on the namespace, open the Virtual Machine service tile and click the **Related objects** tab.

### **Working with the Tanzu Kubernetes Grid service**

After you create a namespace in the Cloud Consumption Interface (CCI), you can select or create a Tanzu Kubernetes Grid cluster that you can deploy on a Supervisor or use as an IaaS resource.

### **Create a TKG cluster**

To create a new Tanzu Kubernetes cluster associated with the namespace, you use the TKG cluster wizard. As you work through the wizard, the pane on the right side of the page displays the YAML code for the cluster you are creating. The following procedure describes how to use the new Tanzu Kubernetes cluster wizard.

1. On the **Supervisor Namespaces** page, click your namespace.
2. Under Services, click **Open** on the Tanzu Kubernetes Grid service tile.
3. On the Tanzu Kubernetes Grid service page, click **Create**.

A wizard guides you through the process of creating a new cluster.

- a. For the configuration type, select the cluster type and the configuration that you want to use to provision the cluster.  
For the configuration, you can choose either the default configuration or a custom configuration based on the v1alpha2 API. If you select **Custom Configuration**, additional configuration settings appear:
  - General Settings. To define storage and networking for the cluster.
  - Control Plane. To define the topology of the cluster controller.
  - Nodepools. To define a group of worker nodes sharing the same resource allocation and storage.
- b. Click **Next** to review and confirm.  
The YAML code that defines the TKG cluster is displayed in the YAML section at the right side of the page. To download a zipped copy of the YAML file generated by the wizard, click the **Download .Zip** button.
- c. After confirming the TKG cluster configuration as shown in the YAML code, click **Finish**.

## **View and edit a TKG cluster**

After you create a TKG cluster, you can click the cluster name on the TKG Services page to display summary information for that instance. Using selections on the summary page, you can:

- Edit the control plane for the number of replicas or for the specified virtual machine class.
- Edit the nodepools for the number of replicas or for the specified virtual machine class.
- Add Volumes to the cluster.
- Download the kubeconfig file that you can use to interact with the TKG cluster instead of using CCI to login to the provisioned TKG cluster.

## **Working with the Volume service**

After you create a namespace, you can create storage volumes in the Cloud Consumption Interface, for use in deployments or in IaaS workflows.

The following procedure describes how to create a new volume associated with the namespace

1. On the **Supervisor Namespaces** page, click your namespace.
2. Under Services, click **Open** on the Volume service tile.
3. On the Volume service page, click **Create**.

A wizard guides you through the process of creating a new volume.

- a. Type a name for the volume.
  - b. Select the **Storage Class** and enter a **Capacity** for the volume.
  - c. Select the **Access Modes** for the volume. The options are:
    - Read Write Once
    - Read Write Many
 Read Write Many is only supported when the vSAN file service is enabled.
  - d. Click **Next** to review and confirm.
- The YAML code that defines the volume is displayed in the YAML section at the right side of the page. To download a zipped copy of the YAML file generated by the wizard, click the **Download .Zip** button.
- e. After confirming the volume configuration as shown in the YAML code, click **Finish**.

To see all storage classes associated with volumes on the namespace, open the Volume service tile and click the **Storage Classes** tab.

## **Other CCI Command Line Interface options**

CCI provides a command line interface (CLI) that enables users to access the CCI API. The CLI supports all UI actions as well as a number of additional actions that are not supported by the UI.

Administrators can manually configure infrastructure resources using the CLI. To use the CLI, the administrator downloads and configures a kubectl plug-in that CCI provides. See [Preparing to use the Command Line Interface to perform CCI tasks](#).

In addition, there are cases in which users might need to use the Aria Automation API to support CCI functionality.

### **Create Supervisor Namespaces and infrastructure resources using kubectl**

Create Supervisor Namespaces and infrastructure resources using kubectl

As a DevOps user, you can create a Supervisor Namespace and create infrastructure resources within the namespace using CCI kubectl commands. These examples show how to create a Supervisor Namespace and add a VM to the namespace.

## **Prerequisites**

- Verify that a Automation administrator has set up the Cloud Consumption Interface infrastructure. See [Setting up the CCI infrastructure using kubectl](#).
- Verify that you are member of at least one project in Automation Service Broker.
- Verify that you are at least an organization member in Automation with the Automation Service Broker User service role.
- Verify that you have:
  - Downloaded the CCI kubectl plug-in.
  - Obtained an API token for the User service role and assigned it as a variable.  
TOKEN='<your\_API\_token>'
  - Used your token to log in to the CCI server.

See [Preparing to use the Command Line Interface to perform CCI tasks](#).

## **Create a Supervisor Namespace**

This example shows how to create a Supervisor Namespace named ns-for-devops-example.

Using kubectl commands, you collect information for the following resources:

- Project
- Region Binding
- Supervisor Namespace Class Binding

Then you add the metadata and specifications to a YAML file to create the Supervisor Namespace.

1. Set the default context to CCI.

```
kubectl config use-context cci
```

2. List available projects.

```
kubectl get projects
```

The result lists the projects that you are in.

| NAME | SHARED RESOURCES |
|------|------------------|
|------|------------------|

```
cci-document true
```

3. List the regions in cci-document.

```
kubectl get regionbinding -n cci-document
```

The result shows all the regions in the project.

| NAME | AGE |
|------|-----|
|------|-----|

```
us-docs-1 2d13h
```

4. List the supervisor namespace classes in cci-document.

```
kubectl get supervisornamespaceclassbinding -n cci-document
```

The result shows all the supervisor namespace classes in the project.

| NAME | AGE |
|------|-----|
|------|-----|

```
docs-class 2d13h
```

5. Create a YAML file for the Supervisor Namespace that you want to create. The following example creates a namespace with:

- cci-document for the project.

- us-docs-1 for the region.

- docs-class for the namespace class.

```
apiVersion: infrastructure.cci.vmware.com/v1alpha1
```

```
kind: SupervisorNamespace
```

```

metadata:
 name: ns-for-devops-example
 namespace: cci-document
spec:
 description: Create_Namespace_example
 regionName: us-docs-1
 className: docs-class

```

6. With the YAML file as input, create a supervisor namespace. In this example, the YAML file is in the same directory as the `kubectl` application.

```
kubectl create -f Create_Supervisor_Namespace.yaml
```

7. Check the status of the supervisor namespace in `cci-document`.

```
kubectl describe supervisornamespace ns-for-devops-example -n cci-document
```

When the result shows `Status: True` and `Type: Ready`, the supervisor namespace is ready to use and appears in the UI:

- For Automation Service Broker, go to **Consume > Supervisor Namespace**.
- For Automation Assembler, go to **Infrastructure > Resources > Supervisors**.

```

Name: ns-for-devops-example
Namespace: cci-document
Labels: <none>
Annotations: infrastructure.cci.vmware.com/wcp-address: 192.168.0.2
API Version: infrastructure.cci.vmware.com/v1alpha1
Kind: SupervisorNamespace

```

#### Metadata:

```

Creation Timestamp: 2023-07-31T17:30:49Z
UID: b2f65844-d545-4a5f-976d-381e079275b1

```

#### Spec:

```

Class Name: docs-class
Class Parameters:

```

```
Description: Create_Namespace_example
```

```
Region Name: us-docs-1
```

#### Status:

##### Conditions:

```
Last Transition Time: 2023-07-31T17:30:50Z
```

```
Status: True
```

```
Type: Ready
```

- Phase: Created
- Events: <none>
8. If you want to delete the supervisor namespace, provide the name of the namespace, the name of the project, and include the --force flag.
- ```
kubectl delete supervisornamespace ns-for-devops-example -n cci-document --force
```

Add a VM to the Supervisor Namespace

This example shows how to create a VM named VM-for-devops-example.

Using kubectl commands, you collect information for the following resources:

- Virtual Machine Class
- Virtual Machine Image
- Storage Class

Then you add resource specifications to a YAML file to create the VM.

1. Log in to the CCI server again and verify that you see the newly created Supervisor Namespace in the response.

```
kubectl cci login --server api.mgmt.cloud.vmware.com --token $TOKEN
```

```
Logging into api.mgmt.cloud.vmware.com
```

```
Getting supervisor namespaces
```

```
Successfully logged into api.mgmt.cloud.vmware.com
```

```
Created kubeconfig contexts:
```

```
cci
cci:cci-document:ns-7lan
cci:cci-document:ns-for-devops-example
cci:supervisor:gp-namespace
```

2. Set the default context so that you do not need to specify the namespace with context in every command.

```
kubectl config use-context cci:cci-document:ns-for-devops-example
```

The result confirms that the context has been switched and every subsequent command will be in the context of cci:cci-document:ns-for-devops-example.

```
Switched to context "cci:cci-document:ns-for-devops-example".
```

3. List available virtual machine classes.

```
kubectl get virtualmachineclasses
```

Select one of the virtual machine classes from the result.

NAME	CPU	MEMORY	AGE
best-effort-2xlarge	8	64Gi	2d15h
best-effort-4xlarge	16	128Gi	2d15h
best-effort-8xlarge	32	128Gi	2d15h
best-effort-large	4	16Gi	2d15h
best-effort-medium	2	8Gi	2d15h
best-effort-small	2	4Gi	2d15h

best-effort-xlarge	4	32Gi	2d15h
best-effort-xsmall	2	2Gi	2d15h
guaranteed-2xlarge	8	64Gi	2d15h
guaranteed-4xlarge	16	128Gi	2d15h
guaranteed-8xlarge	32	128Gi	2d15h
guaranteed-large	4	16Gi	2d15h
guaranteed-medium	2	8Gi	2d15h
guaranteed-small	2	4Gi	2d15h
guaranteed-xlarge	4	32Gi	2d15h
guaranteed-xsmall	2	2Gi	2d15h

4. List available virtual machine images.

```
kubectl get virtualmachineimages
```

Select the image that you want to use.

NAME FORMAT	PROVIDER-NAME AGE	CONTENT-LIBRARY-NAME VERSION	IMAGE-NAME OS-TYPE
vmi-02549e2ab956621e9 OVF	clitem-02549e2ab956621e9 143m	cl-c7a511c539dddc1f1	ubuntu64Guest
groovy-20210415.1-with-ovt-11.3 OVF	clitem-041ff2740d6aeee34a 143m	cl-c7a511c539dddc1f1	ubuntu64Guest
vmi-041ff2740d6aeee34a OVF	clitem-041ff2740d6aeee34a 143m	cl-c7a511c539dddc1f1	jammy- ubuntu64Guest

5. To list available storage policies, use the command to get resource quotas.

```
kubectl get resourcequota
```

The first section of the request is the storage policy.

NAME	AGE	REQUEST	LIMIT
ns-for-devops-example-storagequota	6m22s	wcpglobal-storage-profile.storageclass.storage.k8s.io/requests.storage:	0/9223372036854775807

6. Create a YAML file for the VM that you want to add to the Supervisor Namespace. The following example creates a VM with:

- ns-for-devops-example for the namespace.
- vmi-02549e2ab956621e9 for the VM image.
- guaranteed-small for the VM class.
- wcpglobal-storage-profile for the storage policy.

```
apiVersion: vmoperator.vmware.com/v1alpha1
```

```

kind: VirtualMachine
metadata:
  name: VM-for-devops-example
  namespace: ns-for-devops-example
spec:
  imageName: vmi-02549e2ab956621e9
  className: guaranteed-small
  storageClass: wcpglobal-storage-profile
  powerState: poweredOn

```

- With the YAML file as input, create a VM in the supervisor namespace. In this example, the YAML file is in the same directory as the kubectl application.

```
kubectl create -f Create_VM.yaml
```

- Check the status of the VM creation in ns-for-devops-example.

```
kubectl describe virtualmachine vm-for-devops-example -n ns-for-devops-example
```

When the result shows three Status: True for Type: GuestCustomization, Type:

VirtualMachinePrereqReady, and Type: VirtualMachineTools , the VM has been successfully created in the supervisor namespace.

```
Name:          vm-for-devops-example
Namespace:    ns-for-devops-example

```
kubectl delete virtualmachine vm-for-devops-example -n ns-for-devops-example --force
```

Kubernetes API Reference for the Cloud Consumption Interface

Kubernetes API Reference for the Cloud Consumption Interface

Administrators and developers can act on Cloud Consumption Interface (CCI) API resources that the CCI Kubernetes API server exposes.

Depending on the resource kind, administrators and developers can use the API to perform the following actions.

Resource kind	Admin action verbs	Developer action verbs
<code>CloudAccount</code>	get, list	
<code>Supervisor</code>	get, patch, list	
<code>Project</code>	create, get, update, patch, delete, list	get, list
<code>ProjectRole</code>	get, list	get, list
<code>ProjectRoleBinding</code>	create, get, update, patch, delete, list	get, list
<code>Region</code>	create, get, update, patch, delete, list	get, list
<code>RegionBinding</code>	create, get, update, patch, delete, list	get, list
<code>RegionBindingConfig</code>	create, get, update, patch, delete, list	
<code>SupervisorNamespaceClass</code>	create, get, update, patch, delete, list	get, list
<code>SupervisorNamespaceClassConfig</code>	create, get, update, patch, delete, list	
<code>SupervisorNamespaceClassBinding</code>	create, get, update, patch, delete, list	get, list
<code>SupervisorNamespace</code>	create, get, delete, list	create, get, delete, list

The following examples show the CLI call and responses. Using the CLI requires that you have:

- Downloaded the CCI kubectl plug-in.
- Obtained an API token.
- Logged in to the CCI server.

See [Preparing to use the Command Line Interface to perform CCI tasks](#)

Projects and Users

Project

Administrators create projects to group users and set access to content sources such as cloud templates in Automation Assembler or to catalog items in Automation Service Broker.

`Project` includes the following properties:

- `metadata.name` Project name.
- `spec.description` Optional description.
- `spec.sharedResources` If true, the project shares the Supervisor Namespaces with other users in the project. If false, the project limits namespace access to administrators or the user who created the namespace.

Create project example input.

```

apiVersion: project.cci.vmware.com/v1alpha1
kind: Project
metadata:
  name: demo-project
spec:
  description: This is a demo project
  sharedResources: true

```

Project Role

The project role reflects the available roles of admin, view, or edit that can be assigned to a user in a project.

Project Role	Description
admin	Allows modification and deletion of the namespace.
view	A read-only role on the namespace.
edit	Allows modification of the namespace.

The project roles are read-only and provide available roles when creating the project role binding.

Read project role example input.

```
apiVersion: authorization.cci.vmware.com/v1alpha1
```

```

kind: ProjectRole
metadata:
  name: admin
spec:
  description: project administrator

```

Project Role Binding

Project role binding is used to assign membership to a user or group a role in a project.

ProjectRoleBinding includes the following properties:

- `metadata.name` Name of the project role binding and requires a specific format to reflect the subject type (user or group) and subject name:
`cci:<user/group>:<subject domain>:<subject name>`
- `metadata.namespace` Describes the project name.
- `subjects` Describes the user or group. Only one entry is allowed.
- `roleRef` Describes the role.

Create project role binding example input.

```
apiVersion: authorization.cci.vmware.com/v1alpha1
```

```

kind: ProjectRoleBinding
metadata:
  # name must match the subject kind and name
  name: cci:user:vmware.com:hello

```

```

namespace: demo-project
subjects:
- kind: User # User / Group
name: hello@vmware.com
roleRef:
apiGroup: authorization.cci.vmware.com
kind: ProjectRole
name: admin # admin / edit / view

```

vCenters and Supervisors

This category deals with infrastructure and its functions are for administrators only.

Cloud Account

Cloud accounts are created automatically by vSphere+ or manually by an administrator to register a vCenter and enable datacenters with Supervisors.

Create cloud account example output.

```

Name: cci-ui-volume-service
Namespace: cci-config
Labels: <none>
Annotations: infrastructure.cci.vmware.com/data-collection-status: FINISHED
             infrastructure.cci.vmware.com/last-data-collection-timestamp:
2022-10-24T22:06:08.603Z
API Version: infrastructure.cci.vmware.com/v1alpha1
Kind: CloudAccount
Metadata:
Creation Timestamp: 2022-10-17T12:18:28Z
UID: 2163e7cf-f698-3f1f-afca-f3daa8c730fa
Spec:
Address: 127.193.29.114
Cloud Proxy Name: 2d164fed-bbf3-47cc-8e6b-5226c5277ee4
Events: <none>

```

Supervisor

A Supervisor is created by the system after vCenter data collection has completed. The administrator can update the Supervisor with capability labels for placement and assign it to a region.

- `metadata.labels` Administrators define labels with key-value settings that reflect Supervisor capabilities.
Labels are used to filter Supervisors based on capabilities when creating a namespace.

- `spec.regionNames` Administrators define region names so that a Supervisor can be assigned to a region. A Supervisor can only be assigned to a single region and is not assigned to a region by default.

Update Supervisor example output.

```
Name: bugbash-vc:domain-c8
Namespace: cci-config
Labels: environment=bug-bash-9
Annotations: infrastructure.cci.vmware.com/cloud-account-id: 33a0b2d0-91c8-4629-b04a-65448494d54e
API Version: infrastructure.cci.vmware.com/v1alpha1
Kind: Supervisor
Metadata:
Creation Timestamp: 2022-09-28T04:22:38Z
UID: fbd10d08-bc56-4ec2-93f8-693a7a4b2003
Spec:
Cloud Account Name: bugbash-vc
Display Name: wcp-test-dc-cluster
External Id: domain-c8
Region Names:
us-demo1
Status:
Power State: On
Events: <none>
```

Topology

Region

An administrator creates regions as a grouping mechanism for one or more Supervisors. Regions can be based on various parameters such as geography or infrastructure, and they can include Supervisors from multiple vCenters.

Create region example input.

```
apiVersion: topology.cci.vmware.com/v1alpha1
kind: Region
metadata:
name: us-west1
spec:
description: The us-west1 region
```

Region Binding

An administrator creates Region Bindings to associate regions with projects.

For a user in a project to create to Supervisor Namespaces, both **RegionBinding** and **RegionBindingConfig** must exist.

RegionBinding includes the following properties:

- `metadata.name` Region name and must match an existing region.
- `metadata.namespace` Project name.

Create Region Binding example input.

```
apiVersion: topology.cci.vmware.com/v1alpha1
kind: RegionBinding
metadata:
  name: us-west1
  namespace: demo-project
```

Region Binding Config

To control the supervisor placement logic on a per region basis in a project, an administrator defines **RegionBindingConfig**. With **RegionBindingConfig** defined, an administrator can use Supervisor label key-value pairs to further refine the association of specific Supervisors to projects. For example, an administrator could use a `key: environment` specification to select a Supervisor specified for testing with `value: testing`.

RegionBindingConfig includes the following properties:

- `metadata.name` Region name and must match an existing region.
- `metadata.namespace` Project name.
- `spec.supervisorSelector` selects the supervisors in the project that are available for creating a namespace. To select the correct supervisor, `matchExpressions` define the Supervisor label key, matching operator, and value for the match.

`spec.supervisorSelector` expression matching uses the following operators:

- `operator: In` The region binding tests to see if the key-value matches the Supervisor label key-value. The `matchExpressions` is an array but the array is currently limited to a single entry value.
- `operator: NotIn` The region binding tests to see if the key-value does not match the Supervisor label key-value. The `matchExpressions` is an array but the array is currently limited to a single entry value.
- `operator: Exists` The region binding searches for a match with a Supervisor that contains the label key. Values are not used.
- `operator: DoesNotExist` The region binding searches for a Supervisor that does not contain the label key. Values are not used.

Create Region Binding Config example input.

```
apiVersion: topology.cci.vmware.com/v1alpha1
kind: RegionBindingConfig
metadata:
  name: us-west1
  namespace: demo-project
spec:
  supervisorSelector:
    matchExpressions:
      - key: environment
```

```

operator: In
values:
  - testing
- key: storage
  operator: Exists
- key: storage
  operator: NotIn
values:
  - encrypted

```

Supervisor Namespace Classes

Supervisor Namespace Class

`SupervisorNamespaceClass` defines the the namespace template and optional parameters that can be used to customize the namespace settings during creation.

The default field specifies the parameter value that is used if a user does not provide the parameter value on namespace creation. For example, if `default: false`, `false` is the parameter value.

NOTE

To ensure that a user can create a namespace with partial or no parameter values, every parameter must include a default field and value.

Parameter type definitions:

Parameter type	Properties
Boolean	<ul style="list-style-type: none"> <code>default</code> Default boolean value. <code>enum</code> List of allowed boolean values. Can be used to for a parameter to have only one value, <code>true</code> or <code>false</code>.
Integer	<ul style="list-style-type: none"> <code>minimum</code> Minimum integer value. <code>maximum</code> Maximum integer value. <code>default</code> Default integer value. <code>enum</code> List of allowed integer values.
String	<ul style="list-style-type: none"> <code>minLength</code> Minimum string length. <code>maxLength</code> Maximum string length. <code>default</code> Default string value if not provided by user. <code>pattern</code> regex pattern to validate against value. <code>enum</code> List of allowed string values.

Create Supervisor Namespace Class example input.

```
apiVersion: infrastructure.cci.vmware.com/v1alpha1
```

```
kind: SupervisorNamespaceClass
```

```
metadata:
```

```

name: gold-with-gpu
spec:
description: Gold with GPU enabled supervisor namespace
parameters:
- name: environment
type: String
default: testing
enum:
- testing
- staging
- production
- name: fastStorageClass
type: Boolean
default: false
- name: podCountLimit
type: Integer
minimum: 100
maximum: 1000
default: 500

```

Supervisor Namespace Class Config

To specify the implementation of Supervisor Namespace Classes, an administrator creates a **SupervisorNamespaceClassConfig** with namespace settings. For a project to have access to Supervisor Namespace Class, both **SupervisorNamespaceClass** and **SupervisorNamespaceClassConfig** must exist.

SupervisorNamespaceClassConfig includes the following properties:

- `metadata.name` Supervisor Namespace Class name.
- `metadata.namespace` Project name.
- `spec.storageClasses` Storage class names and limits in megabytes.
- `spec.vmClasses` Names of the VM classes.
- `spec.contentSource` Content library names that are all defined with `type: ContentLibrary`.
- `spec.limits` Limit names and values. Valid limit values include:
 - `config_map_count`
 - `cpu_limit`
 - `cpu_limit_default`
 - `cpu_request_default`
 - `daemon_set_count`
 - `deployment_count`

- job_count
- memory_limit
- memory_limit_default
- memory_request_default
- persistent_volume_claim_count
- pod_count
- replica_set_count
- replication_controller_count
- secret_count
- service_count
- stateful_set_count
- storage_request_limit
- spec.supervisorSelector Supervisors in the project that are available for creating a namespace. To select the correct supervisor, matchExpressions define the label key, matching operator, and label value for the match.

An administrator exposes class parameters that can be consumed when defining the namespace settings values, so that users can customize the namespace settings during request time.

Create Supervisor Namespace Class Configuration example input.

```
apiVersion: infrastructure.cci.vmware.com/v1alpha1

kind: SupervisorNamespaceClassConfig

metadata:

name: gold-with-gpu

spec:

storageClasses:
- name: wcp-storage-class

limit: "100"

- name: "((parameters.fastStorageClass ? 'fast-storage-class' : 'standard-storage-class'))"

vmClasses:
- name: big-vm-class
- name: small-vm-class

contentSources:
- name: global-content-library

type: ContentLibrary

- name: "((parameters.environment))-content-library"

type: ContentLibrary

limits:
- name: cpu_limit
```

```

limit: "1000"
- name: pod_count
  limit: "((parameters.podCountLimit))"
  supervisorSelector:
    matchExpressions:
      - key: gpu-enabled
        operator: In
        values:
          - true

```

This example uses parameters from the Supervisor Namespace Class example as follows:

- `((parameters.fastStorageClass ? 'fast-storage-class' : 'standard-storage-class'))` shows a conditional check to specify a storage class name. `fastStorageClass` is a Boolean type.
 - If the user specifies the parameter value as true, then the name is `fast-storage-class`.
 - If the user specifies the value as false, then the name is `standard-storage-class`.
- `((parameters.podCountLimit))` shows how to specify a value for the pod count limit. `podCountLimit` is an integer type.
 - If the user specifies a value that is within the minimum and maximum values of 100 to 1000 as defined in the Supervisor Namespace Class, that is the value for the pod count limit.
 - If the user specifies no value, the pod count limit is the default value of 500 as defined in the Supervisor Namespace Class.
 - If the user specifies a value outside the minimum and maximum values, the value is invalid and Supervisor Namespace creation will fail with an error that shows the pod count limit is outside of the range of allowed values.

Supervisor Namespace Class Binding

The Supervisor Namespace Class Binding enables the use of Supervisor Namespace Classes when creating a Supervisor Namespace in a project.

SupervisorNamespaceClassBinding includes the following properties:

- `metadata.name` Supervisor Namespace Class Binding name.
- `metadata.namespace` Project name.
- `spec.overrideParameters` Created by the administrator, these parameters are defined values that cannot be changed by a user when creating the Supervisor Namespace. `const` specifies the value for the parameter. These parameters are optional and if defined, are not required for all class parameters.

Create Supervisor Namespace Class Binding example input.

```

apiVersion: infrastructure.cci.vmware.com/v1alpha1
kind: SupervisorNamespaceClassBinding
metadata:
  name: gold-with-gpu
  namespace: demo-project
spec:

```

```

overrideParameters:
  - name: environment
    type: string
    const: testing
supervisorNamespaceClassRef:
  apiVersion: infrastructure.cci.vmware.com/v1alpha1
  kind: SupervisorNamespaceClass
  name: gold

```

In this example, `name: environment` is an override parameter using the `environment` parameter from the Supervisor Namespace Class. By specifying `const: testing`, the user can only create a Supervisor Namespace using this class in a testing environment.

Supervisor Namespaces

Supervisor Namespace

Users can create Supervisor Namespaces in a specific region using a Supervisor Namespace Class as a template. If exposed, optional class parameters can be used to define the Namespace settings.

SupervisorNamespace includes the following properties:

- `metadata.name` Name of the namespace in the project and on the Supervisor.
- `metadata.namespace` Project name.
- `spec.regionName` Region name.
- `spec.className` Supervisor Namespace Class name.
- `spec.classParameters` Optional key-value to override default parameter values.
- `spec.description` Optional namespace description.

Create Supervisor Namespace example input.

```

apiVersion: infrastructure.cci.vmware.com/v1alpha1
kind: SupervisorNamespace
metadata:
  name: demo-ns5
  namespace: demo-project
spec:
  description: Demonstrating supervisor namespace creation
  regionName: us-west2
  className: bronze

```

Create Supervisor Namespace example output.

```

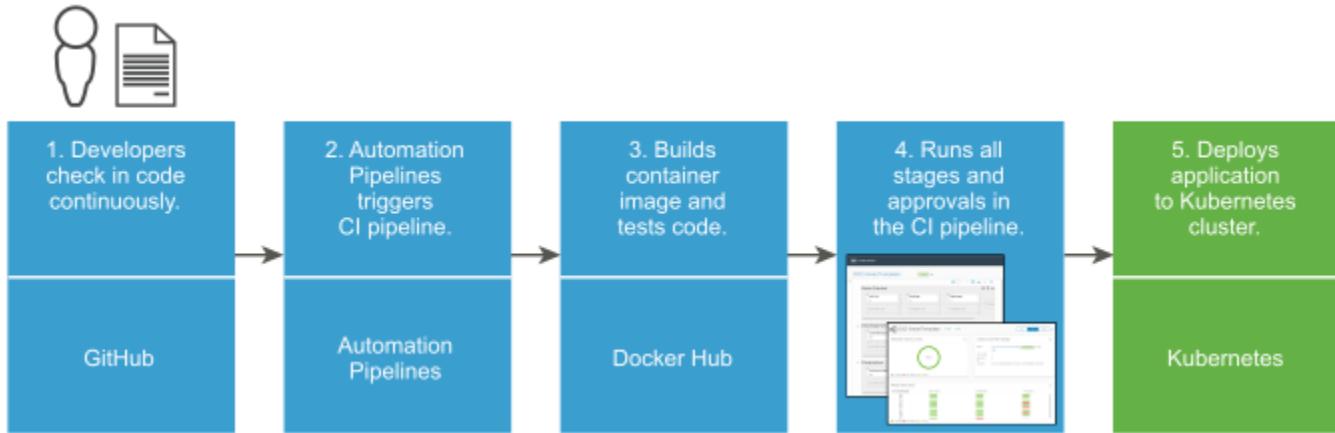

Name:          demo-1
Namespace:     sprint-demo-project

```

```
Labels:          <none>
Annotations:    infrastructure.cci.vmware.com/wcp-address: 10.161.81.40
API Version:   infrastructure.cci.vmware.com/v1alpha1
Kind:          SupervisorNamespace
Metadata:
  Creation Timestamp: 2022-09-13T01:55:57Z
  UID:            my-example-demo-1
Spec:
  Class Name:    demo-class
  Class Parameters:
    Pods:        30
  Description:
    Region Name: us-demo-1
  Status:
    Conditions:
      Last Transition Time: 2022-09-13T01:55:58Z
      Status:          True

      Phase:           Created
    Events:          <none>
```

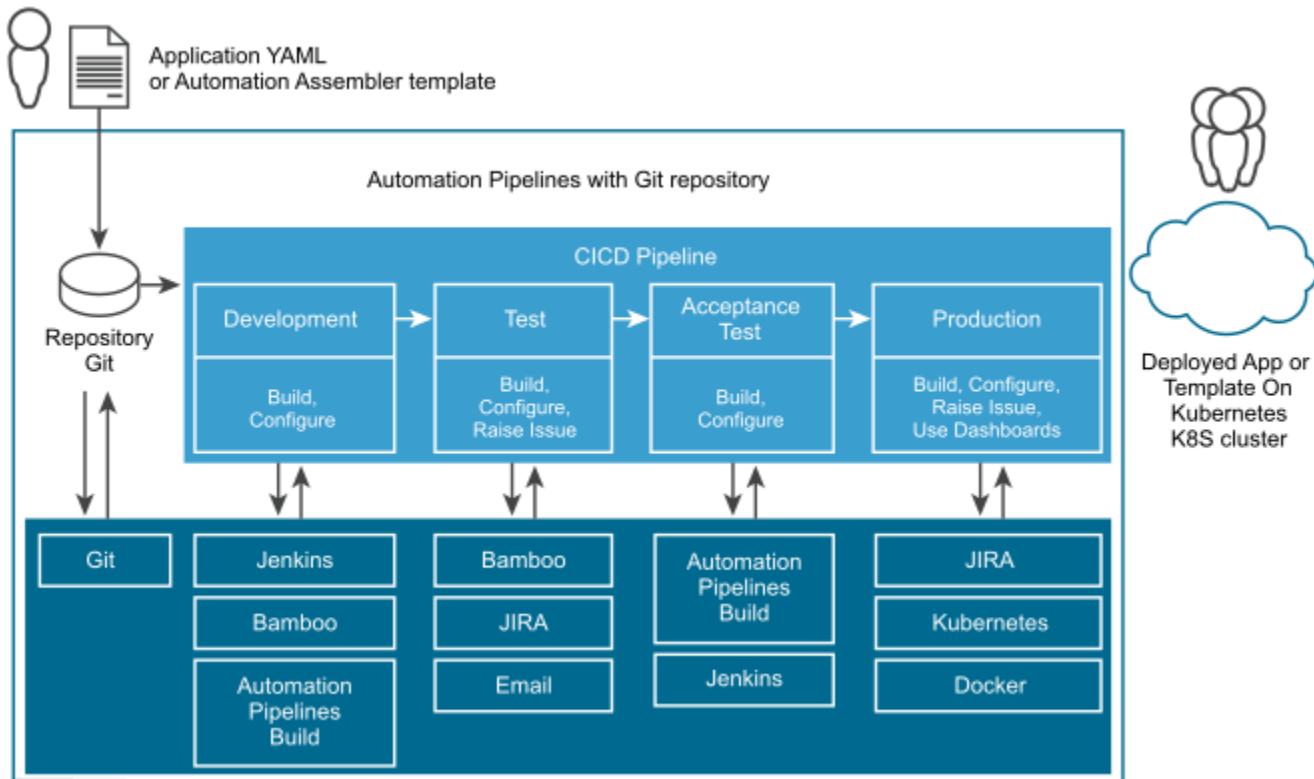

Using Automation Pipelines

VMware Aria Automation Pipelines is a continuous integration and continuous delivery (CICD) tool. By creating pipelines that model the software release process in your DevOps lifecycle, you build the code infrastructure that delivers your software rapidly and continuously.

When you use Automation Pipelines to deliver your software, you integrate two of the most important parts of your DevOps lifecycle: your release process and your developer tools. After the initial setup, which integrates Automation Pipelines with your existing development tools, the pipelines automate your entire DevOps lifecycle.

You create a pipeline that builds, tests, and releases your software. Automation Pipelines uses that pipeline to progress your software from the source code repository, through testing, and on to production.

You can learn more about planning your continuous integration and continuous delivery pipelines at [Planning to natively build, integrate, and deliver your code in](#) .

How Administrators use Automation Pipelines

As an administrator, you create endpoints and ensure that working instances are available for developers. You can create, trigger, and manage pipelines, and more. You have the `Administrator` role, as described in [How do I manage user access and approvals in](#) .

Table 47: How Automation Pipelines Administrators support developers

To support developers...	Here's what you can do...
Provide and manage environments.	<p>Create environments for developers to test and deploy their code.</p> <ul style="list-style-type: none"> • Track status and send email notifications. • Keep your developers productive by ensuring that their environments continuously work. <p>Also see Tutorials for using .</p>
Provide endpoints.	Ensure that developers have working instances of endpoints that can connect to their pipelines.
Provide integrations with other services.	Ensure that integrations to other services are working.
Create pipelines.	<p>Create pipelines that model release processes.</p> <p>To find out more, see Creating and using pipelines in .</p>
Trigger pipelines.	<p>Ensure that pipelines run when events occur.</p> <ul style="list-style-type: none"> • To trigger a standalone, continuous delivery (CD) pipeline whenever a build artifact is created or updated, use the Docker trigger. • To trigger a pipeline when a developer commits changes to their code, use the Git trigger. • To trigger a pipeline when developers review code, merge, and more, use the Gerrit trigger. • To run a standalone continuous delivery (CD) pipeline whenever a build artifact is created or updated, use the Docker trigger. <p>To find out more, see Triggering pipelines in .</p>
Manage pipelines and approvals.	<p>Stay up-to-date on pipelines.</p> <ul style="list-style-type: none"> • View pipeline status, and see who ran the pipelines. • View approvals on pipeline executions, and manage approvals for active and inactive pipeline executions. <p>To find out more, see What are user operations and approvals in .</p> <p>Also, see How do I use custom dashboards to track key performance indicators for my pipeline in .</p>
Monitor developer environments.	Create custom dashboards that monitor pipeline status, trends, metrics, and key indicators. Use the custom dashboards to monitor pipelines that pass or fail in

To support developers...	Here's what you can do...
	<p>developer environments. You can also identify and report on under used resources, and free up resources.</p> <p>You can also see:</p> <ul style="list-style-type: none"> • How long a pipeline ran before it succeeded. • How long a pipeline waited for approval, and notify the user who must approve it. • Stages and tasks that fail most often. • Stages and tasks that take the most time to run. • Releases that development teams have in progress. • Applications that succeeded in being deployed and released. <p>To find out more, see Monitoring pipelines in .</p>
Troubleshoot problems.	<p>Troubleshoot and resolve pipeline failures in developer environments.</p> <ul style="list-style-type: none"> • Identify and resolve problems in continuous integration and continuous delivery environments (CICD). • Use the pipeline dashboards and create custom dashboards to see more. See Monitoring pipelines in . <p>Also, see Setting up to model my release process.</p>

Automation Pipelines is part of VMware Cloud Services.

- Use Automation Assembler to deploy cloud templates.
- Use Automation Service Broker to get cloud templates from the catalog.

How Developers Use Automation Pipelines

As a developer, you use Automation Pipelines to build and run pipelines, and monitor pipeline activity on the dashboards. You have the `User` role, as described in [How do I manage user access and approvals in](#) .

After you run a pipeline, you'll want to know:

- If your code succeeded through all stages of the pipeline. To find out, observe the results in the pipeline executions.
- What to do if the pipeline failed, and what caused the failure. To find out, observe the top errors in the pipeline dashboards.

Table 48: Developers who use Automation Pipelines

To integrate and release your code	Here's what you do
Build pipelines.	<p>Test and deploy your code.</p> <p>Update your code when a pipeline fails.</p>
Connect your pipeline to endpoints.	Connect the tasks in your pipeline to endpoints, such as a GitHub repository.
Run pipelines.	Add a user operation approval task so that another user can approve your pipeline at specific points.

Table continued on next page

Continued from previous page

To integrate and release your code	Here's what you do
View dashboards.	View the results on the pipeline dashboard. You can see trends, history, failures, and more.

Find more documentation in the In-product Support panel

If you don't find the information you need here, you can get more help in the product.

- Click and read the signposts and tooltips in the user interface to get the context-specific information that you need where and when you need it.
- Open the In-product support panel and read the topics that appear for the active user interface page. You can also search in the panel to get answers to questions.

More on Webhooks

You can create multiple webhooks for different branches by using the same Git endpoint and providing different values for the branch name in the webhook configuration page. To create another webhook for another branch in the same Git repository, you don't need to clone the Git endpoint multiple times for multiple branches. Instead, you provide the branch name in the webhook, which allows you to reuse the Git endpoint. If the branch in the Git webhook is the same as the branch in the endpoint, you don't need to provide branch name in the Git webhook page.

Setting up Automation Pipelines to model my release process

Setting up to model my release process

To model your release process, you create a pipeline that represents the stages, tasks, and approvals that you normally use for releasing your software. Automation Pipelines then automates the process that builds, tests, approves, and deploys your code.

- Verify whether any endpoints are already available. In Automation Pipelines, click **Endpoints**.
- Learn about native ways that you can build and deploy your code. See [Planning to natively build, integrate, and deliver your code in](#).
- Determine whether some of the resources that you will use in your pipeline must be marked as restricted. See [How do I manage user access and approvals in](#).
- If you have the user role or the viewer role instead of the administrator role, determine who is the administrator for your Automation Pipelines instance.

Now that you have everything for modeling your software release process, here's how you do it in Automation Pipelines.

1. Examine the projects available in Automation Pipelines and select one that is right for you.
 - If no projects appear, ask a Automation Pipelines administrator who can create a project and make you a member of the project. See [How do I add a project in](#).
 - If you are not a member of any projects listed, ask a Automation Pipelines administrator who can add you as a member of a project.

The screenshot shows the 'Projects' section of the VMware Aria Automation interface. It displays two project cards:

- SHOBHA-TEST...**: No Description, Administrators 1, Members 0. Buttons: OPEN, DELETE.
- test**: No Description, Administrators 3, Members 2. Buttons: OPEN, DELETE.

2. Add any new endpoints that you need for your pipeline.

For example, you might need Git, Jenkins, Automation Pipelines Build, Kubernetes, and Jira.

3. Create variables so that you can reuse values in your pipeline tasks.

To constrain the resources used in your pipelines, such as a host machine, use restricted variables. You can restrict the pipeline from continuing to run until another user explicitly approves it.

Administrators can create secret variables and restricted variables. Users can create secret variables.

You can reuse a variable as many times as you want across multiple pipelines. For example, a variable that defines a host machine can be `HostIPAddress`. To use the variable in a pipeline task, you enter `$ {var.HostIPAddress}`.

The screenshot shows the 'Variables' section of the VMware Aria Automation interface. It displays a table of variables:

Project	Name	Type	Value
1stProject	Test	REGULAR	123
1stProject	Test-Restricted	RESTRICTED	*****
1stProject	Test-Global-name	SECRET	*****

4. If you are an administrator, mark any endpoints and variables that are vital to your business as restricted resources.

When a user who is not an administrator attempts to run a pipeline that includes a restricted resource, the pipeline stops at the task that uses the restricted resource. Then, an administrator must resume the pipeline.

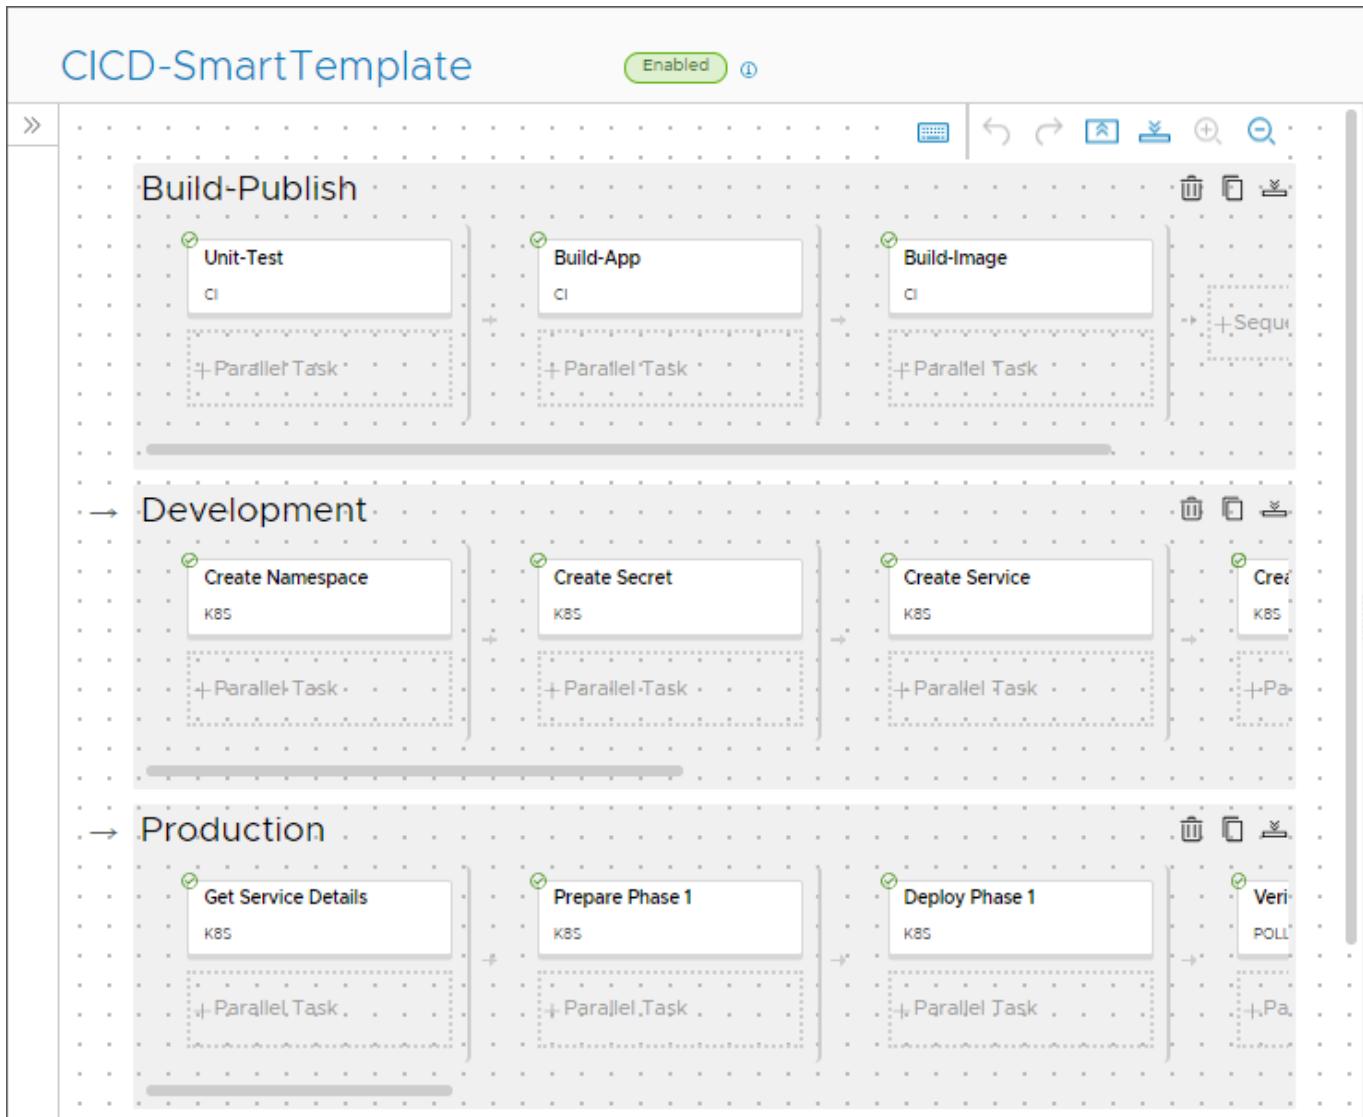

5. Plan the build strategy for your native CICD, CI, or CD pipeline.

Before you create a pipeline that continuously integrates (CI) and continuously deploys (CD) your code, plan your build strategy. The build plan helps you determine what Automation Pipelines needs so that it can natively build, integrate, test, and deploy your code.

How to create a Automation Pipelines native build	Results in this build strategy
Use one of the smart pipeline templates.	<ul style="list-style-type: none"> • Builds all the stages and tasks for you. • Clones the source repository. • Builds and tests your code. • Containerizes your code for deployment. • Populates the pipeline task steps based on your selections.
Add stages and tasks manually.	You add stages, add tasks, and enter the information that populates them.

6. Create your pipeline by using a smart pipeline template, or by manually add stages and tasks to the pipeline.

Then, you mark any resources as restricted. Add approvals where needed. Apply any regular, restricted, or secret variables. Add any bindings between tasks.

7. Validate, enable, and run your pipeline.
8. View the pipeline executions.

Executions (280 items)

[NEW EXECUTION](#) Search Filter Clear

Icon	Name	Status	Stages	ACTIONS
	Demo-Jenkins... #95	COMPLETED	██████	★ Input : 8df0d9a1d365299f2... ☆ Output : NA
	Demo-Jenkins... #94	COMPLETED	██████	★ Input : 6d82d079a8b8921a9... ☆ Output : NA
	Demo-CI_CD-S... #51	COMPLETED	██████	☆ Input : NA ☆ Output : NA
	Demo-CI_CD-S... #50	FAILED	██████	☆ Input : NA ☆ Output : NA

9. To track status and key performance indicators (KPIs), use the pipeline dashboards, and create any custom dashboards.

The screenshot shows the VMware Aria Automation 8.18 interface for the CICD-SmartTemplate project. At the top, there are buttons for CLONE and BACK, and a time filter dropdown set to 7D. Below this, the main content area is divided into three sections:

- Execution Status Counts:** A circular chart showing a total of 1 execution. The legend indicates: Completed (green), Failed (red), Running (blue), and Waiting (yellow). The chart is entirely green.
- Latest Successful Change:** Displays information about the most recent successful change. It shows the change was made by 'd' on 09/06/2018 at 10:21 AM, completed a day ago. The status is 'COMPLETED'.
- Recent Executions:** A table listing recent executions (Execution#) and their stages (Build-Publish, Development, Production). Each stage has a vertical bar chart indicating the status of each stage step. Most steps are green (Completed), but some are red (Failed).

You created a pipeline that you can use in the selected project.

You can also export your pipeline YAML, then import it and reuse it in other projects.

Learn about use cases that you might want to apply in your environment. See [Tutorials for using](#).

How do I add a project in Automation Pipelines

How do I add a project

You create a project and add administrators and members to it. Project members can use features such as creating a pipeline and adding an endpoint. To create, delete, or update a project for a development team, you must be a Automation Pipelines administrator.

- Verify that you have the Automation Pipelines administrator role. See [What are Roles in](#).
- If you do not have the Automation Pipelines administrator role, but you are an administrator in Automation Assembler, you can use the Automation Assembler UI to create, update, or delete projects. See [How do I add a project for my Automation Assembler development team](#).
- If you are adding Active Directory groups to projects, verify that you configured Active Directory groups for your organization. See [How do I enable Active Directory groups in VMware Aria Automation for projects](#). If the groups are not synchronized, they are not available when you try to add them to a project.

A project must exist before you can create a pipeline. When you create a pipeline, you select a project that groups all your pipeline information together. Definitions for endpoints and variables also depend on an existing project.

1. Select **Projects**, and click **New Project**.
2. Enter the project name.
3. Click **Create**.

4. Select the card for the newly created project, and click **Open**.
5. Click the **Users** tab and add users and assign roles.
 - The project administrator can add members.
 - The project member who has a service role can use services.
 - The project viewer can see projects but cannot create, update, or delete them.

For more information about project roles, see [How do I manage user access and approvals in](#) .

6. Click **Save**.

Add endpoints and pipelines that use the project. See [Connecting to endpoints](#) and [Creating and using pipelines in](#) .

After you create a pipeline, the name of the project that groups all your pipeline information together appears on pipeline cards and pipeline execution cards.

How do I manage user access and approvals in Automation Pipelines

How do I manage user access and approvals

Automation Pipelines provides several ways to ensure that users have the appropriate authorization and consent to work with pipelines that release your software applications.

Each member on a team has an assigned role, which gives specific permissions on pipelines, endpoints, and dashboards, and the ability to mark resources as restricted.

User operations and approvals enable you to control when a pipeline runs and must stop for an approval. Your role determines whether you can resume a pipeline, and run pipelines that include restricted endpoints or variables.

Use secret variables to hide and encrypt sensitive information. Use restricted variable for strings, passwords, and URLs that must be hidden and encrypted, and to restrict use in executions. For example, use a secret variable for a password or URL. You can use secret and restricted variables in any type of task in your pipeline.

What are Roles in Automation Pipelines

Depending on your role in Automation Pipelines, you can perform certain actions and access certain areas. For example, your role might enable you to create, update, and run pipelines. Or, you might only have permission to view pipelines.

All actions except restricted means this role has permission to perform create, read, update, and delete actions on entities except for restricted variables and endpoints.

Table 49: Service and Project level access permissions in Automation Pipelines

	Automation Pipelines Roles				
Access levels	Automation Pipelines Administrator	Automation Pipelines Developer	Automation Pipelines Executor	Automation Pipelines Viewer	Automation Pipelines User
Automation Pipelines service level access	All Actions	All actions except restricted	Execution actions	Read only	None
Project level access: Project Admin	All Actions	All Actions	All Actions	All Actions	All Actions

Table continued on next page

Continued from previous page

	Automation Pipelines Roles				
Access levels	Automation Pipelines Administrator	Automation Pipelines Developer	Automation Pipelines Executor	Automation Pipelines Viewer	Automation Pipelines User
Project level access: Project Member	All Actions	All actions except restricted	All actions except restricted	All actions except restricted	All actions except restricted
Project level access: Project Viewer	All Actions	All actions except restricted	Execution actions	Read only	Read only

Users who have the Project Admin role can perform all actions on projects where they are a Project administrator.

A Project administrator can create, read, update, and delete pipelines, variables, endpoints, dashboards, triggers, and start a pipeline that includes restricted endpoints or variables if these resources are in the project where the user is a Project administrator.

Users who have the Service Viewer role can see all the information that is available to the administrator. They cannot take any action unless an administrator makes them a project administrator or a project member. If the user is affiliated with a project, they have the permissions related to the role. The project viewer would not extend their permissions the way that the administrator or member role does. This role is read-only across all projects.

If you have read permissions in a project, you can still see restricted resources.

- To see restricted endpoints, which display a lock icon on the endpoint card, click **Configure > Endpoints**.
- To see restricted and secret variables, which display RESTRICTED or SECRET in the Type column, click **Configure > Variables**.

Table 50: Automation Pipelines service role capabilities

UI Context	Capabilities	Automation Pipelines Administrator role	Automation Pipelines Developer role	Automation Pipelines Executor role	Automation Pipelines Viewer role	Automation Pipelines User role
Pipelines						
	View pipelines	Yes	Yes	Yes	Yes	
	Create pipelines	Yes	Yes			
	Run pipelines	Yes	Yes	Yes		
	Run pipelines that include restricted endpoints or variables	Yes				
	Update pipelines	Yes	Yes			
	Delete pipelines	Yes	Yes			
Pipeline Executions						
	View pipeline executions	Yes	Yes	Yes	Yes	

Table continued on next page

UI Context	Capabilities	Automation Pipelines Administrator role	Automation Pipelines Developer role	Automation Pipelines Executor role	Automation Pipelines Viewer role	Automation Pipelines User role
	Resume, pause, and cancel pipeline executions	Yes	Yes	Yes		
	Resume pipelines that stop for approval on restricted resources	Yes				
Custom Integrations						
	Create custom integrations	Yes	Yes			
	Read custom integrations	Yes	Yes	Yes	Yes	
	Update custom integrations	Yes	Yes			
Endpoints						
	View executions	Yes	Yes	Yes	Yes	
	Create executions	Yes	Yes			
	Update executions	Yes	Yes			
	Delete executions	Yes	Yes			
Mark resources as restricted						
	Mark an endpoint or variable as restricted	Yes				
Dashboards						
	View dashboards	Yes	Yes	Yes	Yes	
	Create dashboards	Yes	Yes			
	Update dashboards	Yes	Yes			
	Delete dashboards	Yes	Yes			

Custom roles and permissions in Automation Pipelines

You can create custom roles in Automation Assembler that extend privileges to users who work with pipelines. When you create a custom role for Automation Pipelines pipelines, you select one or more **Pipeline** permissions.

Select the minimal number of **Pipeline** permissions required for users who will be assigned this custom role.

When a user is assigned to a project and given a role in that project, and that user is assigned a custom role that includes one or more **Pipeline** permissions, they can perform all the actions that the permissions allow. For example, they can create restricted variables, manage restricted pipelines, create and manage custom integrations, and more.

Table 51: Pipeline permissions that you can assign to custom roles

Pipeline Permission	Automation Pipelines Administrator	Automation Pipelines Developer	Automation Pipelines Executor	Automation Pipelines Viewer	Automation Pipelines User	Project Administrator	Project Member	Project Viewer
Manage Pipelines	Yes	Yes				Yes	Yes	
Manage Restricted Pipelines	Yes					Yes		
Manage Custom Integrations	Yes	Yes						
Execute Pipelines	Yes	Yes	Yes			Yes	Yes	
Execute Restricted Pipelines	Yes					Yes		
Manage Executions	Yes					Yes		
Read. This permission is not visible.	Yes	Yes	Yes	Yes		Yes	Yes	Yes

Table 52: How you can use Pipeline permissions with custom roles

Permission	What you can do
Manage Pipelines	<ul style="list-style-type: none"> Create, update, delete, clone pipelines. Release and unrelease pipelines to Automation Service Broker. Create, update, and delete endpoints. Create, update, and delete regular and secret variables. Create, clone, update, and delete a Gerrit listener. Connect and disconnect a Gerrit listener. Create, clone, update, delete a Gerrit trigger. Create, update, and delete a Git webhook. Create, update, and delete a Docker webhook. Use smart pipeline templates to create pipelines. Import pipelines from YAML, and export them to YAML. Create, update, and delete custom dashboards. Read all custom integrations. Read all restricted endpoints and variables, but cannot view their values.

Table continued on next page

Continued from previous page

Permission	What you can do
Manage Restricted Pipelines	<ul style="list-style-type: none"> • Create, update, and delete endpoints. • Mark endpoints as restricted, update restricted endpoints, and delete them. • Create, update, and delete regular and secret variables. • Create, update, and delete restricted variables. • All permissions that you can do with Manage Pipelines.
Manage Custom Integrations	<ul style="list-style-type: none"> • Create and update custom integrations. • Version and release custom integrations. • Delete and deprecate custom integration versions. • Delete custom integrations.
Execute Pipelines	<ul style="list-style-type: none"> • Run pipelines. • Pause, resume, and cancel pipeline executions. • Rerun pipeline executions. • Resume, rerun, and manually trigger a Gerrit trigger event. • Approve a user operation, and can do batch approvals of user operations.
Execute Restricted Pipelines	<ul style="list-style-type: none"> • Run pipelines. • Pause, resume, cancel, and delete pipeline executions. • Rerun pipeline executions. • Sync a running pipeline execution. • Force delete a running pipeline execution. • Resume, rerun, delete, and manually trigger a Gerrit trigger event. • Resolve restricted items and continue the pipeline execution. • Switch user context and continue the pipeline execution after a User Operation task approval. • All permissions that you can do with Execute Pipelines.
Manage Executions	<ul style="list-style-type: none"> • Run pipelines. • Pause, resume, cancel, and delete pipeline executions. • Rerun pipeline executions. • Resume, rerun, delete, and manually trigger a Gerrit trigger event. • All permissions that you can do with Execute Pipelines.

Custom roles can include combinations of permissions. These permissions are organized into groups of capabilities that enable users to manage or run pipelines, with and without restricted resources. These permissions represent all the capabilities that each role can perform in Automation Pipelines.

For example, if you create a custom role and include the permission called **Manage Restricted Pipelines**, users who have the Automation Pipelines Developer role can:

- Create, update, and delete endpoints.
- Mark endpoints as restricted, update restricted endpoints, and delete them.
- Create, update, and delete regular and secret variables.
- Create, update, and delete restricted variables.

Table 53: Example combinations of Pipeline permissions in custom roles

Number of Permissions Assigned to Custom Role	Examples of Combined Permissions	How to use this combination
Single permission	Execute Pipelines	
Two permissions	Manage Pipelines and Execute Pipelines	
Three permissions	Manage Pipelines and Execute Pipelines and Execute Restricted Pipelines	
	Manage Pipelines and Manage Custom Integrations and Execute Restricted Pipelines	This combination might apply to a Automation Pipelines Developer role but be limited to the projects where the user is a member.
	Manage Pipelines and Manage Custom Integrations and Manage Executions	This combination might apply to a Automation Pipelines Administrator but limited to the projects where user is a member.
	Manage Pipelines, Manage Restricted Pipelines, and Manage Custom Integrations	With this combination, a user has full permissions and can create and delete anything in Automation Pipelines.

If you have the Administrator role

As an administrator, you can create custom integrations, endpoints, variables, triggers, pipelines, and dashboards.

Projects enable pipelines to access infrastructure resources. Administrators create projects so that users can group pipelines, endpoints, and dashboards together. Users then select the project in their pipelines. Each project includes an administrator and users with assigned roles.

With the Administrator role, you can mark endpoints and variables as restricted resources, and you can run pipelines that use restricted resources. If a non-administrative user runs the pipeline that includes a restricted endpoint or variable, the pipeline will stop at the task where the restricted variable is used, and an administrator must resume the pipeline.

As an administrator, you can also request that pipelines be published in Automation Service Broker.

If you have the Developer role

You can work with pipelines like an administrator can, except that you cannot work with restricted endpoints or variables.

If you run a pipeline that uses restricted endpoints or variables, the pipeline only runs up to the task that uses the restricted resource. Then, it stops, and a Automation Pipelines administrator or project administrator must resume the pipeline.

If you have the User role

You can access Automation Pipelines, but do not have any privileges as the other roles provide.

If you have the Viewer role

You can see the same resources that an administrator sees, such as pipelines, endpoints, pipeline executions, dashboards, custom integrations, and triggers, but you cannot create, update, or delete them. To perform actions, the Viewer role must also be given the project administrator or project member role.

Users who have the Viewer role can see projects. They can also see restricted endpoints and restricted variables, but cannot see the detailed information about them.

If you have the Executor role

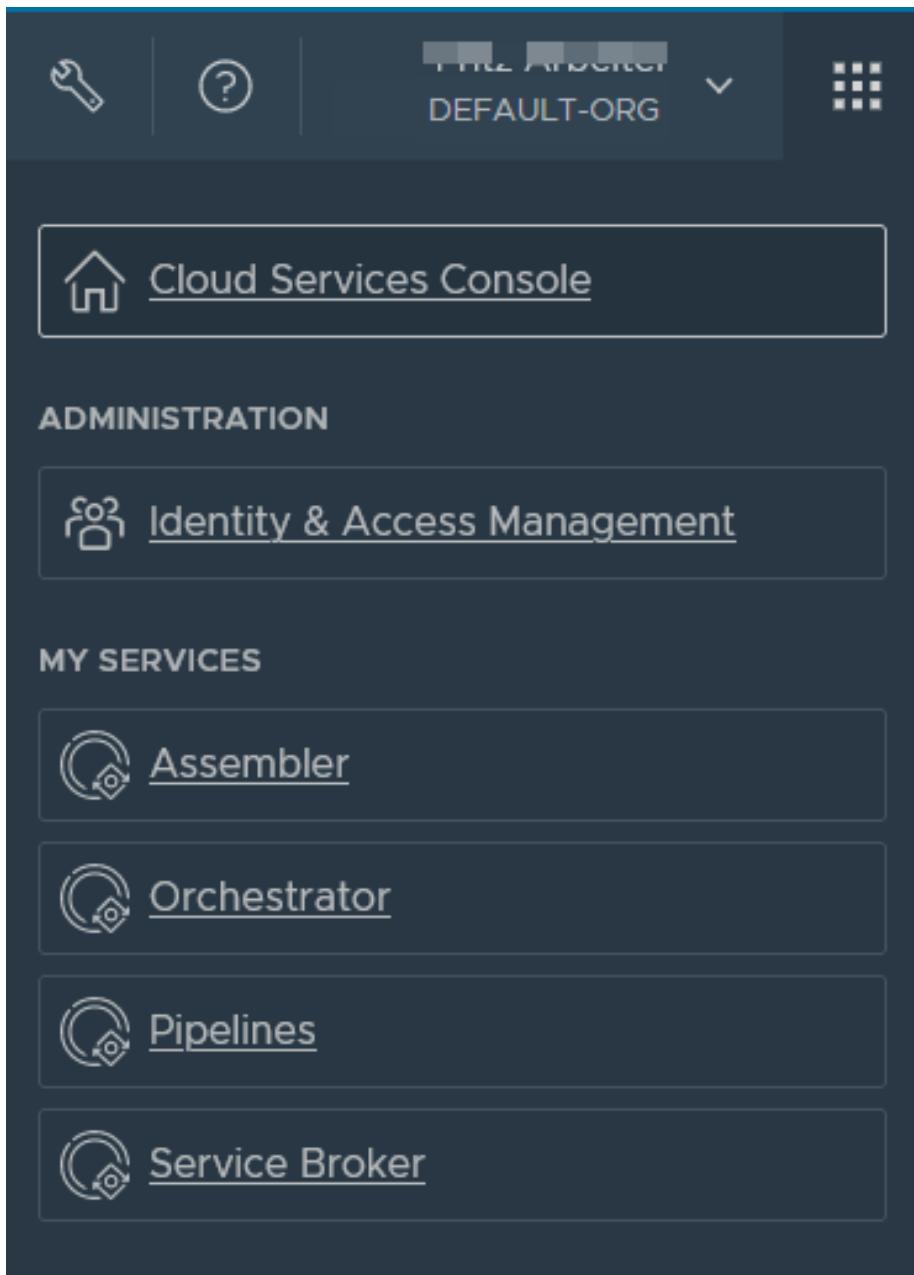

You can run pipelines and take action on user operation tasks. You can also resume, pause, and cancel pipeline executions. But, you cannot modify pipelines.

How do I assign and update roles

To assign and update roles for other users, you must be an administrator and an organization owner.

For more information about roles, see [What are the VMware Aria Automation user roles](#).

1. To see the active users and their roles, in VMware Aria Automation, click the nine dots at the upper right.
2. Click **Identity & Access Management**.

3. A list of **Active Users** appears. To add roles for a user, or change their roles, click the check box next to the user name, and click **Edit Roles**.

4. When you add or change user roles, you can also add access to services.
5. To save your changes, click **Save**.

What are user operations and approvals in Automation Pipelines

What are user operations and approvals

The User Operations area displays pipeline runs that need approval. The required approver can either approve or reject the pipeline run.

When you create a pipeline, you might need to add an approval to a pipeline if:

- A team member needs to review your code.
- Another user needs to confirm a build artifact.
- You must ensure that all testing is complete.
- A task uses a resource that an administrator marked as restricted, and the task needs approval.
- The pipeline will release software to production.

To determine whether to approve a pipeline task, the required approver must have permission and expertise.

When you add a User Operation task, you can set the expiration timeout in days, hours, or minutes. For example, you might need the required user to approve the pipeline in 30 minutes. If they don't approve it in 30 minutes, the pipeline fails as expected.

If you enable sending Email notifications, the User Operation task only sends notifications to approvers who have full email addresses, and not to approver names that are not in an email format.

After the required user approves the task:

- The pending pipeline execution can continue.
- When the pipeline continues, any previous pending requests for approval of that same user operation task are canceled.

The screenshot shows the 'User Operations' page with the following details:

User Operations

GUIDED SETUP

Active Items Inactive Items

Approve **Reject**

	Index#	Execution	Summary	Requested By	Request Date	Approvers
<input type="checkbox"/>	c07b12	Demo2-Jenkins-K8s#7	Testing	fritz	Nov 13, 2019, 11:32:31 AM	fritz@vmware.com
<input type="checkbox"/>	a0a990	Demo2-Jenkins-K8s#6	Testing	fritz	Nov 11, 2019, 1:34:11 PM	k.fritz@vmware.com, fritz@vmware.com

User Operation #8f1728

Request Details

Execution	Demo-Jenkins-K8s #5
Summary	Testing
Approvers	k.fritz@vmware.com, fritz@vmware.com
Requested By	fritz
Requested On	Nov 11, 2019, 1:22:21 PM
Expires On	Nov 14, 2019, 1:22:21 PM

Items per page: 20 | 1 - 7 of 7 items

In the User Operations area, items to approve or reject appear as active or inactive items. Each item maps to a user operation task in a pipeline.

- **Active Items** wait for the approver who must review the task, and approve or reject it. If you are a user who is on the approver list, you can expand the user operation row, and click **Accept** or **Reject**.
- **Inactive Items** were approved or rejected. If a user rejected the user operation, or if the approval on the task timed out, it can no longer be approved.

The Index# is a unique six-character alphanumeric string that you can use as a filter to search for a particular approval.

Pipeline approvals also appear in the **Executions** area.

- Pipelines that are waiting for approval indicate their status as waiting.
- Other states include queued, completed, and failed.
- If your pipeline is in a wait state, the required approver must approve your pipeline task.

Creating and using pipelines in Automation Pipelines

Creating and using pipelines

You can use Automation Pipelines to model your build, test, and deploy process. With Automation Pipelines, you set up the infrastructure that supports your release cycle and create pipelines that model your software release activities. Automation Pipelines delivers your software from development code, through testing, and deploys it to your production instances.

Each pipeline includes stages and tasks. Stages represent your development phases, and tasks perform the required actions that deliver your software application through the stages.

What are Pipelines in Automation Pipelines

A pipeline is a continuous integration and continuous delivery model of your software release process. It releases your software from source code, through testing, to production. It includes a sequence of stages that include tasks that represent the activities in your software release cycle. Your software application flows from one stage to the next through the pipeline.

You add endpoints so that the tasks in your pipeline can connect to data sources, repositories, or notification systems.

Creating Pipelines

You can create a pipeline by starting with a blank canvas, using a smart pipeline template, or by importing YAML code.

- Use the blank canvas. For an example, see [Planning a CICD native build in before manually adding tasks](#).
- Use a smart pipeline template. For an example, see [Planning to natively build, integrate, and deliver your code in](#).
- Import YAML code. Click **Pipelines > Import**. In the **Import** dialog box, select the YAML file or enter the YAML code, and click **Import**.

When you use the blank canvas to create a pipeline, you add stages, tasks, and approvals. The pipeline automates the process that builds, tests, deploys, and releases your application. The tasks in each stage run actions that build, test, and release your code through each stage.

Table 54: Example pipeline stages and uses

Example stage	Examples of what you can do
Development	<p>In a development stage, you can provision a machine, retrieve an artifact, add a build task that creates a Docker host for continuous integration of your code, and more.</p> <p>For example:</p>

Table continued on next page

Continued from previous page

Example stage	Examples of what you can do
	<ul style="list-style-type: none"> To plan and create a continuous integration (CI) build, which delivers your code by using the native build capability in Automation Pipelines, see Planning a continuous integration native build in before using the smart pipeline template.
Test	<p>In a test stage, you can add a Jenkins task to test your software application, and include post-processing test tools such as JUnit and JaCoCo, and more.</p> <p>For example:</p> <ul style="list-style-type: none"> Integrate Automation Pipelines with Jenkins, and run a Jenkins job in your pipeline, which builds and tests your source code. See How do I integrate with Jenkins. Create custom scripts that extend the capability of Automation Pipelines to integrate with your own build, test, and deploy tools. See How do I integrate my own build, test, and deploy tools with. Track trends on post-processing for a continuous integration (CI) pipeline. See How do I use custom dashboards to track key performance indicators for my pipeline in.
Production	<p>In a production stage, you can integrate a cloud template in Automation Assembler that provisions your infrastructure, deploys your software to a Kubernetes cluster, and more.</p> <p>For example:</p> <ul style="list-style-type: none"> To see example stages for development and production, which can deploy your software application in your own Blue-Green deployment model, see How do I deploy my application in to my Blue-Green deployment. To integrate a cloud template into your pipeline, see How do I automate the release of an application that I deploy from a YAML cloud template in. You can also add a deployment task that runs a script to deploy the application. To automate the deployment of your software applications to a Kubernetes cluster, How do I automate the release of an application in to a Kubernetes cluster. To integrate code into your pipeline and deploy your build image, see How do I continuously integrate code from my GitHub or GitLab repository into my pipeline in.

You can export your pipeline as a YAML file. Click **Pipelines**, click a pipeline card, then click **Actions** > **Export**.

Approving pipelines

You can obtain an approval from another team member at specific points in your pipeline.

- To require approval on a pipeline by including a user operation task in a pipeline, see [How do I run a pipeline and see results](#). This task sends an email notification to the user who must review it. The reviewer must either approve or reject the approval before the pipeline can continue to run. If the User Operation task has an expiration timeout set in days, hours, or minutes, the required user must approve the pipeline before the task expires. Otherwise, the pipeline fails as expected.
- In any stage of a pipeline, if a task or stage fails, you can have Automation Pipelines create a Jira ticket. See [How do I create a Jira ticket in when a pipeline task fails](#).

Triggering pipelines

Pipelines can trigger when developers check their code into the repository, or review code, or when it identifies a new or updated build artifact.

- To integrate Automation Pipelines with the Git lifecycle, and trigger a pipeline when developers update their code, use the Git trigger. See [How do I use the Git trigger in to run a pipeline](#).
- To integrate v Automation Pipelines with the Gerrit code review lifecycle, and trigger a pipeline on code reviews, use the Gerrit trigger. See [How do I use the Gerrit trigger in to run a pipeline](#).
- To trigger a pipeline when a Docker build artifact is created or updated, use the Docker trigger. See [How do I use the Docker trigger in to run a continuous delivery pipeline](#).

For more information about the triggers that Automation Pipelines supports, see [Triggering pipelines in](#).

How do I run a pipeline and see results

How do I run a pipeline and see results

You can run a pipeline from the pipeline card, in pipeline edit mode, and from the pipeline execution. You can also use the available triggers to have Automation Pipelines run a pipeline when certain events occur.

- Verify that one or more pipelines are created. See the examples in [Tutorials for using](#).

When all the stages and tasks in your pipeline are valid, the pipeline is ready to be released, run, or triggered.

To run or trigger your pipeline using Automation Pipelines, you can enable and run the pipeline either from the pipeline card, or while you are in the pipeline. Then, you can view the pipeline execution to confirm that the pipeline built, tested, and deployed your code.

When a pipeline execution is in progress, you can delete the execution if you are an administrator or a non-admin user.

- Administrator: To delete a pipeline execution when it is running, click **Executions**. On the execution to delete, click **Actions > Delete**.
- Non-admin user: To delete a running pipeline execution, click **Executions**, and click **Alt Shift d**.

When a pipeline execution is in progress and appears to be stuck, an administrator can refresh the execution from the Executions page or the Execution details page.

- Executions page: Click **Executions**. On the execution to refresh, click **Actions > Sync**.
- Execution details page: Click **Executions**, click the link to the execution details, and click **Actions > Sync**.

To run a pipeline when specific events occur, use the triggers.

- Git trigger can run a pipeline when developers update code.
- Gerrit trigger can run a pipeline when code reviews occur.
- Docker trigger can run a pipeline when an artifact is created in a Docker registry.
- The `curl` command or `wget` command can have Jenkins run a pipeline after a Jenkins build finishes.

For more information about using the triggers, see [Triggering pipelines in](#).

The following procedure shows you how to run a pipeline from the pipeline card, view executions, see execution details, and use the actions. It also shows you how to release a pipeline so that you can add it to VMware Aria Automation Service Broker.

1. Enable your pipeline.

To run or release a pipeline, you must enable it first.

- a) Click **Pipelines**.
- b) On your pipeline card, click **Actions > Enable**.

The screenshot shows the VMware Aria Automation Pipelines interface. At the top, there's a header with the title "Pipelines" and a button "6 items". Below the header are two buttons: "+ NEW PIPELINE" and "IMPORT". The main area displays a list of pipelines. One pipeline, "Demo-Jenkins", is selected and highlighted with a red bar. A context menu is open over this pipeline, listing the following options: Enable, Release, Refresh, View executions, View dashboard, Clone, Export, Delete, View references, and Pin. At the bottom of the pipeline card, there are buttons for "OPEN", "RUN", and "ACTIONS". The "ACTIONS" button is currently active, indicated by a blue outline.

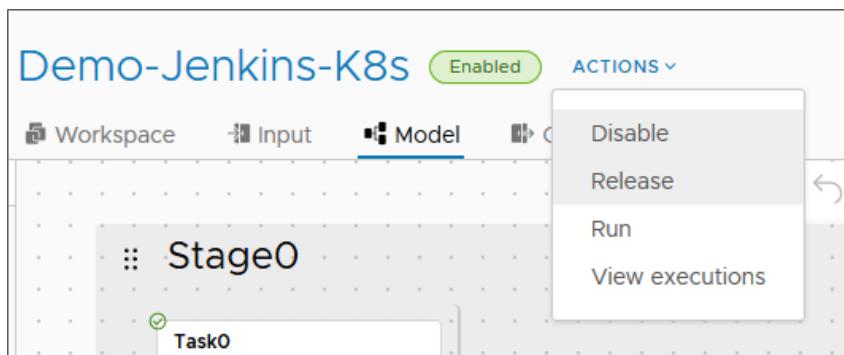

You can also enable your pipeline while you are in the pipeline. If your pipeline is already enabled, **Run** is active, and the **Actions** menu displays **Disable**.

2. Release your pipeline.

If you want to make your pipeline available as a catalog item in VMware Aria Automation Service Broker, you must release it in Automation Pipelines.

- Click **Pipelines**.
- On your pipeline card, click **Actions > Release**.

You can also release your pipeline while you are in the pipeline.

After you release the pipeline, you open Automation Service Broker to add the pipeline as a catalog item and run it. See [Add pipelines to the Automation Service Broker catalog](#).

NOTE

If the pipeline requires more than 120 minutes to run, provide an approximate execution time as a request timeout value. To set or review the request timeout for a project, open Automation Service Broker as administrator and select **Infrastructure > Projects**. Click your project name and then click **Provisioning**.

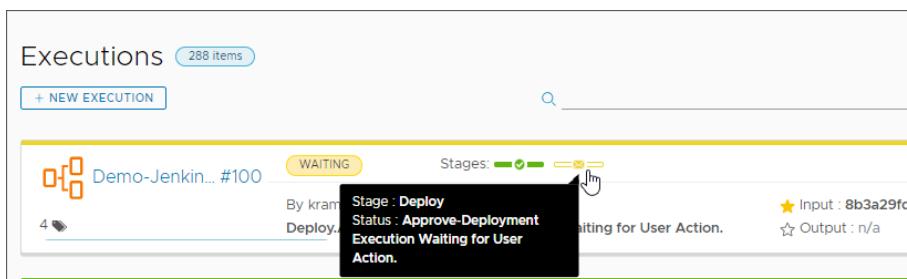

If the request timeout value is not set, an execution that requires more than 120 minutes to run appears as failed with a callback timeout request error. However, the pipeline execution is not affected.

3. On the pipeline card, click **Run**.
4. To view the pipeline as it runs, click **Executions**.

The pipeline runs each stage in sequence, and the pipeline execution displays a status icon for each stage. If the pipeline includes a user operation task, a user must approve the task for the pipeline to continue to run. When a user operation task is used, the pipeline stops running and waits for the required user to approve the task.

For example, you might use the user operation task to approve the deployment of code to a production environment.

If the User Operation task has an expiration timeout set in days, hours, or minutes, the required user must approve the pipeline before the task expires. Otherwise, the pipeline fails as expected.

5. To see the pipeline stage that is waiting for user approval, click the status icon for the stage.

Demo-Jenkins-K8s #100 (WAITING) 4 ACTIONS

Dev

- Build-DemoApp (green)
- Test-DemoApp (green)
- Publish-DemoApp (green)

Deploy

- Approve-Deployment (yellow)
- K8s-AWS (grey)

Stage name: Deploy

Status: WAITING Approve-Deployment Execution Waiting for User Action.

- To see the details for the task, click the task.

After the required user approves the task, a user who has the appropriate role must resume the pipeline. For required roles, see [How do I manage user access and approvals](#) in .

If an execution fails, you must triage and fix the cause of the failure. Then, go to the execution, and click **Actions** > **R-e-run**.

You can resume primary pipeline executions and nested executions.

Demo-Jenkins-K8s #100 (WAITING) 4 ACTIONS

Dev

- Build-DemoApp (green)
- Test-DemoApp (green)
- Publish-DemoApp (green)

Deploy

- Approve-Deployment (yellow)

Task name: Approve-Deployment

Type: UserOperation

Status: WAITING Execution Waiting for User Action.

Execute Task: Always On Condition

Input:

Summary: Demo-Jenkins-K8s is pending deployment for your approval

Description: Demo-Jenkins-K8s is pending deployment for your approval

Users: [REDACTED]

- From the pipeline execution, you can click **Actions** to view the pipeline, and select an action such as **Pause**, **Cancel**, and more. When a pipeline execution is in progress, if you are an administrator you can delete or sync the pipeline execution. If you are a non-admin user, you can delete a running pipeline.
- To navigate easily between executions and see the details for a task, click **Executions**, and click a pipeline run. Then, click the tab at the top and select the pipeline run.

Congratulations! You ran a pipeline, examined the pipeline execution, and viewed a user operation task that required approval for the pipeline to continue to run. You also used the **Actions** menu in the pipeline execution to return to the pipeline model so that you can make any required changes.

To learn more about using Automation Pipelines to automate your software release cycle, see [Tutorials for using](#).

What types of tasks are available in Automation Pipelines

What task types are available

When you configure your pipeline, you add specific types of tasks that the pipeline runs for the actions you need. Each task type integrates with another application and enables your pipeline as it builds, tests, and delivers your applications.

To run your pipeline, whether you must pull artifacts from a repository for deployment, run a remote script, or require approval on a user operation from a team member, Automation Pipelines has the type of task for you!

Automation Pipelines supports canceling a pipeline run on various types of tasks. When you click **Cancel** on a pipeline execution, the task, stage, or entire pipeline enters the canceling state and cancels the pipeline run.

Automation Pipelines allows you to cancel the pipeline run on a task, stage, or the entire pipeline when using these tasks:

- Jenkins
- SSH
- PowerShell
- User Operation
- Pipeline
- Cloud template
- vRO
- POLL

Automation Pipelines does not propagate the cancel behavior to third-party systems for these tasks: CI, Custom Integration, or Kubernetes. Automation Pipelines marks the task as canceled and immediately stops fetching the status without waiting for the task to finish. The task might complete or fail on the third-party system but immediately stops running in Automation Pipelines when you click **Cancel**.

Before you use a task in your pipeline, verify that the corresponding endpoint is available.

Table 55: Obtain an approval or set a decision point

Type of task	What it does	Examples and details
User Operation	A User Operation task enables a required approval that controls when a pipeline runs and must stop for an approval.	See How do I run a pipeline and see results , and How do I manage user access and approvals in .
Condition	Adds a decision point, which determines whether the pipeline continues to run, or stops, based on condition expressions. When the condition is true, the pipeline runs successive tasks. When false, the pipeline stops.	See How do I use variable bindings in a condition task to run or stop a pipeline in .

Table 56: Automate continuous integration and deployment

Type of task	What it does	Examples and details
Cloud template	Deploys an automation cloud template from GitHub and provisions an application, and automates the continuous integration and continuous delivery (CICD) of that cloud template for your deployment.	<p>See How do I automate the release of an application that I deploy from a YAML cloud template in. The cloud template parameters appear after you first select Create or Update, then select Cloud Template and Version. You can add these elements, which accommodate variable bindings, to the input text areas in the cloud template task:</p> <ul style="list-style-type: none"> • Integer • Enumeration string • Boolean • Array variable <p>When you use variable binding in the input, be aware of these exceptions. For enumerations, you must select an enumeration value from a fixed set. For Boolean values, you must enter the value in the input text area.</p> <p>The cloud template parameter appears in the cloud template task when a cloud template in Automation Assembler includes input variables. For example, if a cloud template has an input type of <code>Integer</code>, you can enter the integer directly or as a variable by using variable binding.</p>
CI	The CI task enables continuous integration of your code into your pipeline by pulling a Docker build image from a registry endpoint, and deploying it to a Kubernetes cluster.	See Planning a CICD native build in before using the smart pipeline template .

Table continued on next page

Continued from previous page

Type of task	What it does	Examples and details
	The CI task displays 100 lines of the log as output, and displays 500 lines when you download the logs. The CI tasks requires ephemeral ports 32768 to 61000.	
Custom	The Custom task integrates Automation Pipelines with your own build, test, and deploy tools.	See How do I integrate my own build, test, and deploy tools with .
Kubernetes	Automate the deployment of your software applications to Kubernetes clusters.	See How do I automate the release of an application in to a Kubernetes cluster .
Pipeline	Nests a pipeline in a primary pipeline. When a pipeline is nested, it behaves as a task in the primary pipeline. On the Task tab of the primary pipeline, you can easily navigate to the nested pipeline by clicking the link to it. The nested pipeline opens in a new browser tab.	To find nested pipelines in Executions , enter <code>nested</code> in the search area.

Table 57: Integrate development, test, and deployment applications

Task type...	What it does...	Examples and details...
Bamboo	Interacts with a Bamboo continuous integration (CI) server, which continuously builds, tests, and integrates software in preparation for deployment, and triggers code builds when developers commit changes. It exposes the artifact locations that the Bamboo build produces so that the task can output the parameters for other tasks to use for build and deployment.	Connect to a Bamboo server endpoint and start a Bamboo build plan from your pipeline.
Jenkins	Triggers Jenkins jobs that build and test your source code, runs test cases, and can use custom scripts.	See How do I integrate with Jenkins .
TFS	Allows you to connect your pipeline to Team Foundation Server to manage and invoke build projects, including configured jobs that build and test your code.	For versions of Team Foundation Server that Automation Pipelines supports, see What are Endpoints in .
vRO	Extends the capability of Automation Pipelines by running predefined or custom workflows in VMware Aria Automation Orchestrator. Automation Pipelines supports basic authentication and token-based authentication for VMware Aria Automation Orchestrator. Automation Pipelines uses the API token to authenticate and validate the VMware Aria Automation Orchestrator	See How do I integrate with .

Type of task	What it does	Examples and details
	<p>Automation instance as the SSH host if you need to modify the MaxSessions and MaxOpenSessions configuration settings.</p> <p>The SSH task does not support OpenSSH type private keys. Generate the public/private key pair using one of the following methods:</p> <ul style="list-style-type: none"> On a Windows machine, use PuTTYgen to generate the key pair. On a Mac or Linux machine, use <code>ssh -v</code> to verify that the SSH version is earlier than 7.8, then use <code>ssh -keygen</code> to generate the key pair in a terminal window. <p>NOTE Verify that the generated key does not appear with BEGIN OPENSSH PRIVATE KEY.</p> <p>If the generated public key is an authorized key in the remote machine, refer to one of the following articles to change the OpenSSH private format:</p> <ul style="list-style-type: none"> To use the PuTTY key generator, see https://www.simplified.guide/putty/convert-ssh-key-to-ppk. To use WinSCP, see https://superuser.com/questions/912304/how-do-you-convert-an-ssh-private-key-to-a-ppk-on-the-windows-command-line. <p>When configuring the SSH task, the private key must be entered in plain text. Saving the key as a variable or input changes the key format and the pipeline task will fail to run.</p>	

Creating and using shared pipelines in Automation Pipelines

Creating and using shared pipelines

As a Automation Pipelines administrator, you can share pipelines so that users within an organization can run them on any other project or add them as nested tasks within a pipeline on another project.

Why is a shared pipeline useful

When you share a pipeline, you eliminate the need to create the same pipeline for different projects within an organization. And if you update a shared pipeline, all pipeline users will have the same update.

A shared pipeline can also be used in Automation Service Broker. A Automation Service Broker administrator can add your shared pipeline as catalog item for users to request and run on multiple projects.

Only Automation Pipelines administrators can share or stop sharing pipelines.

How do I share a pipeline

To share a pipeline, click **Pipeline** and select the pipeline that you want to share.

1. Click **Actions > Share across projects**
2. If the pipeline is deactivated, click **Actions > Enable**.
3. To make your shared pipeline available in Automation Service Broker, click **Actions > Release**.

After you release the pipeline, an Automation Service Broker administrator can add it to Automation Service Broker. See [Add pipelines to the Automation Service Broker catalog](#).

How do I run a shared pipeline

To run a shared pipeline, you select the pipeline and select a project.

The pipeline is run in the context of the project you select and only the pipeline model is shared. Any infrastructure such as endpoints or variables used in the pipeline is not shared. If a shared pipeline that uses endpoints or variables is run on a different project, then those endpoints and variables must be available on that project.

For example, let's say that `jenkinsPipeline` uses `projectA` and includes a task with an endpoint named `jenkinsEndpoint`.

The screenshot shows the VMware Aria Automation pipeline editor interface. At the top, the pipeline is named "jenkinsPipeline" with an "Enabled" status and an "ACTIONS" dropdown. Below the header are tabs for "Input", "Workspace", "Model" (which is selected), and "Output". The main workspace on the left displays a pipeline model with a stage named "Stage0". Inside "Stage0", there is a task named "Task0" which is configured to use the "Jenkins" type. To the right of the model, a detailed configuration panel for "Task0" is open. The configuration fields include:

- Task name ***: Task0
- Type ***: Jenkins
- Preconditions**: An empty text input field with a "SYNTAX GUIDE" button.
- Continue on failure**: A checkbox that is unchecked.
- Jenkins** section:
 - Endpoint ***: jenkinsEndpoint
 - Job folder**: A note stating "The path to jobs folder specified in the Jenkins endpoint can be overridden here. If left blank it will take the path from the endpoint if available."
 - Job \$ ***: Build-DemoApp

If you share `jenkinsPipeline` and want to run it in the context of `projectB`, then there must be a `jenkinsEndpoint` on `projectB`. If there is no `jenkinsEndpoint`, create the endpoint on `projectB` before running the shared pipeline.

The following procedure shows how to duplicate an endpoint on another project. You follow similar steps for a variable.

1. Click **Endpoints**. On the endpoint that you want to duplicate, for example `jenkinsEndpoint`, click **Actions > Export**.
2. Click the **Import** button, and select the YAML file for `jenkinsEndpoint`.
3. Edit the file to change the project, such as `projectB` in the following sample YAML code.

```
---
project: projectB
kind: ENDPOINT
name: jenkinsEndpoint
...
...
```

4. Click **Import**.

To run `jenkinsPipeline` on `projectB`, click **Run** on the pipeline card, and select `projectB` as the project.

NOTE

To run the shared pipeline on `projectB`, you must have the Automation Pipelines role of administrator, developer, or executor. If you are a Automation Pipelines viewer or user, you can not run the pipeline unless a Automation Pipelines administrator makes you a project administrator or project member in `projectB`. For more information about roles in Automation Pipelines, see [How do I manage user access and approvals](#) .

[How do I add a shared pipeline to another pipeline](#)

Using shared pipelines as nested tasks within another pipeline enables you to extend pipeline functionality beyond the pipelines that are included in one project. The shared pipelines can be on different projects from each other and from the pipeline where they are included as nested tasks.

The following example shows a pipeline named `master-shared-pipeline-demo` with two nested pipeline tasks.

The screenshot shows the 'master-shared-pipeline-demo' pipeline in the 'Model' tab. The pipeline structure is as follows:

- Stage0:**
 - Task0:** Pipeline
 - + Parallel Task**
- Stage1:**
 - + Parallel Task**

The right panel displays the configuration for **Task0**:

- Task name ***: Task0
- Type ***: Pipeline
- Precondition \$**: (empty field)
- Continue on failure**: (checkbox)
- Pipeline details**:
 - Pipeline ***: (dropdown menu open, showing options like 'testRestGlobal (bhawesh)', 'test-pipeline-1 (bhawesh)', etc.)
- Output**:
 - The result of a task is a JSON object corresponding dot or bracket [] not
 - Name**: (table row)
 - status**: (table row)
 - statusMessage**: (table row)

To specify the pipeline for Task0, select from a list of shared pipelines. Every pipeline name includes the project name. If several shared pipelines have the same name, you can use the project name to select the one you want.

NOTE

To run a pipeline that includes nested pipelines, the pipeline must be able to access any endpoints or variables that are used in the nested pipelines. If it cannot, you must create the content on the project for the pipeline.

How do I use a shared pipeline for rollback

To use a shared pipeline for rollback, you select it from a list of pipelines when you configure rollback for the task. Automation Pipelines filters the list to display only pipelines on the same project or shared pipelines on different projects.

How do I use a shared template in a pipeline

You can use a template shared in Automation Assembler as a template source for a task in a pipeline. Using shared templates provides access to more templates than those included in one project.

Before defining the task in Automation Pipelines, verify that the template is shared in Automation Assembler and that you know the name and version. When a template is shared, an icon next to the project name appears on the list of cloud templates.

To use an Automation Assembler template in your shared pipeline:

- For Task type, select **Automation Template**.
- For Action, select **Create Deployment** or **Update Deployment**.
- If you are updating a deployment, select the Deployment name.
- For Cloud template source, select **Automation Template**.
- For Cloud template name, you either select from the list of templates or type a name. If you do not see the template listed, that is because the template is in a different project from the pipeline and Automation Pipelines only lists the templates that are in the same project.

- For Cloud template version, type the version of the template.

In the following example, `shared-bp` is the shared template that you verified in Automation Assembler and want to use but it is not listed as a selection, so you type the name.

Pipeline-with-Shared-Cloud-Template Enabled ACTIONS

Input Workspace Model Output

Task : Task0 Notifications Rollback VALIDATE TASK

Task name * Task0
Can contain alphanumeric (a-z, A-Z, 0-9), whitespace, hyphen(-), and underscore(_) characters. Dot(.) is not allowed.

Type * Template

Precondition \$ SYNTAX GUIDE

Continue on failure

VMware Cloud Templates & Deployments

Action Create Deployment

Deployment name \$

Cloud template source Cloud Assembly Source Control

Cloud template name \$ * shared-bp Cloud template not present!

Cloud template version \$ * 1

NOTE

If the template that you specify is not shared and you try to use it in a pipeline on a different project, the pipeline will fail to run with a message indicating that the selected template is not shared.

How do I delete or stop sharing a pipeline

If you add a shared pipeline as a nested task or to rollback a task, that pipeline is referenced by the pipeline in which it is used. If you want to delete or stop sharing the pipeline, you must remove it from any pipeline that references it.

For example, if `master-shared-pipeline-demo` includes `Shared-Pipeline` as a nested task, then `Shared-Pipeline` is referenced. You cannot delete or stop sharing `Shared-Pipeline` until you remove it from `master-shared-pipeline-demo`.

Or if `TestRollback` uses `Shared-Pipeline` to rollback a task, then `Shared-Pipeline` is referenced. You cannot delete or stop sharing `Shared-Pipeline` until you remove it from rollback on the task in `TestRollback`.

The following procedure shows how to check a pipeline's references and remove it from the pipeline that references it before you delete or stop sharing it.

- Check for references and update pipeline references if found.

- Click **Pipelines**. On the shared pipeline that you want to check, click **Actions** > **View references**.

- b. Note the names of any **Referred Pipelines**.

- c. Open the pipelines that reference the shared pipeline. Remove the shared pipeline that is being used as a nested task or to rollback a task, and save the pipeline.
2. Delete or stop sharing a pipeline.
- On the pipeline that you want to delete, click **Actions > Delete**.
 - On the pipeline that you want to stop sharing, click **Actions > Stop Sharing**.

How do I use variable bindings in Automation Pipelines pipelines

How do I do use variable bindings in pipelines

Binding a pipeline task means that you create a dependency for the task when the pipeline runs. You can create a binding for a pipeline task in several ways. You can bind a task to another task, bind it to a variable and expression, or bind it to a condition.

How to apply dollar bindings to cloud template variables in a cloud template task

You can apply dollar bindings to cloud template variables in a Automation Pipelines pipeline cloud template task. The way you modify the variables in Automation Pipelines depends on the coding of the variable properties in the cloud template.

If you must use dollar bindings in a cloud template task, but the current version of the cloud template that you're using in the cloud template task doesn't allow it, modify the cloud template in Automation Assembler and deploy a new version. Then, use the new cloud template version in your cloud template task, and add the dollar bindings where needed.

To apply dollar bindings on the types of properties that the Automation Assembler cloud template provides, you must have the correct permissions.

- You must have the same role as the person who created the cloud template deployment in Automation Assembler.
- The person who models the pipeline and the person who runs the pipeline might be two different users and might have different roles.
- If a developer has the Automation Pipelines Executor role and models the pipeline, the developer must also have the same Automation Assembler role of the person who deployed the cloud template. For example, the required role might be Automation Assembler administrator.
- Only the person who models the pipeline can create the pipeline and create the deployment because they have permission.

To use an API token in the cloud template task:

- The person who models the pipeline can give an API token to another user who has the Automation Pipelines Executor role. Then, when the Executor runs the pipeline, it uses the API token and the credentials that the API token creates.
- When a user enters the API token in the cloud template task, it creates the credentials that the pipeline requires.
- To encrypt the API token value, click **Create Variable**.

- If you don't create a variable for the API token, and use it in the cloud template task, the API token value appears in plain text.

To apply dollar bindings to cloud template variables in a cloud template task, follow these steps.

You start with a cloud template that has input variable properties defined, such as `integerVar`, `stringVar`, `flavorVar`, `BooleanVar`, `objectVar`, and `arrayVar`. You can find the image properties defined in the resources section. The properties in the cloud template code might resemble:

```
formatVersion: 1

inputs:

  integerVar:
    type: integer
    encrypted: false
    default: 1

  stringVar:
    type: string
    encrypted: false
    default: bkix

  flavorVar:
    type: string
    encrypted: false
    default: medium

  BooleanVar:
    type: boolean
    encrypted: false
    default: true

  objectVar:
    type: object
    encrypted: false
    default:
      bkix2: bkix2

  arrayVar:
    type: array
    encrypted: false
    default:
      - '1'
```

```

- '2'

resources:

Cloud_Machine_1:
  type: Cloud.Machine
  properties:
    image: ubuntu
    flavor: micro
    count: '${input.integerVar}'

```

You can use dollar sign variables (\$) for `image` and `flavor`. For example:

```

resources:

Cloud_Machine_1:
  type: Cloud.Machine
  properties:
    input: '${input.image}'
    flavor: '${input.flavor}'

```

To use a cloud template in a Automation Pipelines pipeline, and add dollar bindings to it, follow these steps.

1. In Automation Pipelines, click **Pipelines** > **Blank Canvas**.
2. Add an **Automation Templates** task to the pipeline.
3. In the template task, for **Template source** select **Automation Assembler**, enter the cloud template name, and select the cloud template version.
4. Notice that you can enter an API token, which provides credentials for the pipeline. To create a variable that encrypts the API token in the cloud template task, click **Create Variable**.
5. In the **Parameter and Value** table that appears, notice the parameter values. The default value for `flavor` is `small` and the default value for `image` is `ubuntu`.
6. Let's say that you must change the cloud template in Automation Assembler. For example, you:
 - a. Set the `flavor` so that it uses a property of type `array`. Automation Assembler allows comma-separated values for `Flavor` when the type is `array`.
 - b. Click **Deploy**.
 - c. On the Deployment Type page, enter a deployment name, and select the version of the cloud template.
 - d. On the Deployment Inputs page, you can define one or more values for `Flavor`.
 - e. Notice that the Deployment inputs include all the variables defined in your cloud template code, and appear as defined in the cloud template code. For example: Integer Var, String Var, Flavor Var, Boolean Var, Object Var, and Array Var. String Var and Flavor Var are string values, and Boolean Var is a check box.
 - f. Click **Deploy**.
7. In Automation Pipelines, select the new version of the cloud template, and enter values in the **Parameter and Value** table. Cloud templates support the following types of parameters, which enable Automation Pipelines bindings by using dollar sign variables. Slight differences exist between the user interface of the Automation Pipelines cloud

template task and the user interface of the Automation Assembler cloud template. Depending on the coding of a cloud template in Automation Assembler, entering values in the cloud template task in Automation Pipelines might not be allowed.

- For **flavorVar**, if the cloud template defined the type as string or array, enter a string or a comma-separated value array. An example array resembles `test, test`.
- For **BooleanVar**, in the drop-down menu select **true** or **false**. Or, to use a variable binding, enter `$` and select a variable binding from the list.

Parameter	Value
stringVar	raj
integerVar	1
flavorVar	medium
BooleanVar	\$
objectVar	var input comments requestBy executionIndex executionId executionUrl
arrayVar	
Output Parameter	name description Stage0

- For **objectVar**, enter the value with curly brackets and quotation marks in this format: `{"bkix":"bkix":}`.
 - The **objectVar** will be passed to the cloud template, and can be used in various ways depending on the cloud template. It allows a string format for a JSON object, and you can add key-value pairs as comma-separated values in the key-value table. You can enter plain text for a JSON object, or a key-value pair as a normal stringified format for JSON.
 - For **arrayVar**, enter the comma-separated input value as an array in this format: `["1", "2"]`.
8. In the pipeline, you can bind an input parameter to an array.

- Click the **Input** tab.
- Enter a name for the input. For example, `arrayInput`.
- In the **Parameter and Value** table, click in **arrayVar** and enter `${input.arrayInput}`.
- After you save the pipeline and enable it, when the pipeline runs, you must provide an array input value. For example, enter `["1", "2"]` and click **Run**.

Now you have learned how to use dollar sign (\$) variable bindings in a cloud template in a Automation Pipelines pipeline cloud template task.

How to pass a parameter to a pipeline when it runs

You can add input parameters to your pipeline to have Automation Pipelines pass them to the pipeline. Then, when the pipeline runs, a user must enter the value for the input parameter. When you add output parameters to your pipeline, the pipeline tasks can use the output value from a task. Automation Pipelines supports using parameters in many ways that support your own pipeline needs.

For example, to prompt a user for the URL to their Git server when a pipeline with a REST task runs, you can bind the REST task to a Git server URL.

To create the variable binding, you add a URL binding variable to the REST task. When the pipeline runs and reaches the REST task, a user must enter their URL to the Git server. Here's how you would create the binding:

1. In your pipeline, click the **Input** tab.
2. To set the parameter, for **Auto inject parameters** click **Git**.
The list of Git parameters appears, and includes **GIT_SERVER_URL**. If you must use a default value for the Git server URL, edit this parameter.
3. Click **Model**, and click your REST task.
4. On the **Task** tab, in the **URL** area, enter \${}, then select **input** and **GIT_SERVER_URL**.

The screenshot shows the 'Task : Task3' configuration page. Under the 'REST Request' section, the 'URL' field contains the placeholder \${input.GIT_SERVER_URL}. A dropdown menu is open over this field, listing several Git-related parameters: GIT_BRANCH_NAME, GIT_CHANGE_SUBJECT, GIT_COMMIT_ID, GIT_EVENT_DESCRIPTION, GIT_EVENT_OWNER_NAME, GIT_EVENT_TIMESTAMP, GIT_REPO_NAME, and GIT_SERVER_URL. The 'GIT_SERVER_URL' option is currently selected, indicated by a gray background. Below the URL field, there are tabs for 'status', 'responseHeaders', 'responseBody', 'responseJson', and 'responseCode'.

- The entry resembles: \${input.GIT_SERVER_URL}
5. To verify the integrity of the variable binding for the task, click **Validate Task**. Automation Pipelines indicates that the task validated successfully.
 6. When the pipeline runs the REST task, a user must enter the URL of the Git server. Otherwise, the task does not finish running.

How to bind two pipeline tasks by creating input and output parameters

When you bind tasks together, you add a binding variable to the input configuration of the receiving task. Then, when the pipeline runs, a user replaces the binding variable with the required input.

To bind pipeline tasks together, you use the dollar sign variable (\$) in the input parameters and output parameters. This example shows you how.

Let's say you need your pipeline to call a URL in a REST task, and output a response. To call the URL and output the response, you include both input and output parameters in your REST task. You also need a user who can approve the

task, and include a User Operations task for another user who can approve it when the pipeline runs. This example shows you how to use expressions in the input and output parameters, and have the pipeline wait for approval on the task.

1. In your pipeline, click the **Input** tab.

Starred	Name	Value	Description
☆	URL	{Stage0.Task3.input.http://www.docs.vmware.com}	Docs URL

2. Leave the **Auto inject parameters** as **None**.
3. Click **Add**, and enter the parameter name, value, and description, and click **OK**. For example:
 - a. Enter a URL name.
 - b. Enter the value: `{Stage0.Task3.input.http://www.docs.vmware.com}`
 - c. Enter a description.
4. Click the **Output** tab, click **Add**, and enter the output parameter name and mapping.

- a. Enter a unique output parameter name.
- b. Click in the **Reference** area, and enter `$`.
- c. Enter the task output mapping by selecting the options as they pop up. Select the **Stage0**, select **Task3**, select **output**, and select **responseCode**. Then, click **OK**.

The screenshot shows the 'Output' tab of the pipeline configuration for 'rest-ix-1'. The 'Output Parameters' table contains one entry:

Starred ⓘ	Name	Reference
☆	RESTResponse	\${Stage0.Task3.output.responseCode}

5. Save your pipeline.
6. From the **Actions** menu, click **Run**.
7. Click **Actions > View executions**.
8. Click the pipeline execution, and examine the input parameters and output parameters that you defined.

The main area displays a list of executions. One execution is highlighted: 'rest-ix-1#6', which is 'COMPLETED'. The status bar indicates 'Stages: 3/3' with all stages marked as green. Below the status, it says 'By [redacted] on Feb 5, 2020, 1:28:52 PM' and 'Execution Completed.' There are also 'Input' and 'Output' buttons with star icons.

How do I learn more about variables and expressions

To see details about using variables and expressions when you bind pipeline tasks, see [What variables and expressions can I use when binding pipeline tasks in](#).

To learn how to use the pipeline task output with a condition variable binding, see [How do I use variable bindings in a condition task to run or stop a pipeline in](#).

How do I use variable bindings in a condition task to run or stop a pipeline in Automation Pipelines

How do I use variable bindings in a condition task to run or stop a pipeline

You can have the output of a task in your pipeline determine whether the pipeline runs or stops based on a condition that you supply. To pass or fail the pipeline based on the task output, you use the Condition task.

- Verify that a pipeline exists, and that it includes stages and tasks.

You use the **Condition** task as a decision point in your pipeline. By using the Condition task with a condition expression that you provide, you can evaluate any properties in your pipeline, stages, and tasks. The result of the Condition task determines whether the next task in the pipeline runs.

- A true condition allows the pipeline run continue.
- A false condition stops the pipeline.

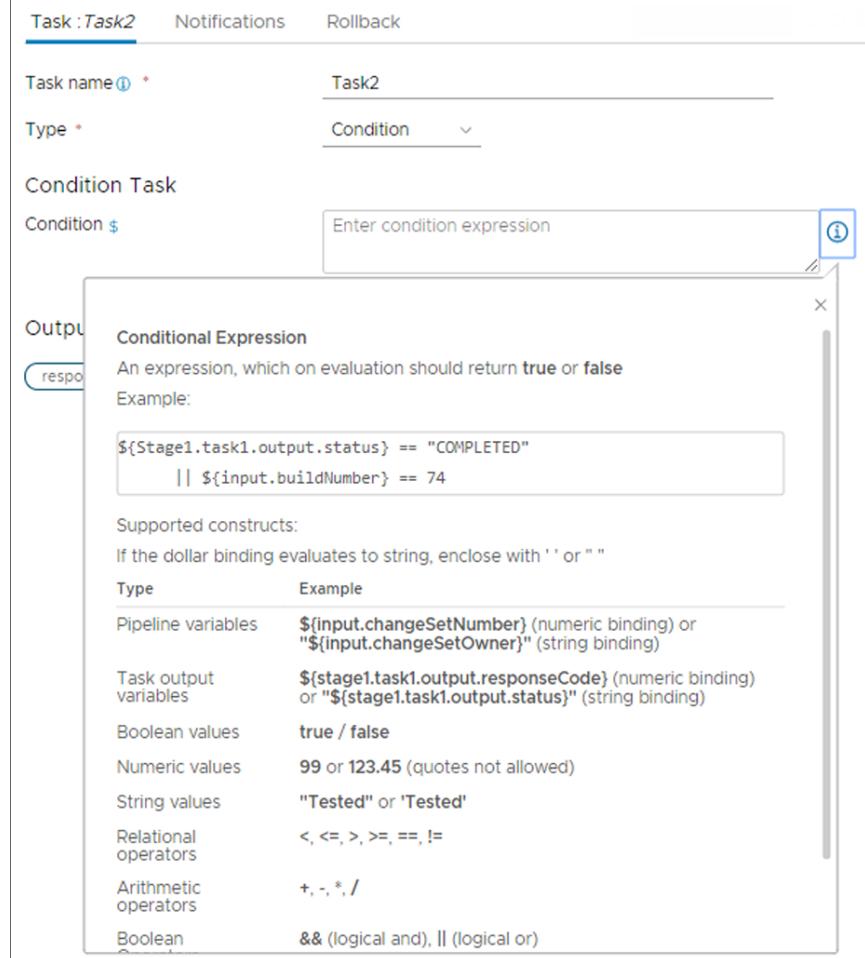

For examples of how to use the output value of one task as the input to the next task by binding the tasks together with a Condition task, see [How do I use variable bindings in pipelines](#).

Table 60: How the Condition task and its condition expression relate to the pipeline

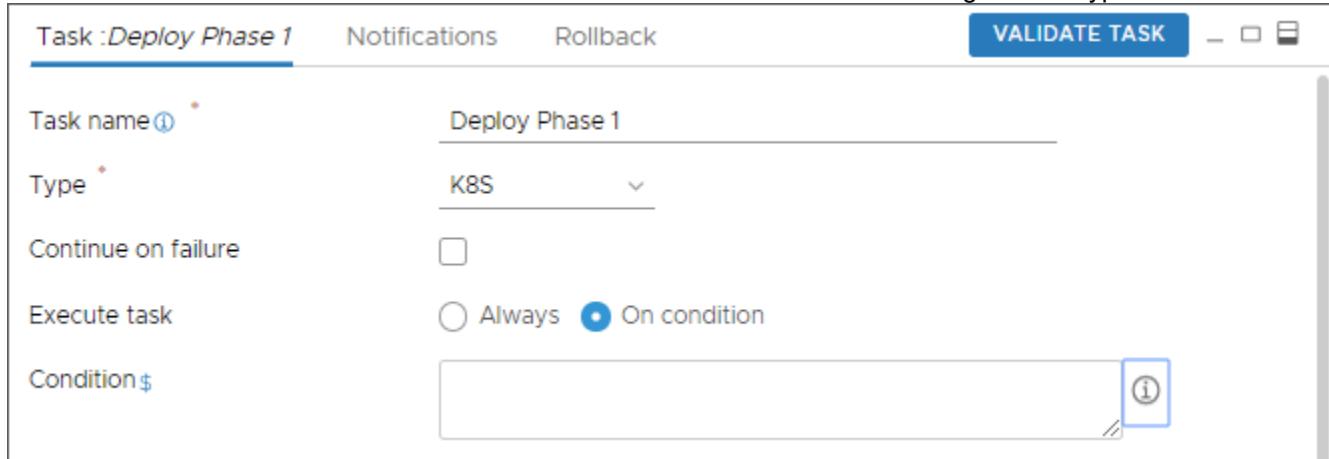

Condition task	What it affects	What it does
Condition task	Pipeline	The Condition task determines whether the pipeline runs or stops at that point, based on whether the task output is true or false.
Condition expression	Condition task output	When the pipeline runs, the condition expression that you include in the Condition task produces a true or false output status. For example, a condition expression can require the Condition task output status as Completed, or use a build number of 74. The condition expression appears on the Task tab in the Condition task.

		 <p>Task : Task2 Notifications Rollback</p> <p>Task name <input type="text" value="Task2"/> * Type <input type="text" value="Condition"/> *</p> <p>Condition Task</p> <p>Condition \$ <input type="text" value="Enter condition expression"/> ⓘ</p> <p>Conditional Expression An expression, which on evaluation should return true or false Example:</p> <pre> \${Stage1.task1.output.status} == "COMPLETED" \${input.buildNumber} == 74</pre> <p>Supported constructs: If the dollar binding evaluates to string, enclose with '' or ""</p> <table> <thead> <tr> <th>Type</th> <th>Example</th> </tr> </thead> <tbody> <tr> <td>Pipeline variables</td> <td> \${input.changeSetNumber} (numeric binding) or "\${input.changeSetOwner}" (string binding)</td> </tr> <tr> <td>Task output variables</td> <td> \${stage1.task1.output.responseCode} (numeric binding) or "\${stage1.task1.output.status}" (string binding)</td> </tr> <tr> <td>Boolean values</td> <td> true / false</td> </tr> <tr> <td>Numeric values</td> <td> 99 or 123.45 (quotes not allowed)</td> </tr> <tr> <td>String values</td> <td> "Tested" or 'Tested'</td> </tr> <tr> <td>Relational operators</td> <td> <, <=, >, >=, ==, !=</td> </tr> <tr> <td>Arithmetic operators</td> <td> +, -, *, /</td> </tr> <tr> <td>Boolean</td> <td> && (logical and), (logical or)</td> </tr> </tbody> </table>	Type	Example	Pipeline variables	\${input.changeSetNumber} (numeric binding) or "\${input.changeSetOwner}" (string binding)	Task output variables	\${stage1.task1.output.responseCode} (numeric binding) or "\${stage1.task1.output.status}" (string binding)	Boolean values	true / false	Numeric values	99 or 123.45 (quotes not allowed)	String values	"Tested" or 'Tested'	Relational operators	<, <=, >, >=, ==, !=	Arithmetic operators	+, -, *, /	Boolean	&& (logical and), (logical or)
Type	Example																			
Pipeline variables	\${input.changeSetNumber} (numeric binding) or "\${input.changeSetOwner}" (string binding)																			
Task output variables	\${stage1.task1.output.responseCode} (numeric binding) or "\${stage1.task1.output.status}" (string binding)																			
Boolean values	true / false																			
Numeric values	99 or 123.45 (quotes not allowed)																			
String values	"Tested" or 'Tested'																			
Relational operators	<, <=, >, >=, ==, !=																			
Arithmetic operators	+, -, *, /																			
Boolean	&& (logical and), (logical or)																			

The **Condition** task differs in function and behavior from the **On Condition** setting in other types of tasks.

Task : Deploy Phase 1 Notifications Rollback VALIDATE TASK

Task name * Type *

Continue on failure

Execute task Always On condition

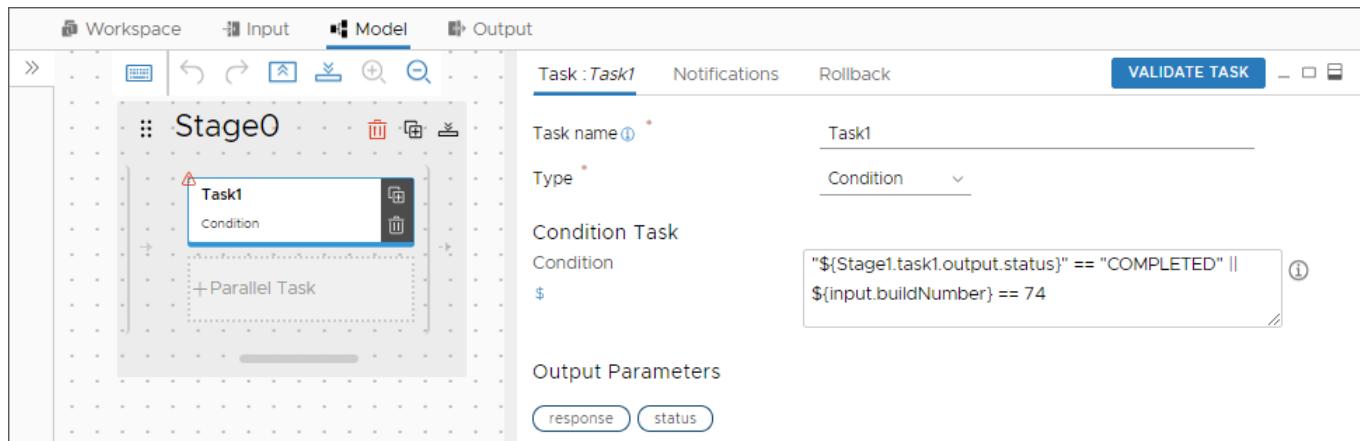

Condition \$ ⓘ

In other types of tasks, the **On Condition** determines whether the current task runs, rather than successive tasks, based on the evaluation of its precondition expression of true or false. The condition expression for the **On Condition** setting produces a true or false output status for the current task when the pipeline runs. The **On Condition** setting appears on the Task tab with its own condition expression.

This example uses the Condition task.

1. In your pipeline, determine the decision point where the Condition task must appear.
2. Add the Condition task before the task that depends on its status of pass or fail.
3. Add a condition expression to the Condition task.

For example: "\${Stage1.task1.output.status}" == "COMPLETED" || \${input.buildNumber} == 74

4. Validate the task.
5. Save the pipeline, then enable and run it.

Watch the pipeline executions and notice whether the pipeline continues running, or stops at the Condition task.

If you roll back a pipeline deployment, you can also use the Condition task. For example, in a rollback pipeline, the Condition task helps Automation Pipelines mark a pipeline failure based on the condition expression, and can trigger a single rollback flow for various failure types.

To roll back a deployment, see [How do I roll back my deployment in](#).

What variables and expressions can I use when binding pipeline tasks in Automation Pipelines

What variables and expressions can I use when binding pipeline tasks

With variables and expressions, you can use input parameters and output parameters with your pipeline tasks. The parameters you enter bind your pipeline task to one or more variables, expressions, or conditions, and determine the pipeline behavior when it runs.

Pipelines can run simple or complex software delivery solutions

When you bind pipeline tasks together, you can include default and complex expressions. As a result, your pipeline can run simple or complex software delivery solutions.

To create the parameters in your pipeline, click the **Input** or **Output** tab, and add a variable by entering the dollar sign \$ and an expression. For example, this parameter is used as a task input that calls a URL: \${Stage0.Task3.input.URL}.

The format for variable bindings uses syntax components called scopes and keys. The **SCOPE** defines the context as input or output, and the **KEY** defines the details. In the parameter example \${Stage0.Task3.input.URL}, the input is the **SCOPE** and the URL is the **KEY**.

Output properties of any task can resolve to any number of nested levels of variable binding.

To learn more about using variable bindings in pipelines, see [How do I use variable bindings in pipelines](#).

Using dollar expressions with scopes and keys to bind pipeline tasks

You can bind pipeline tasks together by using expressions in dollar sign variables. You enter expressions as \${SCOPE.KEY.<PATH>}.

To determine the behavior of a pipeline task, in each expression, **SCOPE** is the context that Automation Pipelines uses. The scope looks for a **KEY**, which defines the detail for the action that the task takes. When the value for **KEY** is a nested object, you can provide an optional **PATH**.

These examples describe **SCOPE** and **KEY**, and show you how you can use them in your pipeline.

Table 61: Using SCOPE and KEY

SCOPE	Purpose of expression and example	KEY	How to use SCOPE and KEY in your pipeline
input	Input properties of a pipeline: \${input.input1}	Name of the input property	To refer to the input property of a pipeline in a task, use this format: tasks: mytask: type: REST input: url: \${input.url} action: get
output	Output properties of a pipeline: \${output.output1}	Name of the output property	To refer to an output property for sending a notification, use this format: notifications: email: - endpoint: MyEmailEndpoint subject: "Deployment"

Table continued on next page

Continued from previous page

SCOPE	Purpose of expression and example	KEY	How to use SCOPE and KEY in your pipeline
			<pre>Successful" event: COMPLETED to: - user@example.org body: Pipeline deployed the service successfully. Refer \${output.serviceURL}</pre>
task input	Input to a task: \$ {MY_STAGE.MY_TASK.input.SOMETHING}	Indicates the input of a task in a notification	When a Jenkins job starts, it can refer to the name of the job triggered from the task input. In this case, send a notification by using this format: <pre>notifications: email: - endpoint: MyEmailEndpoint stage: MY_STAGE task: MY_TASK subject: "Build Started" event: STARTED to: - user@example.org body: Jenkins job \${MY_STAGE.MY_TASK.input.job} started for commit id \${input.COMMITID}.</pre>
task output	Output of a task: \$ {MY_STAGE.MY_TASK.output.SOMETHING}	Indicates the output of a task in a subsequent task	To refer to the output of pipeline task 1 in task 2, use this format:

Table continued on next page

Continued from previous page

SCOPE	Purpose of expression and example	KEY	How to use SCOPE and KEY in your pipeline
			password: \${var.jenkinsPassword}
var	Variable: \${var.myVariable}	Refer to variable in a pipeline	To refer to variable in a pipeline URL, use this format: tasks: task1: type: REST input: action: get url: \${var.MY_SERVER_URL}
task status	Status of a task: \$ {MY_STAGE.MY_TASK.status} \$ {MY_STAGE.MY_TASK.statusMessage}		
stage status	Status of a stage: \$ {MY_STAGE.status} \$ {MY_STAGE.statusMessage}		

Default Expressions

You can use variables with expressions in your pipeline. This summary includes the default expressions that you can use.

Expression	Description
\$ {comments}	Comments provided when at pipeline execution request.
\$ {duration}	Duration of the pipeline execution.
\$ {endTime}	End time of the pipeline execution in UTC, if concluded.
\$ {executedOn}	Same as the start time, the starting time of the pipeline execution in UTC.
\$ {executionId}	ID of the pipeline execution.
\$ {executionUrl}	URL that navigates to the pipeline execution in the user interface.
\$ {name}	Name of the pipeline.

Table continued on next page

Continued from previous page

Expression	Description
<code> \${requestBy}</code>	Name of the user who requested the execution.
<code> \${stageName}</code>	Name of the current stage, when used in the scope of a stage.
<code> \${startTime}</code>	Starting time of the pipeline execution in UTC.
<code> \${status}</code>	Status of the execution.
<code> \${statusMessage}</code>	Status message of the pipeline execution.
<code> \${taskName}</code>	Name of the current task, when used at a task input or notification.

Using SCOPE and KEY in pipeline tasks

You can use expressions with any of the supported pipeline tasks. These examples show you how to define the `SCOPE` and `KEY`, and confirm the syntax. The code examples use `MY_STAGE` and `MY_TASK` as the pipeline stage and task names.

To find out more about available tasks, see [What types of tasks are available in](#).

Table 62: Gating tasks

Task	Scope	Key	How to use SCOPE and KEY in the task
User Operation			
	Input	<p><code>summary</code>: Summary of the request for the User Operation</p> <p><code>description</code>: Description of the request for the User Operation</p> <p><code>approvers</code>: List of approver email addresses, where each entry can be a variable with a comma, or use a semi-colon for separate emails</p> <p><code>approverGroups</code>: List of approver group addresses for the platform and identity</p> <p><code>sendemail</code>: Optionally sends an email notification upon request or response when set to true</p> <p><code>expirationInDays</code>: Number of days that represents the expiry time of the request</p>	<pre>\$ {MY_STAGE.MY_TASK.input.summary} \$ {MY_STAGE.MY_TASK.input.description} \$ {MY_STAGE.MY_TASK.input.approvers} \$ {MY_STAGE.MY_TASK.input.approverGroups} \$ {MY_STAGE.MY_TASK.input.sendemail} \$ {MY_STAGE.MY_TASK.input.expirationInDays}</pre>
	Output	<p><code>index</code>: Six-digit hexadecimal string that represents the request</p> <p><code>respondedBy</code>: Account name of the person who approved/rejected the User Operation</p>	<pre>\$ {MY_STAGE.MY_TASK.output.index} \$ {MY_STAGE.MY_TASK.output.respondedBy}</pre>

Table continued on next page

How to use a variable binding between tasks

This example shows you how to use variable bindings in your pipeline tasks.

Table 70: Sample syntax formats

Example	Syntax
To use a task output value for pipeline notifications and pipeline output properties	<code> \${<Stage Key>.<Task Key>.output.<Task output key>}</code>
To refer to the previous task output value as an input for the current task	<code> \${<Previous/Current Stage key>.<Previous task key not in current Task group>.output.<task output key>}</code>

To learn more

To learn more about binding variables in tasks, see:

- [How do I use variable bindings in pipelines](#)
- [How do I use variable bindings in a condition task to run or stop a pipeline in](#)
- [What types of tasks are available in](#)

How do I send notifications about my pipeline in Automation Pipelines

How do I send notifications about my pipeline

Notifications are ways to communicate with your teams and let them know the status of your pipelines in Automation Pipelines.

- Verify that one or more pipelines are created. See the use cases in [Tutorials for using](#).
- To send email notifications, confirm that you can access a working email server. For help, see your administrator.
- To create tickets, such as a Jira ticket, confirm that the endpoint exists. See [What are Endpoints in](#).
- To send a notification based on an integration, you create a webhook notification. Then, you confirm that the webhook is added and working. You can use notifications with applications such as Slack, GitHub, or GitLab.

To send notifications when a pipeline runs, you can configure Automation Pipelines notifications based on the status of the entire pipeline, stage, or task.

- An email notification sends an email on:
 - Pipeline completion, waiting, failure, cancelation, or start.
 - Stage completion, failure, or start.
 - Task completion, waiting, failure, or start.
- A ticket notification creates a ticket and assigns it to a team member on:
 - Pipeline failure or completion.
 - Stage failure.
 - Task failure.
- A webhook notification sends a request to another application on:
 - Pipeline failure, completion, waiting, cancelation, or start.
 - Stage failure, completion, or start.
 - Task failure, completion, waiting, or start.

For example, you can configure an email notification on a user operation task to obtain approval at a specific point in your pipeline. When the pipeline runs, this task sends email to the person who must approve the task. If the User Operation task has an expiration timeout set in days, hours, or minutes, the required user must approve the pipeline before the task expires. Otherwise, the pipeline fails as expected.

To create a Jira ticket when a pipeline task fails, you can configure a notification. Or, to send a request to a Slack channel about the status of a pipeline based on the pipeline event, you can configure a webhook notification.

You can use variables in all types of notifications. For example, you can use \${var} in the URL of a Webhook notification.

1. Open a pipeline.
2. To create a notification for the overall pipeline status, or the status of a stage or task:

To create a notification for:	What you do:
Pipeline status	Click a blank area on the pipeline canvas.
Status of a stage	Click a blank area in a stage of the pipeline.
Status of a task	Click a task in a stage of the pipeline.

3. Click the **Notifications** tab.
4. Click **Add**, select the type of notification, and configure the notification details.
5. To create a Slack notification when a pipeline succeeds, create a webhook notification.
 - a) Select **Webhook**.
 - b) To configure the Slack notification, enter the information.
 - c) Click **Save**.

- d) When the pipeline runs, the Slack channel receives the notification of the pipeline status. For example, users might see the following on the Slack channel:

Pipelines APP [12:01 AM]

Tested by User1 - Staging Pipeline 'User1-Pipeline', Pipeline ID 'e9b5884d809ce2755728177f70f8a' succeeded

6. To create a Jira ticket, configure the ticket information.

- Select **Ticket**.
- To configure the Jira notification, enter the information.
- Click **Save**.

Notification

Type	<input type="radio"/> Email <input checked="" type="radio"/> Ticket <input type="radio"/> Webhook
Event *	<input checked="" type="radio"/> On Pipeline Failure <input type="radio"/> On Pipeline Completion
Jira endpoint *	Jira-Notification
Create Ticket	<input checked="" type="checkbox"/>
Jira project *	YourProject
Issue type *	Bug
Assignee *	username@yourcompany.com
Summary \$ *	Pipeline failed
Description \$	Research and correct

CANCEL **SAVE**

Congratulations! You learned that you can create various types of notifications in several areas of your pipeline in Automation Pipelines.

For a detailed example of how to create a notification, see [How do I create a Jira ticket in when a pipeline task fails](#).

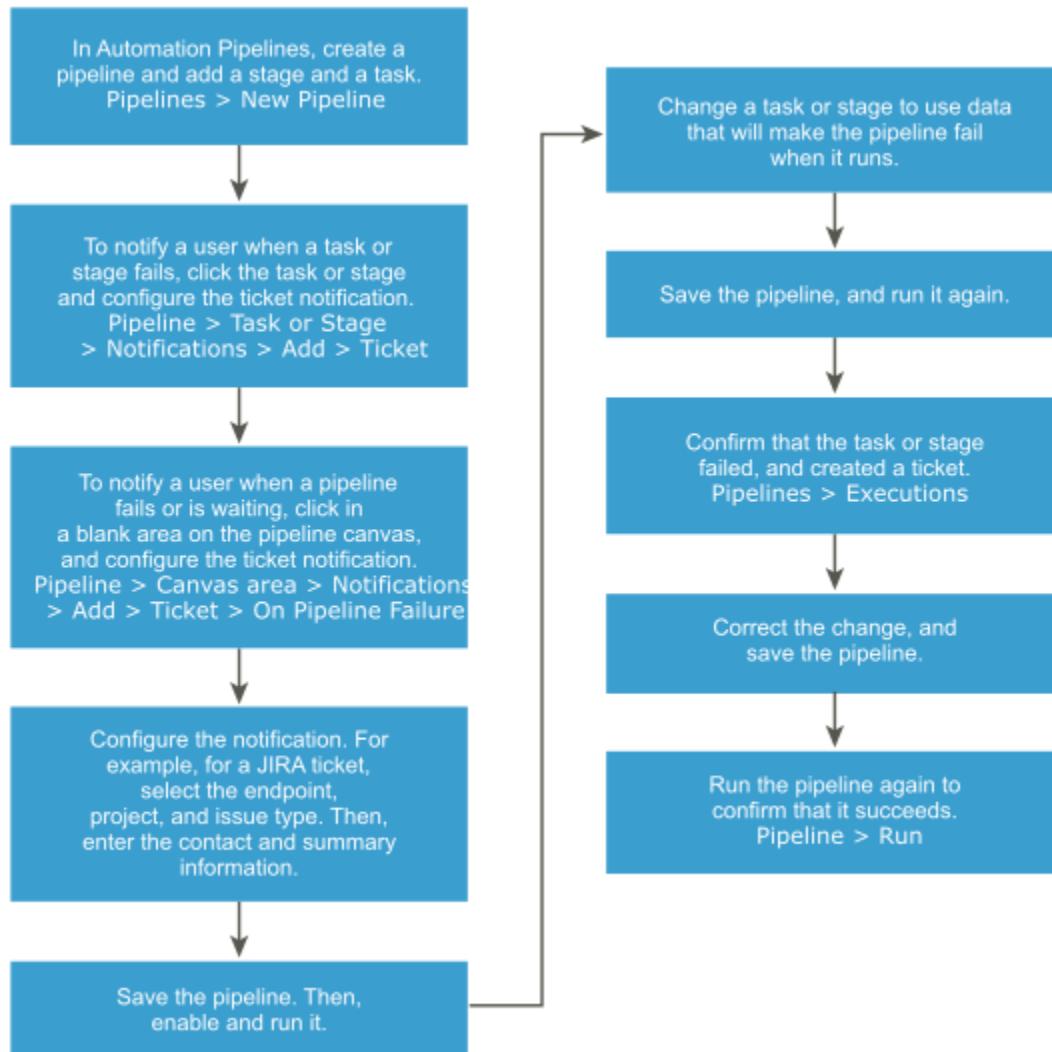

How do I create a Jira ticket in Automation Pipelines when a pipeline task fails

How do I create a Jira ticket when a pipeline task fails

If a stage or task in your pipeline fails, you can have Automation Pipelines create a Jira ticket. You can assign the ticket to the person who must resolve the problem. You can also create a ticket when the pipeline is waiting, or when it succeeds.

- Verify that you have a valid Jira account and can log in to your Jira instance.
- Verify that a Jira endpoint exists, and is working.

You can add and configure notifications on a task, stage, or pipeline. Automation Pipelines creates the ticket based on the status of the task, stage, or pipeline where you add the notification. For example, if an endpoint is not available, you can have Automation Pipelines create a Jira ticket for the task that fails because it cannot connect to the endpoint. You can also create notifications when your pipeline succeeds. For example, you can inform your QA team about pipelines that succeed so that they can confirm the build and run a different test pipeline. Or, you can inform your performance team so that they can measure the performance of the pipeline and prepare for an update to staging or production.

This example creates a Jira ticket when a pipeline task fails.

1. In your pipeline, click a task.
2. In the task configuration area, click **Notifications**.
3. Click **Add**, and configure the ticket information.
 - a) Click **Ticket**.
 - b) Select the Jira endpoint.
 - c) Enter the Jira project and type of issue.
 - d) Enter the email address for the person who receives the ticket.
 - e) Enter a summary and description of the ticket, then click **Save**.

Notification

Send notification type Email Ticket Webhook

When task * Fails

Jira endpoint * TestJira

Create Ticket

Jira project * YourProject

Issue type * Bug

Assignee * username@yourcompany.com

Summary \$ * CI task failed

Description \$ Research and correct

CANCEL **SAVE**

4. Save the pipeline, then enable and run it.
5. Test the ticket.
 - a) Change the task information to include data that makes the task fail.
 - b) Save the pipeline, and run it again.
 - c) Click **Executions**, and confirm that the pipeline failed.
 - d) In the execution, confirm that Automation Pipelines created the ticket and sent it.
 - e) Change the task information back to correct it, then run the pipeline again and ensure that it succeeds.

Congratulations! You had Automation Pipelines create a Jira ticket when the pipeline task failed, and assigned it to the person who was required to solve it.

Continue to add notifications to alert your team about your pipelines.

How do I roll back my deployment in Automation Pipelines

How do I roll back my deployment

You configure rollback as a pipeline with tasks that return your deployment to a previous stable state following a failure in a deployment pipeline. To roll back if a failure occurs, you attach the rollback pipeline to tasks or stages.

- Verify that you are a member of a project in Automation Pipelines. If you are not, ask a Automation Pipelines administrator to add you as a member of a project. See [How do I add a project in](#).

- Set up the Kubernetes clusters where your pipeline will deploy your application. Set up one development cluster and one production cluster.
- Verify that you have a Docker registry setup.
- Identify a project that will group all your work, including your pipeline, endpoints, and dashboards.
- Familiarize yourself with the CD smart template as described in the CD portion of [Planning a CICD native build in before using the smart pipeline template](#), for example:
 - Create the Kubernetes development and production endpoints that deploy your application image to the Kubernetes clusters.
 - Prepare the Kubernetes YAML file that creates the Namespace, Service, and Deployment. If you need to download an image from a privately-owned repository, the YAML file must include a section with the Docker config Secret.

Depending upon your role, your reasons for rollback might vary.

- As a release engineer, I want Automation Pipelines to verify success during a release so that I can know whether to continue with the release or roll back. Possible failures include task failure, a rejection in UserOps, exceeding the metrics threshold.
- As an environment owner, I want to redeploy a previous release so that I can quickly get an environment back to a known-good state.
- As an environment owner, I want to support roll back of a Blue-Green deployment so that I can minimize downtime from failed releases.

When you use a smart pipeline template to create a CD pipeline with the rollback option clicked, rollback is automatically added to tasks in the pipeline. In this use case, you will use the smart pipeline template to define rollback for an application deployment to a Kubernetes cluster using the rolling upgrade deployment model. The smart pipeline template creates a deployment pipeline and one or more rollback pipelines.

- In the deployment pipeline, rollback is required if Update Deployment or Verify Deployment tasks fail.
- In the rollback pipeline, deployment is updated with an old image.

You can also manually create a rollback pipeline using a blank template. Before creating a rollback pipeline, you will want to plan your rollback flow. For more background information about rollback, see [Planning for rollback in](#).

1. Click **Pipelines > New Pipeline > Smart Template > Continuous Delivery**.
2. Enter the information in the smart pipeline template.
 - a) Select a project.
 - b) Enter a pipeline name such as `RollingUpgrade-Example`.
 - c) Select the environments for your application. To add rollback to your deployment, you must select **Prod**.
 - d) Click **Select**, choose a Kubernetes YAML file, and click **Process**.

The smart pipeline template displays the available services and deployment environments.

 - e) Select the service that the pipeline will use for the deployment.
 - f) Select the cluster endpoints for the Dev environment and the Prod environment.
 - g) For the Image source, select **Pipeline runtime input**.
 - h) For the Deployment model, select **Rolling Upgrade**.
 - i) Click **Rollback**.
 - j) Provide the **Health check URL**.

[CREATE](#) [CANCEL](#)

- To create the pipeline named RollbackUpgrade-Example, click **Create**.
The pipeline named RollbackUpgrade-Example appears, and the rollback icon appears on tasks that can roll back in the Development stage and the Production stage.

4. Close the pipeline.

On the Pipelines page, the pipeline that you created appears, and a new pipeline for each stage in your pipeline appears.

- RollingUpgrade-Example. Automation Pipelines deactivates the pipeline that you created by default, which ensures that you review it before you run it.
- RollingUpgrade-Example_Dev_Rollback. Failure of tasks in the development stage, such as **Create service**, **Create secret**, **Create deployment**, and **Verify deployment** invoke this rollback development pipeline. To ensure the rollback of development tasks, Automation Pipelines activates the rollback development pipeline by default.
- RollingUpgrade-Example_Prod_Rollback. Failure of tasks in the production stage, such as **Deploy phase 1**, **Verify phase 1**, **Deploy Rollout phase**, **Finish Rollout phase**, and **Verify rollout phase** invoke this rollback production pipeline. To ensure the rollback of production tasks, Automation Pipelines activates the rollback production pipeline by default.

The screenshot shows the VMware Aria Automation Pipelines interface with three pipelines listed:

- RollbackUpgrade-Example**: State: **Disabled**, Updated By: [redacted], 0 EXECUTIONS.
- RollbackUpgrade-Example_Dev_Rollback**: State: **Enabled**, Updated By: [redacted], 0 EXECUTIONS.
- RollbackUpgrade-Example_Prod_Rollback**: State: **Enabled**, Updated By: [redacted], 0 EXECUTIONS.

5. Enable and run the pipeline you created.

When you start the run, Automation Pipelines prompts you for input parameters. You provide the image and tag for the endpoint in the Docker repository that you are using.

6. On the Executions page, select **Actions > View Execution** and watch the pipeline execution.

The pipeline starts **RUNNING** and moves through the Development stage tasks. If the pipeline fails to run a task during the Development stage, the pipeline named **RollingUpgrade-Example_Dev_Rollback** triggers and rolls back the deployment, and the pipeline status changes to **ROLLING_BACK**.

[◀ BACK](#)

RollbackUpgrade-Example #1 ROLLING_BACK 0 ACTIONS ▾

The Execution did not output any properties	

After rollback, the Executions page lists two RollingUpgrade-Example pipeline executions.

- The pipeline you created rolled back and displays **ROLLBACK_COMPLETED**.
- The rollback development pipeline that triggered and performed the rollback displays **COMPLETED**.

The screenshot shows the 'Executions' list with 604 items. Two executions are highlighted:

- RollbackUpgrade-Example_Dev... #1**: Status: COMPLETED. Triggered by a user on 01/11/2019 at 1:36 PM. Execution Completed. Comments: Triggered to rollback Development.Create Deployment of RollbackUpgrade-Example#1.
- RollbackUpgrade-Example#1**: Status: ROLLBACK_COMPLETED. Triggered by a user on 01/11/2019 at 1:24 PM. Create Deployment ROLLBACK_COMPLETED.

Congratulations! You successfully defined a pipeline with rollback and watched Automation Pipelines roll back the pipeline at the point of failure.

Planning to natively build, integrate, and deliver your code in Automation Pipelines

Planning to natively build, integrate, and deliver your code

Before you have Automation Pipelines build, integrate, and deliver your code by using the native capability that creates a CICD, CI, or CD pipeline for you, plan your native build. Then, you can create your pipeline by using one of the smart pipeline templates, or by manually adding stages and tasks.

To plan for your continuous integration and continuous delivery build, we included several examples that show you how. These plans describe the prerequisites and overviews that can help you prepare and use the native build capability effectively when you build your pipelines.

Configuring the Pipeline Workspace

To run continuous integration tasks and custom tasks, you must configure a workspace for your Automation Pipelines pipeline.

In the pipeline workspace, select the **Type** as Docker or Kubernetes, and provide the respective endpoint. The Docker and Kubernetes platforms manage the entire life cycle of the container that Automation Pipelines deploys for running the continuous integration (CI) task or custom task.

- The Docker workspace requires the Docker host endpoint, builder image URL, image registry, working directory, cache, environment variables, CPU limit, and memory limit. You can also create a clone of the Git repository.
- The Kubernetes workspace requires the Kubernetes API endpoint, builder image URL, image registry, namespace, NodePort, Persistent Volume Claim (PVC), working directory, environment variables, CPU limit, and memory limit. You can also create a clone of the Git repository.

The pipeline workspace configuration has many common parameters, and other parameters that are specific to the type of workspace, as the following table describes.

Table 71: Workspace areas, details, and availability

Selection	Description	Details and availability
Type	Type of workspace.	Available with Docker or Kubernetes.

Table continued on next page

Continued from previous page

Selection	Description	Details and availability
Host Endpoint	Host endpoint where the continuous integration (CI) and custom tasks run.	Available with the Docker workspace when you select the Docker host endpoint. Available with the Kubernetes workspace when you select the Kubernetes API endpoint.
Builder image URL	Name and location of the builder image. A container gets created by using this image on the Docker host and the Kubernetes cluster. The continuous integration (CI) tasks and custom tasks run inside this container.	Example: <code>fedora:latest</code> The builder image must have <code>curl</code> or <code>wget</code> .
Image registry	If the builder image is available in a registry, and if the registry requires credentials, you must create an Image Registry endpoint, then select it here so that the image can be pulled from the registry.	Available with the Docker and Kubernetes workspaces.
Working directory	The working directory is the location inside the container where the steps of the continuous integration (CI) task run, and is the location where the code gets cloned when a Git webhook triggers a pipeline run.	Available with Docker or Kubernetes.
Namespace	If you do not enter a Namespace, Automation Pipelines creates a unique name in the Kubernetes cluster that you provided.	Specific to the Kubernetes workspace.
Proxy	To communicate with the workspace pod in the Kubernetes cluster, Automation Pipelines deploys a single proxy instance in the namespace <code>codestream-proxy</code> for each Kubernetes cluster. You can select either the NodePort or LoadBalancer type, based on the cluster configuration. Which option you select depends on the nature of the deployed Kubernetes cluster. <ul style="list-style-type: none"> Typically, if the Kubernetes API server URL that gets specified in the endpoint is exposed through one of the primary nodes, select NodePort. If the Kubernetes API server URL is exposed by a Load Balancer, such as with Amazon EKS (Elastic Kubernetes Service), select LoadBalancer. 	
NodePort	Automation Pipelines uses NodePort to communicate with the container running inside the Kubernetes cluster. If you do not select a port, Automation Pipelines uses an ephemeral port that Kubernetes assigns. You must ensure that the configuration of firewall rules allows ingress to the ephemeral port range (30000-32767).	Specific to the Kubernetes workspace.

Table continued on next page

Continued from previous page

Selection	Description	Details and availability
	If you enter a port, you must ensure that another service in the cluster is not already using it, and that the firewall rules allow the port.	
Persistent Volume Claim	<p>Provides a way for the Kubernetes workspace to persist files across pipeline runs. When you provide a persistent volume claim name, it can store the logs, artifacts, and cache.</p> <p>For more information about creating a persistent volume claim, see the Kubernetes documentation at https://kubernetes.io/docs/concepts/storage/persistent-volumes/.</p>	Specific to the Kubernetes workspace.
Environment variables	Key-value pairs that get passed here will be available to all continuous integration (CI) tasks and custom tasks in a pipeline when it runs.	<p>Available with Docker or Kubernetes.</p> <p>References to variables can be passed here.</p> <p>Environment variables provided in the workspace get passed to all continuous integration (CI) tasks and custom tasks in the pipeline.</p> <p>If environment variables do not get passed here, those variables must be explicitly passed to each continuous integration (CI) task and custom task in the pipeline.</p>
CPU limits	Limits for CPU resources for the continuous integration (CI) container or custom task container.	The default is 1.
Memory limits	Limits for memory for the continuous integration (CI) container or custom task container.	The unit is MB.
Git clone	When you select Git clone , and a Git webhook invokes the pipeline, the code gets cloned into the workspace (container).	If you do not enable Git clone , you must configure another, explicit continuous integration (CI) task in the pipeline to clone the code first, then perform other steps such as build and test.
Cache	<p>The Automation Pipelines workspace allows you to cache a set of directories or files to speed up subsequent pipeline runs. Examples of these directories include <code>.m2</code> and <code>npm_modules</code>. If you do not require caching of data between pipeline runs, a persistent volume claim is not necessary.</p> <p>Artifacts such as files or directories in the container get cached for re-use across pipeline runs. For example, <code>node_modules</code> or <code>.m2</code> folders can be cached. Cache accepts a list of paths.</p>	<p>Specific to type of workspace.</p> <p>In the Docker workspace, you achieve the Cache by using a shared path in the Docker host for persisting the cached data, artifacts, and logs.</p> <p>In the Kubernetes workspace, to enable the use of Cache, you must provide a persistent volume claim. Otherwise, Cache is unavailable.</p>

Table continued on next page

Continued from previous page

Selection	Description	Details and availability
	<p>For example:</p> <pre>workspace: type: K8S endpoint: K8S-Micro image: fedora:latest registry: Docker Registry path: '' cache: - /path/to/m2 - /path/to/node_modules</pre>	

When using a Kubernetes API endpoint in the pipeline workspace, Automation Pipelines creates the necessary Kubernetes resources such as ConfigMap, Secret, and Pod to run the continuous integration (CI) task or custom task. Automation Pipelines communicates with the container by using the NodePort.

To share data across pipeline runs, you must provide a persistent volume claim, and Automation Pipelines will mount the persistent volume claim to the container to store the data, and use it for subsequent pipeline runs.

Planning a CICD native build in Automation Pipelines before using the smart pipeline template

Planning a CICD native build before using the smart pipeline template

To create a continuous integration and continuous delivery (CICD) pipeline in Automation Pipelines, you can use the CICD smart pipeline template. To plan your CICD native build, you gather the information for the smart pipeline template before you create the pipeline in this example plan.

To create a CICD pipeline, you must plan for both the continuous integration (CI) and continuous delivery (CD) stages of your pipeline.

After you enter the information in the smart pipeline template and save it, the template creates a pipeline that includes stages and tasks. It also indicates the deployment destination of your image based on the types of environment you select, such as Dev and Prod. The pipeline will publish your container image, and perform the actions required that run it. After your pipeline runs, you can monitor trends across the pipeline executions.

When a pipeline includes an image from Docker Hub, you must ensure that the image has `cURL` or `wget` embedded before you run the pipeline. When the pipeline runs, Automation Pipelines downloads a binary file that uses `cURL` or `wget` to run commands.

For information about configuring the workspace, see [Configuring the Pipeline Workspace](#).

Planning the Continuous Integration (CI) stage

To plan the CI stage of your pipeline, you set up the external and internal requirements, and determine the information needed for the CI portion of the smart pipeline template. Here is a summary.

This example uses a Docker workspace.

Endpoints and repositories that you'll need:

- A source code repository where developers check in their code. Automation Pipelines pulls the latest code into the pipeline when developers commit changes.
- A GitHub-Enterprise, GitLab-Enterprise, or Bitbucket-Enterprise service type endpoint for the repository where the developer source code resides.
- A Docker endpoint for the Docker build host that will run the build commands inside a container.
- A Kubernetes endpoint so that Automation Pipelines can deploy your image to a Kubernetes cluster.
- A Builder image that creates the container on which the continuous integration tests run.
- An Image Registry endpoint so that the Docker build host can pull the builder image from it.

You'll need access to a project. The project groups all your work, including your pipeline, endpoints, and dashboards. Verify that you are a member of a project in Automation Pipelines. If you are not, ask a Automation Pipelines administrator to add you as a member of a project. See [How do I add a project in](#).

You'll need a Git webhook that enables Automation Pipelines to use the Git trigger to trigger your pipeline when developers commit code changes. See [How do I use the Git trigger in to run a pipeline](#).

Your build toolsets:

- Your build type, such as Maven.
- All the post-process build tools that you use, such as JUnit, JaCoCo, Checkstyle, and FindBugs.

Your publishing tool:

- A tool such as Docker that will deploy your build container.
- An image tag, which is either the commit ID or the build number.

Your build workspace:

- A Docker build host, which is the Docker endpoint.
- An Image Registry. The CI part of the pipeline pulls the image from the selected registry endpoint. The container runs the CI tasks, and deploys your image. If the registry needs credentials, you must create an Image Registry endpoint, then select it here so that the host can pull the image from the registry.
- URL for the builder image that creates the container on which the continuous integration tasks run.

Planning the Continuous Delivery (CD) stage

To plan the CD stage of your pipeline, you set up the external and internal requirements, and determine the information to enter in the CD portion of the smart pipeline template.

Endpoints that you'll need:

- A Kubernetes endpoint so that Automation Pipelines can deploy your image to a Kubernetes cluster.

Environment types and files:

- All the environment types where Automation Pipelines will deploy your application, such as Dev and Prod. The smart pipeline template creates the stages and tasks in your pipeline based on the environment types you select.

Table 72: Pipeline stages that the CICD smart pipeline template creates

Pipeline content	What it does
Build-Publish stage	Builds and tests your code, creates the builder image, and publishes the image to your Docker host.
Development stage	Uses a development Amazon Web Services (AWS) cluster to create and deploy your image. In this stage, you can create a namespace on the cluster, and create a secret key.

Table continued on next page

Continued from previous page

Pipeline content	What it does
Production stage	Uses a production version of the VMware Tanzu Kubernetes Grid Integrated Edition (formerly known as VMware Enterprise PKS) to deploy your image to a production Kubernetes cluster.

- A Kubernetes YAML file that you select in the CD section of the CICD smart pipeline template. The Kubernetes YAML file includes three required sections for Namespace, Service, and Deployment and one optional section for Secret. If you plan to create a pipeline by downloading an image from a privately-owned repository, you must include a section with the Docker config Secret. If the pipeline you create only uses publicly available images, no secret is required. The following sample YAML file includes four sections.

```

apiVersion: v1
kind: Namespace
metadata:
  name: pipelines
  namespace: pipelines
---
apiVersion: v1
data:
  .dockerconfigjson:
    eyJhdXRocI6eyJodHRwczovL2luZ12345678901ci5pby92MS8iOnsidXN1cm5hbWUiOiJhdXRvbWF0aW9uYm

```

NOTE

The Kubernetes YAML file is also used in the CD smart pipeline template, such as in the following use case examples:

- [How do I deploy my application in to my Blue-Green deployment](#)
- [How do I roll back my deployment in](#)
- [How do I use the Docker trigger in to run a continuous delivery pipeline](#)

To apply the file in the Smart Template, click **Select** and select the Kubernetes YAML file. Then click **Process**. The smart pipeline template displays the available services and deployment environments. You select a service, the cluster endpoint, and the deployment strategy. For example, to use the Canary deployment model, select **Canary** and enter a percentage for the deployment phase.

Smart Template: CI/CD

To see an example of using the smart pipeline template to create a pipeline for a Blue-Green deployment, see [How do I deploy my application in to my Blue-Green deployment.](#)

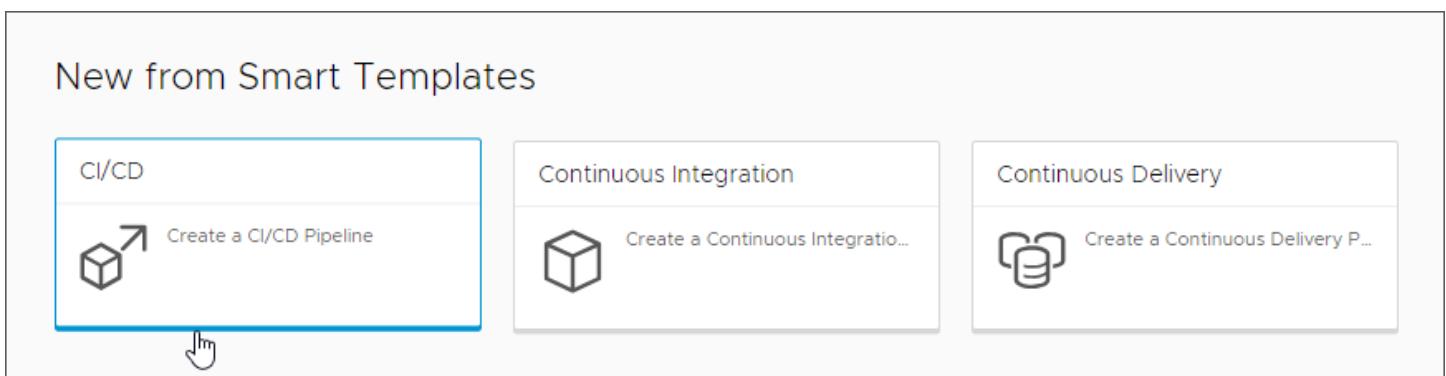

How you'll create the CICD pipeline by using the smart pipeline template

After you gather all the information and set up what you need, here's how you'll create a pipeline from the CICD smart pipeline template.

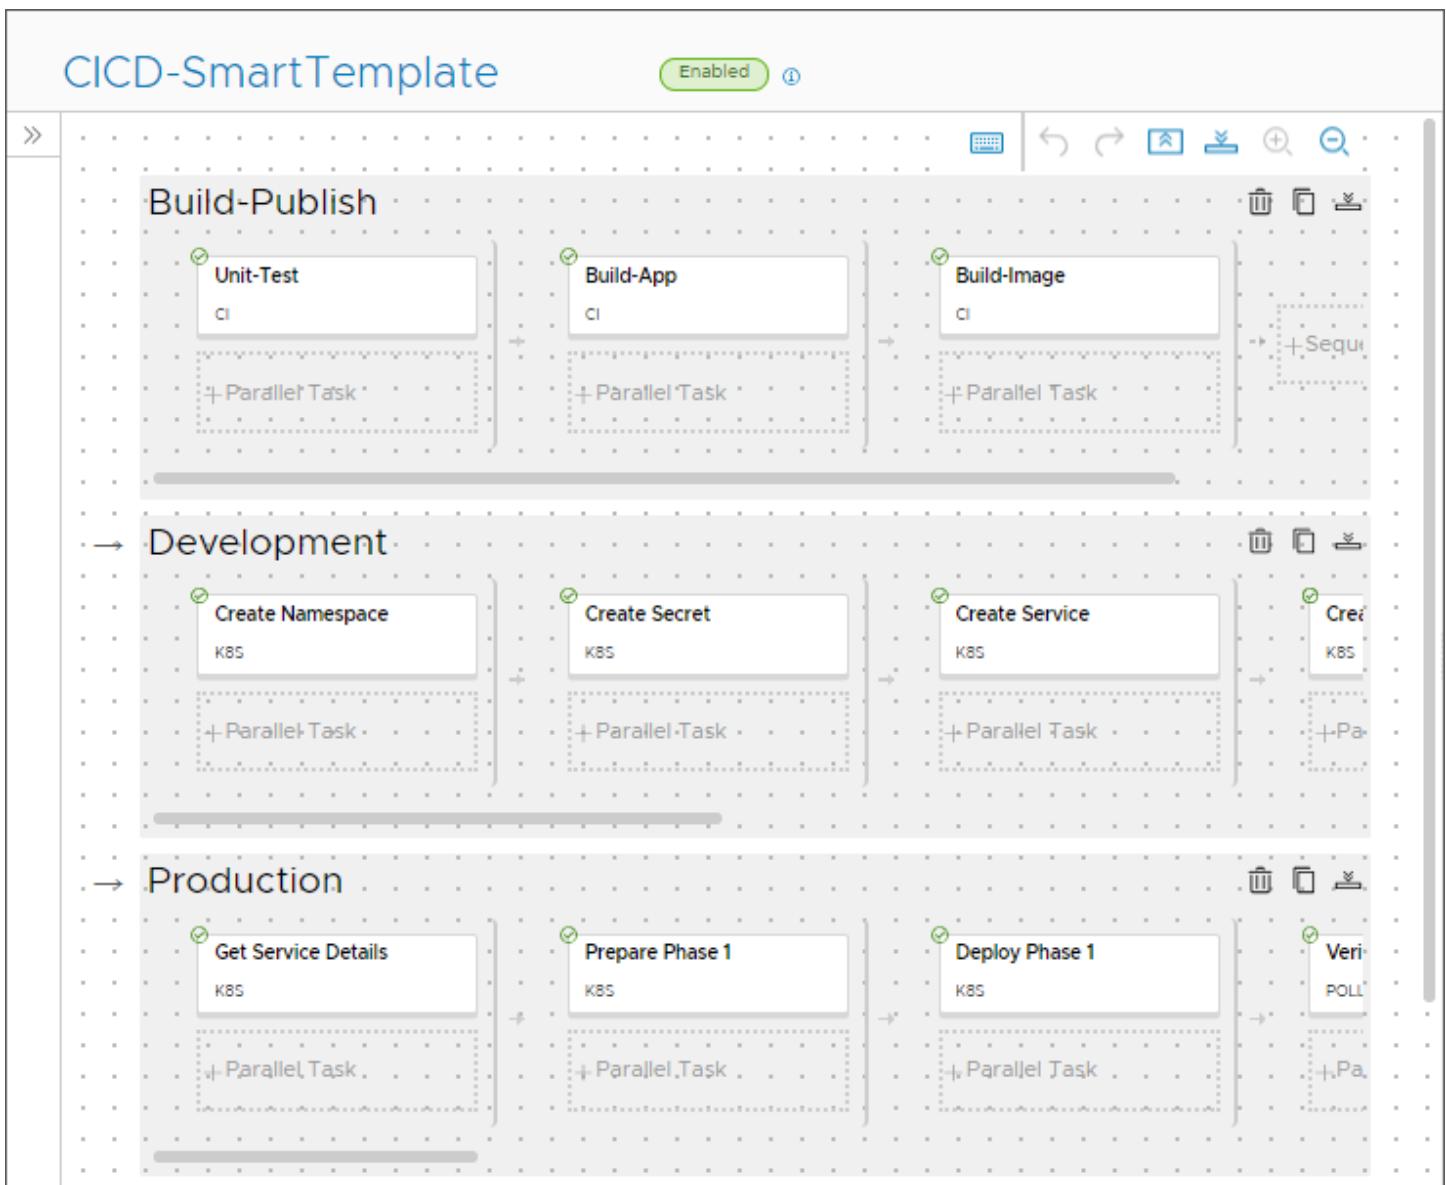

In Pipelines, you'll select **New Pipeline > Smart Templates**.

You'll select the CICD smart pipeline template.

You will fill out the template, and save the pipeline with the stages that it creates. If you need to make any final changes, you can edit the pipeline and save it.

Then, you will enable the pipeline and run it. After it runs, here are some things that you can look for:

- Verify that your pipeline succeeded. Click **Executions**, and search for your pipeline. If it failed, correct any errors and run it again.
- Verify that the Git webhook is operating correctly. The Git **Activity** tab displays the events. Click **Triggers > Git > Activity**.
- Look at the pipeline dashboard and examine the trends. Click **Dashboards**, and search for your pipeline dashboard. You can also create a custom dashboard to report on additional KPIs.

For a detailed example, see [How do I continuously integrate code from my GitHub or GitLab repository into my pipeline in](#)

Planning a continuous integration native build in Automation Pipelines before using the smart pipeline template

Planning a CI native build before using the smart pipeline template

To create a continuous integration (CI) pipeline in Automation Pipelines, you can use the continuous integration smart pipeline template. To plan your continuous integration native build, you gather the information for the smart pipeline template before you create the pipeline in this example plan.

When you fill out the smart pipeline template, it creates a continuous integration pipeline in your repository, and performs the actions so that the pipeline can run. After your pipeline runs, you can monitor trends across the pipeline executions.

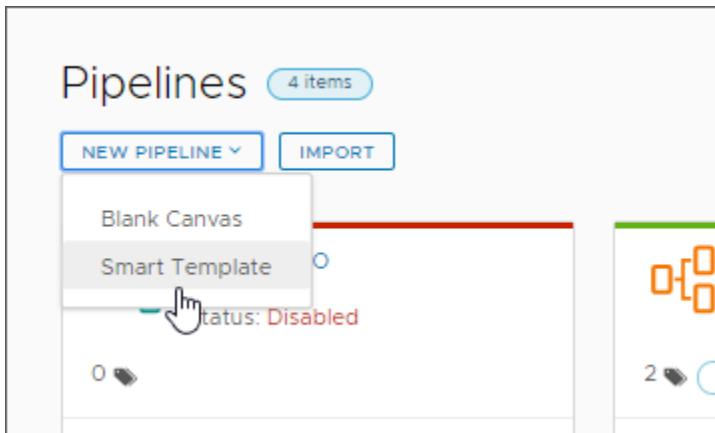

To plan your build before you use the continuous integration smart pipeline template:

- Identify a project that will group all your work, including your pipeline, endpoints, and dashboards.
- Gather the information for your build as described in the continuous delivery portion of [Planning a CICD native build in before using the smart pipeline template](#).

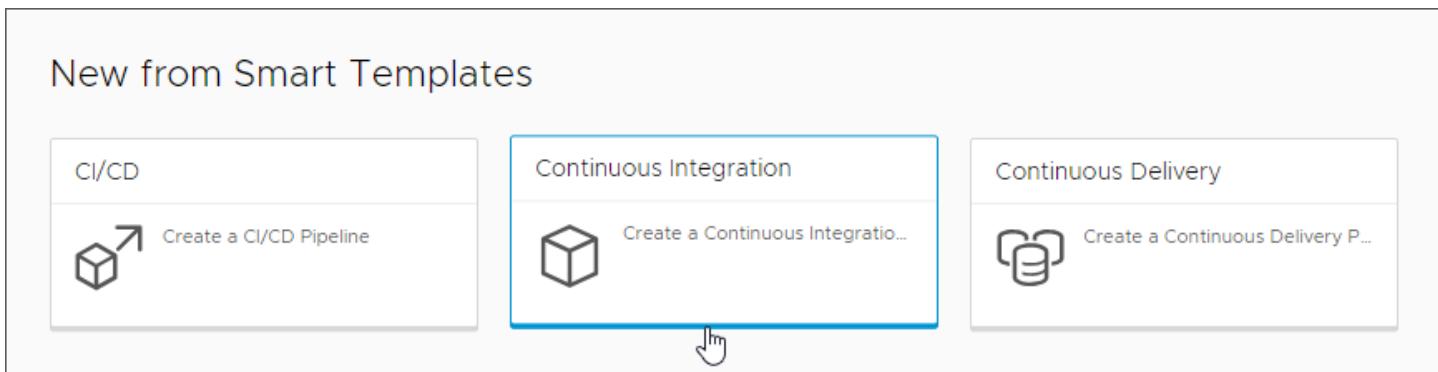

For example, add a Kubernetes endpoint where Automation Pipelines will deploy the container.

Then, you create a pipeline by using the continuous integration smart pipeline template.

In Pipelines, you select **Smart Templates**.

You select the continuous integration smart pipeline template.

To save the pipeline with the stages that it creates, you fill out the template, and enter a name for the pipeline. To save the pipeline with the stages that it creates, click **Create**.

The Automation Pipelines pipeline workspace supports Docker and Kubernetes for continuous integration tasks and custom tasks.

For information about configuring the workspace, see [Configuring the Pipeline Workspace](#).

To make any final changes, you can edit the pipeline. Then, you can enable the pipeline and run it. After the pipeline runs:

- Verify that your pipeline succeeded. Click **Executions**, and search for your pipeline. If it failed, correct any errors and run it again.
- Verify that the Git webhook is operating correctly. The Git **Activity** tab displays the events. Click **Triggers > Git > Activity**.
- Look at the pipeline dashboard and examine the trends. Click **Dashboards**, and search for your pipeline dashboard. To report on more key performance indicators, you can create a custom dashboard.

For a detailed example, see [How do I continuously integrate code from my GitHub or GitLab repository into my pipeline in](#)

Planning a continuous delivery native build in Automation Pipelines before using the smart pipeline template

Planning a CD native build before using the smart pipeline template

To create a continuous delivery (CD) pipeline in Automation Pipelines, you can use the continuous delivery smart pipeline template. To plan your continuous delivery native build, you gather the information for the smart pipeline template before you create the pipeline in this example plan.

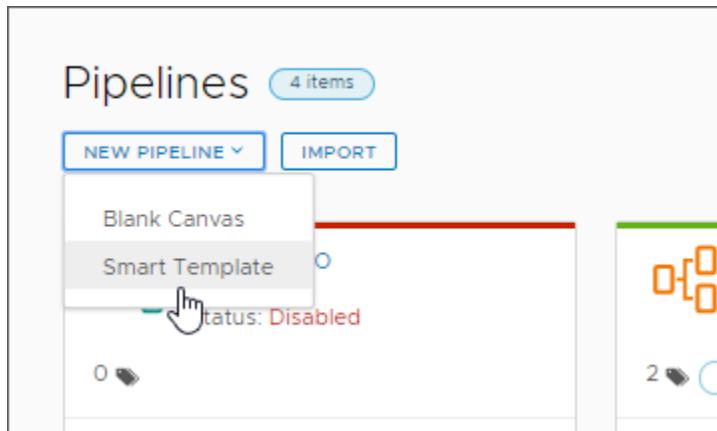

When you fill out the smart pipeline template, it creates a continuous delivery pipeline in your repository, and performs the actions so that the pipeline can run. After your pipeline runs, you can monitor trends across the pipeline executions.

To plan your build before you use the continuous delivery smart pipeline template:

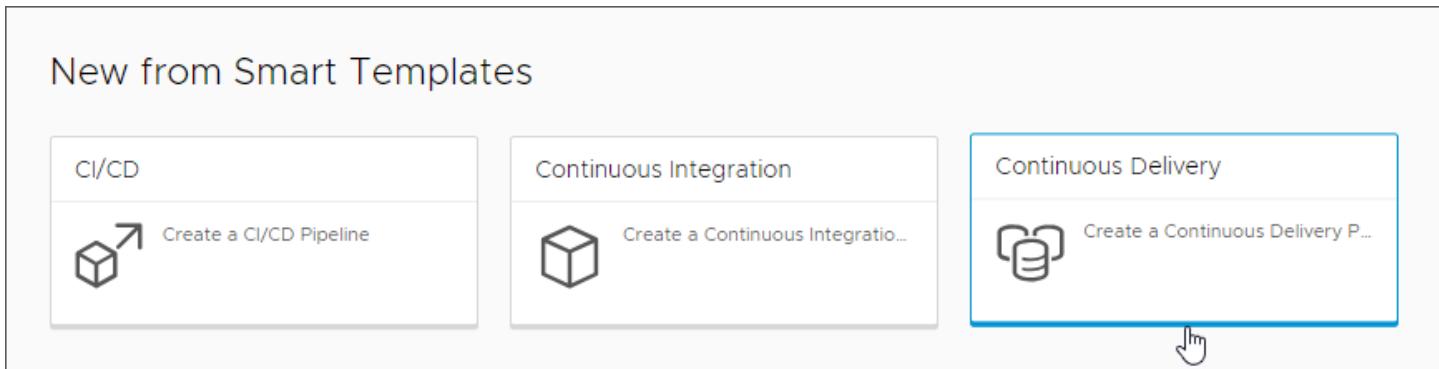

- Identify a project that will group all your work, including your pipeline, endpoints, and dashboards.
- Gather the information for your build as described in the continuous delivery portion of [Planning a CICD native build in Automation Pipelines before using the smart pipeline template](#). For example:
 - Add a Kubernetes endpoint where Automation Pipelines will deploy the container.
 - Prepare the Kubernetes YAML file that creates the Namespace, Service, and Deployment. To download an image from a privately-owned repository, the YAML file must include a section with the Docker config Secret.

Then, you create a pipeline by using the continuous delivery smart pipeline template.

In Pipelines, you select **Smart Templates**.

You select the continuous delivery smart pipeline template.

You fill out the template, and enter a name for the pipeline. To save the pipeline with the stages that it creates, click **Create**.

The Automation Pipelines pipeline workspace supports Docker and Kubernetes for continuous integration tasks and custom tasks.

For information about configuring the workspace, see [Configuring the Pipeline Workspace](#).

To make any final changes, you can edit the pipeline. Then, you can enable the pipeline and run it. After the pipeline runs:

- Verify that your pipeline succeeded. Click **Executions**, and search for your pipeline. If it failed, correct any errors and run it again.
- Verify that the Git webhook is operating correctly. The Git **Activity** tab displays the events. Click **Triggers > Git > Activity**.
- Look at the pipeline dashboard and examine the trends. Click **Dashboards**, and search for your pipeline dashboard. To report on more key performance indicators, you can create a custom dashboard.

For a detailed example, see [How do I continuously integrate code from my GitHub or GitLab repository into my pipeline in](#)

Planning a CICD native build in Automation Pipelines before manually adding tasks

Planning a CICD native build before manually adding tasks

To create a continuous integration and continuous delivery (CICD) pipeline in Automation Pipelines, you can manually add stages and tasks. To plan your CICD native build, you'll gather the information you need, then create a pipeline and manually add stages and tasks to it.

You must plan for both the continuous integration (CI) and continuous delivery (CD) stages of your pipeline. After you create your pipeline and run it, you can monitor trends across the pipeline executions.

When a pipeline includes an image from Docker Hub, you must ensure that the image has `cURL` or `wget` embedded before you run the pipeline. When the pipeline runs, Automation Pipelines downloads a binary file that uses `cURL` or `wget` to run commands.

The Automation Pipelines pipeline workspace supports Docker and Kubernetes for continuous integration tasks and custom tasks.

For information about configuring the workspace, see [Configuring the Pipeline Workspace](#).

Planning the external and internal requirements

To plan the CI and CD stages of your pipeline, the following requirements indicate what you must do before you create your pipeline.

This example uses a Docker workspace.

To create a pipeline from this example plan, you will use a Docker host, a Git repository, Maven, and several post-process build tools.

Endpoints and repositories that you'll need:

- A Git source code repository where developers check in their code. Automation Pipelines pulls the latest code into the pipeline when developers commit changes.
- A Docker endpoint for the Docker build host that will run the build commands inside a container.
- A Builder image that creates the container on which the continuous integration tests run.
- An Image Registry endpoint so that the Docker build host can pull the builder image from it.

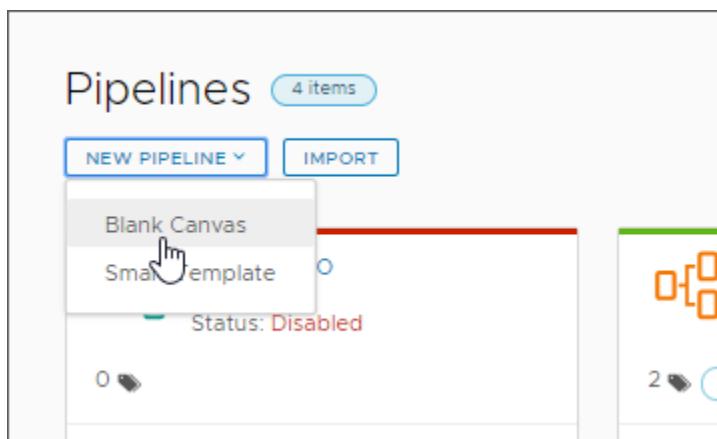

You'll need access to a project. The project groups all your work, including your pipeline, endpoints, and dashboards. Verify that you are a member of a project in Automation Pipelines. If you are not, ask a Automation Pipelines administrator to add you as a member of a project. See [How do I add a project in](#).

You'll need a Git webhook that enables Automation Pipelines to use the Git trigger to trigger your pipeline when developers commit code changes. See [How do I use the Git trigger in to run a pipeline](#).

How you'll create the CICD pipeline and configure the workspace

You'll need to create the pipeline, then configure the workspace, pipeline input parameters, and tasks.

To create the pipeline, you'll click **Pipelines** > **New Pipeline** > **Blank Canvas**.

On the Workspace tab, enter the continuous integration information:

- Include your Docker build host.
- Enter the URL for your builder image.
- Select the image registry endpoint so that the pipeline can pull the image from it. The container runs the CI tasks and deploys your image. If the registry needs credentials, you must first create the Image Registry endpoint, then select it here so that the host can pull the image from the registry.
- Add the artifacts that must be cached. For a build to succeed, artifacts such as directories are downloaded as dependencies. The cache is the location where these artifacts reside. For example, dependent artifacts can include the `.m2` directory for Maven, and the `node_modules` directory for Node.js. These directories are cached across pipeline executions to save time during builds.

Provide details about the container and host for running continuous integration tasks.

Type *

Docker Kubernetes

Host endpoint *

dockerhost-test

Host endpoint for build location in CI task or for running Custom Integration Task code.

Builder image URL\$ *

automation/pipeline-builder:latest

Name and location of the builder image. The CI tasks run on the container that the image creates.

Image registry

Docker Registry

The pipeline pulls the image from the selected registry endpoint. The container runs the CI tasks, and deploys your image. If the host can pull the image from the registry.

Working directory\$

CI pipeline tasks run steps for continuous integration. The working directory is the location where the steps run, and is where co

Cache \$

On the Input tab, configure the pipeline input parameters.

- If your pipeline will use input parameters from a Git, Gerrit, or Docker trigger event, select the trigger type for Auto inject parameters. Events can include Change Subject for Gerrit or Git, or Event Owner Name for Docker. If your pipeline will not use any input parameters passed from the event, leave Auto inject parameters set to **None**.
- To apply a value and description to a pipeline input parameter, click the three vertical dots, and click **Edit**. The value you enter is used as input to tasks, stages, or notifications.
- To add a pipeline input parameter, click **Add**. For example, you might add `approvers` to display a default value for every execution, but which you can override with a different approver at runtime.
- To add or remove an injected parameter, click **Add/Remove Injected Parameter**. For example, remove an unused parameter to reduce clutter on the results page and only display the input parameters that are used.

The input parameters for this pipeline are passed to the pipeline before it runs.

When you add input parameters, and star the most useful or unique input parameter for each pipeline, the parameter appears in locations like the pipeline execution cards. For example, if you include the committer ID (GIT_COMMIT_ID) as an input parameter, you can select it as the starred input parameter to identify which developer commits trigger a pipeline execution before the pipeline runs.

Auto inject parameters

Gerrit Git Docker None

Starred	Name	Value	Description

After you configure the workspace, input parameters, test tasks, and build tasks, save your pipeline.

How to enable and run your pipeline

After you configure your pipeline with stages and tasks, you can save and enable the pipeline.

Then, wait for the pipeline to run and finish, then verify that it succeeded. If it failed, correct any errors and run it again.

After the pipeline succeeds, here are some things you might want to confirm:

- Examine the pipeline execution and view the results of the task steps.
- In the workspace of the pipeline execution, locate the details about your container and the cloned Git repository.
- In the workspace, look at the results of your post-process tools and check for errors, code coverage, bugs, and style issues.
- Confirm that your artifact is preserved. Also confirm that the image was exported with the IMAGE name and value.
- Go to your Docker repository and verify that the pipeline published your container.

For a detailed example that shows how Automation Pipelines continuously integrates your code, see [How do I continuously integrate code from my GitHub or GitLab repository into my pipeline in](#).

Planning for rollback in Automation Pipelines

Planning for rollback

If a pipeline execution fails, you can use rollback to return your environment to a previously stable state. To use rollback, plan a rollback flow and understand how to implement it.

A rollback flow prescribes the steps required to reverse a failure in deployment. The flow takes the form of a rollback pipeline that includes one or more sequential tasks which vary depending on the type of deployment that executed and failed. For example, the deployment and rollback of a traditional application is different from the deployment and rollback of a container application.

To return to a good deployment state, a rollback pipeline typically includes tasks to:

- Clean up states or environments.
- Run a user-specified script to revert changes.
- Deploy a previous revision of a deployment.

To add rollback to an existing deployment pipeline, you attach the rollback pipeline to the tasks or stages in the deployment pipeline that you want to roll back before you run your deployment pipeline.

How do I configure rollback

To configure rollback in your deployment, you need to:

- Create a deployment pipeline.
- Identify potential failure points in the deployment pipeline that will trigger rollback so that you can attach your rollback pipeline. For example, you might attach your rollback pipeline to a condition or poll task type in the deployment pipeline that checks whether a previous task completed successfully. For information on condition tasks, see [How do I use variable bindings in a condition task to run or stop a pipeline in](#).
- Determine the scope of failure that will trigger the rollback pipeline such as a task or stage failure. You can also attach rollback to a stage.
- Decide what rollback task or tasks to execute in the event of a failure. You'll create your rollback pipeline with those tasks.

You can manually create a rollback pipeline or Automation Pipelines can create one for you. You can also select a shared pipeline for rollback.

- Using a blank canvas, you can manually create a rollback pipeline that follows a flow in parallel to an existing deployment pipeline. Then you attach the rollback pipeline to one or more tasks in the deployment pipeline that trigger rollback on failure.
 - Using a smart pipeline template, you can configure a deployment pipeline with the rollback action. Then, Automation Pipelines automatically creates one or more default rollback pipelines with predefined tasks that roll back the deployment on failure.
- For a detailed example on how to configure a CD pipeline with rollback by using a smart pipeline template, see [How do I roll back my deployment in](#).
- By using a shared pipeline for rollback, you do not need to create multiple rollback pipelines that perform the same function. You can select the shared pipeline to rollback tasks for pipelines on different projects.

To see how to configure a pipeline task with rollback using a shared pipeline, see [Creating and using shared pipelines in](#).

What happens if my deployment pipeline has multiple tasks or stages with rollback

If you have multiple tasks or tasks and stages with rollback added, be aware that the rollback sequence varies.

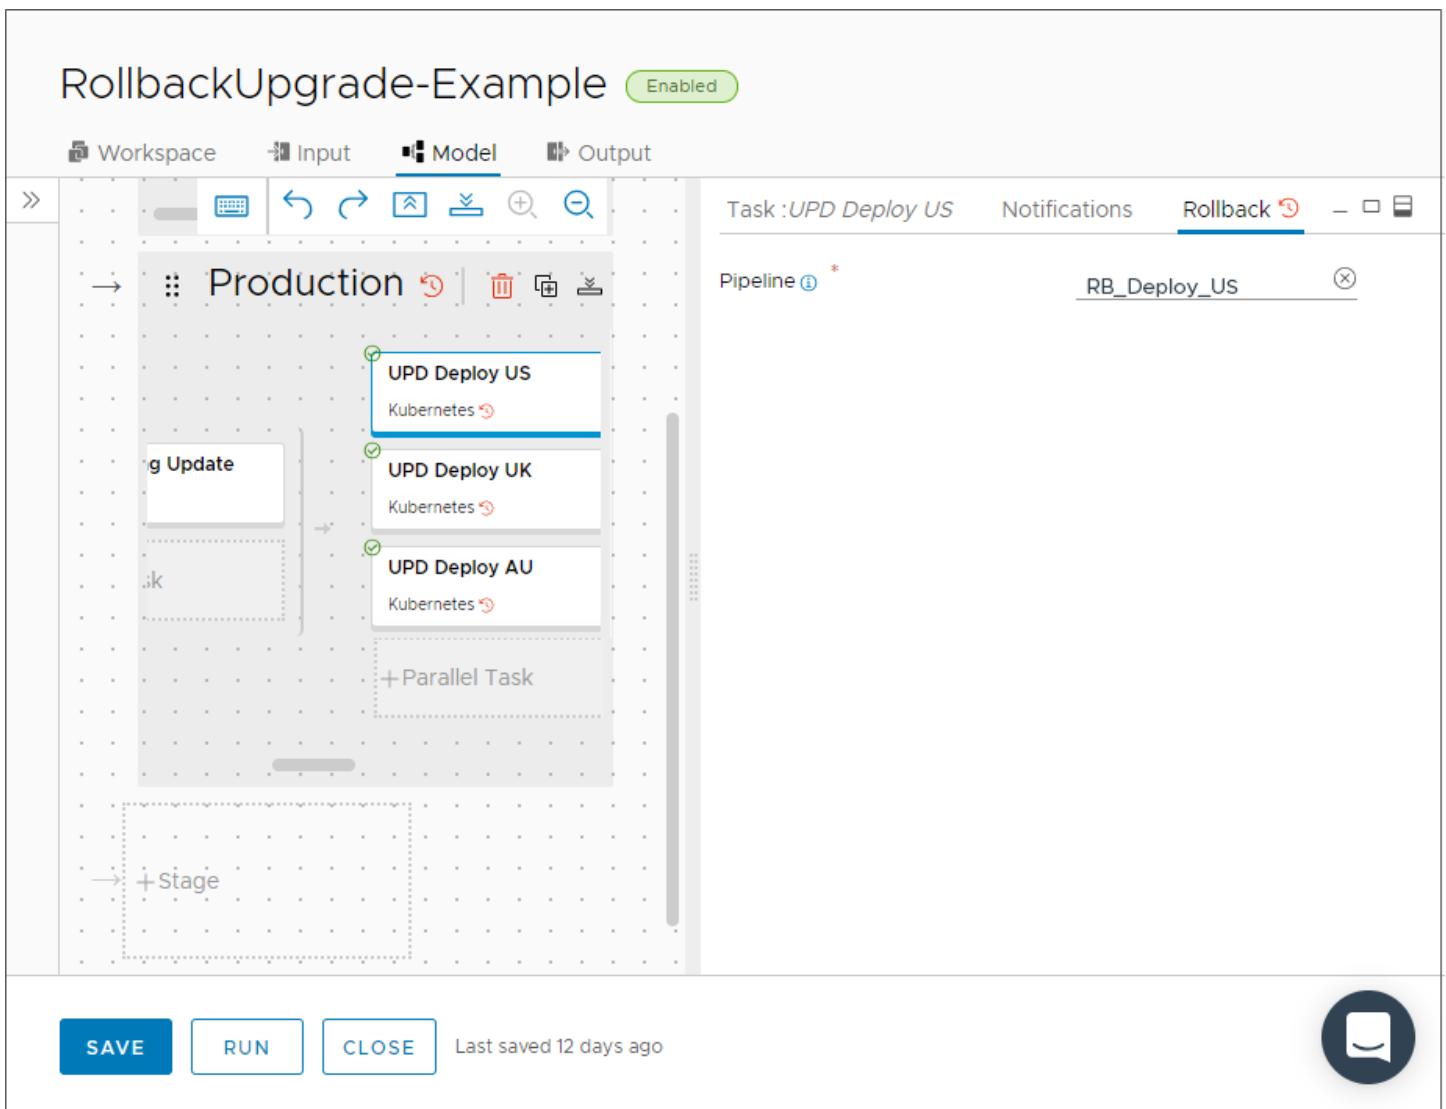

Table 73: Determining rollback sequence

If you add rollback to...	When does roll back occur...
Parallel tasks	If one of the parallel tasks fails, roll back for that task occurs after all the parallel tasks have completed or failed. Rollback does not occur immediately after the task fails.
Both the task within a stage, and the stage	If a task fails, the task rollback runs. If the task is in a group of parallel tasks, the task rollback runs after all the parallel tasks have completed or failed. After the task rollback completes or fails to complete, the stage rollback runs.

Consider a pipeline that has:

- A production stage with rollback.
- A group of parallel tasks, each task with its own rollback.

The task named **UPD Deploy US** has the rollback pipeline **RB_Deploy_US**. If **UPD Deploy US** fails, the rollback follows the flow defined in the **RB_Deploy_US** pipeline.

If **UPD Deploy US** fails, the **RB_Deploy_US** pipeline runs after **UPD Deploy UK** and **UPD Deploy AU** have also completed or failed. Rollback does not occur immediately after **UPD Deploy US** fails. And because the production stage also has rollback, after the **RB_Deploy_US** pipeline runs, the stage rollback pipeline runs.

Tutorials for using Automation Pipelines

Tutorials

Automation Pipelines models and supports your DevOps release lifecycle, and continuously tests and releases your applications to development environments and production environments.

You already set up everything you need so that you can use Automation Pipelines. See [Setting up to model my release process](#).

Now, you can create pipelines that automate the build and test of developer code before you release it to production. You can have Automation Pipelines deploy container-based or traditional applications.

Table 74: Using Automation Pipelines in your DevOps lifecycle

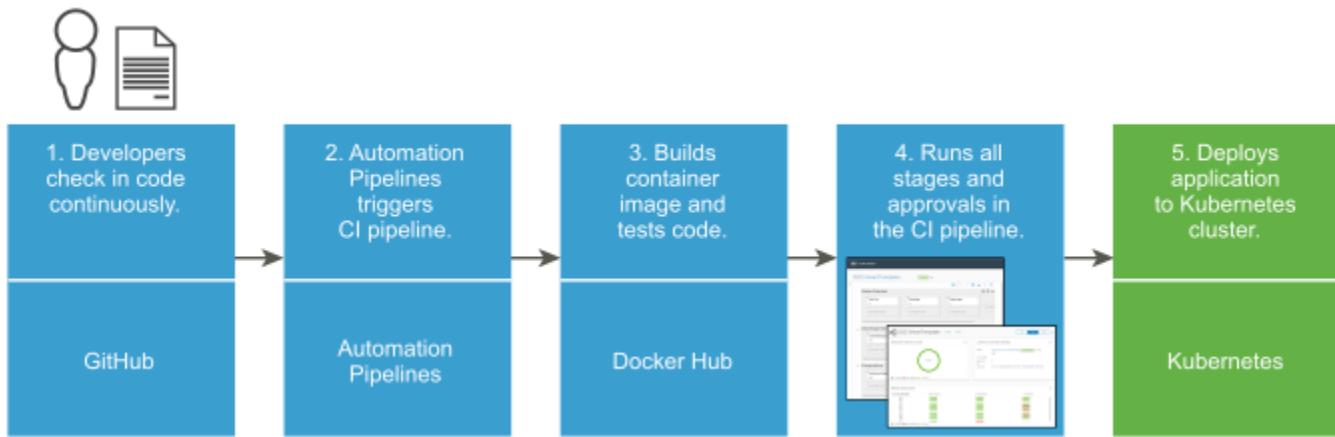

Features	Examples of what you can do
Use the native build capability in Automation Pipelines.	<p>Create Continuous Integration and Delivery (CICD), Continuous Integration (CI), and Continuous Delivery (CD) pipelines that continuously integrate, containerize, and deliver your code.</p> <ul style="list-style-type: none"> • Use a smart pipeline template that creates a pipeline for you. • Manually add stages and tasks to a pipeline.
Release your applications and automate releases.	<p>Integrate and release your applications in various ways.</p> <ul style="list-style-type: none"> • Continuously integrate your code from a GitHub or a GitLab repository into your pipeline. • Integrate a Docker Host to run Continuous Integration tasks as documented in this blog article about creating a Docker host. • Automate the deployment of your application by using a YAML cloud template. • Automate the deployment of your application to a Kubernetes cluster. • Release your application to a Blue-Green deployment. • Integrate Automation Pipelines with your own build, test, and deploy tools. • Use a REST API that integrates Automation Pipelines with other applications.
Track trends, metrics, and key performance indicators (KPIs).	Create custom dashboards and gain insight about the performance of your pipelines.
Resolve problems.	When a pipeline run fails, have Automation Pipelines create a Jira ticket.

How do I continuously integrate code from my GitHub or GitLab repository into my pipeline in Automation Pipelines

How do I continuously integrate code from my GitHub or GitLab repository into my pipeline

As a developer, you want to continuously integrate your code from a GitHub repository or a GitLab Enterprise repository. Whenever your developers update their code and commit changes to the repository, Automation Pipelines can listen for those changes, and trigger the pipeline.

- Plan for your continuous integration build. See [Planning a continuous integration native build in before using the smart pipeline template](#).
- Verify that a GitLab source code repository exists. For help, see your Automation Pipelines administrator.
- Add a Git endpoint. For an example, see [How do I use the Git trigger in to run a pipeline](#).
- To have Automation Pipelines listen for changes in your GitHub repository or your GitLab repository, and trigger a pipeline when changes occur, add a webhook. For an example, see [How do I use the Git trigger in to run a pipeline](#).
- Add a Docker host endpoint, which creates a container for the continuous integration task that multiple continuous integration tasks can use. For more information about endpoints, see [What are Endpoints in](#).
- Obtain the image URL, the build host, and the URL for the build image. For help, see your Automation Pipelines administrator.
- Verify that you use JUnit and JaCoCo for your test framework tools.
- Set up an external instance for your continuous integration build: Jenkins, TFS, or Bamboo. The Kubernetes plug-in deploys your code. For help, see your Automation Pipelines administrator.

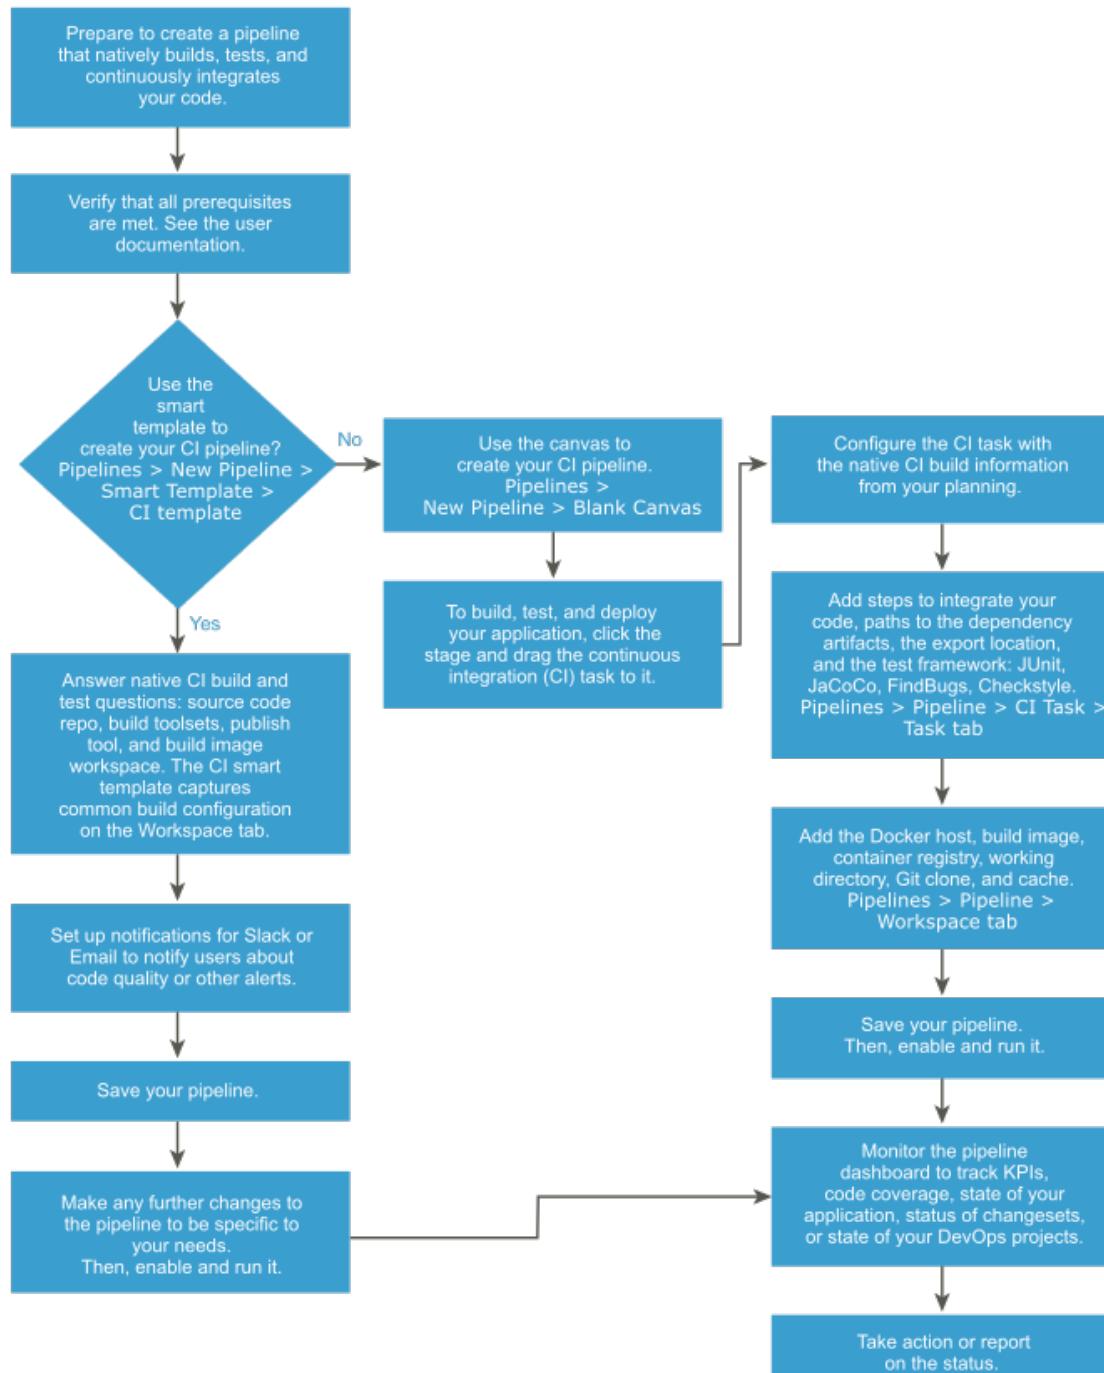

To have Automation Pipelines trigger your pipeline on code changes, you use the Git trigger. Automation Pipelines then triggers your pipeline every time you commit changes to your code.

The Automation Pipelines pipeline workspace supports Docker and Kubernetes for continuous integration tasks and custom tasks.

For more information about configuring the workspace, see [Configuring the Pipeline Workspace](#).

The following flowchart shows the workflow that you can take if you use a smart pipeline template to create your pipeline, or build the pipeline manually.

Figure 15: Workflow that uses a smart pipeline template or creates a pipeline manually

The following example uses a Docker workspace.

To build your code, you use a Docker host. You use JUnit and JaCoCo as your test framework tools, which run unit tests and code coverage, and you include them in your pipeline.

Then you can use the continuous integration smart pipeline template that creates a continuous integration pipeline that builds, tests, and deploys your code to your project team Kubernetes cluster on AWS. To store the code dependency artifacts for your continuous integration task, which can save time in code builds, you can use a cache.

In the pipeline task that builds and tests your code, you can include several continuous integration steps. These steps can reside in the same working directory where Automation Pipelines clones the source code when the pipeline triggers.

To deploy your code to the Kubernetes cluster, you can use a Kubernetes task in your pipeline. You must then enable and run your pipeline. Then, make a change to your code in the repository, and watch the pipeline trigger. To monitor and report on your pipeline trends after your pipeline runs, use the dashboards.

In the following example, to create a continuous integration pipeline that continuously integrates your code into your pipeline, you use the continuous integration smart pipeline template. This example uses a Docker workspace.

Optionally, you can manually create the pipeline, and add stages and tasks to it. For more information about planning a continuous integration build and manually creating the pipeline, see [Planning a CICD native build in before manually adding tasks](#).

1. Follow the prerequisites.
2. To create the pipeline by using the smart pipeline template, open the continuous integration smart pipeline template and fill out the form.
 - a) Click **Pipelines** > **New Pipeline** > **Smart Template** > **Continuous Integration**.
 - b) Answer the questions in the template about your source code repository, build toolsets, publishing tool, and the build image workspace.
 - c) Add Slack notifications or Email notifications for your team.
 - d) To have the smart pipeline template create the pipeline, click **Create**.
 - e) To make any further changes to the pipeline, click **Edit**, make your changes, and click **Save**.
 - f) Enable the pipeline and run it.
3. To create the pipeline manually, add stages and tasks to the canvas, and include your native continuous integration build information in the continuous integration task.
 - a) Click **Pipelines** > **New Pipeline** > **Blank Canvas**.
 - b) Click the stage, then drag the several continuous integration tasks from the navigation pane to the stage.
 - c) To configure the continuous integration task, click it, and click the **Task** tab.
 - d) Add the steps that continuously integrate your code.
 - e) Include the paths to the dependency artifacts.
 - f) Add the export location.
 - g) Add the test framework tools that you'll use.
 - h) Add the Docker host and build image.
 - i) Add the container registry, working directory, and cache.
 - j) Save the pipeline, then enable it.
4. Make a change to your code in your GitHub repository or GitLab repository. The Git trigger activates your pipeline, which starts to run.
5. To verify that the code change triggered the pipeline, click **Triggers** > **Git** > **Activity**.
6. To view the execution for your pipeline, click **Executions**, and verify that the steps created and exported your build image.

The screenshot shows the VMware Aria Automation Pipeline Details page for a pipeline named "CICD-SmartTemplate #51". The pipeline has completed successfully with a status of "COMPLETED" and 6 steps. The tasks listed are "Build-Publish" and "Development". Under "Build-Publish", the tasks are "Unit-Test", "Build-App", and "Build-Image" (which is highlighted). Under "Development", the tasks are "Create Namespace", "Create Secret", "Create Service", and "Create Deployment".

Task name: Build-Image [VIEW OUTPUT JSON](#)

Type: CI **Status:** COMPLETED Execution Completed.

Input >

- To monitor the pipeline dashboard so that you can track KPIs and trends, click **Dashboards > Pipeline Dashboards**.

Congratulations! You created a pipeline that continuously integrates your code from a GitHub repository or GitLab repository into your pipeline, and deploys your build image.

To learn more, see the additional resources under *Getting Started with VMware Aria Automation*.

How do I automate the release of an application that I deploy from a YAML cloud template in Automation Pipelines

How do I automate the release of an application that I deploy from a YAML cloud template?

As a developer, you need a pipeline that fetches an automation cloud template from an on-premises GitHub instance every time you commit a change. You need the pipeline to deploy a WordPress application to either Amazon Web Services (AWS) EC2 or a data center. Automation Pipelines calls the cloud template from the pipeline and automates the continuous integration and continuous delivery (CI/CD) of that cloud template to deploy your application.

- Add the YAML code for the WordPress application to your GitHub instance.

- Add a webhook for the Git trigger so that your pipeline can pull your YAML code whenever you commit changes to it. In Automation Pipelines, click **Triggers > Git > Webhooks for Git**.
- To work with a cloud template task, you must have any of the Automation Assembler roles.

To create and trigger your pipeline, you'll need a cloud template in Automation Assembler.

For **Template source** in your Automation Pipelines cloud template task, you can select either:

- **Automation Assembler** as the source control. In this case, you do not need a GitLab or GitHub repository.
- **Source Control** if you use GitLab or GitHub for source control. In this case, you must have a Git webhook and trigger the pipeline through the webhook.

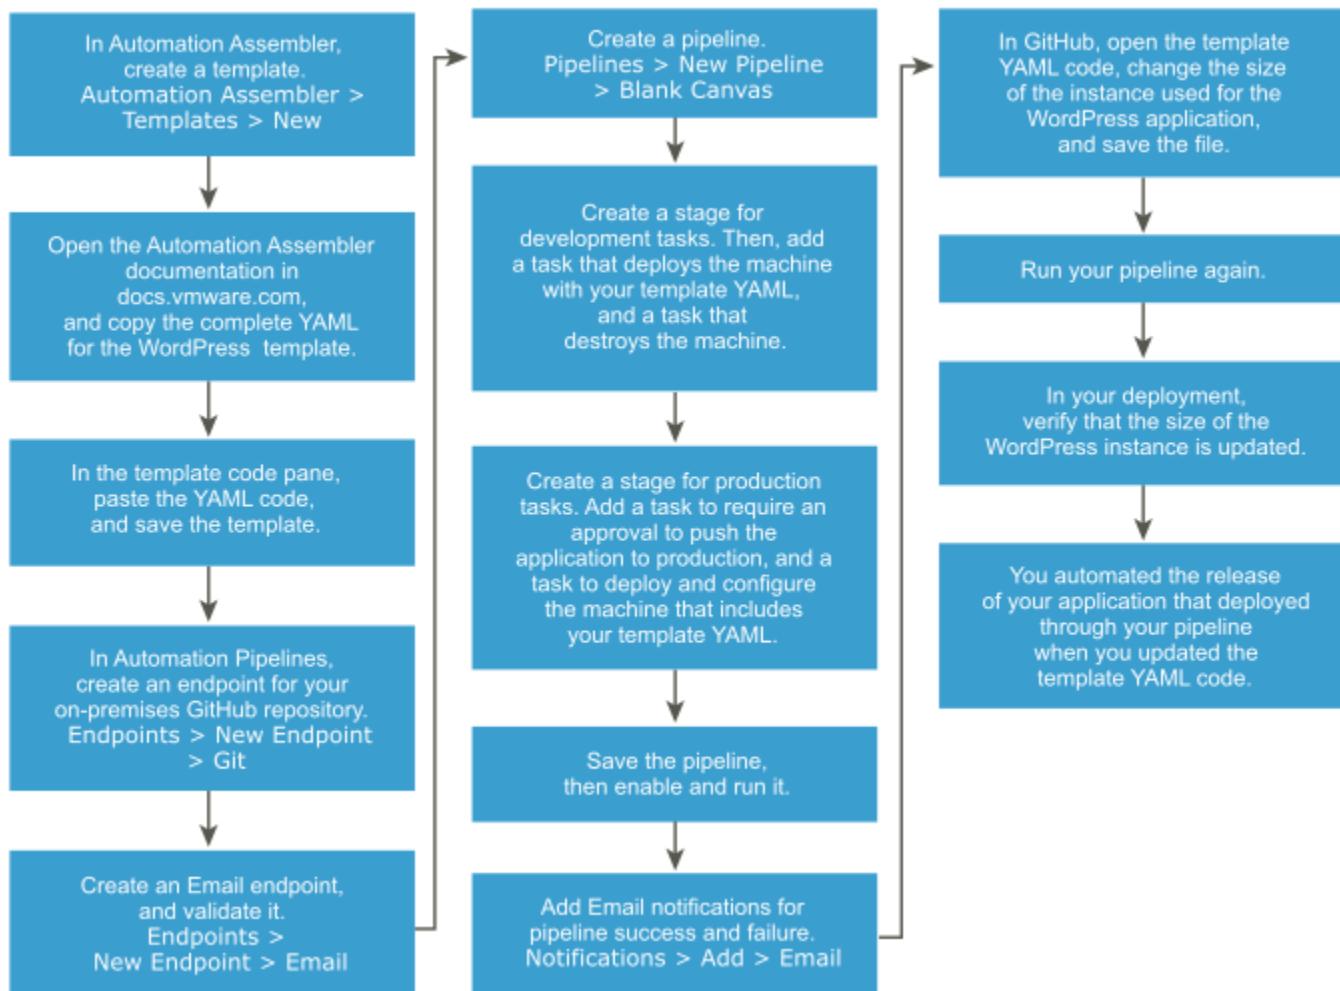

If you have a YAML cloud template in your GitHub repository, and want to use that cloud template in your pipeline, here's what you'll need to do.

1. In Automation Assembler, push the cloud template to your GitHub repository.
2. In Automation Pipelines, create a Git endpoint. Then, create a Git webhook that uses your Git endpoint and your pipeline.
3. To trigger your pipeline, update any file in your GitHub repository and commit your change.

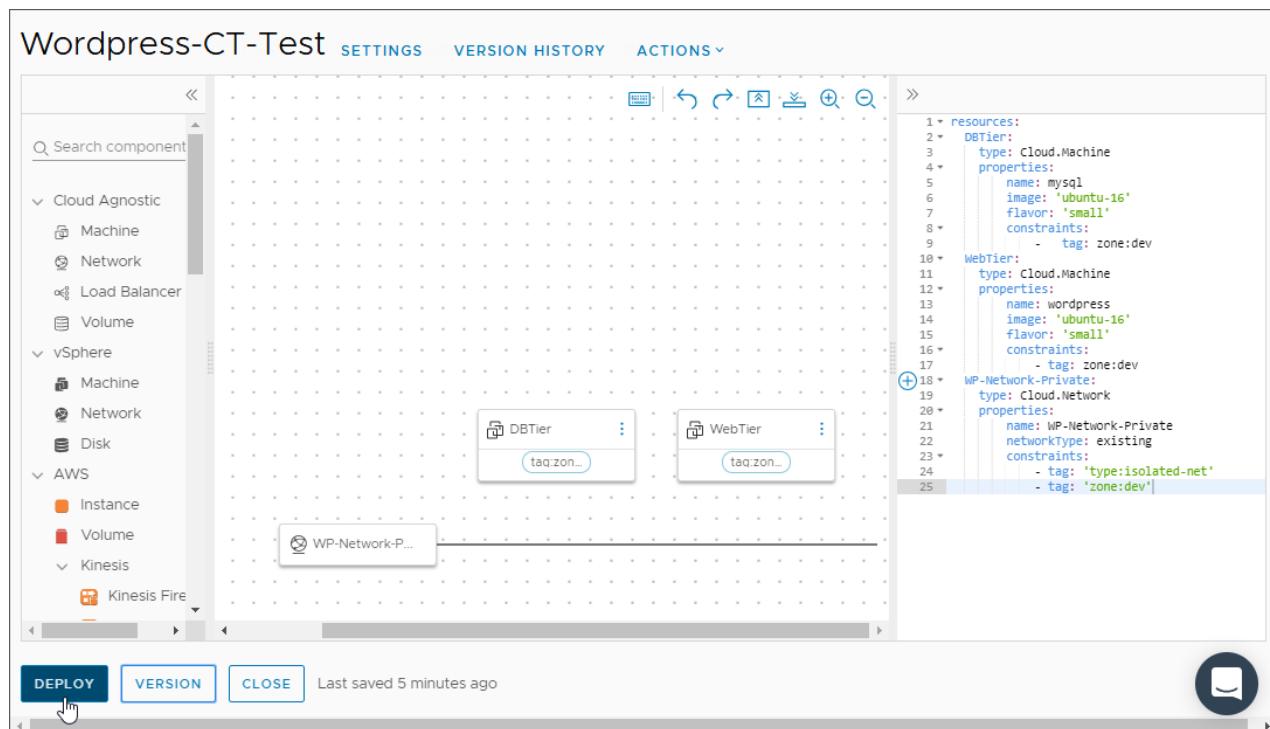

If you don't have a YAML cloud template in your GitHub repository, and want to use a cloud template from source control, use this procedure to learn how. It shows you how to create a cloud template for a WordPress application, and trigger it from an on-premises GitHub repository. Whenever you make a change to the YAML cloud template, the pipeline triggers and automates the release of your application.

- In Automation Assembler, you'll add a cloud account, add a cloud zone, and create the cloud template.
- In Automation Pipelines, you'll add an endpoint for the on-premises GitHub repository that hosts your cloud template. Then, you'll add the cloud template to your pipeline.

This use case example shows you how to use a cloud template from an on-premises GitHub repository.

1. In Automation Assembler, follow these steps.
 - a) Click **Templates**, then create a cloud template and a deployment for the WordPress application.
 - b) Paste the WordPress YAML code that you copied to your clipboard into your cloud template, and deploy it.

2. In Automation Pipelines, create endpoints.

- Create a Git endpoint for your on-premises GitHub repository where your YAML file resides.
- Add an Email endpoint that can notify users about the pipeline status when it runs.

New endpoint

Project * Pipeline

Type * Email

Name * Enter value here

Description

Mark as restricted non-restricted

Sender's Address * eg: abc@xyz.com

Encryption Method * SSL

Outbound Host * myimap.org

Outbound Port * Port number

Outbound Protocol * smtp

Outbound Username username

Outbound Password password

CREATE **VALIDATE** **CANCEL**

The screenshot shows the 'New endpoint' configuration interface. The 'Type' dropdown is set to 'Email'. The 'Name' field is empty and has a placeholder 'Enter value here'. The 'Mark as restricted' toggle is off, and the 'non-restricted' option is selected. The 'VALIDATE' button is highlighted in blue.

3. Create a pipeline, and add notifications for pipeline success and failure.

Send notification type Email Ticket Webhook

When pipeline Completes Is Waiting Fails Is cancelled Starts to run

Email server * --Select Email server--

Send Email

To \$ * Email IDs of recipients

Subject \$ * Email Subject

Body \$ * 1

CANCEL SAVE

4. Add a stage for development, and add a cloud template task.

- a) Add a cloud template task that deploys the machine, and configure the task to use the cloud template YAML for the WordPress application.
resources:

```
DBTier:
  type: Cloud.Machine
  properties:
    name: mysql
    image: 'ubuntu-16'
    flavor: 'small'
  constraints:
    - tag: zone:dev
```

```
WebTier:
  type: Cloud.Machine
  properties:
```

```
name: wordpress
image: 'ubuntu-16'
flavor: 'small'
constraints:
  - tag: zone:dev
WP-Network-Private:
  type: Cloud.Network
  properties:
    name: WP-Network-Private
    networkType: existing
  constraints:
    - tag: 'type:isolated-net'
    - tag: 'zone:dev'
```

- b) Add a cloud template task that destroys the machine to free up resources.
5. Add a stage for production, and include approval and deployment tasks.
- a) Add a User Operation task to require approval to push the WordPress application to production.
 - b) Add a cloud template task to deploy the machine and configure it with the cloud template YAML for the WordPress application.

When you select **Create**, the deployment name must be unique. If you leave the name blank, Automation Pipelines assigns it a unique random name.

Here's what you must know if you select **Rollback** in your own use case: If you select the **Rollback** action and enter a **Rollback Version**, the version must be in the form of n-X. For example, n-1, n-2, n-3, and so on. If you create and update the deployment in any location other than Automation Pipelines, rollback is allowed.

Task :Deploy CT Notifications Rollback VALIDATE TASK

Task name **Deploy CT**

6. Run the pipeline.

To verify that each task completed successfully, click the task in the execution, and examine the status in the deployment details to see detailed resource information.

7. In GitHub, modify the flavor of the WordPress server instance from small to medium.

When you commit changes, the pipeline triggers. It pulls your updated code from the GitHub repository and builds your application.

WebTier:

```
type: Cloud.Machine
properties:
  name: wordpress
  image: 'ubuntu-16'
  flavor: 'medium'
constraints:
  - tag: zone:dev
```

- Run the pipeline again, verify that it succeeded, and that it changed the flavor of the WordPress instance from small to medium.

Congratulations! You automated the release of your application that you deployed from a YAML cloud template.

To learn more about how you can use Automation Pipelines, see [Tutorials for using](#).

For more information, see the additional resources in the *Getting Started with VMware Aria Automation* guide.

How do I automate the release of an application in Automation Pipelines to a Kubernetes cluster

How do I automate the release of an application to a Kubernetes cluster

As a Automation Pipelines administrator or developer, you can use Automation Pipelines and VMware Tanzu Kubernetes Grid Integrated Edition (formerly known as VMware Enterprise PKS) to automate the deployment of your software applications to a Kubernetes cluster. This use case mentions other methods that you can use to automate the release of your application.

- Verify that the application code to deploy resides in a working GitHub repository.
- Verify that you have a working instance of Jenkins.
- Verify that you have a working email server.
- In Automation Pipelines, create an email endpoint that connects to your email server.
- Set up two Kubernetes clusters on Amazon Web Services (AWS), for development and production, where your pipeline will deploy your application.
- Verify that the GitHub repository contains the YAML code for your pipeline, and alternatively a YAML file that defines the metadata and specifications for your environment.

In this use case, you will create a pipeline that includes two stages, and will use Jenkins to build and deploy your application.

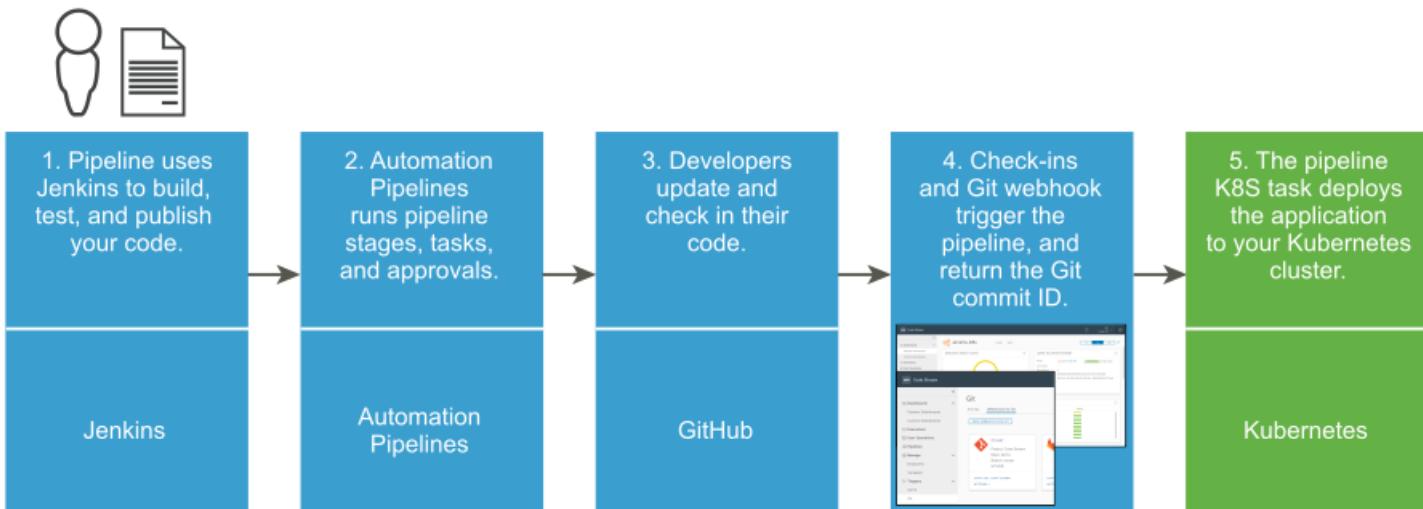

- The first stage is for development. It uses Jenkins to pull your code from a branch in your GitHub repository, then build, test, and publish it.
- The second stage is for deployment. It runs a user operation task that requires approval from key users before the pipeline can deploy your application to your Kubernetes cluster.

When using a Kubernetes API endpoint in the pipeline workspace, Automation Pipelines creates the necessary Kubernetes resources such as ConfigMap, Secret, and Pod to run the continuous integration (CI) task or custom task. Automation Pipelines communicates with the container by using the NodePort.

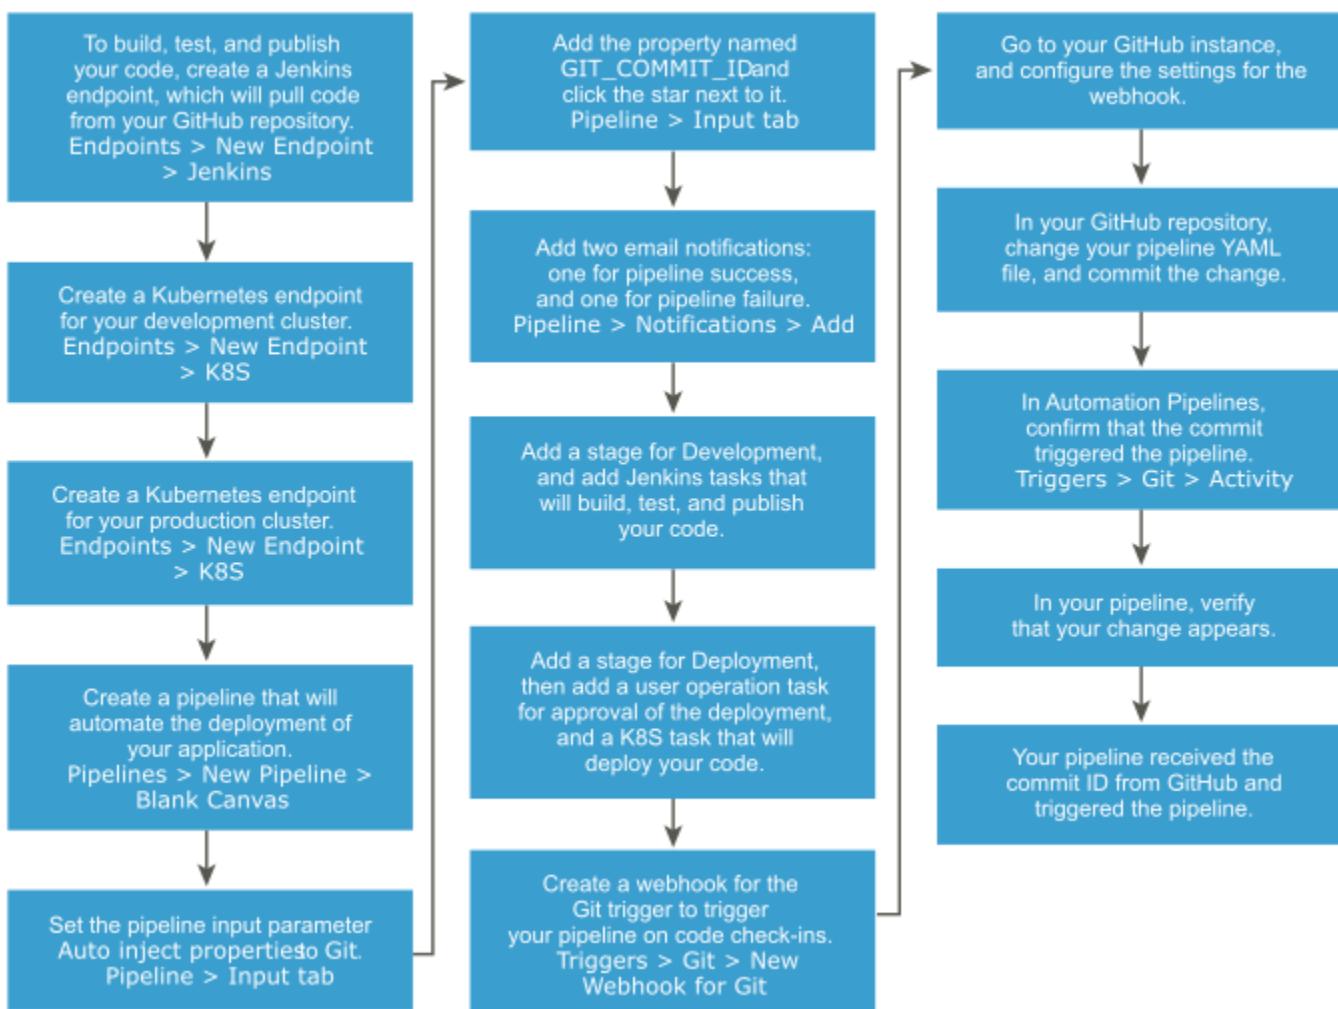

To share data across pipeline runs, you must provide a persistent volume claim, and Automation Pipelines will mount the persistent volume claim to the container to store the data, and use it for subsequent pipeline runs.

The Automation Pipelines pipeline workspace supports Docker and Kubernetes for continuous integration tasks and custom tasks.

For more information about configuring the workspace, see [Configuring the Pipeline Workspace](#).

The development tools, deployment instances, and pipeline YAML file must be available so that your pipeline can build, test, publish, and deploy your application. The pipeline will deploy your application to development and production instances of Kubernetes clusters.

Other methods that automate the release of your application:

- Instead of building your application by using Jenkins, you can use the Automation Pipelines native build capability and a Docker build host.
- Instead of deploying your application to a Kubernetes cluster, you could deploy it to an Amazon Web Services (AWS) cluster.

For more information about using the Automation Pipelines native build capability and a Docker host, see:

- [Planning a CICD native build in before using the smart pipeline template](#)
- [Planning a CICD native build in before manually adding tasks](#)

1. In Automation Pipelines, click **Endpoints > New Endpoint**, and create a Jenkins endpoint that you will use in your pipeline to pull code from your GitHub repository.
2. To create Kubernetes endpoints, click **New Endpoint**.
 - a) Create an endpoint for your development Kubernetes cluster.
 - b) Create an endpoint for your production Kubernetes cluster.

The URL for your Kubernetes cluster might or might not include a port number.

For example:

`https://10.111.222.333:6443`

`https://api.kubernetesserver.fa2c1d78-9f00-4e30-8268-4ab81862080d.k8s-user.com`

3. Create a pipeline that deploys a container of your application, such as Wordpress, to your development Kubernetes cluster, and set the input properties for the pipeline.
 - a) To allow your pipeline to recognize a code commit in GitHub that will trigger the pipeline, in the pipeline click the **Input** tab and select **Auto inject properties**.
 - b) Add the property named **GIT_COMMIT_ID**, and click the star next to it.

When the pipeline runs, the pipeline execution will display the commit ID that the Git trigger returns.

Starred	Name	Value	Description
★	GIT_BRANCH_NAME		
★	GIT_CHANGE_SUBJECT		
★	GIT_COMMIT_ID		
★	GIT_EVENT_DESCRIPTION		
★	GIT_EVENT_OWNER_NAME		
★	GIT_EVENT_TIMESTAMP		
★	GIT_REPO_NAME		
★	GIT_SERVER_URL		

4. Add notifications to send an Email when the pipeline succeeds or fails.
 - a) In the pipeline, click the **Notifications** tab, and click **Add**.
 - b) To add an email notification when the pipeline finishes running, select **Email**, and select **Completes**. Then, select the email server, enter email addresses, and click **Save**.

- c) To add another email notification for a pipeline failure, select **Fails**, and click **Save**.

Notification

Send notification type Email Ticket Webhook

- Add a development stage to your pipeline, and add tasks that build, test, and publish your application. Then, validate each task.
 - To build your application, add a Jenkins task that uses the Jenkins endpoint, and runs a build job from the Jenkins server. Then, for the pipeline to pull your code, enter the Git branch in this form: `$ {input.GIT_BRANCH_NAME}`
 - To test your application, add a Jenkins task that uses the same Jenkins endpoint, and runs a test job from the Jenkins server. Then, enter the same Git branch.
 - To publish your application, add a Jenkins task that uses the same Jenkins endpoint, and runs a publish job from the Jenkins server. Then, enter the same Git branch.

6. Add a deployment stage to your pipeline, then add a task that requires an approval for deployment of your application, and another task that deploys the application to your Kubernetes cluster. Then, validate each task.
 - a) To require an approval on the deployment of your application, add a User Operation task, add Email addresses for the users who must approve it, and enter a message. Then, enable **Send email**.
 - b) To deploy your application, add a Kubernetes task. Then, in the Kubernetes task properties, select your development Kubernetes cluster, select the **Create** action, and select the **Local Definition** payload source. Then select your local YAML file.
7. Add a Git webhook that enables Automation Pipelines to use the Git trigger, which triggers your pipeline when developers commit their code.

Git

Activity [Webhooks for Git](#)

8. To test your pipeline, go to your GitHub repository, update your application YAML file, and commit the change.
 - a) In Automation Pipelines, verify that the commit appears.
 - a) Click **Triggers > Git > Activity**.
 - b) Look for the trigger of your pipeline.
 - c) Click **Dashboards > Pipeline Dashboards**.
 - d) On your pipeline dashboard, find the GIT_COMMIT_ID in the latest successful change area.
9. Check your pipeline code and verify that the change appears.

Congratulations! You automated the deployment of your software application to your Kubernetes cluster.

Example pipeline YAML that deploys an application to a Kubernetes cluster

For the type of pipeline used in this example, the YAML resembles the following code:

```

apiVersion: v1
kind: Namespace

        - name: jfrog
```

To deploy your software application to your production Kubernetes cluster, perform the steps again and select your production cluster.

To learn more about integrating Automation Pipelines with Jenkins, see [How do I integrate with Jenkins](#).

How do I deploy my application in Automation Pipelines to my Blue-Green deployment

How do I deploy my application to my Blue-Green deployment

Blue-Green is a deployment model that uses two Docker hosts that you deploy and configure identically in a Kubernetes cluster. With the Blue and Green deployment model, you reduce the downtime that can occur in your environment when your pipelines in Automation Pipelines deploy your applications.

- Verify that you can access a working Kubernetes cluster on AWS.
- Verify that you set up a Blue-Green deployment environment, and configured your Blue and Green instances to be identical.
- Create a Kubernetes endpoint in Automation Pipelines that deploys your application image to the Kubernetes cluster on AWS.
- Familiarize yourself with using the CICD smart pipeline template. See [Planning a CICD native build in Automation Pipelines before using the smart pipeline template](#).

The Blue and Green instances in your deployment model each serve a different purpose. Only one instance at a time accepts the live traffic that deploys your application, and each instance accepts that traffic at specific times. The Blue instance receives the first version of your application, and the Green instance receives the second.

The load balancer in your Blue-Green environment determines which route the live traffic takes as it deploys your application. By using the Blue-Green model, your environment remains operational, users don't notice any downtime, and your pipeline continuously integrates and deploys your application to your production environment.

The pipeline that you create in Automation Pipelines represents your Blue-Green deployment model in two stages. One stage is for development, and the other stage is for production.

The Automation Pipelines pipeline workspace supports Docker and Kubernetes for continuous integration tasks and custom tasks.

For information about configuring the workspace, see [Configuring the Pipeline Workspace](#).

Table 75: Development stage tasks for Blue-Green deployment

Task type	Task
Kubernetes	Create a namespace for your Blue-Green deployment.
Kubernetes	Create a secret key for Docker Hub.
Kubernetes	Create the service used to deploy the application.
Kubernetes	Create the Blue deployment.
Poll	Verify the Blue deployment.
Kubernetes	Remove the namespace.

Table 76: Production stage tasks for Blue-Green deployment

Task type	Task
Kubernetes	Green gets the service details from Blue.
Kubernetes	Get the details for the Green replica set.
Kubernetes	Create the Green deployment, and use the secret key to pull the container image.
Kubernetes	Update the service.
Poll	Verify that the deployment succeeded on the production URL.
Kubernetes	Finish the Blue deployment.
Kubernetes	Remove the Blue deployment.

To deploy your application in your own Blue-Green deployment model, you create a pipeline in Automation Pipelines that includes two stages. The first stage includes the Blue tasks that deploy your application to the Blue instance, and the second stage includes Green tasks that deploy your application to the Green instance.

You can create your pipeline by using the CICD smart pipeline template. The template creates your pipeline stages and tasks for you, and includes the deployment selections.

If you create your pipeline manually, you must plan your pipeline stages. For an example, see [Planning a CICD native build in before manually adding tasks](#).

In this example, you use the CICD smart pipeline template to create your Blue-Green pipeline.

1. Click **Pipelines** > **New Pipeline** > **Smart Templates** > **CI/CD template**.
2. Enter the information for the CI portion of the CICD smart pipeline template, and click **Next**.
For help, see [Planning a CICD native build in before using the smart pipeline template](#).
3. Complete the CD portion of the smart pipeline template
 - a) Select the environments for your application deployment. For example, **Dev** and **Prod**.
 - b) Select the service that the pipeline will use for the deployment.
 - c) In the Deployment area, select the cluster endpoint for the Dev environment and the Prod environment.
 - d) For the Production deployment model, select **Blue-Green**, and click **Create**.

CREATE BACK CANCEL

Congratulations! You used the smart pipeline template to create a pipeline that deploys your application to your Blue-Green instances in your Kubernetes production cluster on AWS.

Example YAML code for some Blue-Green Deployment Tasks

The YAML code that appears in Kubernetes pipeline tasks for your Blue-Green deployment might resemble the following examples that create the Namespace, Service, and Deployment. If you need to download an image from a privately-owned repository, the YAML file must include a section with the Docker config Secret. See the CD portion of [Planning a CICD native build in before using the smart pipeline template](#).

After the smart pipeline template creates your pipeline, you can modify the tasks as needed for your own deployment.

YAML code to create an example namespace:

```
apiVersion: v1
kind: Namespace
metadata:
  name: pipelines-82855
  namespace: pipelines-82855
```

YAML code to create an example service:

```
apiVersion: v1
kind: Service
metadata:
  labels:
    app: pipelines-demo
  name: pipelines-demo
  namespace: bluegreen-799584
spec:
  minReadySeconds: 0
```

ports:

```
- port: 80
```

selector:

```
  app: pipelines-demo
  tier: frontend
  type: LoadBalancer
```

YAML code to create an example deployment:

```
apiVersion: extensions/v1
kind: Deployment
metadata:
  labels:
    app: pipelines-demo
  name: pipelines-demo
  namespace: bluegreen-799584
spec:
  minReadySeconds: 0
```

replicas: 1

selector:

```

matchLabels:
  app: pipelines-demo
  tier: frontend
template:
metadata:
labels:
  app: pipelines-demo
  tier: frontend
spec:
containers:
- image: ${input.image}:${input.tag}
  name: pipelines-demo
ports:
- containerPort: 80
  name: pipelines-demo
imagePullSecrets:
- name: jfrog-2
minReadySeconds: 0

```

To learn more about how you can use Automation Pipelines, see [Tutorials for using](#).

To roll back a deployment, see [How do I roll back my deployment in](#).

For more information, see the additional resources in the *Getting Started with VMware Aria Automation* guide.

How do I integrate my own build, test, and deploy tools with Automation Pipelines

How do I integrate my own build, test, and deploy tools

As a DevOps administrator or developer, you can create custom scripts that extend the capability of Automation Pipelines.

- To write your custom script, verify that you have one of these languages: Python 2, Python 3, Node.js, or any of the shell languages: Bash, sh, or zsh.
- Generate a container image by using the installed Node.js or the Python runtime.

With your script, you can integrate Automation Pipelines with your own Continuous Integration (CI) and Continuous Delivery (CD) tools and APIs that build, test, and deploy your applications. Custom scripts are especially useful if you do not expose your application APIs publicly.

Your custom script can do almost anything you need for your build, test, and deploy tools integrate with Automation Pipelines. For example, your script can work with your pipeline workspace to support continuous integration tasks that build and test your application, and continuous delivery tasks that deploy your application. It can send a message to Slack when a pipeline finishes, and much more.

The Automation Pipelines pipeline workspace supports Docker and Kubernetes for continuous integration tasks and custom tasks.

For more information about configuring the workspace, see [Configuring the Pipeline Workspace](#).

You write your custom script in one of the supported languages. In the script, you include your business logic, and define inputs and outputs. Output types can include number, string, text, and password. You can create multiple versions of a custom script with different business logic, input, and output.

The scripts that you create reside in your Automation Pipelines instance. You can import YAML code to create a custom integration or export your script as a YAML file to use in another Automation Pipelines instance.

You have your pipeline run a released version of your script in a custom task. If you have multiple released versions, you can set one of them as latest so that it appears with **latest -->** when you select the custom task.

When a pipeline uses a custom integration, if you attempt to delete the custom integration, an error message appears and indicates that you cannot delete it.

Deleting a custom integration removes all versions of your custom script. If you have an existing pipeline with a custom task that uses any version of the script, that pipeline will fail. To ensure that existing pipelines do not fail, you can deprecate and withdraw the version of your script that you no longer want used. If no pipeline is using that version, you can delete it.

Table 77: What you do after you write your custom script

What you do...	More information about this action...
Add a custom task to your pipeline.	<p>The custom task:</p> <ul style="list-style-type: none"> Runs on the same container as other CI tasks in your pipeline. Includes input and output variables that your script populates before the pipeline runs the custom task. Supports multiple data types and various types of meta data that you define as inputs and outputs in your script.
Select your script in the custom task.	You declare the input and output properties in the script.
Save your pipeline, then enable and run it.	When the pipeline runs, the custom task calls the version of the script specified and runs the business logic in it, which integrates your build, test, and deploy tool with Automation Pipelines.
After your pipeline runs, look at the executions.	Verify that the pipeline delivered the results you expected.

When you use a custom task that calls a Custom Integration version, you can include custom environment variables as name-value pairs on the pipeline **Workspace** tab. When the builder image creates the workspace container that runs the CI task and deploys your image, Automation Pipelines passes the environment variables to that container.

For example, when your Automation Pipelines instance requires a Web proxy, and you use a Docker host to create a container for a custom integration, Automation Pipelines runs the pipeline and passes the Web proxy setting variables to that container.

Table 78: Example environment variable name-value pairs

Name	Value
HTTPS_PROXY	http://10.0.0.255:1234
https_proxy	http://10.0.0.255:1234
NO_PROXY	10.0.0.32, *.dept.vsphere.local
no_proxy	10.0.0.32, *.dept.vsphere.local
HTTP_PROXY	http://10.0.0.254:1234
http_proxy	http://10.0.0.254:1234
PATH	/usr/local/sbin:/usr/local/bin:/usr/sbin:/usr/bin:/sbin:/bin

Name-value pairs appear in the user interface like this:

Environment variables

`https_proxy`
`http://10.0.0.255:1234`

`PATH`
`/usr/local/sbin:/usr/local/bin:/usr/sbin:/usr/bin:/sbin:/bin`

Provide environment variables to pass for container creation

- +

This example creates a custom integration that connects Automation Pipelines to your Slack instance, and posts a message to a Slack channel.

1. Create the custom integration.

- a) Click **Custom Integrations** > **New**, and enter a relevant name.
- b) Select the preferred runtime environment.
- c) Click **Create**.

Your script opens, and displays the code, which includes the required runtime environment. For example, `runtime: "nodejs"`. The script must include the runtime, which the builder image uses, so that the custom task that you add to your pipeline succeeds when the pipeline runs. Otherwise, the custom task fails.

The main areas of your custom integration YAML include the runtime, code, input properties, and output properties. This procedure explains various types and syntax.

Custom integration YAML keys	Description
runtime	Task runtime environment where Automation Pipelines runs the code, which can be one of these case-insensitive strings: <ul style="list-style-type: none"> • nodejs • python2 • python3 • shell If nothing is provided, shell is the assumed default.
code	Custom business logic to run as part of the custom task.
inputProperties	Array of input properties to capture as part of the custom task configuration. These properties are normally used in the code.
outputProperties	Array of output properties you can export from the custom task to propagate to the pipeline.

2. Declare the input properties in your script by using the available data types and meta data.

The input properties are passed in as context to your script in the `code:` section of the YAML.

Custom task YAML input keys	Description	Required
type	Types of input to render:	Yes

Table continued on next page

Continued from previous page

Custom task YAML input keys	Description	Required
	<ul style="list-style-type: none"> • text • textarea • number • checkbox • password • select 	
name	Name or string of the input to the custom task, which gets injected into the custom integration YAML code. Must be unique for each input property defined for a custom integration.	Yes
title	Text string label of the input property for the custom task on the pipeline model canvas. If left empty, name is used by default.	No
required	Determines whether a user must enter the input property when they configure the custom task. Set to true or false. When true, if a user does not provide a value when they configure the custom task on the pipeline canvas, the state of the task remains as unconfigured.	No
placeHolder	Default text for the input property entry area when no value is present. Maps to the html placeholder attribute. Only supported for certain input property types.	No
defaultValue	Default value that populates the input property entry area when the custom task renders on the pipeline model page.	No
bindable	Determines whether the input property accepts dollar sign variables when modeling the custom task on the pipeline canvas. Adds the \$ indicator next to the title. Only supported for certain input property types.	No
labelMessage	String that acts as a help tooltip for users. Adds a tooltip icon i next to the input title.	No
enum	<p>Takes in an array of values that displays the select input property options. Only supported only for certain input property types.</p> <p>When a user selects an option, and saves it for the custom task, the value of inputProperty corresponds to this value and appears in the custom task modeling.</p> <p>For example, the value 2015.</p> <ul style="list-style-type: none"> • 2015 • 2016 • 2017 • 2018 • 2019 • 2020 	No
options	Takes in an array of objects by using optionKey and optionValue . <ul style="list-style-type: none"> • optionKey. Value propagated to the code section of the task. • optionValue. String that displays the option in the user interface. Only supported only for certain input property types.	No

Table continued on next page

Continued from previous page

Custom task YAML input keys	Description	Required
	<p>Options:</p> <p>optionKey: key1. When selected and saved for the custom task, the value of this inputProperty corresponds to key1 in the code section.</p> <p>optionValue: 'Label for 1'. Display value for key1 in the user interface, and does not appear anywhere else for the custom task.</p> <p>optionKey: key2</p> <p>optionValue: 'Label for 2'</p> <p>optionKey: key3</p> <p>optionValue: 'Label for 3'</p>	
minimum	Takes in a number that acts as the minimum value that is valid for this input property. Only supported for number type input property.	No
maximum	Takes in a number that acts as the maximum value that is valid for this input property. Only supported for number type input property.	No

Table 79: Supported data types and meta data for custom scripts

Supported data types	Supported meta data for input
<ul style="list-style-type: none"> String Text List: as a list of any type Map: as map[string]any Secure: rendered as password text box, encrypted when you save the custom task Number Boolean: appears as text boxes URL: same as string, with additional validation Selection, radio button 	<ul style="list-style-type: none"> type: One of String Text ... default: Default value options: List or a map of options, to be used with selection or radio button min: Minimum value or size max: Maximum value or size title: Detailed name of the text box placeHolder: UI placeholder description: Becomes a tool tip

For example:

```
inputProperties:
  - name: message
    type: text
    title: Message
    placeHolder: Message for Slack Channel
    defaultValue: Hello Slack
    bindable: true
```

```

labelInfo: true
labelMessage: This message is posted to the Slack channel link provided in
the code

```

3. Declare the output properties in your script.

The script captures output properties from the business logic `code:` section of your script, where you declare the context for the output.

When the pipeline runs, you can enter the response code for the task output. For example, 200.

Keys that Automation Pipelines supports for each **outputProperty**.

key	Description
type	Currently includes a single value of <code>label</code> .
name	Key that the code block of the custom integration YAML emits.
title	Label in the user interface that displays outputProperty .

For example:

`outputProperties:`

```

- name: statusCode
  type: label
  title: Status Code

```

4. To interact with the input and output of your custom script, get an input property or set an output property by using context.

For an input property: `(context.getInput("key"))`

For an output property: `(context.setOutput("key", "value"))`

For Node.js:

```

var context = require("./context.js")
var message = context.getInput("message");
//Your Business logic
context.setOutput("statusCode", 200);

```

For Python:

```

from context import getInput, setOutput
message = getInput('message')
//Your Business logic
setOutput('statusCode', '200')

```

For Shell:

```
# Input, Output properties are environment variables
echo ${message} # Prints the input message
//Your Business logic
export statusCode=200 # Sets output property statusCode
```

5. In the `code:` section, declare all the business logic for your custom integration.

For example, with the Node.js runtime environment:

```
code: |
  var https = require('https');

  var context = require("./context.js")

  //Get the entered message from task config page and assign it to message var
  var message = context.getInput("message");
  var slackPayload = JSON.stringify(
    {
      text: message
    });

  const options = {
    hostname: 'hooks.slack.com',
    port: 443,
    path: '/YOUR_SLACK_WEBHOOK_PATH',
    method: 'POST',
    headers: {
      'Content-Type': 'application/json',
      'Content-Length': Buffer.byteLength(slackPayload)
    }
  };

  // Makes a https request and sets the output with statusCode which
  // will be displayed in task result page after execution
```

```

const req = https.request(options, (res) => {
    context.setOutput("statusCode", res.statusCode);
});

req.on('error', (e) => {
    console.error(e);
});

req.write(slackPayload);

req.end();

```

6. Before you version and release your custom integration script, download the context file for Python or Node.js and test the business logic that you included in your script.
 - a) Place the pointer at the top of the canvas, then click the context file button. For example, if your script is in Python click **CONTEXT.PY**.
 - b) Modify the file and save it.
 - c) On your development system, run and test your custom script with the help of the context file.
7. Apply a version to your custom integration script.
 - a) Click **Version**.
 - b) Enter the version information.
 - c) Click **Release Version** so that you can select the script in your custom task.
 - d) To create the version, click **Create**.

Creating Version

Version *	1.0
Description	New
Change Log	New for 1.0
Release Version ⓘ	<input checked="" type="checkbox"/>

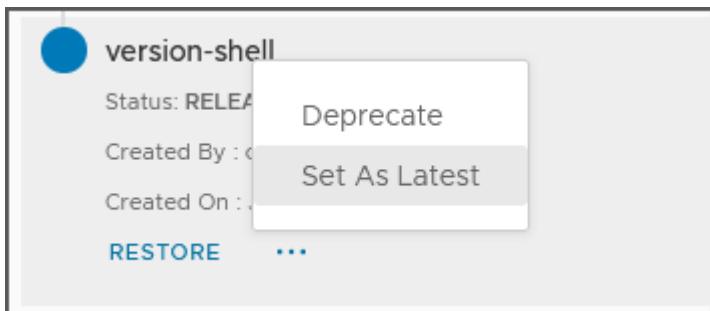

CANCEL **CREATE**

8. You can set any released version of a custom integration script as the latest so that the version appears with the **latest -->** label on the pipeline canvas.

- Place the pointer at the top of the canvas, then click **Version History**.
- To see available actions, click the horizontal ellipsis for the version that you want and select **Set As Latest**.

NOTE

Only released versions appear with the **Set As Latest** action.

- To confirm the version selection, click **Set As Latest**.
 - To exit **Version History** and return to the script editor canvas, click the back arrow.
- To save the script, click **Save**.
To export your script as a YAML file to use in another Automation Pipelines instance, click **Actions** > **Export** on the custom integration card and select the versions to export.
 - In your pipeline, configure the workspace.
This example uses a Docker workspace.

- Click the **Workspace** tab.
- Select the Docker host and the builder image URL.

Workspace	
Host	Docker-saas
Builder image URL	node:latest
Image registry	--Select Container Registry Endpoint--
Working directory	
Cache	
Git clone	If this pipeline links to Git through a webhook, the pipeline triggers on Git events. For CI tasks, the linked Git repository, which receives details from the Git webhook, automatically clones the workspace.

- Add a custom task to your pipeline, and configure it.

- Click the **Model** tab.
- Add a task, select the type as **Custom**, and enter a relevant name.
- Select your custom integration script and version. If a version of the script has been set as latest, that version appears with **latest -->** before the version name.
- To display a custom message in Slack, enter the message text.

Any text you enter overrides the `defaultValue` in your custom integration script.

- Save and enable your pipeline.
 - Click **Save**.
 - On the pipeline card, click **Actions > Enable**.
- Run your pipeline.
 - Click **Run**.
 - Look at the pipeline execution.
 - Confirm that the output includes the expected status code, response code, status, and declared output.
You defined **statusCode** as an output property. For example, a **statusCode** of 200 might indicate a successful Slack post, and a **responseCode** of 0 might indicate that the script succeeded without error.
 - To confirm the output in the execution logs, click **Executions**, click the link to your pipeline, click the task, and look at the logged data. For example:

The screenshot shows the VMware Aria Automation Pipeline interface. At the top, there's a navigation bar with a back arrow labeled 'BACK', the pipeline name 'custom-int-demo #5', a 'COMPLETED' status indicator, a '0' badge, and an 'ACTIONS' dropdown.

Stage0 (Completed):

- Task0 (Completed)
- Task1 (Completed)

Task details:

Task name	Task1	VIEW OUTPUT JSON
Type	Custom

Continue on failure	<input type="checkbox"/>	
Execute task	<input checked="" type="radio"/> Always	<input type="radio"/> On condition

Output:

statusCode	200
Response code	0
Logs	<pre> 1 + node -r ./context.js app.js 2 3 </pre>

[View Full Log](#)

- If an error occurs, troubleshoot the problem and run the pipeline again.

For example, if a file or module in the base image is missing, you must create another base image that includes the missing file. Then, provide the Docker file, and push the image through the pipeline.

Congratulations! You created a custom integration script that connects Automation Pipelines to your Slack instance, and posts a message to a Slack channel.

Continue to create custom integrations to support using custom tasks in your pipelines, so that you can extend the capability of Automation Pipelines in the automation of your software release lifecycle.

How do I use the resource properties of a cloud template task in my next task

When you use a cloud template task in Automation Pipelines, a common question is how to use the output of that task in a subsequent task in your pipeline. To use the output of a cloud template task, such as a cloud machine, you must know how to find the resource properties in the deployment details of the cloud template task, and the IP address of the cloud machine.

- Verify that you have a working VMware Cloud Template that is versioned.
- Verify that the deployment of the VMware Cloud Template succeeded in Automation Assembler.
- Verify that you have a pipeline that includes a cloud template task that uses that VMware Cloud Template.
- Verify that your pipeline ran and succeeded.

For example, the deployment details of a VMware Cloud Template include the cloud machine resource and its IP address. In your pipeline, you can use the cloud machine and IP address as a variable to bind a cloud template task to a REST task.

The method that you use to find the IP address for the cloud machine is not typical, because the deployment of the VMware Cloud Template must finish before the deployment details are available. Then, you can use the resources from the VMware Cloud Template deployment to bind your pipeline tasks.

- The resource properties that appear in a cloud template task in your pipeline are defined in the VMware Cloud Template in Automation Assembler.
- You might not know when a deployment of that cloud template finished.
- A cloud template task in Automation Pipelines can only display the output properties of the VMware Cloud Template after the deployment finished.

This example can be especially useful if you are deploying an application and invoking various APIs. For example, if you use a cloud template task that calls a VMware Cloud Template, which deploys a Wordpress application with a REST API, you can locate the IP address of the deployed machine in the deployment details, and use the API to test it.

The cloud template task supports you to use variable binding by displaying the type ahead auto fill details. It is up to you how you bind the variable.

This example shows you how to:

- Find the deployment details and resource properties for your cloud template task in a pipeline that ran and succeeded.
 - Find the cloud machine IP address in the resources section of the deployment details.
 - Add a REST task subsequent to the cloud template task in your pipeline.
 - Bind the cloud template task to the REST task by using the cloud machine IP address in the URL of the REST task.
 - Run your pipeline and watch the binding work from the cloud template task to the REST task.
1. In your pipeline, locate the IP address of the cloud machine in the resources section of your cloud template task deployment details.
 - a) Click **Actions > View executions**.
 - b) In a pipeline run that succeeded, click the link to the pipeline execution.

The screenshot shows the 'Executions' page with a single item. The pipeline name is 'pipelinebp-IX#1', status is 'COMPLETED', and it has one stage also marked as 'COMPLETED'. The execution was completed on Nov 4, 2020, at 2:36:04 PM. There are no tags or comments present.

- c) Under the pipeline name, click the link to the **Task**.

The screenshot shows the details for the completed task 'Task0' under Stage0. The task status is 'COMPLETED'. Below the task details, there is a table with the following information:

Project	bhawesh
Execution	pipelinebp-IX #1
Status	COMPLETED
Message	Execution Completed.

- d) In the Output area, locate the Deployment details.

- e) In the resources section of the deployment details, locate the cloud machine name.
You will include the syntax for the cloud machine name in the URL of your REST task.
- f) To find the binding expression for the output property of the cloud template task, click **VIEW OUTPUT JSON**, search for the address property, and locate the cloud machine IP address.
The binding expression appears below the property and search icon in the JSON output.

Stage0.Task0.output

```

16
17     "resources": {
18         "Cloud_Machine_1[0]": {
19             "id": "/resources/compute/f5a846f3-c97c-4145-9e28-951c36bd721c",
20             "name": "Cloud_Machine_1[0]",
21             "powerState": "ON",
22             "address": "10.108.79.51",
23             "resourceLink": "/resources/compute/f5a846f3-c97c-4145-9e28-951c36bd721c",
24             "componentTypeId": "Cloud.vSphere.Machine",
25             "endpointType": "vsphere",
26             "resourceName": "Cloud_Machine_1-mcm187515-152919380820",
27             "resourceId": "f5a846f3-c97c-4145-9e28-951c36bd721c",
28             "resourceDesLink": "/resources/compute-descriptions/fcb270b0-34bd-4b27-bc4b-7bfcc78bed23",
29             "zone": "Automation / [REDACTED]",
30             "countIndex": "0",
31             "image": "ubuntu",
32             "count": "1",
33             "flavor": "small"
}
Path finder address 

```

`${Stage0.Task0.output.deploymentDetails.resources['Cloud_Machine_1[0]'].address}`

`${Stage0.Task0.output.deploymentDetails.resources['Cloud_Machine_1[0]'].networks[0].address}`

The address resource property displays the cloud machine IP address. For example:

```
"resources": {
    "Cloud_Machine_1[0]": {
        "name": "Cloud_Machine_1[0]",
        "powerState": "ON",
        "address": "10.108.79.51",
        "resourceName": "Cloud_Machine_1-mcm187515-152919380820"
    }
}
```

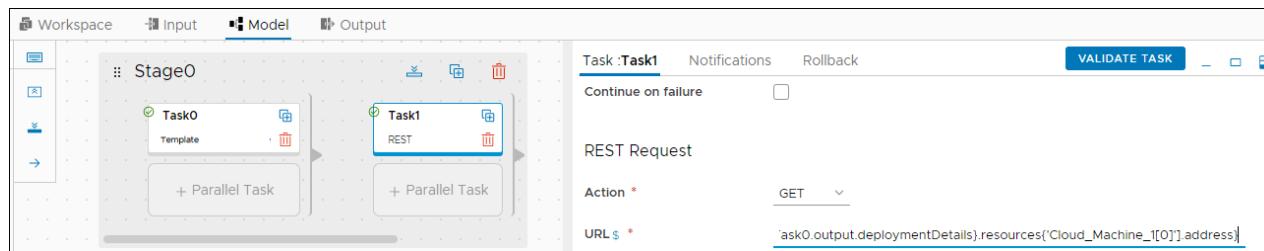

2. Return to your pipeline model, and enter the URL in your REST task.

- Click **Actions > View Pipeline**.
- Click the REST task.
- In the REST Request URL area, enter \$, select the **Stage, Task, output, deploymentDetails**, and enter resources.

The ability to type ahead with auto fill is available up to the point that you must enter resources.

- Enter the rest of the cloud machine resource from the deployment details as:

```
{'Cloud_Machine_1[0]'].address}
```

For the cloud machine entry, you must use the square bracket notation as shown.

The complete URL format is: \$

```
{Stage0.Task0.output.deploymentDetails.resources['Cloud_Machine_1[0]'].address}
```

3. Run your pipeline and watch the REST task use the cloud machine and IP address from the output of your cloud template task as the URL to test.

Congratulations! You found the cloud machine name and IP address in the deployment details and JSON output of a cloud template task, and used them to bind your cloud template task output to your REST task URL input in your pipeline.

Continue to explore using binding variables from resources in the cloud template task with other tasks in your pipeline.

How do I use a REST API to integrate Automation Pipelines with other applications

How do I use a REST API to integrate with other applications

Automation Pipelines provides a REST plug-in, which allows you to integrate Automation Pipelines with other applications that use a REST API so that you can continuously develop and deliver software applications that must interact with each other. The REST plug-in invokes an API, which sends and receives information between Automation Pipelines and another application.

With the REST plug-in, you can:

- Integrate external REST API-based systems into a Automation Pipelines pipeline.
- Integrate a Automation Pipelines pipeline as part of the flow of external systems.

The REST plug-in works with any REST API, and supports GET, POST, PUT, PATCH, and DELETE methods to send or receive information between Automation Pipelines and other applications.

Table 80: Preparing a pipeline to communicate over the REST API

What you do	What happens as a result
Add a REST task to your pipeline.	The REST task communicates information between applications, and can provide status information for a successive task in the pipeline stage.
In the REST task, select the REST action and include the URL.	The pipeline task calls the URL when the pipeline runs. For POST, PUT, and PATCH actions, you must include a payload. In the payload, you can bind your pipeline and task properties when the pipeline runs.
Consider this example.	Example use of the REST plug-in: You can add a REST task to get information that is needed for a subsequent pipeline task.

Similar to using the REST plug-in to invoke an API, you can include a Poll task in your pipeline to invoke a REST API and poll it until it completes and the pipeline task meets the exit criteria. See [What types of tasks are available in](#) . You can also use REST APIs to import and export a pipeline, and use the example scripts to run a pipeline. In this procedure, the REST task gets a build tag from one service and a subsequent CI task uses the build tag to get a CICD build number.

1. To create a pipeline, click **Pipelines** > **New Pipeline** > **Blank Canvas**.
2. In your pipeline stage, click **+ Sequential Task**.
3. In the task pane, add the REST task:
 - a) Enter a name for the task.

- b) In the Type drop-down menu, select **REST**.
- c) In the REST Request area, select **GET**.

To have the REST task request data from another application, you select the GET method. To send data to another application, you select the POST method.

- d) Enter the URL that identifies the REST API endpoint used to obtain the build tag. For example:

`https://devops.mycompany.com:8001/job/service-build/api/json`

NOTE

Automation Pipelines does not support %2F as URL encoding for / as in:

`https://gitlab.com/api/v4/projects/1234567/repository/files/FOLDERNAME%2Ftest.yaml`

When specifying the REST API endpoint, use a basic URL format such as:

`https://gitlab.com/api/v4/projects/1234567/repository/files/FOLDERNAME/test.yaml`

For a REST task to import data from another application, you can include the payload variable. For example, for an import action, you can enter `${Stage0.export.responseBody}`. If the response data size exceeds 5 MB, the REST task might fail.

- e) To provide authorization for the task, click **Add Headers** and enter header keys and values, such as:

Key	Value
Accept	application/json
Content-Type	application/json

The screenshot shows the VMware Aria Automation Pipeline Editor interface. On the left, there's a workspace with a Stage0 stage containing a Task0 REST task. The Task0 task is selected, and its configuration panel is displayed on the right. The configuration includes:

- Task : Task0**
- Notifications** and **Rollback** sections
- Task name**: Task0
- Type**: REST
- Continue on failure**: Unchecked
- Execute task**: Always (radio button selected)
- REST Request** section:
 - Action**: GET
 - URL**: Enter URL
 - Agent endpoint**: -Select Agent endpoint-
 - Headers**:

Accept	application/json
Content-Type	application/json
- Output Parameters**: status

At the bottom of the editor, there are buttons for **SAVE**, **RUN**, and **CLOSE**, and a message indicating the pipeline was last saved an hour ago.

4. Add subsequent task that uses information from the REST task response.

5. To save your pipeline, click **Save**.
6. On the pipeline tab, click **Enable pipeline**.

The screenshot shows the VMware Aria Automation pipeline editor interface. At the top, there's a toolbar with tabs for 'Workspace', 'Input', 'Model' (which is selected), and 'Output'. Below the toolbar is a navigation bar with icons for back, forward, search, and refresh. The main area is divided into two sections: a workspace on the left and a pipeline configuration on the right.

Workspace: Shows 'Stage 0' with a single 'Task0' node labeled 'REST'. There are also '+ Parallel Task' and '+ Sequential Task' options available for dragging and dropping.

Pipeline Configuration:

- Project:** Project-1
- Pipeline name:** Test
- Enable pipeline:** A toggle switch is turned on.
- Concurrency:** Set to 10.
- Description:** An empty text field.
- Icon:** Buttons for 'CHANGE' and 'REMOVE'.
- Tags:** An input field with placeholder 'Enter tags for pipeline'.

7. Click **Save**, then click **Close**.
8. Click **Run**.
9. To watch the pipeline run, click **Executions**.

The screenshot shows the 'Executions' page. At the top, it says 'Executions' with '10 items' and a '+ NEW EXECUTION' button. There's also a search bar and filter icons.

Actions	Stages	By	Created	Status
ACTIONS	RUNNING	By system-user	on 11/26/2018 3:11 PM	RUNNING
				Input : n/a Output : n/a

The table lists one execution entry: 'Test#1' with status 'RUNNING', created by 'system-user' on '11/26/2018 3:11 PM', and both input and output status as 'n/a'.

10. To verify that the REST task returns the information you expect, examine the pipeline execution and the task results.
 - a) After the pipeline completes, to confirm that the other application returned the data you requested, click the link to the pipeline execution.
 - b) Click the REST task in the pipeline.
 - c) In the pipeline execution, click the task, observe the task details, and verify that the REST task returned the expected results.

The task details display the response code, body, header keys, and values.

Congratulations! You configured a REST task that invoked a REST API and sent information between Automation Pipelines and another application by using the REST plug-in.

Continue to use REST tasks in your pipelines to run commands and integrate Automation Pipelines with other applications so that you can develop and deliver your software applications. Consider using poll tasks that poll the API until it completes, and the pipeline task meets the exit criteria.

How do I leverage pipeline as code in Automation Pipelines

How do I leverage pipeline as code

As a DevOps administrator or developer, you might want to create a pipeline in Automation Pipelines by using YAML code, instead of using the user interface. When you create pipelines as code, you can use any editor and insert comments in the pipeline code.

- Verify that you have a code editor.
- If you plan to store your pipeline code in a source control repository, verify that you can access a working instance.

In your pipeline code, you can refer to external configurations such as environment variables and security credentials. When you update variables that you use in your pipeline code, you can update them without having to update the pipeline code.

You can use the pipeline YAML code as a template to clone and create other pipelines, and share the templates with others.

You can store your pipeline code templates in a source control repository, which versions them and tracks updates. By using a source control system, you can easily back up your pipeline code, and restore it if needed.

1. In your code editor, create a file.
2. Copy and paste the sample pipeline code, and update it to reflect your specific pipeline needs.
3. To include an endpoint to your pipeline code, copy and paste the example endpoint code, and update it to reflect your endpoint.

When using a Kubernetes API endpoint in the pipeline workspace, Automation Pipelines creates the necessary Kubernetes resources such as ConfigMap, Secret, and Pod to run the continuous integration (CI) task or custom task. Automation Pipelines communicates with the container by using the NodePort.

The Automation Pipelines pipeline workspace supports Docker and Kubernetes for continuous integration tasks and custom tasks.

For more information about configuring the workspace, see [Configuring the Pipeline Workspace](#).

4. Save the code.
5. To store and version your pipeline code, check the code into your source control repository.
6. When you create a continuous integration and delivery pipeline, you must import the Kubernetes YAML file.

To import the Kubernetes YAML file, select it in the Continuous Delivery area of the smart pipeline template, and click **Process**. Or, use the API.

By using the code examples, you created the YAML code that represents your pipeline and endpoints.

Example YAML code for a pipeline and endpoints

This example YAML code includes sections that represent the workspace for the Automation Pipelines native build, stages, tasks, notifications, and more in a pipeline.

For examples of code for supported plug-ins, see [Connecting to endpoints](#)

Run your pipeline, and make any adjustments as needed. See [How do I run a pipeline and see results](#).

How do I use Search in Automation Pipelines

What is Search

You use the search feature to find where specific items or other components are located. For example, you might want to search for activated or deactivated pipelines. Because if a pipeline is deactivated, it cannot run.

What can I search

You can search in:

- Projects
- Endpoints
- Pipelines
- Executions
- Pipeline Dashboards, Custom Dashboards
- Gerrit Triggers and Servers
- Git Webhooks
- Docker Webhooks

You can perform a column-based filter search in:

- User Operations
- Variables
- Trigger Activity for Gerrit, Git, and Docker

You can perform a grid-based filter search on the **Activity** page for each trigger.

How does search work

The criteria for a search vary depending on the page you are on. Each page has different search criteria.

Where you search	Criteria to use for search
Pipeline Dashboards	Name, Description, Tags, Link, Project
Custom Dashboards	Name, Description, Link (UUID of an item on the dashboard), Updated By, Created By, Project
Executions	Status, Show, Name, Triggered By, Comments, Reason, Tags, Link (UUID of the execution), Pipeline Link, Project, Executed by, and Status message by using this format: <key>:<value>
Pipelines	Name, Description, Tags, Link, Project, Updated by, Created by
Projects	Name, Description
Endpoints	Name, Description, Type, Project, Updated by
Gerrit triggers	Name, Gerrit project, Updated By, Created By, Branch, Listener, Project
Gerrit listeners	Name, Status, Project
Git Webhooks	Name, Server Type, Repo, Branch, Pipeline, Description, Project

Where:

- Link is the UUID of a pipeline, execution, or widget on a dashboard.
- Status message notation examples:
 - Notation: statusMessage:<value>
 - Example: statusMessage:Execution failed
- Status or states depend on the search page.
 - For executions, the possible values include: completed, failed, rolling back, or canceling.
 - For pipelines, the possible state values include: enabled, disabled, or released.
 - For triggers, possible status values include: enabled or disabled.
- Executed by, Created by, or Updated by refers to the user that is logged in.

Search appears at the upper right of every valid page. When you start typing into the search blank, Automation Pipelines knows the context of the page and suggests options for the search.

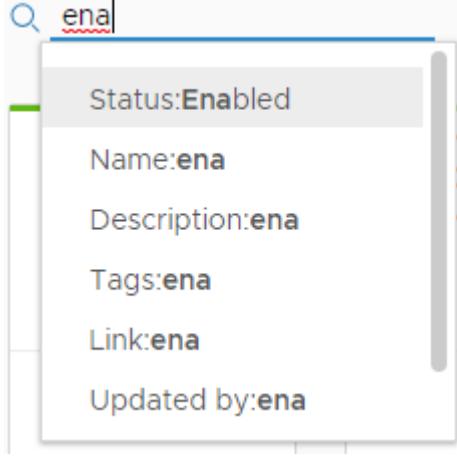

Methods you can use to search	How to enter it
Type a portion of the search parameter. For example, to add a status filter that lists all the enabled pipelines, type ena.	 <p>The screenshot shows a search interface with a search bar containing 'ena'. Below the search bar is a dropdown menu listing several search terms starting with 'ena': 'Status:Enabled', 'Name:ena', 'Description:ena', 'Tags:ena', 'Link:ena', and 'Updated by:ena'. Each suggestion is displayed in a separate card-like box.</p>

Table continued on next page

Continued from previous page

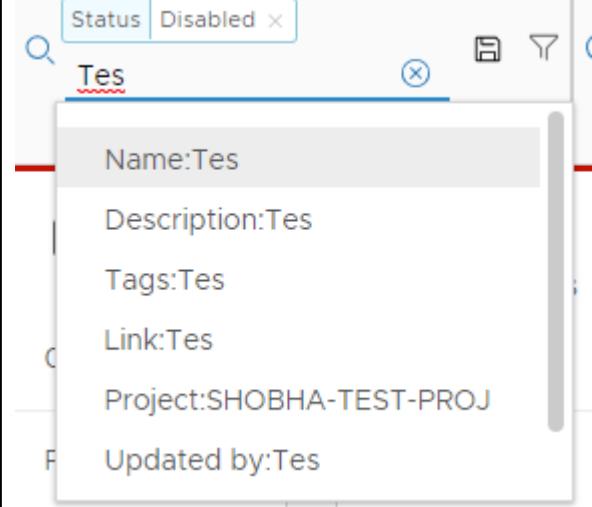

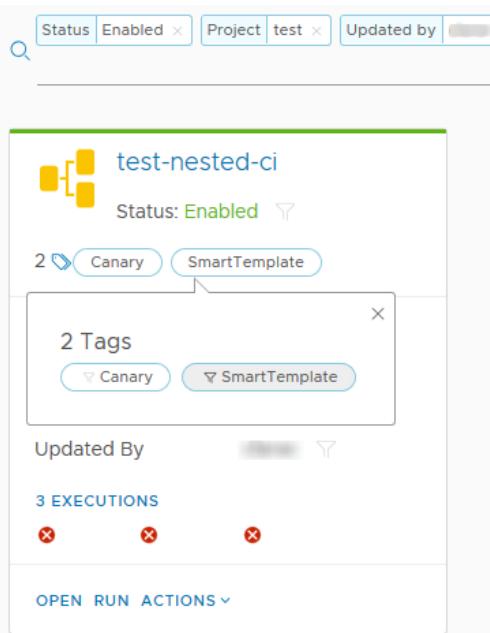

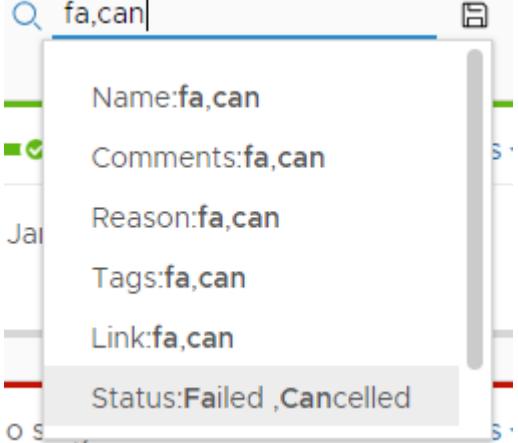

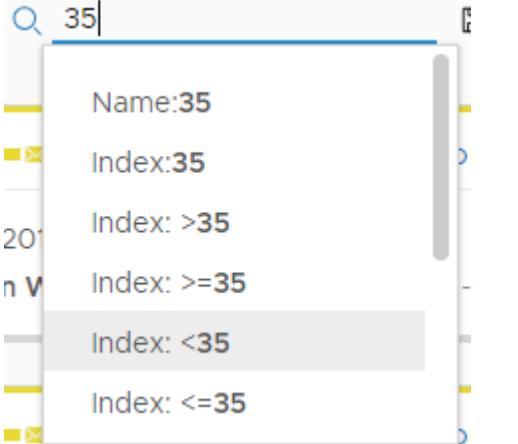

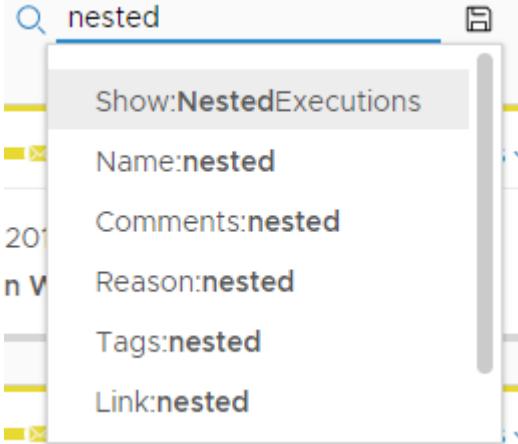

Methods you can use to search	How to enter it
<p>To reduce the number of items found, add a filter. For example, to add a name filter type Tes. The filter works as an AND with the existing Status:disabled filter and only displays the deactivated pipelines that have Tes in the name.</p> <p>When you add another filter, the remaining options appear: Name, Description, Tags, Link, Project, and Updated by.</p>	
<p>To reduce the number of items displayed, click the filter icon on properties of a pipeline or a pipeline execution.</p> <ul style="list-style-type: none"> For pipelines, Status, Tags, Project, and Updated by each have a filter icon. For executions, Tags, Executed by, and Status Message each have a filter icon. <p>For example on the pipeline card, click the icon to add the filter for the SmartTemplate tag to the existing filters for: Status:Enabled, Project:test, Updated by:user and Tags:Canary.</p>	

Table continued on next page

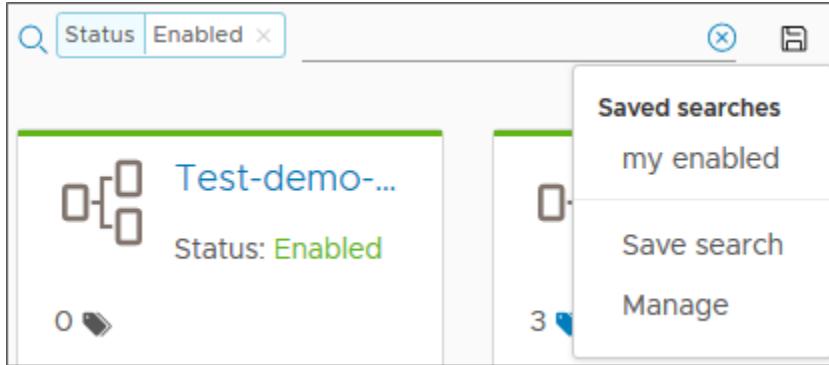

Continued from previous page

Methods you can use to search	How to enter it
<p>Use a comma separator to include all items in two execution states.</p> <p>For example, type <code>fa,can</code> to create a status filter that works as an OR to list all failed or canceled executions.</p>	 <p>The screenshot shows a search bar with the text "fa,can". Below the search bar is a dropdown menu with several options: "Name:fa,can", "Comments:fa,can", "Reason:fa,can", "Tags:fa,can", "Link:fa,can", and "Status:Failed ,Cancelled". The "Status" option is highlighted with a gray background.</p>
<p>Type a number to include all items within an index range.</p> <p>For example, type <code>35</code> and select <code><</code> to list all executions with an index number less than 35.</p>	 <p>The screenshot shows a search bar with the text "35". Below the search bar is a dropdown menu with several options: "Name:35", "Index:35", "Index: >35", "Index: >=35", "Index: <35", and "Index: <=35". The "Index: <35" option is highlighted with a gray background.</p>
<p>Pipelines that are modeled as tasks become nested executions and are not listed with all executions by default.</p> <p>To show nested executions, type <code>nested</code> and select the Show filter.</p>	 <p>The screenshot shows a search bar with the text "nested". Below the search bar is a dropdown menu with several options: "Show:NestedExecutions", "Name:nested", "Comments:nested", "Reason:nested", "Tags:nested", and "Link:nested". The "Show" option is highlighted with a gray background.</p>

How do I save a favorite search

You can save favorite searches to use on each page by clicking the disk icon next to the search area.

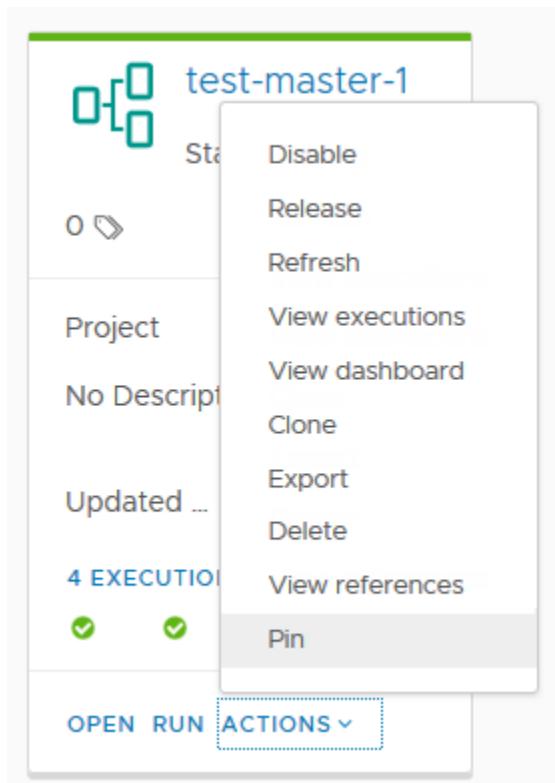

- You save a search by typing the parameters for search and clicking the icon to give the search a name such as my activated.
- After saving a search, you click the icon to access the search. You can also select **Manage** to rename, delete, or move the search in the list of saved searches.

Searches are tied to your user name and only appear on the pages for which the search applies. For example, if you saved a search named `my activated` for **Status:enabled** on the pipelines page, the `my activated` search is not available on the Gerrit triggers page, even though **Status:enabled** is a valid search for a trigger.

Can I save a favorite pipeline

If you have a favorite pipeline or dashboard, you can pin it so that it always appears at the top of your pipelines or dashboards page. On the pipeline card, click **Actions** > **Pin**.

Connecting Automation Pipelines to endpoints

Connecting to endpoints

Automation Pipelines integrates with development tools through a plug-in. Supported plug-in types include Jenkins, Bamboo, VMware Aria Operations, Bugzilla, Team Foundation Server, Git, and more.

You can also develop your own plug-in that integrates Automation Pipelines with other development applications.

To integrate Automation Pipelines with Jira, you do not need an external plug-in, because Automation Pipelines includes the Jira ticket creation capability as a notification type. To create Jira tickets on pipeline status, you must add a Jira endpoint.

What are Endpoints in Automation Pipelines

What are Endpoints

An endpoint is an instance of a DevOps application that connects to Automation Pipelines and provides data for your pipelines to run, such as a data source, repository, or notification system.

Your role in Automation Pipelines determines how you use endpoints.

- Administrators and developers can create, update, delete, and view endpoints.
- Administrators can mark an endpoint as restricted, and run pipelines that use restricted endpoints.
- Users who have the viewer role can see endpoints, but cannot create, update, or delete them.

For more information, see [How do I manage user access and approvals in](#).

To connect Automation Pipelines to an endpoint, follow these steps.

1. Add a task in your pipeline
2. Configure the task so that it communicates with the endpoint.
3. Verify that Automation Pipelines can connect to the endpoint by clicking **Validate**.
4. Then, when you run the pipeline, the task connects to the endpoint so that it can run the task.

For information about the task types that use these endpoints, see [What types of tasks are available in](#).

Table 81: Endpoints that Automation Pipelines supports

Endpoint	What it provides	Versions supported	Requirements
Bamboo	Creates build plans.	6.9.*	
Docker	Native builds can use Docker hosts for deployment.		When a pipeline includes an image from Docker Hub, you must ensure that the image has <code>cURL</code> or <code>wget</code> embedded before you run the pipeline. When the pipeline runs, Automation Pipelines downloads a binary file that uses <code>cURL</code> or <code>wget</code> to run commands.
Docker Registry	Registers container images so that a Docker build host can pull images.	2.7.1	
Gerrit	Connects to a Gerrit server for reviews and trigger	2.14.*	
Git	Triggers pipelines when developers update code and check it in to the repository.	Git Hub Enterprise 2.1.8 Git Lab Enterprise 11.9.12-ee	

Table continued on next page

Continued from previous page

Endpoint	What it provides	Versions supported	Requirements
Jenkins	Builds code artifacts.	1.6.* and 2.*	
Jira	Creates a Jira ticket when a pipeline task fails.	8.3.*	
Kubernetes	Automates the steps that deploy, scale, and manage containerized applications.	All versions supported for Automation Assembler 8.4 and later 1.18 for Automation Assembler 8.3 and prior	When using a Kubernetes API endpoint in the pipeline workspace, Automation Pipelines creates the necessary Kubernetes resources such as ConfigMap, Secret, and Pod to run the continuous integration (CI) task or custom task. Automation Pipelines communicates with the container by using the NodePort. For more information about configuring the workspace, see Configuring the Pipeline Workspace .
PowerShell	Create tasks that run PowerShell scripts on Windows or Linux machines.	4 and 5	
SSH	Create tasks that run SSH scripts on Windows or Linux machines.	7.0	
TFS, Team Foundation Server	Manages source code, automated builds, testing, and related activities.	2015 and 2017	
VMware Aria Automation Orchestrator	Arranges and automates the workflows in your build process.	7.* and 8.*	

Example YAML code for a GitHub endpoint

This example YAML code defines a GitHub endpoint that you can refer to in a Git task.

```
---
name: github-k8s
tags: [
]
kind: ENDPOINT
properties:
  serverType: GitHub
  repoURL: https://github.com/autouser/testrepok8s
  branch: master
  userName: autouser
  password: encryptedpassword
```

```

privateToken: ''
description: ''
type: scm:git
isLocked: false
---

```

How do I integrate Automation Pipelines with Jenkins

How do I integrate with Jenkins

Automation Pipelines provides a Jenkins plug-in, which triggers Jenkins jobs that build and test your source code. The Jenkins plug-in runs test cases, and can use custom scripts.

- Set up a Jenkins server that runs version 1.561 or later.
- Verify that you are a member of a project in Automation Pipelines. If you are not a member, ask a Automation Pipelines administrator to add you as a member of a project. See [How do I add a project in](#).
- Verify that a job exists on the Jenkins server so that your pipeline task can run it.

To run a Jenkins job in your pipeline, you use a Jenkins server, and add the Jenkins endpoint in Automation Pipelines. Then, you create a pipeline and add a Jenkins task to it.

When you use the Jenkins task and a Jenkins endpoint in Automation Pipelines, you can create a pipeline that supports multi-branch jobs in Jenkins. The multi-branch job includes individual jobs in each branch of a Git repository. When you create pipelines in Automation Pipelines that support multi-branch jobs:

- The Jenkins task can run Jenkins jobs that reside in multiple folders on the Jenkins server.
- You can override the folder path in the Jenkins task configuration so that it uses a different folder path, which overrides the default path defined in the Jenkins endpoint in Automation Pipelines.
- Multi-branch pipelines in Automation Pipelines detect Jenkins job files of type `.groovy` in a Git repository or a GitHub repository, and start creating jobs for each branch that it scans in the repository.
- You can override the default path defined in the Jenkins endpoint with a path provided in the Jenkins task configuration, and run a job and pipeline that is associated with any branch inside a main Jenkins job.

1. Add and validate a Jenkins endpoint.
 - a) Click **Endpoints > New Endpoint**.
 - b) Select a project, and for the type of endpoint select **Jenkins**. Then, enter a name and a description.
 - c) If this endpoint is a business-critical component in your infrastructure, enable **Mark as restricted**.
 - d) Enter the URL for the Jenkins server.
 - e) Enter the user name and password to log in to the Jenkins server. Then, enter the remaining information.

Table 82: Remaining information for the Jenkins endpoint

Endpoint entry	Description
Folder Path	<p>Path for the folder that groups your jobs. Jenkins can run all jobs in the folder. You can create sub folders. For example:</p> <ul style="list-style-type: none"> • <code>folder_1</code> can include <code>job_1</code> • <code>folder_1</code> can include <code>folder_2</code>, which can include <code>job_2</code> <p>When you create an endpoint for <code>folder_1</code>, the folder path is <code>job/folder_1</code>, and the endpoint only lists <code>job_1</code>.</p>

Table continued on next page

Continued from previous page

Endpoint entry	Description
	To obtain the list of jobs in the child folder named <code>folder_2</code> , you must create another endpoint that uses the folder path as <code>/job/folder_1/job/folder_2/</code> .
Folder Path for multi-branch Jenkins jobs	To support multi-branch Jenkins jobs, in the Jenkins task, you enter the full path that includes the Jenkins server URL and the complete job path. When you include a folder path in the Jenkins task, that path overrides the path that appears in the Jenkins endpoint. With the custom folder path in the Jenkins task, Automation Pipelines only displays jobs that are present in that folder. <ul style="list-style-type: none"> • For example: <code>https://server.yourcompany.com/job/project</code> • If the pipeline must also trigger the main Jenkins job, use: <code>https://server.yourcompany.com/job/project/job/main</code>
URL	Host URL of the Jenkins server. Enter the URL in the form of <code>protocol://host:port</code> . For example: <code>http://192.10.121.13:8080</code>
Polling Interval	Interval duration for Automation Pipelines to poll the Jenkins server for updates.
Request Retry Count	Number of times to retry the scheduled build request for the Jenkins server.
Retry Wait Time	Number of seconds to wait before retrying the build request for the Jenkins server.

- f) Click **Validate**, and verify that the endpoint connects to Automation Pipelines. If it does not connect, correct any errors, then click **Save**.

Edit Endpoint

Project	test1
Type	Jenkins
Name *	aa

2. To build your code, create a pipeline, and add a task that uses your Jenkins endpoint.
 - a) Click **Pipelines** > **New Pipeline** > **Blank Canvas**.
 - b) Click the default stage.
 - c) In the Task area, enter a name for the task.
 - d) Select the task type as **Jenkins**.
 - e) Select the Jenkins endpoint that you created.
 - f) From the drop-down menu, select a job from the Jenkins server that your pipeline will run.
 - g) Enter the parameters for the job.
 - h) Enter the authentication token for the Jenkins job.

4. Look at the execution details and status on the pipeline dashboard.

You can identify any failures, and why it failed. You can also see trends about the pipeline execution durations, completions, and failures.

The screenshot shows the 'Build and Deploy' section of the VMware Aria Automation interface. At the top, there are buttons for 'CLONE' and 'BACK'. To the right are filters for '1D', '7D', and '14D', and a refresh icon. Below this is a chart titled 'Recent Executions' showing the status of various executions (#29 to #20) across 'Stage0'. The chart uses color coding: green for completed, red for failed, blue for running, and yellow for waiting. Below the chart is a table titled 'Execution Details' with columns for Execution#, Status, Status Message, Duration, and Updated On. The table lists seven entries, with the first two failing and the others completing successfully. At the bottom of the table are navigation icons for search, sort, and filtering.

Execution#	Status	Status Message	Duration	Updated On
#29	FAILED	Execution failed on task 'Stage0.Deployment'. namespaces "prod1" already exists	1m 32s	08/19 10:49PM

Congratulations! You integrated Automation Pipelines with Jenkins by adding an endpoint, creating a pipeline, and configuring a Jenkins task that builds your code.

Example YAML for a Jenkins build task

For the type of Jenkins build task used in this example, the YAML resembles the following code, with notifications turned on:

```

test:

type: Jenkins

endpoints:
  jenkinsServer: jenkins

input:
  job: Add two numbers

parameters:
  Num1: '23'

```

```
Num2: '23'
```

Review the other sections to learn more. See [Connecting to endpoints](#).

How do I integrate Automation Pipelines with Git

How do I integrate with Git

Automation Pipelines provides a way to trigger a pipeline if a code change occurs in your GitHub, GitLab, or Bitbucket repository. The Git trigger uses a Git endpoint on the branch of the repository that you want to monitor. Automation Pipelines connects to the Git endpoint through a webhook.

- Verify that you can access the GitHub, GitLab, or Bitbucket repository to which you plan to connect.
- Verify that you are a member of a project in Automation Pipelines. If you are not, ask a Automation Pipelines administrator to add you as a member of a project. See [How do I add a project in](#).

To define a Git endpoint in Automation Pipelines, you select a project and enter the branch of the Git repository where the endpoint is located. The project groups the pipeline with the endpoint and other related objects. When you choose the project in your webhook definition, you select the endpoint and pipeline to trigger.

NOTE

If you define a webhook with your endpoint and you later edit the endpoint, you cannot change the endpoint details in the webhook. To change the endpoint details, you must delete and redefine the webhook with the endpoint. See [How do I use the Git trigger in to run a pipeline](#).

You can create multiple webhooks for different branches by using the same Git endpoint and providing different values for the branch name in the webhook configuration page. To create another webhook for another branch in the same Git repository, you don't need to clone the Git endpoint multiple times for multiple branches. Instead, you provide the branch name in the webhook, which allows you to reuse the Git endpoint. If the branch in the Git webhook is the same as the branch in the endpoint, you don't need to provide branch name in the Git webhook page.

1. Define a Git endpoint.

- a) Click **Endpoints > New Endpoint**.
- b) Select a project, and for the endpoint type select **Git**. Then, enter a name and description.
- c) If this endpoint is a business-critical component in your infrastructure, enable **Mark as restricted**.

When you use a restricted endpoint in a pipeline, an administrator can run the pipeline and must approve the pipeline execution. If an endpoint or variable is marked as restricted, and a non-administrative user triggers the pipeline, the pipeline pauses at that task, and waits for an administrator to resume it.

A Project administrator can start a pipeline that includes restricted endpoints or variables if these resources are in the project where the user is a Project administrator.

When a user who is not an administrator attempts to run a pipeline that includes a restricted resource, the pipeline stops at the task that uses the restricted resource. Then, an administrator must resume the pipeline.

For more information about restricted resources, and custom roles that include the permission called **Manage Restricted Pipelines**, see:

- [How do I manage user access and approvals in](#)
 - [Setting up to model my release process](#)
- d) Select one of the supported Git server types.
 - e) Enter the URL for the repository with the API gateway for the server in the path. For example:

For GitHub, enter: <https://api.github.com/vmware-example/repo-example>

For BitBucket, enter: `https://api.bitbucket.org/{user}/{repo_name}` or `http(s)://bitbucket-enterprise-server/rest/api/1.0/users/{username}/repos/{repo_name}`

- f) Enter the branch in the repository where the endpoint is located.
- g) Select the Authentication type and enter the user name for GitHub, GitLab, or BitBucket. Then enter the private token that goes with the user name.
 - Password. To create a webhook later, you must enter the private token for the password. Webhooks for Git do not support endpoints created using basic authentication.
Use secret variables to hide and encrypt sensitive information. Use restricted variable for strings, passwords, and URLs that must be hidden and encrypted, and to restrict use in executions. For example, use a secret variable for a password or URL. You can use secret and restricted variables in any type of task in your pipeline.
 - Private token. This token is Git-specific and provides access to a specific action. See https://docs.gitlab.com/ee/user/profile/personal_access_tokens.html. You can also create a variable for the private token.

2. Click **Validate**, and verify that the endpoint connects to Automation Pipelines.

If it does not connect, correct any errors, then click **Create**.

CREATE **VALIDATE** **CANCEL**

To learn more, review the other sections. See [How do I use the Git trigger in to run a pipeline](#).

How do I integrate Automation Pipelines with Gerrit

How do I integrate with Gerrit

Automation Pipelines lets you trigger a pipeline when a code review occurs in your Gerrit project. The trigger for Gerrit definition includes the Gerrit project and the pipelines that must run for different event types.

- Verify that you can access the Gerrit server to which you plan to connect.
- Verify that you are a member of a project in Automation Pipelines. If you are not a member, ask a Automation Pipelines administrator to add you as a member of a project. See [How do I add a project in](#).

The trigger for Gerrit uses a Gerrit listener on the Gerrit server that you will monitor. To define a Gerrit endpoint in Automation Pipelines, you select a project and enter the URL for the Gerrit server. Then you specify the endpoint when you create a Gerrit listener on that server.

If you are using a Gerrit server as a Automation Pipelines endpoint in a VMware Aria Automation instance that has FIPS enabled, you must verify that your Gerrit configuration file includes the correct message authentication keys. If the Gerrit server configuration file does not include the correct message authentication keys, the server cannot start up correctly, and displays this message: `PrivateKey/PassPhrase is incorrect`

The following procedure shows how to define a Gerrit endpoint that you can use in your Gerrit listener definition. In the event that you need to edit an endpoint, an optional step at the end of the procedure explains how and when to perform the update.

1. Define a Gerrit endpoint.

- a) Click **Configure > Endpoints** and click **New Endpoint**.
- b) Select a project, and for the type of endpoint, select **Gerrit**. Then, enter a name and a description.
- c) If this endpoint is a business-critical component in your infrastructure, enable **Mark as restricted**.
- d) Enter the URL for the Gerrit server.

To use the default port, you can provide a port number with the URL or leave the value blank.

e) Enter a username and password for the Gerrit server.

If the password must be encrypted, click **Create Variable** and select the type:

- Secret. The password resolves when a user who has any role runs the pipeline.
- Restricted. The password resolves when a user who has the Admin role runs the pipeline.

For the value, enter the password that must be secure, such as the password of a Jenkins server.

f) For the private key, enter the SSH key used to access the Gerrit server securely.

This key is the RSA private key that resides in the `.ssh` directory.

g) If a passphrase is associated with the private key, enter the passphrase.

To encrypt the passphrase, click **Create Variable** and select the type:

- Secret. The password resolves when a user who has any role runs the pipeline.
- Restricted. The password resolves when a user who has the Admin role runs the pipeline.

For the value, enter the passphrase that must be secure, such as the passphrase for an SSH server.

2. Click **Validate**, and verify that the Gerrit endpoint in Automation Pipelines connects to the Gerrit server.

If it does not connect, correct any errors, then click **Validate** again.

New endpoint

Project	test
Type	Gerrit
Name *	Gerrit-Demo-Endpoint
Description	
Mark restricted	<input checked="" type="checkbox"/> non-restricted
URL *	http://example-gerrit.mycompany.com:8080
Username *	pipelines_user
Password *	***** ✖ CREATE VARIABLE
Private Key *	<pre>-----BEGIN RSA PRIVATE KEY----- Proc-Type: 4,ENCRYPTED DEK-Info: AES-128-CBC,F00CE0B6526AF67DC77ADCD0962DBF92</pre> ▲ ▼
Pass Phrase ?	***** ✖ CREATE VARIABLE
CREATE VALIDATE CANCEL	

3. Click **Create**.
4. Verify that the VMware Aria Automation environment has FIPS enabled, or have your Jenkins job create the environment with FIPS enabled by using the Jenkins URL.
 - a) To run the command from the command line, connect to your VMware Aria Automation 8.x appliance over SSH, and log in as the root user. For example, connect to your fully qualified domain name URL, such as <https://cava-1-234-567.yourcompanyFQDN.com> on port 22, 5480, or 443.
 - b) To check for FIPS on VMware Aria Automation, run the command **vracli security fips**.
 - c) Verify that the command returns **FIPS mode: strict**.
5. If your Gerrit server is an endpoint in a VMware Aria Automation instance that has FIPS enabled, ensure that your Gerrit configuration file includes the correct message authentication (MAC) keys.
 - a) Open Gerrit and create an SSH key pair.
 - b) Locate the Gerrit server configuration file at '\$site_path'/etc/gerrit.config.
 - c) Verify that the Gerrit server configuration file includes one or more message authentication code (MAC) keys, except for hmac-MD5.

NOTE

In FIPS mode, hmac-MD5 is not a supported MAC algorithm. To ensure that the Gerrit server starts up correctly, the Gerrit server configuration file must exclude this algorithm. If the Gerrit server does not start up correctly, it displays this message: `PrivateKey/PassPhrase is incorrect`

Supported message authentication code (MAC) key names that begin with a plus sign (+) are enabled. The MAC key names that begin with a hyphen (-) are removed from the list of default MACs. By default, these supported MACs are available in Automation Pipelines for the Gerrit server:

- hmac-md5-96
- hmac-sha1
- hmac-sha1-96
- hmac-sha2-256
- hmac-sha2-512

6. Before updating a Gerrit endpoint to change a URL or private key for example, check to see if the endpoint is connected to a Gerrit listener.

- If the endpoint is not connected to a Gerrit listener, perform the following steps to update the endpoint:
 1. Click **Configure > Endpoints** and click **Open** on the endpoint that you want to update.
 2. Update the endpoint definition.
 3. click **Validate** to verify that the Gerrit endpoint in Automation Pipelines connects to the Gerrit server.
 4. Click **Save**.
- If the endpoint is connected to a Gerrit listener, perform the following steps to update the endpoint:
 1. Disconnect any attached Gerrit listeners. See [How do I use the Gerrit trigger in to run a pipeline](#).
 2. Perform the steps to configure the new endpoint.
 3. Validate and save the updated endpoint definition.
 4. Connect the Gerrit listeners again.

NOTE

If the Gerrit listeners do not disconnect, this might be because current Gerrit endpoint values have changed so that the listeners can no longer communicate with the Gerrit server. If this problem occurs, first make changes in the endpoint definition so that the listeners can communicate with the Gerrit server. Then disconnect the Gerrit listeners and reconnect them.

To learn more, review the other sections. See [How do I use the Gerrit trigger in to run a pipeline](#).

How do I integrate Automation Pipelines with VMware Aria Automation Orchestrator

How do I integrate with VMware Aria Automation Orchestrator

Automation Pipelines can integrate with VMware Aria Automation Orchestrator (Orchestrator) to extend its capability by running Orchestrator workflows. VMware Aria Automation Orchestrator includes many predefined workflows that can integrate with third-party tools. These workflows help to automate and manage your DevOps processes, automate bulk operations, and more.

- Verify that as an administrator you can access an on-premises instance of VMware Aria Automation Orchestrator. For help, see your own administrator and the [vRealize Orchestrator documentation](#).

- Verify that you are a member of a project in Automation Pipelines. If you are not, ask a Automation Pipelines administrator to add you as a member of a project. See [How do I add a project in](#).
- In Automation Pipelines, create a pipeline and add a stage.

For example, you can use a workflow in an `Orchestrator` task in your pipeline to enable a user, remove a user, move VMs, integrate with test frameworks to test your code as the pipeline runs, and much more. To browse examples of code for VMware Aria Automation Orchestrator workflows, go to <https://developer.broadcom.com/> and click **Code Sample**. With a VMware Aria Automation Orchestrator workflow, your pipeline can run an action as it builds, tests, and deploys your application. You can include predefined workflows in your pipeline, or you can create and use custom workflows. Each workflow includes inputs, tasks, and outputs.

To run an `Orchestrator` workflow in your pipeline, the workflow must appear in the list of available workflows in the `Orchestrator` task that you include in your pipeline.

Before the workflow can appear in the `Orchestrator` task in your pipeline, an administrator must perform the following steps in VMware Aria Automation Orchestrator:

1. Apply the `CODESTREAM` tag to the `Orchestrator` workflow.
2. Mark the `Orchestrator` workflow as global.
 - a) In VMware Aria Automation Orchestrator, find the workflow that you need to use in your pipeline, such as a workflow to enable a user.
If you need a workflow that does not exist, you can create it.
 - b) In the search bar, enter `Tag workflow` to find the workflow named `Tag workflow`.
 - c) On the card named `Tag workflow`, click **Run**, which displays the configuration area.
 - d) In the `Tagged workflow` text area, enter the name of the workflow to use in your Automation Pipelines pipeline, then select it from the list.
 - e) In the `Tag and Value` text areas, enter `CODESTREAM` in capital letters.
 - f) Click the check box named **Global tag**.
 - g) Click **Run**, which attaches the tag named `CODESTREAM` to the workflow that you need to select in your Automation Pipelines pipeline.
 - h) In the navigation pane, click **Workflows** and confirm that the tag named `CODESTREAM` appears on the workflow card that your pipeline will run.

After you log in to Automation Pipelines, and add an `Orchestrator` task to your pipeline, the tagged workflow appears in the workflow list.

2. In Automation Pipelines, create an endpoint for your VMware Aria Automation Orchestrator instance.
 - a) Click **Endpoints** > **New Endpoint**.
 - b) Select a project.
 - c) Enter a relevant name.
 - d) Enter the URL of the VMware Aria Automation Orchestrator endpoint.

Use this format: `https://orchestrator-appliance.yourdomain.local:8281`

Do not use this format: `https://orchestrator-appliance.yourdomain.local:8281/vco/api`

The URL for a VMware Aria Automation Orchestrator instance that is embedded in the VMware Aria Automation appliance, is the FQDN for the appliance without a port. For example: `https://automation-appliance.yourdomain.local/vco`

For external VMware Aria Automation Orchestrator appliances starting with VMware Aria Automation 8.x, the FQDN for the appliance is `https://orchestrator-appliance.yourdomain.local`

For external VMware Aria Automation Orchestrator appliances included with VMware Aria Automation 7.x, the FQDN for the appliance is `https://orchestrator-appliance.yourdomain.local:8281/vco`

If a problem occurs when you add the endpoint, you might need to import a YAML configuration with a SHA-256 certificate fingerprint with the colons removed. For example, `B0:01:A2:72...` becomes `B001A272...`. The sample YAML code resembles:

```
```

project: Demo
kind: ENDPOINT
name: external-orchestrator
description: ''
type: orchestrator
properties:
 url: https://yourVROhost.yourdomain.local
 username: yourusername
 password: yourpassword
 fingerprint: <your_fingerprint>
```

```

- e) Click **Accept Certificate** in case the URL that you entered needs a certificate.
- f) If the VMware Aria Automation Orchestrator endpoint is version 8.0 to 8.7, you can select **Basic Auth** or **Token** for the Authentication type. If the VMware Aria Automation Orchestrator endpoint is version is 8.8 or later, you must select **Token** for the Authentication type.

NOTE

If the VMware Aria Automation Orchestrator endpoint is version 8.8 or later, do not select **Basic Auth**. Basic Auth is not supported and endpoint creation will fail.

- If you select **Basic Auth**, enter the user name and password for the VMware Aria Automation Orchestrator server.
If you're using a non-local user for authentication, you must omit the domain part of the user name. For example, to authenticate with `svc_vro@yourdomain.local` you must enter `svc_vro` in the **Username** text area.
- If you select **Token** for the authentication type, generate the Private Token.
The VMware Cloud Services API token authenticates you for external API connections with Automation Pipelines. To obtain the API token:
 1. Click **Generate Token**.
 2. Enter the email address associated with your user name and password and click **Generate**.
The token that you generate is valid for six months. It is also known as a refresh token.
 - To keep the token as a variable for future use, click **Create Variable**, enter a name for the variable and click **Save**.

- To keep the token as a text value for future use, click **Copy** and paste the token into a text file to save locally.

You can choose to both create a variable and store the token in a text file for future use.

3. Click **Close**.

3. Prepare your pipeline to run the **Orchestrator task**.

- Add an **Orchestrator task** to your pipeline stage.
- Enter a relevant name.
- In the Workflow Properties area, select the VMware Aria Automation Orchestrator endpoint.
- Select the workflow that you tagged as **CODESTREAM** in VMware Aria Automation Orchestrator.

If you select a custom workflow that you created, you might need to enter the input parameter values.

e) For **Execute task**, click **On condition**.

The screenshot shows the configuration of an Orchestrator workflow task. The task name is set to "Orchestrator workflow". The type is set to "Orchestrator". There is a precondition section with a "SYNTAX GUIDE" button. Under "Workflow Properties", the endpoint is set to "vvro" and the workflow is set to "Test". An "Output" section is also present.

f) Enter the conditions that apply when the pipeline runs.

When to run pipeline...	Select conditions...
On Condition	Runs the pipeline task only if the defined condition is evaluated as true. If the condition is false, the task is skipped.

Table continued on next page

Continued from previous page

When to run pipeline...	Select conditions...
	<p>The Orchestrator task allows you to include a boolean expression, which uses the following operands and operators.</p> <ul style="list-style-type: none"> • Pipeline variables such as <code>\$ {pipeline.variableName}</code>. Only use curly brackets when entering variables. • Task output variables such as <code>\$ {Stage1.task1.machines[0].value.hostIp[0]}</code>. • Default pipeline binding variables such as <code>\$ {releasePipelineName}</code>. • Case insensitive Boolean values such as, <code>true</code>, <code>false</code>, <code>'true'</code>, <code>'false'</code>. • Integer or decimal values without quotation marks. • String values used with single or double quotation marks such as <code>"test"</code>, <code>'test'</code>. • String and Numeric types of values such as <code>== Equals</code> and <code>!= Not Equals</code>. • Relational operators such as <code>></code>, <code>>=</code>, <code><</code>, and <code><=</code>. • Boolean logic such as <code>&&</code> and <code> </code>. • Arithmetic operators such as <code>+</code>, <code>-</code>, <code>*</code>, and <code>/</code>. • Nested expressions using round brackets. • Strings that include the literal value <code>ABCD</code> are evaluated as false, and the task is skipped. • Unary operators are not supported. <p>An example condition might be <code>\$ {Stage1.task1.output} == "Passed" \$ {pipeline.variableName} == 39</code></p>
Always	If you select Always , the pipeline runs the task without conditions.

- g) Enter a message for the greeting.
 - h) Click **Validate Task**, and correct any errors that occur.
4. Save, enable, and run your pipeline.
 5. After the pipeline runs, examine the results.
 - a) Click **Executions**.
 - b) Click the pipeline.
 - c) Click the task.
 - d) Examine the results, input value, and properties.

You can identify the workflow execution ID, who responded to the task and when, and any comments they included.

Congratulations! You tagged a VMware Aria Automation Orchestrator workflow for use in Automation Pipelines, and added an Orchestrator task in your Automation Pipelines pipeline so that it runs a workflow that automates an action in your DevOps environment.

Orchestrator task output format

The output format for an Orchestrator task resembles this example.

```
[ {
    "name": "result",
    "type": "STRING",
    "description": "Result of workflow run.",
    "value": ""

},
{
    "name": "message",
    "type": "STRING",
    "description": "Message",
    "value": ""

}]
```

Continue to include Orchestrator workflow tasks in your pipelines so that you can automate tasks in your development, test, and production environments.

Triggering pipelines in Automation Pipelines

Triggering pipelines

You can have Automation Pipelines trigger a pipeline when certain events occur.

For example:

- The Docker trigger can run a pipeline when a new artifact gets created or updated.
- The trigger for Git can trigger a pipeline when developers update code.
- The trigger for Gerrit can trigger a pipeline when developers review code.

How do I use the Docker trigger in Automation Pipelines to run a continuous delivery pipeline

How do I use the Docker trigger to run a continuous delivery pipeline

As a Automation Pipelines administrator or developer, you can use the Docker trigger in Automation Pipelines. The Docker trigger runs a standalone continuous delivery (CD) pipeline whenever a build artifact is created or updated. The Docker trigger runs your CD pipeline, which pushes the new or updated artifact as a container image to a Docker Hub repository. The CD pipeline can run as part of your automated builds.

- Verify that a continuous delivery (CD) pipeline exists in your Automation Pipelines instance. Also verify that it includes one or more Kubernetes tasks that deploy your application. See [Planning to natively build, integrate, and deliver your code in](#).

- Verify that you can access an existing Kubernetes cluster where your CD pipeline can deploy your application for development.
- Verify that you are a member of a project in Automation Pipelines. If you are not, ask a Automation Pipelines administrator to add you as a member of a project. See [How do I add a project in](#).

For example, to continuously deploy your updated container image through your CD pipeline, use the Docker trigger. When your container image gets checked into the Docker registry, the webhook in Docker Hub notifies Automation Pipelines that the image changed. This notification triggers the CD pipeline to run with the updated container image, and upload the image to the Docker Hub repository.

To use the Docker trigger, you perform several steps in Automation Pipelines.

Table 83: How to use the Docker trigger

What you do...	More information about this action...
Create a Docker registry endpoint.	<p>For Automation Pipelines to trigger your pipeline, you must have a Docker Registry endpoint. If the endpoint does not exist, you can select an option that creates it when you add the webhook for the Docker trigger.</p> <p>The Docker registry endpoint includes the URL to the Docker Hub repository.</p>
Add input parameters to the pipeline that auto inject Docker parameters when the pipeline runs.	<p>You can inject Docker parameters into the pipeline. Parameters can include the Docker event owner name, image, repository name, repository namespace, and tag.</p> <p>In your CD pipeline, you include input parameters that the Docker webhook passes to the pipeline before the pipeline triggers.</p>
Create a Docker webhook.	<p>When you create the Docker webhook in Automation Pipelines, it also creates a corresponding webhook in Docker Hub. The Docker webhook in Automation Pipelines connects to Docker Hub through the URL that you include in the webhook.</p> <p>The webhooks communicate with each other, and trigger the pipeline when an artifact is created or updated in Docker Hub.</p> <p>If you update or delete the Docker webhook in Automation Pipelines, the webhook in Docker Hub is also updated or deleted.</p>
Add and configure a Kubernetes task in your pipeline.	When an artifact is created or updated in the Docker Hub repository, the pipeline triggers. Then, it deploys the artifact through the pipeline to the Docker host in your Kubernetes cluster.
Include a local YAML definition in the task.	The YAML definition that you apply to the deployment task includes the Docker container image. If you need to download an image from a privately-owned repository, the YAML file must include a section with the Docker config Secret. See the CD portion of Planning a CICD native build in Automation Pipelines before using the smart pipeline template

When an artifact is created or updated in the Docker Hub repository, the webhook in Docker Hub notifies the webhook in Automation Pipelines, which triggers the pipeline. The following actions occur:

1. Docker Hub sends a POST request to the URL in the webhook.
2. Automation Pipelines runs the Docker trigger.
3. The Docker trigger starts your CD pipeline.
4. The CD pipeline pushes the artifact to the Docker Hub repository.
5. Automation Pipelines triggers its Docker webhook, which runs a CD pipeline that deploys the artifact to your Docker host.

In this example, you create a Docker endpoint and a Docker webhook in Automation Pipelines that deploys your application to your development Kubernetes cluster. The steps include the example code for the payload that Docker posts to the URL in the webhook, the API code that it uses, and the authentication code with the secure token.

1. Create a Docker registry endpoint.
 - a) Click **Endpoints**.
 - b) Click **New Endpoint**.
 - c) Start typing name of existing project.
 - d) Select the type as **Docker Registry**.
 - e) Enter a relevant name.
 - f) Select the server type as **DockerHub**.
 - g) Enter the URL to the Docker Hub repository.
 - h) Enter the name and password that can access the repository.

New endpoint

Project *

Type *

Name *

Description

Mark restricted non-restricted

Cloud proxy *

Server type *

Repo URL *
ACCEPT CERTIFICATE

Username *

Password *
CREATE VARIABLE

CREATE **VALIDATE** **CANCEL**

2. In your CD pipeline, set the input properties to auto inject Docker parameters when the pipeline runs.

The screenshot shows the 'Input' tab for a pipeline named 'sm-1'. The 'Docker' option is selected under 'Auto inject parameters'. A table lists Docker injected parameters:

Starred ⓘ	Name
⋮ ⭐	DOCKER_EVENT_OWNER_NAME
⋮ ⭐	DOCKER_IMAGE
⋮ ⭐	DOCKER_REPO_NAME
⋮ ⭐	DOCKER_REPO_NAMESPACE
⋮ ⭐	DOCKER_TAG

3. Create a Docker webhook.

- Click **Triggers > Docker**.
- Click **New Webhook for Docker**.
- Select a project.
- Enter a relevant name.
- Select your Docker registry endpoint.

If the endpoint does not yet exist, click **Create Endpoint** and create it.

- Select the pipeline with Docker injected parameters for the webhook to trigger. See [In your CD pipeline, set the input properties to auto inject Docker parameters when the pipeline runs..](#)

If the pipeline was configured with custom added input parameters, the Input Parameters list displays parameters and values. You can enter values for input parameters that will be passed to the pipeline with the trigger event. Or you can leave the values blank, or use the default values if defined.

For more information about parameters on the input tab, see [How you'll create the CICD pipeline and configure the workspace](#).

- Enter the API Token.

The VMware Cloud Services API token authenticates you for external API connections with Automation Pipelines. To obtain the API token:

- Click **Generate Token**.
- Enter the email address associated with your user name and password and click **Generate**. The token that you generate is valid for six months. It is also known as a refresh token.
 - To keep the token as a variable for future use, click **Create Variable**, enter a name for the variable and click **Save**.
 - To keep the token as a text value for future use, click **Copy** and paste the token into a text file to save locally.

You can choose to both create a variable and store the token in a text file for future use.

3. Click **Close**.

h) Enter the build image.

i) Enter a tag.

j) Click **Save**.

The webhook card appears with the Docker webhook enabled. If you want to make a dummy push to the Docker Hub repository without triggering the Docker webhook and running a pipeline, click **Disable**.

4. In your CD pipeline, configure your Kubernetes deployment task.

- In the Kubernetes task properties, select your development Kubernetes cluster.
- Select the **Create** action.
- Select the **Local Definition** for the payload source.
- Then select your local YAML file.

For example, Docker Hub might post this local YAML definition as the payload to the URL in the webhook:

```
{
  "callback_url": "https://registry.hub.docker.com/u/svendowideit/testhook/hook/2141b5bi5i5b02bec211i4eeih0242eg11000a/",
  "push_data": {
    "images": [
      "27d47432a69bca5f2700e4dff7de0388ed65f9d3fb1ec645e2bc24c223dc1cc3",
    ]
  }
}
```

```

"51a9c7c1f8bb2fa19bcd09789a34e63f35abb80044bc10196e304f6634cc582c",
"..." ,
],
"pushed_at": 1.417566161e+09,

"status": "Active"
}
}

```

The API that creates the webhook in Docker Hub uses this form: https://cloud.docker.com/v2/repositories/%3CUSERNAME%3E/%3CREPOSITORY%3E/webhook_pipeline/

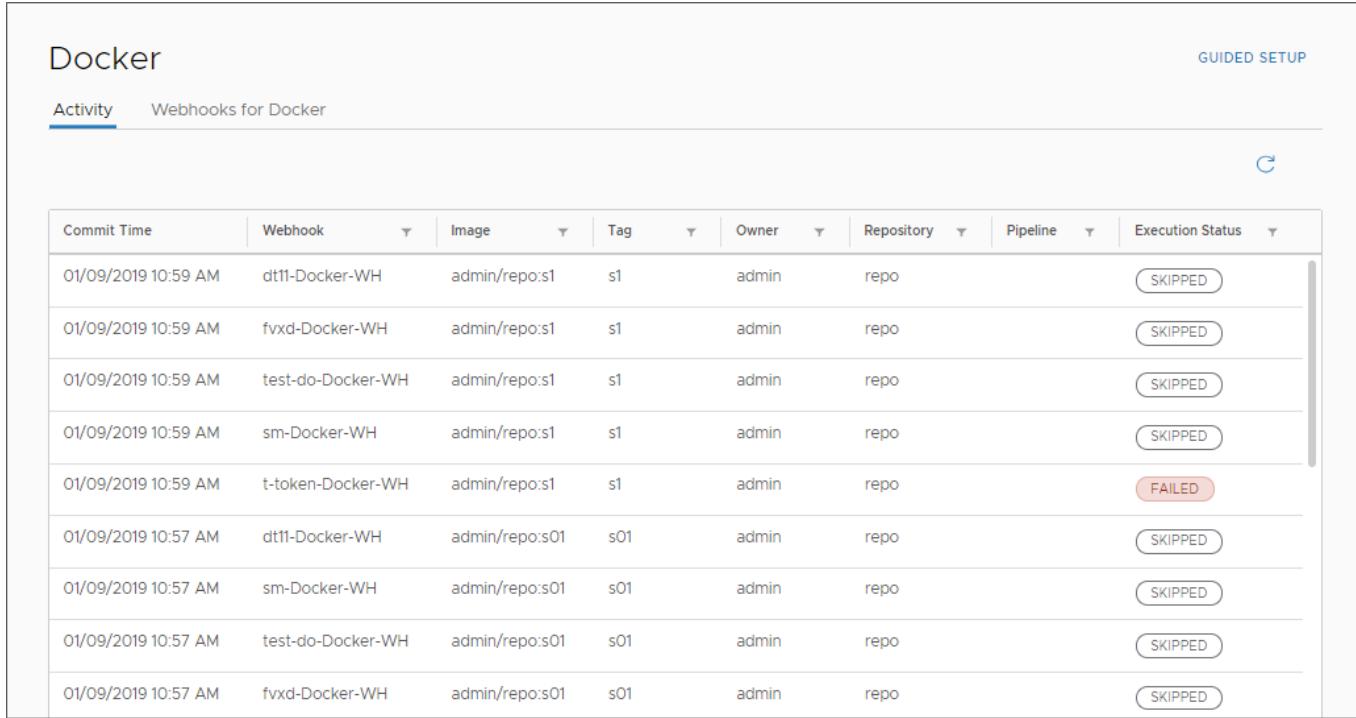

The JSON code body resembles:

```
{
  "name": "demo_webhook",
  "webhooks": [
    {
      "name": "demo_webhook",
      "hook_url": "http://www.google.com"
    }
  ]
}
```

To receive events from the Docker Hub server, the authentication scheme for the Docker webhook that you create in Automation Pipelines uses an allowlist authentication mechanism with a random string token for the webhook. It filters events based on the secure token, which you can append to `hook_url`.

Automation Pipelines can verify any request from the Docker Hub server by using the configured secure token. For example: `hook_url = IP:Port/pipelines/api/docker-hub-webhooks?secureToken = ""`

5. Create a Docker artifact in your Docker Hub repository. Or, update an existing artifact.
6. To confirm that the trigger occurred, and see the activity on the Docker webhook, click **Triggers > Docker > Activity**.

The screenshot shows the 'Docker' activity page in the VMware Aria Automation web interface. The table below lists the activity details:

Commit Time	Webhook	Image	Tag	Owner	Repository	Pipeline	Execution Status
01/09/2019 10:59 AM	dt11-Docker-WH	admin/repo:s1	s1	admin	repo		SKIPPED
01/09/2019 10:59 AM	fvxd-Docker-WH	admin/repo:s1	s1	admin	repo		SKIPPED
01/09/2019 10:59 AM	test-do-Docker-WH	admin/repo:s1	s1	admin	repo		SKIPPED
01/09/2019 10:59 AM	sm-Docker-WH	admin/repo:s1	s1	admin	repo		SKIPPED
01/09/2019 10:59 AM	t-token-Docker-WH	admin/repo:s1	s1	admin	repo		FAILED
01/09/2019 10:57 AM	dt11-Docker-WH	admin/repo:s01	s01	admin	repo		SKIPPED
01/09/2019 10:57 AM	sm-Docker-WH	admin/repo:s01	s01	admin	repo		SKIPPED
01/09/2019 10:57 AM	test-do-Docker-WH	admin/repo:s01	s01	admin	repo		SKIPPED
01/09/2019 10:57 AM	fvxd-Docker-WH	admin/repo:s01	s01	admin	repo		SKIPPED

7. Click **Executions**, and observe your pipeline as it runs.

The screenshot shows the 'Executions' list with one item, 'sm-1-IX#1', which is currently running. The pipeline has a single stage named 'Development' that is also running. The stage contains several tasks: 'Create Namespace' (status: green checkmark), 'Create Secret' (status: green checkmark), 'Create Service' (status: green checkmark), 'Create Deployment' (status: blue circle), 'Verify Deployment' (status: grey circle), and 'Delete Namespace' (status: grey circle).

- Click the running stage and view the tasks as the pipeline runs.

This screenshot provides a detailed view of the 'Development' stage of the 'sm-1-IX #1' pipeline. The stage is currently running. The tasks within the stage are: 'Create Namespace' (status: green checkmark), 'Create Secret' (status: green checkmark), 'Create Service' (status: green checkmark), 'Create Deployment' (status: blue circle), 'Verify Deployment' (status: grey circle), and 'Delete Namespace' (status: grey circle). Below the stage, it shows the stage name 'Development' and the status 'RUNNING RUNNING'.

Congratulations! You set up the Docker trigger to run your CD pipeline continuously. Your pipeline can now upload new and updated Docker artifacts to the Docker Hub repository.

Verify that your new or updated artifact is deployed to the Docker host in your development Kubernetes cluster.

How do I use the Git trigger in Automation Pipelines to run a pipeline

How do I use the Git trigger to run a pipeline

As a Automation Pipelines administrator or developer, you can integrate Automation Pipelines with the Git life cycle by using the Git trigger. When you make a code change in GitHub, GitLab, or Bitbucket Enterprise, the event communicates with Automation Pipelines through a webhook and triggers a pipeline. The webhook works with GitLab, GitHub, and Bitbucket on-premises enterprise versions when both Automation Assembler and the enterprise version are reachable on the same network.

- Verify that you are a member of a project in Automation Pipelines. If you are not, ask a Automation Pipelines administrator to add you as a member of a project. See [How do I add a project in](#).
- Verify that you have a Git endpoint on the GitHub branch you want to monitor. See [How do I integrate with Git](#).
- Verify that you have rights to create a webhook in the Git repository.
- If configuring a webhook in GitLab, change the default network settings in GitLab enterprise to enable outbound requests and allow the creation of local webhooks.

NOTE

This change is only required for GitLab enterprise. These settings do not apply to GitHub or Bitbucket.

- Log in to your GitLab enterprise instance as administrator.
- Go to network settings using a URL such as, `http://{{gitlab-server}}/admin/application_settings/network`.

3. Expand **Outbound requests** and click:
 - Allow requests to the local network from web hooks and services.
 - Allow requests to the local network from system hook.
- For the pipelines you want to trigger, verify that you have set the input properties to inject Git parameters when the pipeline runs.

	Starred ⓘ	Name
:	★	GIT_BRANCH_NAME
:	★	GIT_CHANGE_SUBJECT
:	★	GIT_COMMIT_ID
:	★	GIT_EVENT_DESCRIPTION
:	★	GIT_EVENT_OWNER_NAME
:	★	GIT_EVENT_TIMESTAMP
:	★	GIT_REPO_NAME
:	★	GIT_SERVER_URL

For information about input parameters, see [How you'll create the CICD pipeline and configure the workspace](#).

When you add the webhook for Git in Automation Pipelines, it also creates a webhook in the GitHub, GitLab, or the Bitbucket repository. If you update or delete the webhook later, that action also updates or deletes the webhook in GitHub, GitLab, or Bitbucket.

Your webhook definition must include a Git endpoint on the branch of the repository that you will monitor. To create the webhook, Automation Pipelines uses the Git endpoint. If the endpoint does not exist, you can create it when you add the webhook. This example assumes that you have a predefined Git endpoint in GitHub.

NOTE

To create a webhook your Git endpoint must use a private token for authentication, it cannot use a password.

You can create multiple webhooks for different branches by using the same Git endpoint and providing different values for the branch name in the webhook configuration page. To create another webhook for another branch in the same Git repository, you don't need to clone the Git endpoint multiple times for multiple branches. Instead, you provide the branch name in the webhook, which allows you to reuse the Git endpoint. If the branch in the Git webhook is the same as the branch in the endpoint, you don't need to provide branch name in the Git webhook page.

This example shows you how to use the Git trigger with a GitHub repository, but the prerequisites include preparations required if another Git server type is used.

1. In Automation Pipelines, click **Triggers > Git**.

2. Click the **Webhooks for Git** tab, then click **New Webhook for Git**.

- Select a project.
- Enter a meaningful name and description for the webhook.
- Select a Git endpoint configured for the branch you want to monitor.

When you create your webhook, the webhook definition includes the current endpoint details.

- If you later change the Git type, Git server type, or Git repository URL in the endpoint, the webhook will no longer be able to trigger a pipeline because it will try to access the Git repository using the original endpoint details. You must delete the webhook and create it again with the endpoint.
- If you later change the authentication type, username, or private token in the endpoint, the webhook will continue to work.
- If you are using a BitBucket repository, the URL for the repository must be in one of these formats:
`https://api.bitbucket.org/{user}/{repo_name}` or `http(s)://bitbucket-enterprise-server/rest/api/1.0/users/{username}/repos/{repo_name}`.

NOTE

If you previously created a webhook using a Git endpoint that uses a password for basic authentication, you must delete and redefine the webhook with a Git endpoint that uses a private token for authentication.

See [How do I integrate with Git](#).

d) Enter the branch that you want the webhook to monitor.

If you leave the branch unspecified, the webhook monitors the branch that you configured for the Git endpoint. If you use a regex as a branch name, changes made on any branch matching the regex will trigger the pipeline.

e) Generate a secret token for the webhook.

If you use a secret token, Automation Pipelines generates a random string token for the webhook. Then, when the webhook receives Git event data, it sends the data with the secret token. Automation Pipelines uses the information to determine if the calls are coming from the expected source such as the configured GitHub instance, repository, and branch. The secret token provides an extra layer of security that is used to verify that the Git event data is coming from the correct source.

f) Provide file inclusions or exclusions as conditions for the trigger.

- File inclusions. If any of the files in a commit match the files specified in the inclusion paths or regex, the commit triggers the pipelines. With a regex specified, Automation Pipelines only triggers the pipelines when filenames in the changeset match the expression provided. The regex filter is useful when configuring a trigger for multiple pipelines on a single repository.
- File exclusions. When all the files in a commit match the specified files in the exclusion paths or regex, the pipelines do not trigger.
- Prioritize exclusions. When toggled on, Prioritize Exclusion ensures that pipelines do not trigger even if any of the files in a commit match the files specified in the exclusion paths or regex. The default setting is off.

If conditions meet both the file inclusions and file exclusions, pipelines do not trigger.

In the following example, both file inclusions and file exclusions are conditions for the trigger.

The screenshot shows a configuration panel for a Git event. It includes sections for Inclusions and Exclusions, each with dropdown menus for type (PLAIN or REGEX) and a text input field for the pattern. There are also minus (-) and plus (+) buttons to manage the rules. A toggle switch at the bottom is labeled "Prioritize Exclusion".

Inclusions	Type	Pattern	Actions
	PLAIN	runtime/src/main/a.java	- +
	REGEX	([a-z A-Z]+[/][a-z A-Z])+	- +

Exclusions	Type	Pattern	Actions
	PLAIN	runtime/pom.xml	- +
	PLAIN	runtime/demo.yaml	- +

Prioritize Exclusion

- For file inclusions, a commit with any change to `runtime/src/main/a.java` or any Java file will trigger pipelines configured in the event configuration.
- For file exclusions, a commit with changes only in both files will not trigger the pipelines configured in the event configurations.

- g) For the Git event, select a **Push** or **Pull** request.
- h) Enter the API Token.

The VMware Cloud Services API token authenticates you for external API connections with Automation Pipelines. To obtain the API token:

1. Click **Generate Token**.
2. Enter the email address associated with your user name and password and click **Generate**. The token that you generate is valid for six months. It is also known as a refresh token.
 - To keep the token as a variable for future use, click **Create Variable**, enter a name for the variable and click **Save**.
 - To keep the token as a text value for future use, click **Copy** and paste the token into a text file to save locally.
 You can choose to both create a variable and store the token in a text file for future use.
3. Click **Close**.

- i) Select the pipeline for the webhook to trigger.

If the pipeline includes custom added input parameters, the Input Parameters list displays parameters and values. You can enter values for input parameters that pass to the pipeline with the trigger event. Or, you can leave the values blank, or use the default values if defined.

For information about Auto inject input parameters for Git triggers, see the [Prerequisites](#).

- j) Click **Create**.
The webhook appears as a new card.
3. Click the webhook card.
When the webhook data form reappears, you see a webhook URL added to the top of the form. The Git webhook connects to the GitHub repository through the webhook URL.

Git

Activity [Webhooks for Git](#)

Webhook URL <https://.../api/git-webhook-listeners/0998005d-9707-402e-bfbd-619e9965d698>
Copy the URL that you generated to the Webhooks settings page of your Git repository.

Project test

Name * git-regex-webhook

Description git webhook for branches with prefix as ab

Endpoint GitHub-SaaS

Branch (ab)(.)ⁱ
Branch name provided here will take precedence over the branch specified in the endpoint.

Secret token * wX6ub84PgE4jCucY6r8GncoiRtB=

For improved security, copy the secure token that you generated to the Webhooks settings page of your Git repository, + "git_webhookBranchNameMsg". The branch name provided here takes precedence over the branch specified in the endpoint.

[GENERATE](#)

File

Inclusions --Select-- Value [+](#)
If any of the files in the commit match the inclusion paths or regex, the pipeline(s) will trigger.

Exclusions --Select-- Value [+](#)
If all the files in the commit match the exclusion paths or regex, the pipeline(s) will NOT trigger.
If both of the above conditions for inclusions and exclusions are met, the pipeline(s) will NOT trigger.

Prioritize Exclusion No
When prioritize exclusion is true, if any of the files in the commit match the exclusion paths or regex, the pipeline will NOT trigger.
This is true even if some of the files match Inclusion paths or regex.

Trigger

https://api.mgmt.../pipeline/api/git-webhook-listeners/2497334aaa912075578faebcf81... (push)	Edit Delete

- To make a code change, click the **Code** tab and select a file on the branch. After you edit the file, commit the change.
- To verify that the webhook URL is working, click the **Settings** tab and select **Webhooks** again. At the bottom of the webhooks list, a green checkmark appears next to the webhook URL.

- Return to Automation Pipelines to view the activity on the Git webhook. Click **Triggers** > **Git** > **Activity**. Under Execution Status, verify that the pipeline run has started.

The screenshot shows the VMware Aria Automation UI under the 'Git' section. The 'Activity' tab is selected. A table lists the execution details of a pipeline run. The status is shown as 'STARTED'.

Commit Time	Commit ID	Webhook	Change Subject	Owner	Branch	Repository	Events	Execution	Execution Status
Jan 15, 2019 9:42 PM	adk63c0058...	test-webhook	Update index.html	etauser	master	demo-project	PUSH	-	STARTED

- Click **Executions** and track your pipeline as it runs.

To observe the pipeline run, you can press refresh.

Congratulations! You successfully used the trigger for Git!

How do I use the Gerrit trigger in Automation Pipelines to run a pipeline

How do I use the Gerrit trigger to run a pipeline

As a Automation Pipelines administrator or developer, you can integrate Automation Pipelines with the Gerrit code review life cycle by using the Gerrit trigger. The event triggers a pipeline to run when you create a patch set, publish drafts, merge code changes on the Gerrit project, or directly push changes on the Git branch.

- Verify that you are a member of a project in Automation Pipelines. If you are not, ask a Automation Pipelines administrator to add you as a member of a project. See [How do I add a project in](#).
- Verify that you have a Gerrit endpoint configured in Automation Pipelines. See [How do I integrate with Gerrit](#).
- Verify that you know your Gerrit release version.
- For pipelines to trigger, verify that you set the input properties of the pipeline as **Gerrit**, which allows the pipeline to receive the Gerrit parameters as inputs when the pipeline runs.

Starred	Name
☆	GERRIT_BRANCH
☆	GERRIT_CHANGE_COMMIT_MESSAGE
☆	GERRIT_CHANGE_ID
☆	GERRIT_CHANGE_NUMBER
☆	GERRIT_CHANGE_OWNER_EMAIL
☆	GERRIT_CHANGE_OWNER_NAME
☆	GERRIT_CHANGE_OWNER_USERNAME
☆	GERRIT_CHANGE_SUBJECT

For information about input parameters, see [How you'll create the CICD pipeline and configure the workspace](#).

When you add the Gerrit trigger, you select a Gerrit listener, a Gerrit project on the Gerrit server, and you configure Gerrit events. In the Gerrit listener definition, you select a Gerrit endpoint. If you need to update the Gerrit endpoint after connecting the listener, you must disconnect the listener first, then update the endpoint.

In this example, you first configure a Gerrit listener, then you use that listener in a Gerrit trigger with two events on three different pipelines.

1. In Automation Pipelines, click **Triggers > Gerrit**.
2. Click the **Listeners** tab, then click **New Listener**.

NOTE

If the Gerrit listener that you plan to use for the Gerrit trigger is already defined, skip this step.

- a) Select a project.
- b) Enter a name for the Gerrit listener.
- c) Select a Gerrit endpoint.
- d) Enter the API Token.

The VMware Cloud Services API token authenticates you for external API connections with Automation Pipelines. To obtain the API token:

1. Click **Generate Token**.
2. Enter the email address associated with your user name and password and click **Generate**. The token that you generate is valid for six months. It is also known as a refresh token.
 - To keep the token as a variable for future use, click **Create Variable**, enter a name for the variable and click **Save**.
 - To keep the token as a text value for future use, click **Copy** and paste the token into a text file to save locally.
3. Click **Close**.

If you created a variable, the API token displays the variable name that you entered by using dollar binding. If you copied the token, the API token displays the masked token.

Gerrit		
Activity	Triggers	Listeners
Project *	test1	(X)
Name *	Gerrit-Demo-Listener	
Endpoint *	corporate-gerrit	▼
API token *	\$(var.CSUser API Token)	<input checked="" type="checkbox"/> CREATE VARIABLE GENERATE TOKEN
CREATE VALIDATE CANCEL		

- e) To validate the token and endpoint details, click **Validate**.

Your token expires after 90 days.

- f) Click **Create**.
- g) On the listener card, click **Connect**.

The listener starts monitoring all activity on the Gerrit server and listens for any activated triggers on that server. To stop listening for a trigger on that server, you deactivate the trigger.

NOTE

To update a Gerrit endpoint that is connected to a listener, you must disconnect the listener before updating the endpoint.

- Click **Configure > Triggers > Gerrit**.
- Click the **Listeners** tab.
- Click **Disconnect** on the listener that is connected to the endpoint that you want to update.

3. Click the **Triggers** tab, then click **New Trigger**.

4. Select a project on the Gerrit server.

5. Enter a name.

The Gerrit trigger name must be unique.

6. Select a configured Gerrit listener.

By using the Gerrit listener, Automation Pipelines provides a list of Gerrit projects that are available on the server.

7. Select a project on the Gerrit server.

8. Enter the branch in the repository that the Gerrit listener will monitor.

9. Provide file inclusions or exclusions as conditions for the trigger.

- You provide file inclusions that trigger the pipelines. When any of the files in a commit match the files specified in the inclusion paths or regex, pipelines trigger. With a regex specified, Automation Pipelines only triggers pipelines with filenames in the changeset that match the expression provided. The regex filter is useful when configuring a trigger for multiple pipelines on a single repository.
- You provide file exclusions that keep pipelines from triggering. When all the files in a commit match the files specified in the exclusion paths or regex, the pipelines do not trigger.
- **Prioritize Exclusion**, when toggled on, ensures that pipelines do not trigger. The pipelines won't trigger even if any of the files in a commit match the files specified in the exclusion paths or regex. The default setting for **Prioritize Exclusion** is turned off.

If the conditions meet both the file inclusion and the file exclusion, pipelines do not trigger.

In the following example, both the file inclusions and the file exclusions are conditions for the trigger.

File ①	
Inclusions	PLAIN ▾ <input type="text" value="runtime/src/main/a.java"/> - +
	REGEX ▾ <input type="text" value="([a-zA-Z]+/[a-zA-Z]+)"/> - +
Exclusions	PLAIN ▾ <input type="text" value="runtime/pom.xml"/> -
	PLAIN ▾ <input type="text" value="runtime/demo.yaml"/> - +
Prioritize Exclusion	<input checked="" type="checkbox"/>

- For file inclusions, a commit that has any change to `runtime/src/main/a.java` or any Java file will trigger the pipelines configured in the event configuration.

- For file exclusions, a commit that has changes only in both files will not trigger the pipelines configured in the event configuration.

10. Click **New Configuration**.

- a) For a Gerrit event, select **Patchset Created**, **Draft Published**, or **Change Merged**. Or, for a direct push to Git that bypasses Gerrit, select **Direct Git push**.

NOTE

As of Gerrit release version 2.15, draft changes and draft change sets are no longer supported. So if you are running Gerrit release version 2.15 or later, **Draft Published** is not a supported event.

- b) Select the pipeline that will trigger.

If the pipeline includes custom added input parameters, the Input Parameters list displays parameters and values. You can enter values for input parameters to be passed to the pipeline with the trigger event. Or, you can leave the values blank, or use the default values.

NOTE

If default values are defined:

- Any values you enter for the input parameters will override the default values defined in the pipeline model.
- The default values in the trigger configuration will not change if the parameter values in the pipeline model change.

For information about Auto inject input parameters for Gerrit triggers, see the [Prerequisites](#).

- c) For **Patchset Created**, **Draft Published**, and **Change Merged**, some actions appear with labels by default. You can change the label or add comments. Then, when the pipeline runs, the label or comment appears on the **Activity** tab as the **Action taken** for the pipeline.

The Gerrit Event configuration allows you to enter comments by using a variable for the Success comment or Failure comment. For example: \${var.success} and \${var.failure}.

- d) Click **Save**.

To add multiple trigger events on multiple pipelines, click **New Configuration** again.

In the following example, you can see events for three pipelines:

- If a **Change Merged** event occurs in the Gerrit project, the pipeline named **Gerrit-Pipeline** triggers.
- If a **Patchset Created** event occurs in the Gerrit project, the pipelines named **Gerrit-Trigger-Pipeline** and **Gerrit-Demo-Pipeline** trigger.

Gerrit

[GUIDED SETUP](#)

[Activity](#) [Triggers](#) [Listeners](#)

Project * test1 [×](#)

Name * Gerrit-Demo-Trigger

Gerrit Listener * Gerrit-Demo-Listener

Gerrit project * Gerrit-Demo-Project

Branch * master

File ⓘ

Inclusions -- Select Type -- value [+](#)

Exclusions -- Select Type -- value [+](#)

Prioritize Exclusion

[+ NEW CONFIGURATION](#)

Event Type	Pipeline	Label
Change Merged	Gerrit-Pipeline	Verified
Patchset Created	Gerrit-Trigger-Pipeline	Verified
Patchset Created	Gerrit-Demo-Pipeline	Verified
3 configurations		

11. Click **Create**.

The Gerrit trigger appears as a new card on the **Triggers** tab, and is set as **Disabled** by default.

12. On the trigger card, click **Enable**.

After you activate the trigger, it can use the Gerrit listener, which starts monitoring events that occur on the branch of the Gerrit project.

To create a trigger that has the same file inclusion conditions or file exclusion conditions, but with a different repository than the one you included when you created the trigger, on the trigger card click **Actions > Clone**. Then, on the cloned trigger, click **Open**, and change the parameters.

Congratulations! You successfully configured a Gerrit trigger with two events on three different pipelines.

After you commit a code change in the Gerrit project, observe the **Activity** tab for the Gerrit event in Automation Pipelines. Verify that the list of activities includes entries that correspond to every pipeline execution in the trigger configuration.

When an event occurs, only pipelines in the Gerrit trigger that relate to the particular type of event can run. In this example, if a patch set is created, only the **Gerrit-Trigger-Pipeline** and the **Gerrit-Demo-Pipeline** will run.

Information in the columns on the **Activity** tab describe each Gerrit trigger event. You can select the columns that appear by clicking the column icon that appears below the table.

- The **Change Subject** and **Execution** columns are empty when the trigger was a direct Git push.
 - The **Trigger for Gerrit** column displays the trigger that created the event.
 - The **Listener** column is turned off by default. When you select it, the column displays the Gerrit listener that received the event. A single listener can appear as associated with multiple triggers.
 - The **Trigger Type** column is turned off by default. When you select it, the column displays the type of trigger as AUTOMATIC or MANUAL.
 - Other columns include **Commit Time**, **Change#**, **Status**, **Message**, **Action taken**, **User**, **Gerrit project**, **Branch**, and **Event**.

To control the activity for a completed or failed pipeline run, click the three dots at the left of any entry on the Activity screen.

- If the pipeline fails to run because of a mistake in the pipeline model or another problem, correct the mistake and select **Re-run**, which runs the pipeline again.

- If the pipeline fails to run because of a network connectivity issue or another problem, select **Resume**, which restarts the same pipeline execution, and saves run time.
- Use **View Execution**, which opens the pipeline execution view. See [How do I run a pipeline and see results](#).
- Use **Delete** to delete the entry from the Activity screen.

If a Gerrit event fails to trigger a pipeline, you can click **Trigger Manually**, then select the trigger for Gerrit, enter the Change-Id, and click **Run**.

NOTE

Trigger Manually only works for valid Gerrit events such as **Patchset created**, **Change Merged**, and **Draft-published**.

Monitoring pipelines in Automation Pipelines

Monitoring pipelines

As a Automation Pipelines administrator or developer, you need insight about the performance of your pipelines in Automation Pipelines. You need to know how effectively your pipelines release code from development, through testing, and to production.

To gain insight, you use Automation Pipelines dashboards to monitor the trends and results of a pipeline execution. You can use the default pipeline dashboards to monitor a single pipeline, or create custom dashboards to monitor multiple pipelines.

- Pipeline metrics include statistics such as mean times, which are available on the pipeline dashboard.
- To see metrics across multiple pipelines, use the custom dashboards.

What does the pipeline dashboard show me in Automation Pipelines

What does the pipeline dashboard show me

A pipeline dashboard is a view of the results for a specific pipeline that ran, such as trends, top failures, and successful changes. Automation Pipelines creates the pipeline dashboard when you create a pipeline.

The dashboard contains the widgets that display pipeline execution results.

Pipeline Execution Status Counts Widget

You can view the total number of executions of a pipeline over a period of time grouped by status: Completed, Failed, or Canceled. To see how the pipeline execution status has changed over longer or shorter periods of time, change the duration on the display.

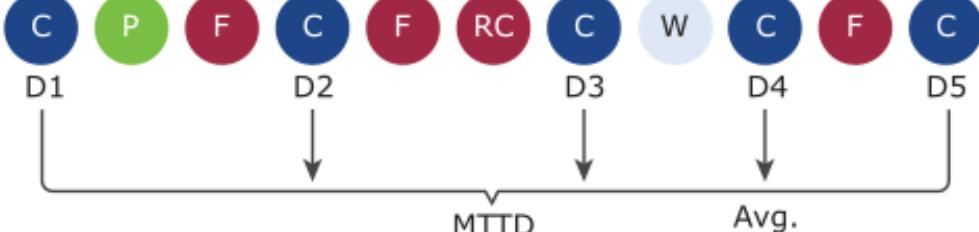

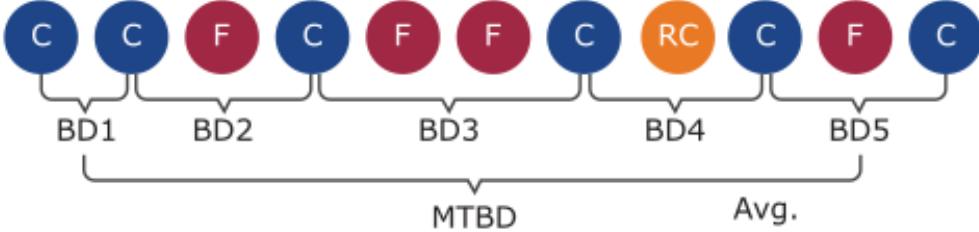

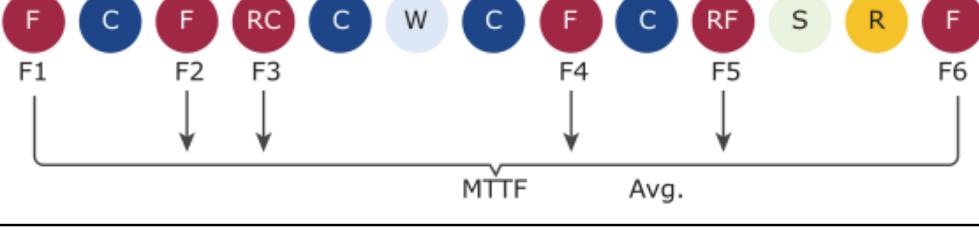

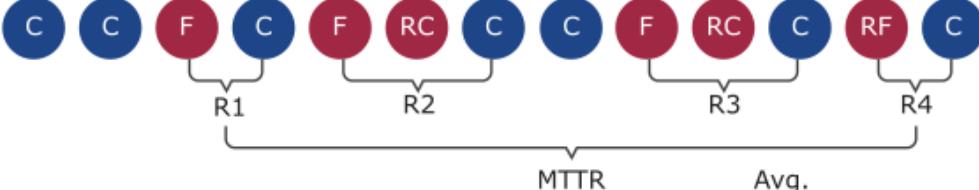

Pipeline Execution Statistics Widget

The pipeline execution statistics include the mean times to recover, deliver, or fail a pipeline over time.

The following states apply to all pipeline executions:

- Completed
- Failed
- Waiting
- Running
- Canceled
- Queued
- Not Started
- Rolling Back
- Rollback Completed
- Rollback Failed
- Paused

Table 84: Measuring mean times

What gets measured...	What it means...
Average CI	Average time spent in the continuous integration phase, measured by time in the CI task type.
Mean time to delivery (MTTD)	Average duration of all COMPLETED runs over a period of time. D1, D2, and so forth is the amount of time to deliver each COMPLETED run. 
Mean time between deliveries (MTBD)	Average time elapsed between successful deliveries over a period of time. The time elapsed between two consecutive COMPLETED runs is the time between successful deliveries, such as BD1, BD2 and so forth. MTBD indicates how often a production environment updates. 
Mean time to failure (MTTF)	Average duration of runs that end in FAILED, ROLLBACK_COMPLETED or ROLLBACK_FAILED states over a period of time. F1, F2, and so forth is the amount of time for a run to end in FAILURE, ROLLBACK_COMPLETED, or ROLLBACK FAILED. 
Mean time to recovery (MTTR)	Average time to recovery from a failure over a period of time. The time to recovery from a failure is the time elapsed between a run with a final status of FAILED, ROLLBACK_COMPLETED, or ROLLBACK_FAILED and the next immediate successful run with a COMPLETED status. R1, R2 and so forth, is the amount of time to recovery after each FAILED or ROLLBACK_FAILED run. 

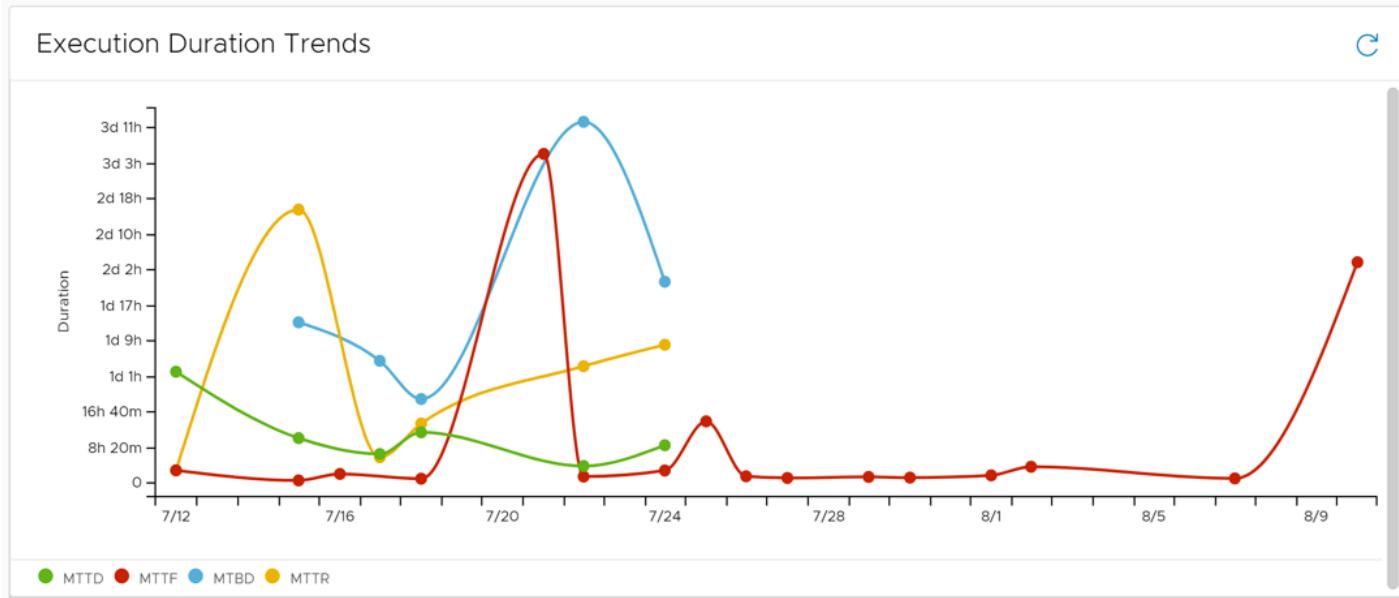

Top Failed Stages and Tasks Widgets

Two widgets display the top failed stages and tasks in a pipeline. Each measurement reports the number and percentage of failures for development and post-development environments for each pipeline and project, averaged over a week or month. You view the top failures to troubleshoot problems in the release automation process.

For example, you can configure the display for a particular duration such as the last seven days and note the top failed tasks during that period of time. If you make a change in your environment or pipeline and run the pipeline again, then check the top failed tasks over a longer duration such as the last 14 days, the top failed tasks may have changed. With that result, you will know that the change in your release automation process improved the success rate of your pipeline execution.

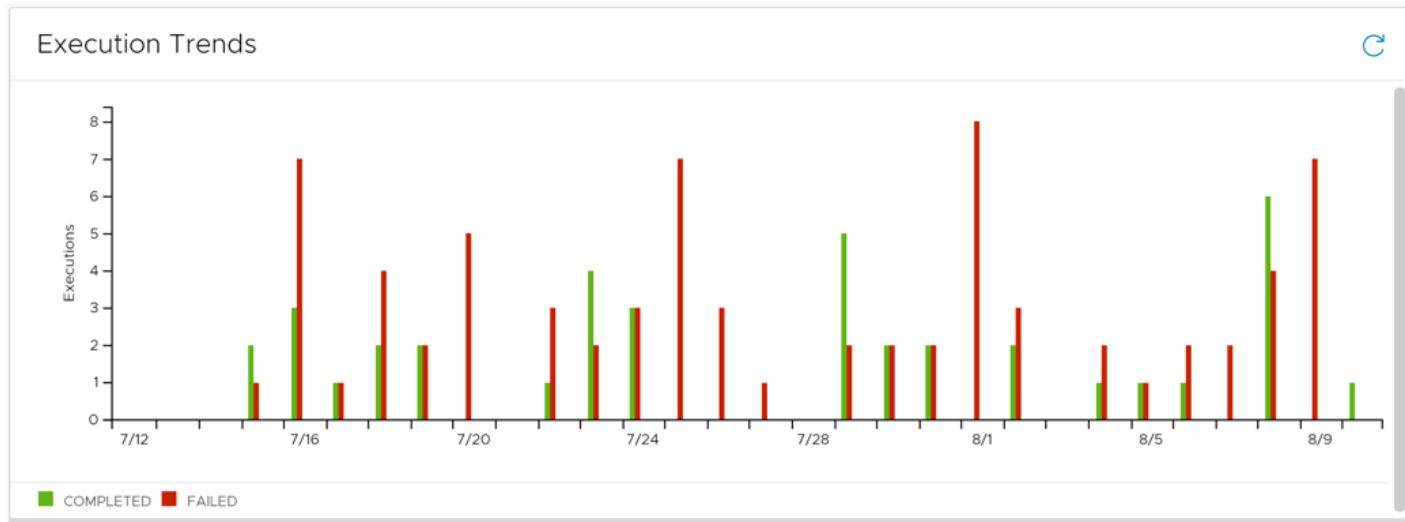

Pipeline Execution Duration Trends Widget

Pipeline execution duration trends show the MTTD, MTTF, MTBD, and MTTR, over a period of time.

Pipeline Execution Trends Widget

Pipeline execution trends show the total daily runs of a pipeline, grouped by status over a period of time. Except for the current day, most daily aggregation counts only show COMPLETED and FAILED runs.

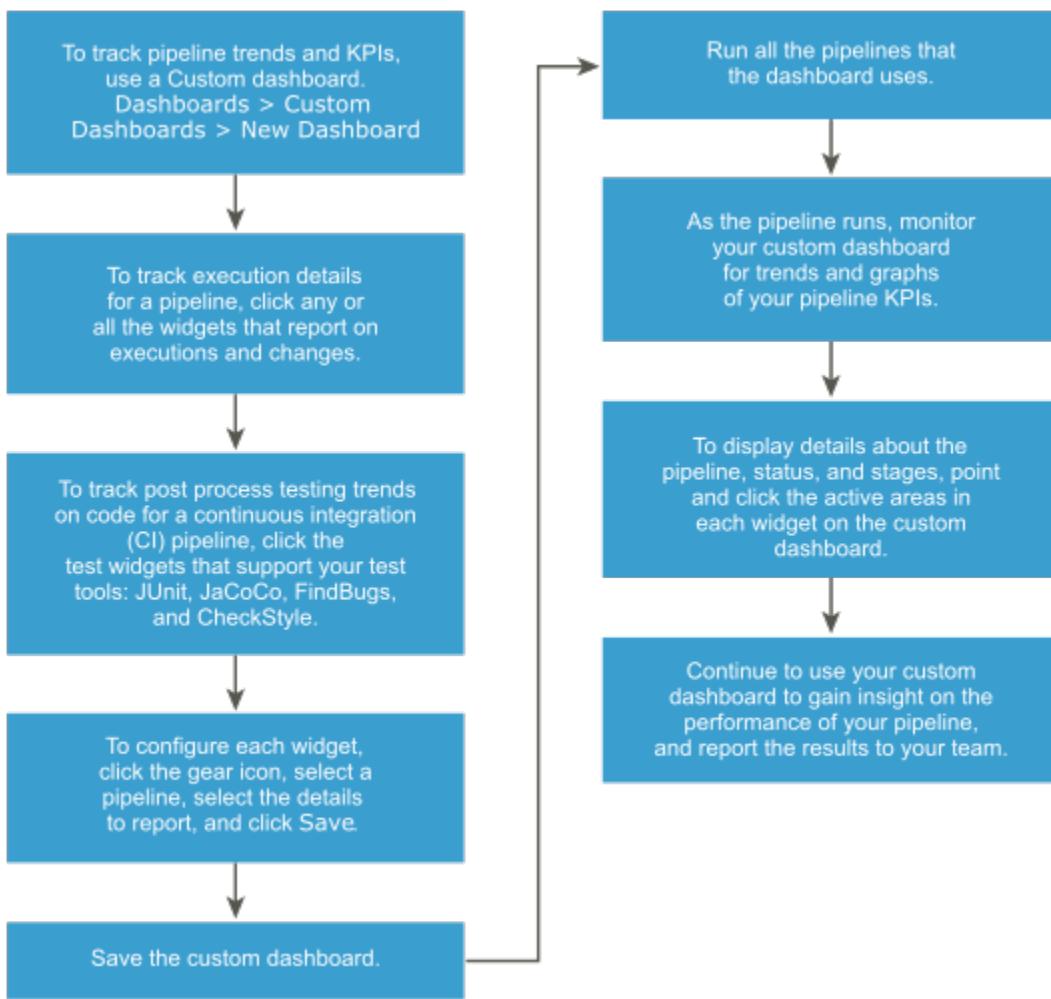

How do I use custom dashboards to track key performance indicators for my pipeline in Automation Pipelines

How do I use custom dashboards to track key performance indicators

As a Automation Pipelines administrator or developer, you create the custom dashboard to display the results you want to see for one or more pipelines that ran. For example, you can create a project-wide dashboard with KPIs and metrics gathered from multiple pipelines. If an execution warning or failure is reported, you can use the dashboard to troubleshoot the failure.

- Verify that one or more pipelines exist. In the user interface, click **Pipelines**.
- For the pipelines that you intend to monitor, verify that they ran successfully. Click **Executions**.

To track trends and key performance indicators for your pipelines by using a custom dashboard, you add widgets to the dashboard, and configure them to report on your pipelines.

1. To create a custom dashboard, click **Dashboards > Custom Dashboards > New Dashboard**.
2. To customize the dashboard so that it reports on specific trends and key performance indicators for your pipeline, click a widget.

For example, to display details about the pipeline status, stages, tasks, how long it ran, and who ran it, click the **Execution Details** widget. Or, for a continuous integration (CI) pipeline, you can track the trends on post-processing by using the widgets for JUnit, JaCoCo, FindBugs, and CheckStyle.

The screenshot shows the 'IX KPIs' dashboard with the 'Execution Details' table. The table has columns: Execution ID, Execution#, Status, Status Message, Stages, Tasks, Task0 (Stage0), and Duration.

Execution ID	Execution#	Status	Status Message	Stages	Tasks	Task0 (Stage0)	Duration
178f62eef...	#2	WAITING	Stage0.Task0 Execution Waiting for User Action.	●	☒	☒	15s
5503c1e51...	#1	COMPLETED	Execution Completed.	●	✓	✓	1h 28m 7s

3. Configure each widget that you add.
 - a) On the widget, click the gear icon.
 - b) Select a pipeline, set the available options, and select the columns to display.
 - c) To save the widget configuration, click **Save**.

- d) To save the custom dashboard, click **Save**, and click **Close**.
4. To display more information about the pipeline, click the active areas on the widgets.

For example, in the **Execution Details** widget, click an entry in the Status column to display more information about the pipeline execution. Or, on the **Latest Successful Change** widget, to display a summary of the pipeline stage and task, click the active link.

Congratulations! You created a custom dashboard that monitors trends and KPIs for your pipelines.

Continue to monitor the performance of your pipelines in Automation Pipelines, and share the results with your manager and teams to continue to improve the process to release your applications.

Using Automation Orchestrator

Using VMware Aria Automation Orchestrator provides information about the workflow automation features and functionality of the Automation Orchestrator Client.

The VMware Aria Automation Orchestrator user interface

You use the Automation Orchestrator Client to manage VMware Aria Automation Orchestrator services and objects.

You can access the Automation Orchestrator Client at https://your_Automation-Orchestrator_FQDN/orchestration-ui.

UI element	Description
Dashboard	Use the Automation Orchestrator Client Dashboard and profiling feature to gather useful metric data about your VMware Aria Automation Orchestrator environment and workflows.
Workflows	Create, edit, schedule, run, and delete workflows.
Actions	Create, edit, and delete actions. The action editor supports automatic completion for common script elements included in the VMware Aria Automation Orchestrator API Explorer.
Policies	Create, edit, run, and delete policies.
Packages	Create, delete, export, and import packages containing VMware Aria Automation Orchestrator objects.
Configurations	Create, run, and delete configuration elements.
Resources	Export, import, and update resource elements.
Groups	Users with administrator rights can assign roles to users in the Automation Orchestrator Client and add them to groups.
Audit Logs	View the different events, such as when an object is created, that are recorded in the Automation Orchestrator Client.
Git Repositories	Create an integration to a Git repository and use the integration to manage the development of workflows and other VMware Aria Automation Orchestrator objects across multiple deployments. See How Can I Use Git Branching to Manage My Object Inventory .
Deleted Items	Restore deleted Automation Orchestrator Client objects, such as workflows, actions, policies, configuration elements, and resource elements.
API Explorer	Explore the API commands available in the Automation Orchestrator Client. NOTE The Automation Orchestrator Client communicates with the VMware Aria Automation Orchestrator REST API through a REST proxy.

Automation Orchestrator Client Usage Dashboard

The Automation Orchestrator Client dashboard provides a useful tool for monitoring, managing, and troubleshooting Automation Orchestrator Client workflows.

Information on the Automation Orchestrator Client dashboard is spread among five panels.

Window	Description
Workflow runs	Provides visual data about the number of running, waiting, and failed workflow runs.
Favorite workflows	Displays workflows added to favorites.
Waiting for input	Displays pending workflow runs that require further user interaction. These workflows are also displayed in the notifications menu in the upper-right corner of the UI.
Recent workflow runs	Manage recent workflow runs. Shows the name, state, start date, and end date of the workflow run.
Requiring Attention	Displays failed workflow runs and workflow run performance metrics.

Intended Audience

This information is intended for experienced system administrators who are looking for a tool that can help them to run and manage VMware Aria Automation Orchestrator workflows.

Content organization in the Automation Orchestrator Client

Content organization

Manage how your VMware Aria Automation Orchestrator object inventory is displayed in the Automation Orchestrator Client.

The Automation Orchestrator Client supports three different view types for objects such as workflows, actions, policies, resources, and configurations: Card View, List View, and Tree View. You can change the current view type from the top-right corner of the page.

Card View

The Card View is the default view type used in the Automation Orchestrator Client. Information on the individual inventory object, such as a workflow, is displayed in a separate card element.

The screenshot shows the VMware Aria Automation 8.18 Automation Orchestrator Client interface. On the left, there is a sidebar with various navigation icons. The main area is titled "Workflows" and shows "20 of 465" items. A "Filter..." search bar is present. Below it, a "NEW WORKFLOW" button is highlighted in blue. The main content area displays three workflow cards in a grid:

- Python workflow 2**: PythonFolder, Version: 1.0.0. Buttons: OPEN, RUN, ACTIONS ▾.
- Python workflow 1**: PythonFolder, Version: 1.0.0. Buttons: OPEN, RUN, ACTIONS ▾.
- Execute a custom query on a database**: Library, SQL, Version: 0.0.1. Buttons: DETAILS, RUN, ACTIONS ▾.

At the top right of the main area, there are additional buttons for "Edit", "Help", and "View".

List View

List View displays information on your VMware Aria Automation Orchestrator objects organized as a list. For more information about the actions you can perform on the object, click the vertical ellipses icon to the left of the object.

Name	Tags	Version	Description
Python workflow 2	PythonFolder	1.0.0	
Python workflow 1	PythonFolder	1.0.0	
Execute a custom query on a database	Library SQL	0.0.1	Executes a custom query on a specified database and returns the number of affected rows. You can run the workflow to update, delete, and insert queries.
JDBC URL generator	Library JDBC	0.0.8	Solicits information to generate a connection URL for JDBC database connections. The workflow emits the connection string it generates as output via the system log, and confirms the string can create a connection to the specified database.

Tree View

You can organize your object inventory under hierarchical folders in Tree View. Each VMware Aria Automation Orchestrator object type has a root level folder. You cannot create new objects, such as workflows, under the root folder. You must create separate folders organized under the root folder. Each folder includes tools to help you manage its content, such as a content filter.

NOTE

Each folder has a separate content filter. You cannot filter content across folders.

For more information about folders, see [Create a folder or subfolder in the Automation Orchestrator Client](#).

NOTE

When you select an object from the Tree View, it opens in a read-only mode. To edit the object content, such as workflow variables or the workflow schema, click **Edit** from the top options menu.

Name	Type
Python workflow 1	Workflow
Python workflow 2	Workflow

Create a folder or subfolder in the Automation Orchestrator Client

Create folders or subfolders

Organize your VMware Aria Automation Orchestrator objects by using a hierarchical folder structure.

You can create folders and subfolders to organize the following types of VMware Aria Automation Orchestrator objects:

- Workflows
- Actions
- Policies
- Configuration elements
- Resource elements

1. Log in to the Automation Orchestrator Client.
2. From the left navigation pane, select an object page, such as **Workflows**.

3. From the top-right, select the tree view icon ().
4. To create a subfolder, select a parent folder from the tree view on the left.
5. Click **New Folder**.
6. Enter a name and description, and click **Save**.
7. Add objects or subfolders to the newly created folder.
8. To edit the folder name, select **Actions > Edit**.

Move objects or folders in the Automation Orchestrator Client

Move objects or folders

Reorganize your VMware Aria Automation Orchestrator content by moving the content into another folder.

You cannot move actions between action modules, or move any objects to a root folder. The root folder includes the main object folders and subfolders, but cannot be used to store objects.

1. Log in to the Automation Orchestrator Client.
2. From the left navigation pane, select an object page, such as **Workflows**.

3. From the top-right, select the tree view icon ().
4. Expand the tree view, and select the object or folder you want to move.
5. Drag the object or folder to its new parent folder.

NOTE

You can also move objects into new folders directly from the object editor. On the **Summary** tab, click **Select Folder**, and select the new parent folder for the object. Another move option is to select objects from the table on the folder page. This option is useful for performing batch move operations that include multiple VMware Aria Automation Orchestrator objects.

Delete a Folder or Subfolder in the Automation Orchestrator Client

Delete Folders or Subfolders

Delete obsolete folders or subfolders from your Automation Orchestrator Client.

You cannot delete the corresponding root-level folder of each VMware Aria Automation Orchestrator object type.

1. Log in to the Automation Orchestrator Client.
2. From the left navigation pane, select an object page, such as **Workflows**.

3. From the top-right, select the tree view icon ().
4. Tick the check box next to the folder you want to delete.

NOTE

To delete a subfolder, select the parent folder from the tree view and then tick the check box.

5. Click **Delete**.
6. If the selected folder is empty.
 - a) Confirm that you want to delete to folder.
 - b) Click **Delete**.
7. If the selected folder contains Automation Orchestrator Client objects or subfolders.
 - a) Confirm that you want to delete the folder.
 - b) Click **Delete**.
You receive the message Could not delete item 'your_folder_name': Folder 'your_folder_name' is not empty.
 - c) To delete the folder and all its content, click **Force delete**.
 - d) Confirm that you want to delete the folder, and click **Delete**.

NOTE

You can also perform a batch delete by selecting multiple objects from the table included in the folder menu.

Setting up the Automation Orchestrator Client for your organization

Setting up the Automation Orchestrator Client

To take full advantage of the functionality of the Automation Orchestrator Client, you must configure your user permissions and learn how you can use version history to manage your objects.

VMware Aria Automation Orchestrator user roles and group permissions

User roles and groups

VMware Aria Automation Orchestrator administrators can set permissions that control access to features and content in the Automation Orchestrator Client. Access rights are separated into user roles and group permissions.

Roles control what Automation Orchestrator Client features users can view and use. Access to the role management functionality depends on the license type of your VMware Aria Automation Orchestrator environment.

Table 85: License-Based Access to VMware Aria Automation Orchestrator Role Management

License	Authentication	
	vSphere	VMware Aria Automation
VMware vSphere Standard	Roles management is not available. Groups support only Run permissions.	Not applicable
VMware vSphere Foundation		
VMware Cloud Foundation	Manage roles in the Automation Orchestrator Client.	Manage roles through Identity and Access Management in VMware Aria Automation. See Configure Roles in

Table continued on next page

Continued from previous page

License	Authentication	
	vSphere	VMware Aria Automation
	See Assign Roles in the Automation Orchestrator Client .	

Group permissions control what Automation Orchestrator Client content users can view and use, such as workflows, actions, policies, configuration elements, and resource elements. Access to out of the box system VMware Aria Automation Orchestrator content like standard workflows and actions is shared among all users.

Access rights of users with administrator and viewer roles are not restricted by group permissions. Access rights of users without an assigned role and users with a workflow designer role depend on the group assigned to them. You can extend the access rights of these users by modifying their group permissions. In this way, you can organize users into common projects. For example, you can create a group that includes users working on developing a custom VMware Aria Automation Orchestrator plug-in and allow them to modify only content that is specific to their group.

Table 86: VMware Aria Automation Orchestrator User Roles and Groups Permissions

Role	Access Rights					
Administrator	Administrators can access all Automation Orchestrator Client features and content, including the content created by specific groups. Responsible for setting user roles, creating and deleting groups, and adding users to groups. Administrators are not limited by group permissions.					
	Tenant administrators from VMware Aria Automation environments used to authenticate VMware Aria Automation Orchestrator have Administrator rights by default.					
Viewer	Viewers have read-only access to all content in the Automation Orchestrator Client, but cannot create, edit, run, or export content. Viewers can also see all groups and group content. Viewers are not limited by group permissions.					
The Viewer role overwrites the Workflow Designer role when set to the same user account.						
Group Permissions						
	No assigned group	Run	Run and edit			
Workflow Designer	<ul style="list-style-type: none"> View system content. View and run own content. Create, run, edit, and delete own content. 	<ul style="list-style-type: none"> View system content View and run own runs. Create, run, edit, and delete own content. Add own content to the group. Run group content, but cannot edit it. 	<ul style="list-style-type: none"> View system content. View and run own runs. Create, run, edit, and delete own content. Add own content to the group. Run and edit group content. <p>Not available for VMware Aria Automation Orchestrator instances authenticated with vSphere.</p>			
User without an assigned role	<ul style="list-style-type: none"> View own runs. Respond to user interaction requests. 	<ul style="list-style-type: none"> View and run own runs. View and run group content. 	<ul style="list-style-type: none"> View and run own runs. View and run group content. 			

Table continued on next page

Continued from previous page

Role	Access Rights
	<p>These access rights are granted by default to users in VMware Aria Automation and vSphere without an assigned VMware Aria Automation Orchestrator role and group.</p> <p>To be able to create, edit, and add content, users in this group must be assigned a Workflow Designer role.</p> <p>Not available for VMware Aria Automation Orchestrator instances authenticated with vSphere.</p>

Assign Roles in the Automation Orchestrator Client

As an administrator, you can add users to the Automation Orchestrator Client and set what features they can view and use.

Role management controls the access of users from the VMware Aria Automation Orchestrator identity provider to the features of the Automation Orchestrator Client. Role management covers both the Automation Orchestrator Client user interface and the API functionality.

NOTE

Client-side role management is only available for VMware Aria Automation Orchestrator instances authenticated with vSphere that use a VMware Cloud Foundation license. For information on assigning roles to VMware Aria Automation Orchestrator authenticated with VMware Aria Automation, see [Configure Roles in](#).

1. Log in to the VMware Aria Automation Orchestrator as an administrator.
2. Navigate to **Administration > Roles Management**.
3. Click **Add**.
4. Search for the user or group you want to add to the Automation Orchestrator Client.
5. Select the user's role. For more information on roles, see [user roles and group permissions](#).
6. Click **Save**.

Configure Automation Orchestrator Client Roles in VMware Aria Automation

You can assign service roles for the Automation Orchestrator Client in the **Identity & Access Management** page in VMware Aria Automation. Service roles can be assigned for the embedded Automation Orchestrator Client and standalone VMware Aria Automation Orchestrator instances authenticated with VMware Aria Automation.

- Verify that appropriate users and groups are imported from a valid vIDM instance.
- Before assigning a VMware Aria Automation Orchestrator service role to your user, verify that your user has an assigned organization role in VMware Aria Automation. See, *Administering Users and Groups in VMware Aria Automation* in *Administering VMware Aria Automation*.

VMware Aria Automation Orchestrator service roles manage what features of the embedded Automation Orchestrator Client users can access. For more information on VMware Aria Automation Orchestrator roles, see [user roles and group permissions](#).

NOTE

Standalone VMware Aria Automation Orchestrator instances authenticated with vSphere that use a VMware Cloud Foundation license can assign roles directly in the Automation Orchestrator Client. See [Assign Roles in the Automation Orchestrator Client](#).

1. From the top-right header drop-down menu, select the **Identity & Access Management** option.

2. On the **Active Users** tab, search for the email address of the user you want to assign to VMware Aria Automation Orchestrator.
3. Select the check box next to the user, and click **Edit Roles**.
4. Click **Add Service Access**.
5. From the left drop-down menu, select **Orchestrator**.
6. From the right drop-down menu, select the role you want to assign to the user.
7. Click **Save**.

Create Groups in the Automation Orchestrator Client

As an administrator, you can use groups to set what VMware Aria Automation Orchestrator content users can view and access in the Automation Orchestrator Client.

You can use the Automation Orchestrator Client to set group permissions to VMware Aria Automation Orchestrator workflows, actions, policies, configuration elements, resource elements, and packages.

NOTE

Users from VMware Aria Automation Orchestrator instances authenticated with vSphere, can only have **Run** group permissions.

1. Log in to the VMware Aria Automation Orchestrator as an administrator.
2. Navigate to **Administration > Groups**.
3. Click **New Group**.
4. On the **Summary** tab, add a name and description for the group.
5. On the **Users** tab, click **Add**.
 - a) Search for a user you want to add to the group.
 - b) Assign group permissions to the user.
 - c) Click **Add**.
6. On the **Items** tab, add VMware Aria Automation Orchestrator objects to the group.

NOTE

You can also add an object to existing groups when that object is being created in the Automation Orchestrator Client. To add the object, select the group from the **Accessible by** drop-down menu on the **Summary/General** tab of the object editor.

7. Click **Save**.

VMware Aria Automation Orchestrator Object Version History

The Automation Orchestrator Client maintains a version history record for each VMware Aria Automation Orchestrator object. Using the version history, you can compare different VMware Aria Automation Orchestrator object versions and revert to a previous version.

VMware Aria Automation Orchestrator creates a version history record for each VMware Aria Automation Orchestrator object when you save the object. Subsequent changes to VMware Aria Automation Orchestrator objects create a new version history record. The previous versions history records are preserved and can be used to track changes to the object and revert the object to a previous version. Reverting an object to a previous version creates a new version history record.

The Automation Orchestrator Client tracks the version history of the following VMware Aria Automation Orchestrator objects:

- Workflows
- Actions

- Packages
- Policies
- Resource elements
- Configuration elements

NOTE

Generated workflows do not appear in the workflow version history. For example, the workflows generated by the **Generate CRUD workflows for a table** workflow do not appear on the **Version History** tab and cannot be pushed to any configured Git repositories. To include these workflows in the VMware Aria Automation Orchestrator version history, duplicate the generated workflows.

You can access the version history of an object from the **Version History** tab of the object editor page. If you are attempting to edit an object at the same time as another user, a merge conflict might occur. To resolve the merge conflict, click **Resolve** to the right of the error message. On the **Resolve Conflicts** window you have three options:

- **Use theirs**. Resolve the merge conflict by using the changes made by the other user.
- **Use ours**. Resolve the merge conflict by using your changes.
- **Resolve**. Resolve the merge conflict by editing the displayed change model. If the provided model is invalid, this option is unavailable.

Restore a Workflow to an Earlier Version

You can restore a workflow to a previously saved version.

1. Log in to the VMware Aria Automation Orchestrator Client.
2. Navigate to **Library > Workflows**, and select a workflow.
3. Select the **Version History** tab.
4. To view a comparison between the versions, select a workflow version and select another version from the **Diff against** drop-down menu.
A window displays the differences between the current workflow version and the selected workflow version.
5. To restore the workflow to another version , click **Restore**.
The workflow state is reverted to the state of the selected version.

NOTE

You can also restore a workflow version from the graphic difference tool view. See [Visual Comparison Between Workflow Versions](#).

Visual Comparison Between Workflow Versions

Compare changes between workflow versions with the graphic difference tool.

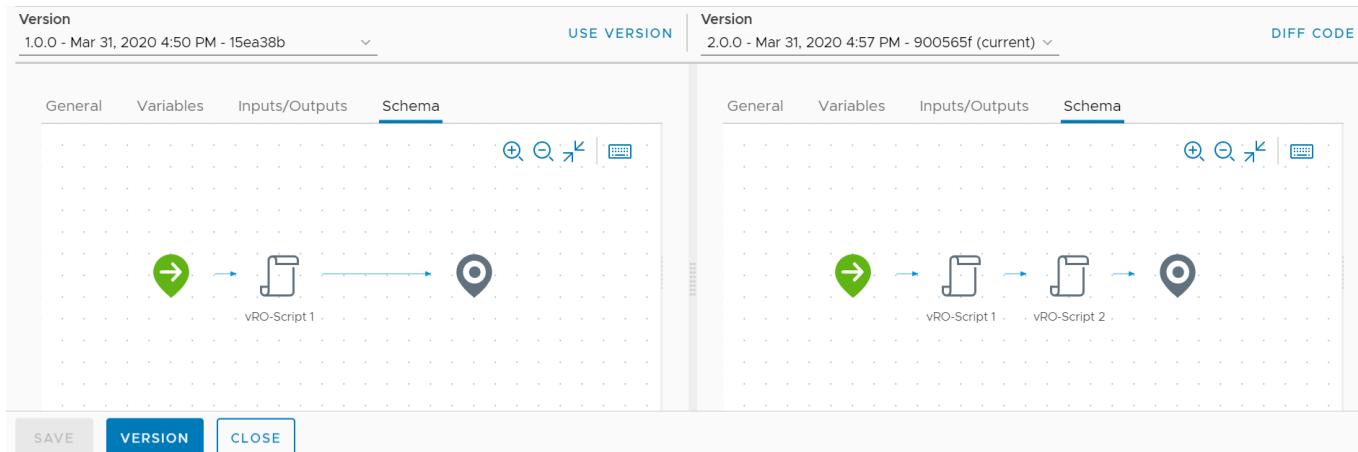

Create a workflow.

By default, the VMware Aria Automation Orchestrator Version History displays differences between workflow versions in a YAML form. You can also perform a visual comparison between different workflow versions. You can view changes in:

- The general workflow information, such as version number and workflow description.
 - The variables used in the workflow.
 - The input and output parameters of the workflow.
 - The workflow schema.
1. Log in to the Automation Orchestrator Client.
 2. Navigate to **Library > Workflows**, and select one of your workflows.
 3. Edit the content of the workflow.
For example, you can add an extra **Scriptable task** element on the **Schema** tab.

4. Click **Save**.
5. Select the **Version History** tab.
6. From the top-right, select **Diff Visually**.

You can now perform a visual comparison between two selected workflow versions. You can select which versions to compare from the **Version** drop-down menu.

7. You can restore a workflow to another version by selecting **Use Version**.

Reset Your VMware Aria Automation Orchestrator Content Inventory to a Previous State with Git

By using an earlier Git commit, you can reset your VMware Aria Automation Orchestrator content to an earlier state.

- Configure a connection to a GitHub or GitLab repository. See [Configure a Connection to a Git Repository](#).
- Push a local change set to the configured Git repository.

You can reset your VMware Aria Automation Orchestrator content to a previous state by selecting a specific commit.

1. Log in to the Automation Orchestrator Client.
2. Navigate to **Administration > Git History**.
3. Select a change set you want to reset to and click **Reset to this**.
4. Confirm that you want to reset to this specific commit and click **Ok**.

The VMware Aria Automation Orchestrator content inventory is reset to the state specified in the commit. Relevant VMware Aria Automation Orchestrator content is reverted to a previous version. If the content did not exist when the commit was pushed, it is removed from the inventory.

To restore the VMware Aria Automation Orchestrator inventory to the latest state saved to the Git repository, perform a **Pull** command from the **Git History** window.

VMware Aria Automation Orchestrator Use Cases

These use cases demonstrate part of the functionality of the VMware Aria Automation Orchestrator platform.

These use cases present example values only. Your own environment structure and naming conventions can vary.

How Can I Use Git Branching to Manage My VMware Aria Automation Orchestrator Object Inventory

Use branching to organize how your VMware Aria Automation Orchestrator content is managed in your Git repository.

By using Git, you can increase the flexibility for your VMware Aria Automation Orchestrator developers by providing a centralized repository. For example, you can use Git to manage the workflow development across multiple VMware Aria Automation Orchestrator environments.

NOTE

To use Git to manage your object inventory, your VMware Aria Automation Orchestrator deployment must use a VMware Cloud Foundation license. For more information, see *VMware Aria Automation Orchestrator Feature Enablement with Licenses* in *Installing and Configuring VMware Aria Automation Orchestrator*.

You can now push and pull objects to and from branches. You can use branching to manage the development of specific groups of VMware Aria Automation Orchestrator objects, before they are merged back into your main branch.

In this use case, you are using a GitLab project to manage VMware Aria Automation Orchestrator objects that use the Python runtime. This use case represents an example of the Git functionality in VMware Aria Automation Orchestrator and does not represent the limits of the feature scope.

NOTE

If you are more familiar with GitHub, you can use a GitHub repository for this use case.

Prepare Your GitLab Environment

Create a Git branch for your VMware Aria Automation Orchestrator Python objects.

Create a GitLab project for your VMware Aria Automation Orchestrator environment. See [Create a project](#).

1. Log in to your GitLab account.
2. Navigate to your GitLab project.
3. On the left navigation pane, select **Repository** > **Branches**.
4. On the **Overview** tab, click **New Branch**.
5. Under **Branch name**, enter `Python-branch`.
6. Leave the **Create from** option as `master`.
7. Click **Create branch**.

You have created a branch for your Python-based VMware Aria Automation Orchestrator objects.

The screenshot shows the 'Branches' page in a GitLab project. The left sidebar has links for Repository, Files, Commits, Branches (which is selected and highlighted in blue), Tags, Contributors, Graph, Compare, and Issues (with 0 results). The main area has tabs for Overview, Active, Stale, and All. A search bar says 'Filter by branch name' and a red button says 'Delete merged branches'. A green button says 'New branch'. Below, it says 'Protected branches can be managed in project settings'. Under 'Stale branches', there is one entry for 'test_branch'. Under 'All branches', there are three entries: 'test_branch' (stale, 0 commits, merge request, compare, delete), 'master' (default, protected, stale, 0 commits, merge request, compare, delete), and 'Python-branch' (stale, 0 commits, merge request, compare, delete).

Branch	Status	Commits	Actions
test_branch	Stale	0	Merge request, Compare, Delete
master	Stale	0	Merge request, Compare, Delete
Python-branch	Stale	0	Merge request, Compare, Delete

Configure a Connection to a Git Repository

As an **administrator**, you can configure a connection between your VMware Aria Automation Orchestrator deployment and a Git repository or project.

- Verify that your VMware Aria Automation Orchestrator environment uses a VMware Cloud Foundation license.

- Generate an access token for your GitLab project and copy it to your clipboard for use during the configuration process. See [Creating a personal access token](#).

NOTE

For this use case, you are using a GitLab project. If you are more familiar with GitHub, you can use a GitHub repository. For information generating a GitHub token, see [Creating a personal access token for the command line](#).

To use Git for management of your VMware Aria Automation Orchestrator object inventory, you must configure a connection to your Git repository by using the Automation Orchestrator Client.

NOTE

You cannot add multiple Git repositories from different accounts over SSH because VMware Aria Automation Orchestrator creates one SSH key for each instance. To add multiple Git repositories, you can add them over HTTP as described in this documentation.

Be aware of the following limitations when using a Git repository with your VMware Aria Automation Orchestrator deployment:

- Only SHA-1 commit hashes are supported.
- SHA-1 commit hash conflict between the internal Git repository and the remote Git repository are possible and are not automatically resolved. In such scenarios, all local changes should be discarded.
- Performing manual changes in the Git repository causes merge conflicts when pulling the remote Git repository in the Automation Orchestrator Client. If the end of line sequence is changed both revisions will appear to be the same, but will always result in a merge conflict that must be resolved.

1. Log in to the Automation Orchestrator Client as an **administrator**.
2. Navigate to **Administration** > **Git Repositories**.
3. Click **Add Repository**.
4. Enter the URL address of your Git repository.
For example, <https://gitlab.com/myusername/my-vro-repo>.

NOTE

You can also establish a connection with the SSH protocol.

5. Enter the user name for your Git profile.
6. Enter the access token of your Git repository.
7. To validate the connection to the Git repository, click **Validate**.
8. Change the name used to identify the repository in the Automation Orchestrator Client.
9. Add a short description for the connected Git repository.
10. To activate the connected Git repository, click **Make active repository**.

NOTE

Only one Git repository can be active at a time. You can change the active Git repository from the **Git Repositories** page.

11. Select the branch to which you want to push your changes. For this use case, you are using **Python-branch**. See [Prepare Your GitLab Environment](#).

NOTE

You can change the selected Git branch at any time after you finish the initial Git configuration.

12. To finish the configuration process, click **Save**.

Navigate back to the **Git Repositories** menu and confirm that the status of the repository is **Active**.

Push Changes to a Git Repository

Push the changes that you made to local VMware Aria Automation Orchestrator objects to your integrated Git repository. In this use case, you push changes to a Python-based VMware Aria Automation Orchestrator action to a specific Git branch.

- Verify that you have created a Git branch. See [Prepare Your GitLab Environment](#).
- Verify that you have configured a connection with a Git repository. See [Configure a Connection to a Git Repository](#).
- Verify that your Git integration is set to push changes to the **Python-branch** Git branch.
- Create a Python-based VMware Aria Automation Orchestrator object.

You can push a local change set to a Git repository. Each change set can consist of one or more modified VMware Aria Automation Orchestrator objects.

NOTE

The process of pushing and discarding change sets to a Git repository is not limited by group permissions. Therefore, a workflow developer from one group can push or discard local changes made by another developer.

1. Log in to the Automation Orchestrator Client.
2. Edit your Python action.
 - a) Navigate to **Library > Actions**, and select your Python action.
 - b) Make some minor changes to the action, such as changing the description.
 - c) Save the action.
3. Push your changes to the Git repository.

NOTE

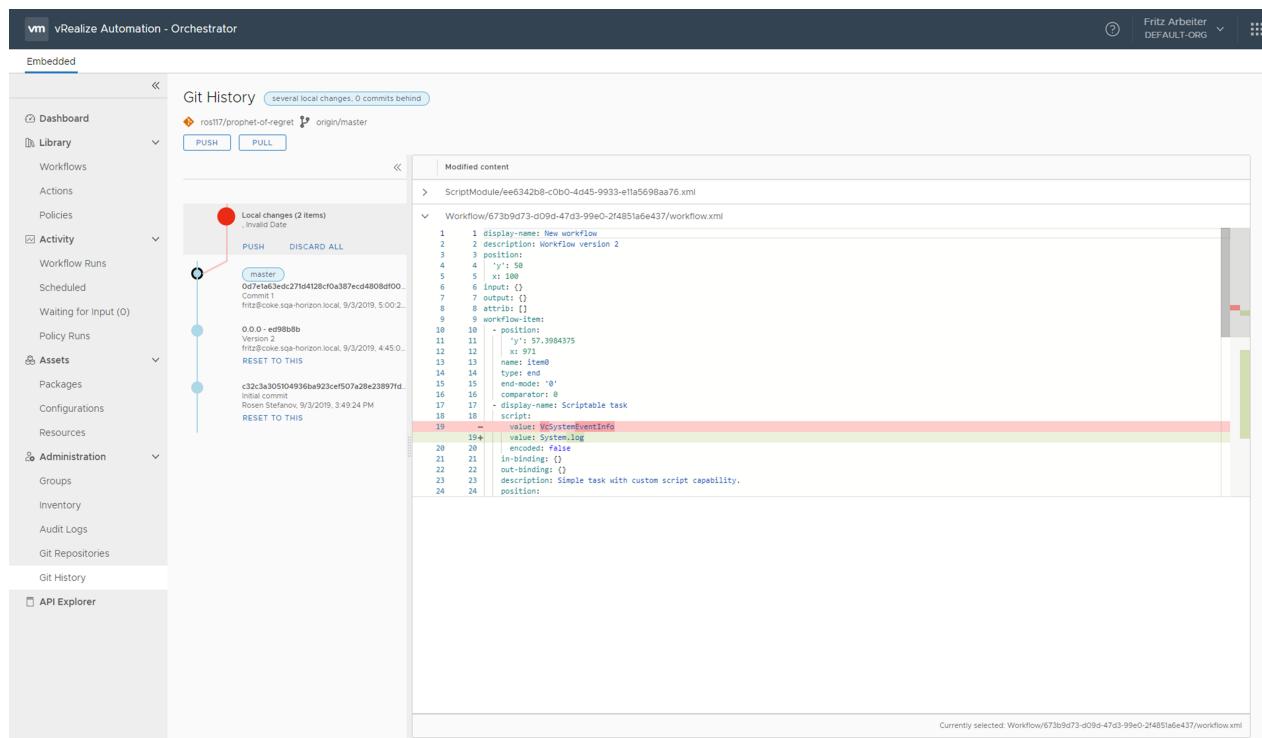

You can also push local changes on a per-object level by clicking the **Version** option displayed at the bottom of the object editor.

- a) Navigate to **Administration > Git History**.

The **Git History** page displays the current differences between the local version branch and the selected Git repository branch. You can expand the entry for any modified VMware Aria Automation Orchestrator object to view the version differences.

NOTE

You can discard a local change set by select **Discard all**.

- b) Click **Push**.
 - c) Enter a commit title.
 - d) Enter a short description for the commit.
 - e) Select the changes to your Python action that you want to push to the Git repository.
4. To finish pushing the local change set to the Git repository, click **Push**.

After you finish development in your Git branch, merge it with the main branch. See [How to create a merge request](#).

Managing Workflows

A workflow is a series of actions and decisions that you run sequentially. VMware Aria Automation Orchestrator provides a library of workflows that perform common management tasks. VMware Aria Automation Orchestrator also provides libraries of the individual actions that the workflows perform.

Workflows combine actions, decisions, and results that, when performed in a particular order, finish a specific task or a specific process in a virtual environment. Workflows perform tasks such as provisioning virtual machines, backing up, performing regular maintenance, sending emails, performing SSH operations, managing the physical infrastructure, and other general utility operations. Workflows accept inputs according to their function. You can create workflows that run according to defined schedules, or that run if certain anticipated events occur. Information can be provided by you, by other users, by another workflow or action, or by an external process such as a Web service call from an application. Workflows perform some validation and filtering of information before they run.

Workflows can call upon other workflows. For example, you can have workflow that calls up another workflow to create a new virtual machine.

You create workflows by using the Automation Orchestrator Client interface's integrated development environment (IDE), that provides access to the workflow library and the ability to run workflows on the workflow engine. The workflow engine can also take objects from external libraries that you plug in to VMware Aria Automation Orchestrator. This feature allows you to customize processes or implement functions that third-party applications provide.

Standard workflows in the VMware Aria Automation Orchestrator workflow library

VMware Aria Automation Orchestrator provides a standard library of workflows that you can use to automate operations in your virtual infrastructure. The workflows in the standard library are locked in the read-only state. To customize a standard workflow, you must duplicate that workflow. Duplicate workflows or custom workflows that you create are fully editable.

You can access the workflow library are accessible at **Library > Workflows**. Both standard and custom workflows are organized by using tags. For example, to access the **Generate key pair** workflow, enter **SSH** in the workflow library search box.

NOTE

You cannot add new tags to standard workflows, unless you duplicate the workflow.

Create Workflows in the Automation Orchestrator Client

Create Workflows

You can use the Automation Orchestrator Client to create and edit workflows.

1. Log in to the VMware Aria Automation Orchestrator Client.
2. Select **Library > Workflows**.
3. Click **New Workflow**.
4. Enter the name of the new workflow and click **Create**.
5. Use the workflow editor to configure the variables, workflow inputs and outputs, schema structure, and presentation of the workflow.
6. To finish editing the workflow, click **Save**.

NOTE

You can track changes to workflows in the **Version History** tab. For more information, see [Object Version History](#).

You can use the VMware Aria Automation Orchestrator token replay feature to optimize the performance of your workflows. For more information, see [Using Workflow Token Replay in the](#) .

Edit Workflows and Actions from the Parent Workflow

Edit workflows and actions directly from the parent workflow in the Automation Orchestrator Client.

Create a workflow that calls up another workflow, action, or both.

Editing child workflows and actions directly from the parent workflow can help streamline workflow development.

1. Log in to the VMware Aria Automation Orchestrator Client.
2. Navigate to **Library > Workflows**, and select your workflow.
3. Select the **Schema** tab.
4. Depending on the object type, double-click the **Workflow element** or **Action element** in the workflow canvas.
5. Edit the object.
6. To finish editing the child workflow or action, click **Save**.
7. To return to the parent workflow, close the object editor.

VMware Aria Automation Orchestrator Input Form Designer

If a workflow requires input parameters, it opens a dialog box in which users enter the required values. You can organize the content, layout, and presentation of this dialog box with the input form designer.

The input form designer is located in the **Input Form** tab of the workflow editor. This designer consists of a navigation menu, design canvas, and properties menu. You can drag inputs and generic elements from the left menu to the design canvas. In the canvas, you can set the position of the input parameters, organize them into separate input tabs, and configure the input parameter properties.

NOTE

You cannot use content from the **Variables** tab of the workflow editor in the input form designer. You can only use parameters from the **Input/Output** tab.

Generic elements

You can add generic elements, like drop-down menus and password text boxes, to the input form designer. Generic elements do not correspond to actual input parameters, but can be bound to input parameters.

Create the Workflow Input Parameters Dialog Box in the Automation Orchestrator Client

You can use the input form designer to create and customize the workflow input parameter dialog box.

Verify that the workflow has a defined list of input parameters.

1. Log in to the VMware Aria Automation Orchestrator Client.
2. Navigate to **Library > Workflows**.
3. Select your custom workflow.
4. Click the **Input Form** tab.
5. Create tabs for use in the input dialog box.

You can use tabs to organize the structure of your dialog box.

6. Select your input parameters.
7. Edit the properties of the input parameters.

For more information on input parameter properties, see [Input Parameter Properties in the](#) .

8. Add generic elements to the canvas and bind them to input parameters.
9. Add external validation to the input parameters. For more information, see [Validate workflow inputs using actions](#).
10. Click **Save**.

You created the layout of the workflow dialog box and set the properties of the input parameters.

Input Parameter Properties in the Automation Orchestrator Client

You can set parameter properties to constrain the input parameters that users provide when they run VMware Aria Automation Orchestrator workflows.

With VMware Aria Automation Orchestrator, you can define the parameter properties used to quantify the input parameter values used in workflows. The parameter properties you define impose limits on the types and values of the input parameters that users can provide in VMware Aria Automation Orchestrator workflows.

Parameter properties validate the input parameters and modify the presentation of the text boxes that appear in the input parameters dialog box. Some parameter properties can create dependencies between parameters.

Parameter Property	Description
Label	Set the input parameter label.
Display type	Set the input text box display type.
Visibility	Set the visibility of the input parameter.
Read-only	Set the input text box as read-only.
Custom help	Set the input parameter signpost description.
Default value	Set the default value of the input parameter.
Step	Used for number type inputs. Set by how much the value of the input parameter increases per click.
Required	Sets if the input parameter value is mandatory or not.
Regular expression	Validates the input by using a regular expression.
Minimum value	Set the minimum value or length of the parameter.
Maximum value	Set the maximum value or length of the parameter.
Match text box	Set the input parameter value to match the value of another input parameter.
Value source	<p>Set the value source of the parameter properties in the Appearance, Value, and Constraints tabs.</p> <p>NOTE You can import the value of external actions by using External source. The filtering of available actions is done by parameter type.</p>

Validate VMware Aria Automation Orchestrator workflow inputs using actions

Validate workflow inputs using actions

Use external actions to validate the inputs of your custom workflows.

Create a custom workflow with input parameters. For more information, see [Create Workflows in the](#).

You can use the input form designer to create external validations for your workflow inputs. External validations use action scripts that return a string value when the input parameter value contains an error. If the input parameter value is valid, the external validation returns nothing.

1. Log in to the VMware Aria Automation Orchestrator Client.
2. Create a validation action.
 - a) Navigate to **Library > Actions**.
 - b) Click **New Action**.
 - c) Enter the required information on the **Summary** tab.
 - d) Enter the validation action input parameters.

NOTE

The names of the validation action input parameters must be identical to the names of the workflow input parameters that are being validated.

- e) Enter the script of the validation action on the **Script** tab.

```
if (in_1=="invalid") {
    return "in_1 can't be
invalid!";
}

if (in_2=="invalid") {
    return "in_2 can't be
invalid!";
}

//inputs are valid, return nothing
```

NOTE

The preceding script is a simple example and does not represent the full scope of the validation scripts that can be used.

- f) Click **Save**.
3. Apply external validation.
 - a) Navigate to **Library > Workflows**.
 - b) Select your custom workflow.
 - c) Select the **Input Form** tab.
 - d) On the **Validations** tab, drag and drop the **Orchestrator validation** element into the canvas.
 - e) In the canvas, select the validation element, enter a validation label, and select the validation action.
 - f) Create additional validation elements.
 - g) Click **Save**.
4. Run the workflow.
If the validation encounters an error, it returns a string. If the validation is successful, the validation returns nothing and the workflow run continues.

You created an external validation for your custom VMware Aria Automation Orchestrator workflow.

Requests for User Interaction in the Automation Orchestrator Client

Workflows can request additional user input before they can finish.

Workflows requiring further user interaction suspend operations until the requested input parameters are provided by the user. Workflows define which users can provide the requested information and send requests for interaction accordingly. Workflows waiting for user input are displayed in the **Recent Workflow Runs** panel of the Automation Orchestrator Client dashboard and the top-right notification menu.

Schedule Workflows in the Automation Orchestrator Client

Schedule Workflows

You can use scheduling to automate your VMware Aria Automation Orchestrator workflow runs.

When you schedule workflow runs, you set the date, time, and intervals at which the scheduled task runs.

1. Log in to the VMware Aria Automation Orchestrator Client.
2. Select your workflow from the **Library** menu, and on the workflow panel, click **Schedule**.
3. Configure the scheduled task parameters in the **General**, **Scheduling**, and **Workflow** categories.

NOTE

The **Workflow** parameter category is visible only for workflows that require input parameters.

Parameter	Description
Name	The name of the scheduled task.
Description	A short description detailing the purpose of the scheduled task.
Start	The date and time of the first scheduled run of the workflow.
Start if in the past	Select whether to start the workflow, if the scheduled time is in the past. Yes starts the scheduled workflow immediately. No starts the workflow at the next scheduled recurrence.
Schedule	Set the recurrence pattern and event trigger entries of the scheduled task.

4. Click **Create**.

You have created a scheduled task for the workflow. Scheduled workflows appear under **Activity** > **Scheduled**. You can delete scheduled tasks by clicking **Delete** on the schedule panel.

Edit Scheduled Task in the Automation Orchestrator Client

Scheduled tasks can be edited to change parameters such as the starting user, date, time, and recurrence of the scheduled workflow.

Create a scheduled workflow task.

1. Log in to the VMware Aria Automation Orchestrator Client.
2. Select your scheduled task from **Activity** > **Scheduled**.
3. Click **Edit** on the workflow panel.
4. Edit the scheduled task parameters.

NOTE

Input parameters set when creating the scheduled task are read-only and cannot be edited. To change these parameters, create a new scheduled task for this workflow.

Parameter	Description
Starting user	Change the authentication of the scheduled task. Click Use Current User to set the scheduled task authentication to the current user. Editing this parameter can be useful for use cases where the authentication provider for VMware Aria Automation Orchestrator has changed and the previous user credentials used when creating the scheduled task are no longer valid. The new user authentication is set after changes to the scheduled task are saved.
Name	The name of the scheduled task.
Description	A short description detailing the purpose of the scheduled task.
Start	The date and time of the first scheduled run of the workflow.
Start if in the past	Select whether to start the workflow, if the scheduled time is in the past. Yes starts the scheduled workflow immediately. No starts the workflow at the next scheduled recurrence.
Schedule	Set the recurrence pattern and event trigger entries of the scheduled task.

- To finish editing the scheduled task, click **Save**.

Find Object References in Workflows

As a workflow developer, you can use object reference information to optimize your development life cycle.

Develop a workflow that includes at least one object reference.

With the Automation Orchestrator Client, you can find object reference information. This feature has two functions:

- **Find Dependencies:** find information about object dependencies in your workflows. Dependencies can include other workflows, actions, resource elements, and configuration elements.

NOTE

Found dependencies can also include commented out code. For example, a workflow can include a line of code referencing an action that is commented out. The addition of commented out code in the list of found dependencies is expected behavior.

- **Find Usages:** learn if the selected workflow is used in other workflows in the Automation Orchestrator Client library.

You can access information about object references from the workflow editor or from the Automation Orchestrator Client library in either Card View, List View, or Tree View. For more information on the different types of content organization of the Automation Orchestrator Client library, see [Content organization in the](#).

The following procedure demonstrates how you can access object references from the workflow editor.

1. Log in to the VMware Aria Automation Orchestrator Client.
2. Navigate to **Library > Workflows**, and select your workflow.
3. To find information about object dependencies, click **Find Dependencies**.

NOTE

While on the dependencies pop-up window, you can select referenced objects from the list. Selecting an object opens a separate Automation Orchestrator Client tab where you can view the details of the selected object or edit it.

4. To find information about where the selected workflow is used, click **Find Usages**.

VMware Aria Automation Orchestrator script environments

Script environments

You can now add modules and libraries for use in your VMware Aria Automation Orchestrator scripts as dependencies directly from the Automation Orchestrator Client.

In previous releases of VMware Aria Automation Orchestrator you could only add dependencies to your scripts by adding them to a ZIP package. You can now add modules and libraries you want to use as dependencies in your scripts by creating an environment directly from the Automation Orchestrator Client. Your environment can include multiple modules and libraries for use in your scripts.

In this use case, you are creating an lodash environment that you can use for your Node.js scripts in VMware Aria Automation Orchestrator.

NOTE

Similarly to other VMware Aria Automation Orchestrator objects such as workflows and actions, environments can be exported to other VMware Aria Automation Orchestrator deployments as part of a package.

1. Log in to the VMware Aria Automation Orchestrator Client.
2. Navigate to **Assets > Environments**, and click **New Environment**.
3. Under the **General** tab, enter a name for your environment.
4. Enter a description, version number, tags, and group permissions for the action.

NOTE

The ID is generated automatically after the environment is created.

5. Set the runtime environment and add dependencies and dependency variables.
 - a) Select the **Definitions** tab.
 - b) Under **Runtime Environment**, verify that Node.js is selected.
 - c) Edit the memory limit and timeout properties.
 - d) Under **Dependencies**, click **Add**, and enter the following values:

Name	lodash
Version	4.17.21
6. Click **Add**.
7. Add environment variables.
8. To finish creating your new script environment, click **Create**.
9. After the environment is created, select the **Download Logs** tab on the environment editor page and validate that the lodash library is downloaded successfully.

You can now use lodash in workflow scripting tasks or actions by selecting the environment from the **Runtime Environment** drop-down menu of your workflow scripting schema element or VMware Aria Automation Orchestrator action.

Managing Actions

You can modify your VMware Aria Automation Orchestrator workflows by adding actions scripts.

The Automation Orchestrator Client provides libraries of predefined actions and an action editor for custom action scripts. Actions represent individual functions that you use as building blocks in workflows.

Actions are JavaScript functions. Actions can take multiple input parameters and have a single return value. Actions can call on any object in the VMware Aria Automation Orchestrator API, or objects in any API that you import into VMware Aria Automation Orchestrator by using a plug-in.

When a workflow runs, an action takes input parameters from the workflow's variables. These variables can be either the workflow's initial input parameters, or variables that other elements in the workflow set when they run.

The action editor includes an autocomplete feature for scripts and an API Explorer featuring the available scripting types and their documentation.

Create Actions in the Automation Orchestrator Client

Create Actions

You can use the Automation Orchestrator Client to create, edit, and delete action scripts.

Before creating a Python, Node.js, or PowerShell script, verify that you are familiar with the core concepts for developing VMware Aria Automation Orchestrator compatible scripts that use these runtimes. See [Core Concepts for Python, Node.js, and PowerShell Scripts](#).

You can use the following runtimes when creating actions:

- Python 3.10
- Node.js 20
- PowerCLI 13 (PowerShell 7.4)

NOTE

The PowerCLI runtime includes PowerShell and the following modules: VMware.PowerCLI, PowerNSX, PowervRA.

- PowerShell 7.4

NOTE

The PowerCLI 12 and Node.js 18 runtimes are deprecated and will be removed in a future release.

1. Log in to the VMware Aria Automation Orchestrator Client.
2. Navigate to **Library > Actions**.
3. Click **New Action**.
4. On the **General** tab, enter the name and module name of the action.

NOTE

The name and module name must be unique for every action. The action name must be a valid JavaScript function. The action name must be a single word that can only contain letters, numbers, and the dollar ("\$") and underscore ("_") symbols. The module name must consist of words separated by the dot (".") character.

5. Create a description, version number, tags, and group permissions for the action.
6. On the **Script** tab, add action inputs, select the return type of the output, and write the script.
7. To finish editing the action, click **Save**.
A message states that the action is saved.

Running and Debugging Actions

You can improve your actions by running and debugging them directly from the action editor.

You can run and debug actions directly from the action editor of the Automation Orchestrator Client. With this feature, you can guarantee that your actions perform as expected when they are integrated into your workflows.

Run Actions in the Automation Orchestrator Client

Run Actions

As a workflow designer, you want to run your actions before integrating them into a workflow.

Create an action. See [Create Actions in the](#).

1. Log in to the Automation Orchestrator Client.
2. Navigate to **Library > Actions**, and select the action you want to run.
3. Click **Run**.
4. Enter the required input parameters, and click **Run**.

After the action run finishes, click the **Results/Inputs** tab. If the action run encountered an error, it is displayed on this tab in a red color. You can view the details of the action run from the **Action Results** element.

NOTE

The results of the action run are not saved.

Debug Actions in the Automation Orchestrator Client

Debug Actions

As a workflow designer, you can debug actions by inserting breakpoints into your script.

Create an action. See [Create Actions in the](#).

VMware Aria Automation Orchestrator includes a built-in debugging tool that you can use to debug the script and input properties of your action. The debug process can be initiated in the action editor by inserting breakpoints into the script lines of your action.

NOTE

The built-in debugging tool only works with actions that use the default JavaScript runtime.

1. Log in to the Automation Orchestrator Client.
2. Navigate to **Library > Actions**, and select the action you want to debug.
3. In the action editor, add breakpoints to the lines of your action script you want to debug.
4. Click **Debug**.
5. Enter the input parameters of your action, and click **Run**.
An action run in debug mode begins.
6. When the action run is paused after reaching a breakpoint, select one of the following options:

Option	Description
Continue	Resumes the action run until another breakpoint is reached or the action run finishes.
Step into	Step into the current action function. If the debugger cannot go deeper into the current line of the function, it performs a Step over operation.
Step over	The debugger continues into the next line of the current function.

Table continued on next page

Continued from previous page

Option	Description
Step return	The debugger goes into the line that will perform when the current function returns.

7. On the **Debugger** tab, add expressions.
8. On the **Debugger** tab, edit the value of your variables.

Core Concepts for Python, Node.js, and PowerShell Scripts

When creating your script for use in VMware Aria Automation Orchestrator, you must verify that your script has the correct structure and formatting.

Supported Runtimes

For developing VMware Aria Automation Orchestrator actions and workflows, you can use the following runtimes:

- Python 3.10
- Node.js 20
- PowerCLI 13 (PowerShell 7.4)

NOTE

The PowerCLI runtime includes PowerShell and the following modules: VMware.PowerCLI, PowerNSX, PowervRA.

- PowerShell 7.4

NOTE

The PowerCLI 12 and Node.js 18 runtimes are deprecated and will be removed in a future release.

You can add any custom source code to the new runtimes, but to accept context and inputs, and return a result from and to the VMware Aria Automation Orchestrator engine, you must follow the correct functional format.

Scripting Recommendations

For simpler scripting tasks, you can add **Scriptable task** elements to your workflow schema. You can use VMware Aria Automation Orchestrator actions for more complex scripting tasks.

Using actions provides two specific benefits:

- Actions can be created, updated, imported, and exported independently from workflows.
- Actions are standalone objects that can be run and debugged in their own environment which can lead to a smoother development process. See [Running and Debugging Actions](#).

Script Function Requirements

The default name for your script function is `handler`. The function accepts two arguments, `context` and `input`. `Context` is a map object, containing system information. For example, `vroURL` can contain the URL of the VMware Aria Automation Orchestrator instance you want to call, while `executionId` contains the token ID of a workflow run.

An input is a map object containing all inputs that are provided to the actions. For example, if you define an input in your action called `myInput`, you can access it from the `inputs` argument, such as `inputs.myInput` or `inputs["myInput"]`, depending on your runtime. Anything that you return from the function, is the result of the action. Therefore, the return type of your action must correspond to the type of content that the script returns in VMware Aria Automation Orchestrator. If you return a primitive number, the action return type must be a number type. If you return a string, the action return type must be a string type. If you return a complex object, the return type must be mapped to either `Properties` or `Composite Type`. These same principles also apply to arrays.

Supported input and output parameter types for Python, Node.js, and PowerShell runtimes:

- String
- Number
- Boolean
- Date
- Properties
- Composite Type

Define the Entry Handler

By default, the value of the entry handler is `handler.handler`. This value means that the VMware Aria Automation Orchestrator engine looks for a top-level file in your ZIP package called `handler.py`, `handler.js`, or `handler.ps1`, that includes a function called `handler`. Any differences to the names of the function and handler file must be reflected in the value of the entry handler. For example, if your main handler is called `index.js` and your function is called `callMe`, you must set the value for the entry handler to `index.callMe`.

Debug Runtime Scripts in an External IDE

VMware Aria Automation Orchestrator supports debugging Python and Node.js scripts in an external IDE. You cannot debug PowerShell scripts in an external IDE.

Runtime Limits for Python, Node.js, and PowerShell Scripts

Some Python, Node.js, or PowerShell scripts can require you to change the memory and timeout values in the Automation Orchestrator Client.

The Automation Orchestrator Client uses a set of default memory and timeout values for Python, Node.js, and PowerShell action scripts:

- Memory: 64 MB
- Timeout: 180 seconds

If your action script exceeds one or both of these default values, the action run fails. For example, your action script might use multiple third-party dependency modules. In such a scenario, the default memory limit of 64 MB might not be enough. To avoid failed action runs due to insufficient resources, change the memory and timeout values from the action editor.

NOTE

You can also consider breaking up your script into multiple scriptable task elements, that can be added to your workflows.

1. Log in to the Automation Orchestrator Client.
2. Navigate to **Library > Actions**, and select your action.
3. Select the **Script** tab.
4. Under **Runtime limits**, change the memory and timeout values.
5. Click **Save**.
6. To test the new runtime limits, click **Debug**.

Managing Policies

Policies are event triggers that monitor the activity of the system. Policies respond to predefined events issued by changes in the status or performance of specific VMware Aria Automation Orchestrator objects.

Policies are a series of rules, gauges, thresholds, and event filters that run certain workflows or scripts when specific predefined events occur in VMware Aria Automation Orchestrator or in the technologies that VMware Aria Automation

Orchestrator accesses through plug-ins. VMware Aria Automation Orchestrator constantly evaluates the policy rules while the policy is running. For instance, you can implement policy gauges and thresholds that monitor the behavior of vCenter objects of the `VC:HostSystem` and `VCVirtualMachine` types.

Create and apply Automation Orchestrator policies

Create and apply policies

You can use policies to monitor the activity of the Automation Orchestrator system for specific events.

1. Log in to the VMware Aria Automation Orchestrator Client.
 2. Navigate to **Library > Policies**.
 3. Select **New Policy**.
 4. Enter a policy name and version number.
 5. On the **Variables** tab, click **New**.
 - a) Enter the variable name.
 - b) Select the variable type.

To create an array of policy variables, select the **Array** check box.
 - c) Enter the variable value.
 - To import the value of a configuration element variable, you can use **Bind to configuration**.
 - d) Click **Save**.
6. On the **Definition** tab, add policy elements and set event handlers.
- For more information on policy elements, see [Policy Elements in the](#) .
7. Click **Save**.

To start a policy, select the policy and click **Run**. Enter the policy run name and, if prompted, the required input parameters.

To view the policy status, navigate to **Activity > Policy Runs**.

Policy Elements in the Automation Orchestrator Client

Policy Elements

You can use policy elements to run predefined VMware Aria Automation Orchestrator workflows or scripts when an event occurs.

You can add a policy element to trigger workflow or script runs as a response to events triggered by objects. With the periodic event element, you can schedule workflow or script runs. With the root element, you can set the start or stop behavior of policies. Policy elements can have event handlers that define when policy elements must run.

NOTE

Event handlers that activate policy elements can be either workflows or action scripts. If you add both a workflow and a script to an event handler, the policy ignores the script trigger and only uses the workflow trigger.

Event Handler	Description
OnInit	The policy element is triggered every time you start the policy.
OnExit	The policy element is triggered every time you stop the policy.

Table continued on next page

Continued from previous page

Event Handler	Description
OnExecute	Used by the periodic event element. Triggers the policy element during the time specified in the periodic event element.

NOTE

Technologies plugged in to the VMware Aria Automation Orchestrator database can possess unique event handlers. For example, through the SNMP plug-in, you can use the **OnTrap** event handler when creating SNMP-based policy elements.

Policy elements are configured on the **Definition** tab of the policy edit window.

Manage Policy Runs in the Automation Orchestrator Client

Manage Policy Runs

You can use the Automation Orchestrator Client to manage the policy priority and server start-up behavior of policies for when the VMware Aria Automation Orchestrator server is restarted.

Create and run a policy. For more information, see [Create and apply policies](#).

1. Log in to the VMware Aria Automation Orchestrator as an administrator.
2. Navigate to **Activity > Policy Runs**.
3. Click the policy run you want to manage.
4. Click **Stop**.
The policy state changes to **Stopped**.
5. On the **General** tab, set the policy priority and server start-up behavior.
6. To restart the policy, click **Run**.
The policy state changes to **Running**.

Managing Resource Elements

Workflows can use objects that you create independently of VMware Aria Automation Orchestrator as attributes. To use external objects as attributes in workflows, you import them into the server as resource elements.

Objects that VMware Aria Automation Orchestrator workflows can use as resource elements include image files, scripts, XML templates, HTML files, and so on. Any workflows that run in the VMware Aria Automation Orchestrator server can use any resource elements that you import into VMware Aria Automation Orchestrator.

After you import an object into VMware Aria Automation Orchestrator as a resource element, you can make changes to the object in a single location, and propagate those changes automatically to all the workflows that use this resource element.

The maximum size for a resource element is 16 MB.

You can import, export, restore, update, and delete a resource element.

Managing Packages

Use the Automation Orchestrator Client to create, export, and import packages. Packages can be used to export workflow objects for use on other VMware Aria Automation Orchestrator instances.

Packages can contain workflows, actions, policies, configuration elements, or resources elements.

When you add an element to a package, VMware Aria Automation Orchestrator checks for dependencies and adds any dependent elements to the package. For example, if you add a workflow that uses actions or other workflows, VMware Aria Automation Orchestrator adds those actions and workflows to the package.

NOTE

VMware Aria Automation Orchestrator dependencies added to a package can also include commented out code. For example, a workflow can include a line of code referencing an action that is commented out. In such a scenario, the action is added to the package regardless. The addition of commented out code in the package is expected behavior.

When you import a package, the server compares the versions of the different elements of its contents to matching local elements. The comparison shows the differences in versions between the local and imported elements. The user can decide whether to import the package, or can select specific elements to import.

For most objects created in the Automation Orchestrator Client, aside from resource elements, packages are the only way to export and import these objects.

Packages use digital rights management to control how the receiving server can use the contents of the package.

VMware Aria Automation Orchestrator signs packages and encrypts the packages for data protection. Packages can track which users export and redistribute elements by using X509 certificates.

Create a Package in the Automation Orchestrator Client

Create Packages

You can export and import workflows, policies, actions, plug-in references, resource elements, and configuration elements in packages. All dependent elements related to package objects are added to the package automatically, to ensure compatibility between versions. To delete dependent elements, you must first remove the related package object.

Verify that the VMware Aria Automation Orchestrator server contains objects like workflows, actions, and policies, that you can add to a package.

For most objects created in the Automation Orchestrator Client, aside from resource elements, packages are the only way to export and import these objects.

1. Log in to the VMware Aria Automation Orchestrator Client.
2. Navigate to **Assets > Packages**.
3. Click **New Package**.
4. On the **General** tab, enter a name and description for the package.

NOTE

You cannot use special characters when naming packages in the Automation Orchestrator Client.

5. On the **Content** tab, click **Add**.
6. Select the objects that you want to add to the package and click **Add**.

NOTE

Dependent elements are added to the package automatically, but are not displayed in the **Content** tab during package creation. To view dependent elements, select the **Content** tab after package creation.

7. To finish creating the package, click **Create**.

Export a Package in the Automation Orchestrator Client

Export Packages

You can use the Automation Orchestrator Client to export packages to another VMware Aria Automation Orchestrator environment.

Create a package containing the VMware Aria Automation Orchestrator objects you want to export. For more information, see [Create a Package in the](#).

1. Log in to the VMware Aria Automation Orchestrator Client.
2. Navigate to **Assets > Packages**.
3. Click **Export** on the package.
4. Select additional export options.

Option	Description
Add configuration attribute values to package	Export the attribute values of the configuration elements.
Add configuration SecureString attribute values to package	Export the SecureString configuration attribute values.
Add global tags to package	Export the global tags.

5. Set the access rights for users who import the package.

Option	Description
View contents	The user can view the package content.
Add to package	The user can add content from the imported package to other packages.
Edit contents	The user can edit the package content.

6. Click **Ok**.

NOTE

Files with the `.package` extension are saved to a default folder on your local machine. To set a custom folder, you can change the storage settings in your browser.

You exported the package. You can now use the exported objects on another VMware Aria Automation Orchestrator environment.

Import a Package in the Automation Orchestrator Client

Import Packages

Use the Automation Orchestrator Client to import workflow packages. By importing packages, you can reuse objects from one VMware Aria Automation Orchestrator server on another server.

- Back up any standard VMware Aria Automation Orchestrator objects that you have modified.
- On the remote server, create and export a package with the objects you want to import.

1. Log in to the VMware Aria Automation Orchestrator Client.

2. Navigate to **Assets > Packages**.

3. Click **Import**, browse to the `.package` file that you want to import, and click **Open**.

4. Review the imported package information.

- a) The **General** tab contains information about the imported package like the name, description, number of contained items, and certificate information.

You might be prompted to indicate that you trust the publisher certificate of the source VMware Aria Automation Orchestrator instance before you can import the file.

- b) The **Package elements** tab lists the objects included in the import file. If the version of an object in the package is later than the version on the server, the system selects that object version for import. Earlier versions of VMware Aria Automation Orchestrator elements must be selected manually.

- c) Deselect **Import Configuration Attribute Values** if you do not want to import the attribute values of the configuration elements from the package.
 - d) From the drop-down menu, select whether you want to import tags.
5. Click **Import**.

Troubleshooting in the Automation Orchestrator Client

You can troubleshoot and monitor your VMware Aria Automation Orchestrator instance by using metrics, token replay, validation, and debugging.

Metric Data in the Automation Orchestrator Client

VMware Aria Automation Orchestrator administrators can use workflow profiling and the System Dashboard metrics to troubleshoot the VMware Aria Automation Orchestrator system and workflows.

The profiling feature gathers metric data about workflow runs. Workflow profiling is enabled by default. To deactivate automatic profiling, navigate to **Control Center** > **Extension Properties** > **profiler-8.18.0**.

The other source for metric data in the Automation Orchestrator Client is the System Dashboard, that provides system level metrics. For more information, see [Using the System Dashboard](#).

Profile Workflows in the Automation Orchestrator Client

You can profile your workflow runs to troubleshoot and optimize your VMware Aria Automation Orchestrator environment.

Run a workflow.

You can use the profiling feature of the Automation Orchestrator Client to gather useful metric data about your workflow runs. This data can be used to optimize the performance of your workflows. By default, workflow runs are profiled automatically. You can deactivate automatic profiling from the **Extension Properties** page of the VMware Aria Automation Orchestrator Control Center and run the profiler manually. To do a manual profiling run, find your workflow in the library and select **Actions** > **Profile**.

1. Log in to the VMware Aria Automation Orchestrator Client.
2. Navigate to **Activity** > **Workflow Runs**.
3. Select a workflow run.
On the workflow run schema, you can see data about the individual workflow items. Data includes total run duration, max duration, and number of item runs. You can filter this information from the drop-down menu on the top right of the page.
4. Select the **Performance** tab.

This tab provides you with metric data on workflow run CPU times, run duration, token size, and workflow item data.

NOTE

If the workflow run is suspended, for example, when the workflow is waiting for further input, the CPU times metric only captures the runtime thread that occurred before completion.

Use the data gathered from profiling to optimize your workflow.

Using the VMware Aria Automation Orchestrator System Dashboard

As an administrator, you can use the Automation Orchestrator Client System Dashboard to gather useful metric data about the nodes of your VMware Aria Automation Orchestrator environment.

You can access the System Dashboard from by clicking the **System** tab, on the top of Automation Orchestrator Client dashboard page. Provided data includes:

- Node status
- Node properties
- Cluster settings. You can only view the cluster settings from the System Dashboard. To change these settings, go to the **Orchestrator Cluster Management** page of the VMware Aria Automation Orchestrator Control Center.
- Threads info
- Heap memory
- Non-heap memory
- File system use
- Authentication data
- Orchestrator database connection pool
- Process input arguments

This data can be used to monitor the state of individual nodes of your VMware Aria Automation Orchestrator environment and troubleshoot problems. To navigate between individual nodes, click the tab associated with a node on the top of the System Dashboard.

Using Workflow Token Replay in the Automation Orchestrator Client

You can use the token replay feature to view the transitions between items in workflow runs.

- Enable the token replay feature from the Control Center.
 1. Log in to the Control Center as **root**.
 2. Select **Extension Properties**.
 3. Click **tokenreplay-8.18.0**.
 4. To enable the token replay feature, click **Enable**.
 5. Click **Save**.

NOTE

It can take up to 5 minutes for the VMware Aria Automation Orchestrator server to refresh the extension.

- Run a workflow.

NOTE

By default, the token replay does not run automatically for all workflow runs on your VMware Aria Automation Orchestrator server. You can run token replays for each workflow individually, or enable the token replay extension for all workflows from the **Extension Properties** page of the Control Center.

The token replay feature records contextual information for each transition between workflow items. For each workflow item, token replay records when the workflow run started, ended, and what variables were changed at the end of the workflow item run. Token replay also references the generated script log messages for each workflow item.

NOTE

Data about workflow item transitions is stored in the VMware Aria Automation Orchestrator PostgreSQL database. This data is removed from the database when the workflow run is deleted.

1. Enable token replay for all workflow runs on your VMware Aria Automation Orchestrator server.

NOTE

To run individual token replays without enabling the feature from the Control Center, click **Run with replay** on the workflow editor page.

- a) Log in to the Control Center as **root**.
- b) Select **Extension Properties**.
- c) Click **tokenreplay-8.18.0**.
- d) To enable the token replay feature for all workflows, verify that **Record replay for all workflow runs** is enabled.
- e) Click **Save**.

NOTE

It can take up to 5 minutes for the VMware Aria Automation Orchestrator server to refresh the extension.

2. Log in to the VMware Aria Automation Orchestrator as an administrator.

3. Navigate to **Activity > Workflow Runs**.

4. Select a workflow run.

5. Select a workflow run item from the left menu.

The **Variable** and **Logs** tabs now display information specific for that workflow item.

Validating Workflows

VMware Aria Automation Orchestrator provides a workflow validation tool. Validating a workflow helps identify errors in the workflow and checks that the data flows from one element to the next correctly.

By default, VMware Aria Automation Orchestrator always performs a workflow validation when you run a workflow.

When you validate a workflow, the validation tool creates a list of any errors or warnings. Clicking an error in the list highlights the workflow element that contains the error.

If you run the validation tool in the workflow editor, the tool provides suggested quick fixes for the errors it detects. Some quick fixes require additional information or input parameters. Other quick fixes resolve the error for you.

Workflow validation checks the data bindings and connections between elements. Workflow validation does not check the data processing that each element in the workflow performs. As a result, a valid workflow might run incorrectly and produce erroneous results if a function in a schema element is incorrect.

Validate a Workflow and Fix Validation Errors in the Automation Orchestrator Client

You must validate a workflow before you can run it. You can only fix validation errors if you have opened the workflow for editing.

Verify that you have a complete workflow to validate, with schema elements linked and bindings defined.

1. Log in to the VMware Aria Automation Orchestrator as an administrator.
2. Navigate to **Library > Workflows** and select the workflow you want to validate.
3. Click **Edit**.
4. Click **Validate** from the top menu.
If the workflow is valid, a confirmation message appears. If the workflow is invalid, a list of errors appears.
5. For an invalid workflow, click an error message and take appropriate steps to resolve the problem.

The validation tool highlights the schema element in which the error occurs by adding a red icon to it. Where possible, the validation tool displays a quick fix action.

- If you agree with the proposed quick fix action, click it to perform that action.
- If you disagree with the proposed quick fix action, close the Workflow Validation dialog box and fix the schema element manually.

IMPORTANT

Always check that the fix that VMware Aria Automation Orchestrator proposes is appropriate.

For example, the proposed action might be to delete an unused attribute, when in fact that attribute might not be bound correctly.

6. Repeat the preceding steps until you have eliminated all validation errors.

You validated a workflow and fixed the validation errors.

You can run the workflow.

Debug Workflow Scripts in the Automation Orchestrator Client

You can debug workflow runs by inserting breakpoints in the script of workflow items.

When a breakpoint is reached, you have several options to continue the debugging process. When you debug an element from the workflow schema, you can view the general information about the workflow run, modify the workflow variables, add expressions to watch, and view log messages.

NOTE

Perform all script debugging in a non-production environment.

1. Log in to the VMware Aria Automation Orchestrator as an administrator.
2. Select a workflow from the library.
3. Open the workflow schema, select a workflow element, and click the **Scripting** tab.
4. To insert a breakpoint, click the red circle to the left of the line number.

NOTE

You can only insert breakpoints in workflow elements with scripting.

5. To run the workflow in the debugging mode, click **Debug**.
If the workflow requires input parameters, you must provide them.
6. When the workflow run is paused after reaching a breakpoint, select one of the available options.

Option	Description
Continue	Resumes the workflow run until another breakpoint is reached or the workflow run finishes.
Step into	You can use this option to step into a workflow element. You cannot step into a nested workflow element when you debug a workflow in the workflow editor.
Step over	Skips the current element in the schema and pauses the workflow run on the next element.

NOTE

You can instruct the debugger to ignore the current breakpoint by clicking the breakpoint. This changes the breakpoint symbol to a green triangle.

7. On the **Debugger** tab, insert expressions to watch.
You can use expressions to follow the completion of specific variables.

-
8. On the **Debugger** tab, modify the values of variables.

Debug Workflows by Schema Element

As a workflow designer, you can debug individual schema elements.

1. Log in to the Automation Orchestrator Client.
2. Navigate to **Library > Workflows**, and select your workflow.
3. Select the **Schema** tab.
4. Select the workflow element you want to debug, and click the debug button on the top-left of the element.

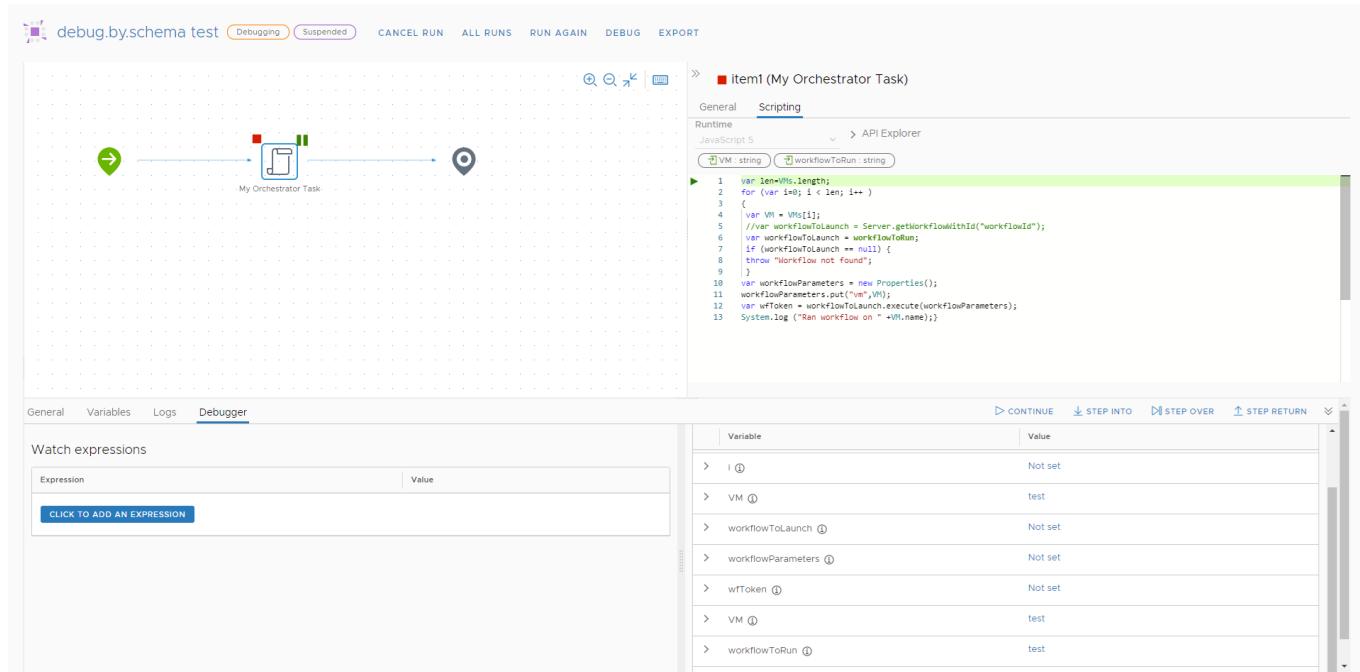

NOTE

By adding a breakpoint to a **Workflow Element** schema element, you can debug child workflows directly from the parent workflow. When the debugger reaches the **Workflow Element** schema element, it opens the schema view of the child workflow.

5. Repeat for any other schema elements you want to debug.
6. Click **Debug**.
7. Enter the requested input parameter values, and click **Run**.
The workflow run begins, and is suspended when the debugger reaches a schema element with a breakpoint.
8. When at a breakpoint, select one of the following options:

Option	Description
Continue	Resumes the workflow run until another breakpoint is reached or the workflow run finishes.
Step into	Step into the current workflow function. If the debugger cannot go deeper into the current line of the function, it performs a Step over operation.
Step over	The debugger continues into the next line of the current function.
Step return	The debugger goes into the line that will perform when the current function returns.

9. On the **Variables** tab, edit the value of your workflow variables.

Configuring a Photon OS Container for Python Packages

Depending on the operating system (OS) used for compiling your Python script, your workflows or actions can fail after importing the relevant ZIP archive to the Automation Orchestrator Client.

Install Docker. See [Get Docker](#).

The OS of the runtime container used for Python in VMware Aria Automation Orchestrator is based on Photon 3.0. Python script packages compiled for another OS, such as Linux for example, are incompatible with the runtime container. This problem can cause the Python script to fail, when you attempt to use it as part of your VMware Aria Automation Orchestrator workflows or actions. In such a scenario, you receive the following error message in your logs:
-04:00errorCannot find module action

To resolve this problem, you must install the required Python package in a Photon OS container folder.

1. Navigate to the parent folder of your Python script.
2. Create a container with the base Photon image by mounting a container folder to your parent folder.

NOTE

The following script is a singular Docker command that you must run in its entirety to create a suitable container.

```
docker run -ti -v
$(pwd)/<name_of_folder_that_contains_your_python_script>/:/
<name_of_folder_that_contains_your_python_script>
photon:3.0
```

3. Install Python in the container.

```
tdnf install -y python3-3.7.5-5.ph3 python3-pip-3.7.5-5.ph3
```

-
4. Navigate to the container folder that includes your Python script.
 5. Add your Python script and packages.

NOTE

Install packages required for your Python script in the `lib` folder.

```
pip3 install <package_name> -t lib/
```

6. Exit the container and navigate to the local folder you mounted to the container.
7. Compress all relevant files and folders into a ZIP archive.
8. Import the ZIP archive into the Automation Orchestrator Client and validate the script by running it as part of an action.

Using Automation Orchestrator Plug-Ins

With the VMware Aria Automation Orchestrator plug-ins, you can access and control external technologies and applications, such as virtualization management tools, email systems, databases, directory services, and remote control interfaces. Exposing an external technology in an Automation Orchestrator plug-in lets you incorporate objects and functions in workflows and run workflows on the objects of that external technology.

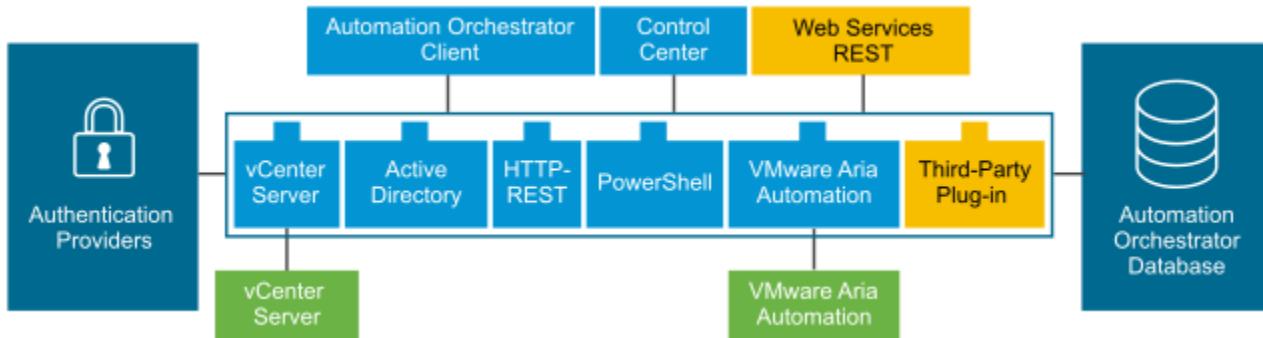

Automation Orchestrator provides a standard set of preinstalled plug-ins, including plug-ins for vCenter and VMware Aria Automation, to allow you to orchestrate tasks in the different environments that the plug-ins expose. In addition, the open plug-in architecture lets you develop plug-ins to access other applications. Automation Orchestrator implements open standards to simplify integration with external systems.

Plug-ins extend the Automation Orchestrator scripting engine with new object types and methods, and plug-ins publish notification events from the external system that triggers events in Automation Orchestrator and in the plugged-in technology. Plug-ins provide an inventory of JavaScript objects that you can access on the **Inventory** page of the Automation Orchestrator Client. Each plug-in contains packages of workflows and actions that you can run on the objects in the inventory to automate the typical use cases of the integrated product.

Automation Orchestrator Architecture

The standard set of plug-ins is automatically installed with the Automation Orchestrator server. You might need to configure some of the plug-ins, for example the vCenter plug-in, before you start using them.

Automation Orchestrator connects to an authentication provider to manage user accounts and to a preconfigured PostgreSQL database to store information from the workflows that it runs. You can access Automation Orchestrator, the objects it exposes, and the default workflows through the Automation Orchestrator Client, or through web services. You use the Automation Orchestrator and Control Center to monitor and configure workflows and services.

Access the Automation Orchestrator API Explorer

You use the Automation Orchestrator API Explorer as an in-product reference guide to JavaScript objects exposed by Automation Orchestrator and all installed plug-ins. To access the API explorer, navigate to the **API Explorer** page in the Automation Orchestrator Client.

You can consult an online version of the Scripting API for the Automation Orchestrator plug-ins on the Automation Orchestrator documentation home page.

Intended Audience

This guide is intended for advanced vSphere administrators and experienced system administrators who are familiar with virtual machine technology and data center operations.

Managing Automation Orchestrator plug-ins

Managing plug-ins

On the **System Settings** page of Automation Orchestrator, you can view a list of all plug-ins that are installed in Automation Orchestrator and perform basic management actions.

Change the plug-In logging level

Instead of changing the logging level for Automation Orchestrator, you can change it only for specific plug-ins.

Activate or deactivate a plug-in

You can activate or deactivate a plug-in by selecting the plug-in and clicking **Enable/Disable**.

This action does not remove the plug-in file.

Configuring the Automation Orchestrator plug-ins

The default Automation Orchestrator plug-ins come with configuration workflows. You can run these workflows to register endpoints for management.

The configuration workflows have the *configuration* tag. For example, to access workflows that are used to manage AMQP brokers and subscriptions, enter the tags *AMQP* and *Configuration* in the search text box of the workflow library.

Plug-ins installed with the Automation Orchestrator server

Automation Orchestrator includes a collection of standard plug-ins. Each plug-in exposes an external product API to the Automation Orchestrator platform. Plug-ins provide inventory classes, additional object types for the scripting engine, and publish notification events from the external system. Each plug-in also provides a library of workflows for automating the typical use cases of the integrated external products.

You can see the list of installed plug-ins on the **Manage Plug-Ins** page in Control Center.

Table 87: Plug-Ins Installed with Automation Orchestrator

Plug-In	Purpose	Configuration
Active Directory	Provides interaction between Automation Orchestrator and Microsoft Active Directory.	See Configuring and the Auto Deploy Plug-In .
AMQP	Interact with Advanced Message Queuing Protocol (AMQP) servers, also known as brokers.	See Configuring the Plug-In .
Auto Deploy	Perform different operations associated with vCenter server ESXi hosts.	See Configuring and the Auto Deploy Plug-In .
Configuration	Provides workflows for configuring and managing the Automation Orchestrator server keystores and trusted certificates.	None
Dynamic Types	Define dynamic types and create and use objects of these dynamic types.	See Using the Dynamic Types Plug-In .
Enumeration	Provides common Enumerated Types that can be used in workflows by other plug-ins.	See Time Zone Codes
HTTP-REST	Manage REST Web services through an interaction between Automation Orchestrator and REST hosts.	See Configuring the Plug-In .
Library	Provides workflows that act as basic building blocks for customization and automation of client processes. The workflow library includes templates for life-cycle management, provisioning, disaster recovery, hot backup, and other standard system management	None

Table continued on next page

Continued from previous page

Plug-In	Purpose	Configuration
	processes. You can copy and edit the templates to modify them according to your needs.	
Mail	Uses Simple Mail Transfer Protocol (SMTP) to send email from workflows.	Set the default values for the <code>EmailMessage</code> object to use. See Define the default SMTP connection .
Multi-Node	Contains workflows for hierarchical management, management of Automation Orchestrator instances, and scale-out of Automation Orchestrator activities.	See Using the plug-in .
Net	Uses the Jakarta Apache Commons Net Library. Provides implementations of the Telnet, FTP, POP3, and IMAP protocols. The POP3 and IMAP protocols is used for reading email. With the Mail plug-in, the Net plug-in provides complete email sending and receiving capabilities in workflows.	
PowerShell	Manage PowerShell hosts and run custom PowerShell operations.	See Using the plug-in .
SNMP	Connect and receive information from SNMP-enabled systems and devices.	
SOAP	Manage SOAP Web services by providing interaction between Automation Orchestrator and SOAP hosts.	See Configuring the plug-in .
SQL	Provides the Java Database Connectivity (JDBC) API, which is the industry standard for database-independent connectivity between the Java programming language and a wide range of databases. The databases include SQL databases and other tabular data sources, such as spreadsheets or flat files. The JDBC API provides a call-level API for SQL-based database access from workflows.	
SSH	Provides an implementation of the Secure Shell v2 (SSH-2) protocol. Allows remote command and file transfer sessions with password and public key-based authentication in workflows. Supports keyboard-interactive authentication. Optionally, the SSH plug-in can provide remote file system browsing directly in the Automation OrchestratorClient inventory.	See Add an SSH Host .
vCenter	Provides access to the vCenter API so that you can incorporate all the vCenter objects and functions into the management processes that you automate by using Automation Orchestrator.	See Configuring the vCenter Server Plug-In .
vCloud Suite API (vAPI)	Provides access to the API services exposed by any vAPI provider.	
VMware Aria Automation	The plug-in comes pre-installed with Automation Orchestrator deployments that are embedded in VMware Aria Automation. Integrates Automation Orchestrator with VMware Aria Automation.	See Using the Plug-In for .

Table continued on next page

Continued from previous page

Plug-In	Purpose	Configuration
vSphere Update Manager (VUM)	Provides interaction between Automation Orchestrator and VMware vSphere Update Manager/vSphere Lifecycle Manager.	See Connect the plug-in to .
XML	A complete Document Object Model (DOM) XML parser that you can implement in workflows. Alternatively, you can use the ECMAScript for XML (E4X) implementation in the Automation Orchestrator JavaScript API.	

Plug-In Components

The components of each plug-in, such as workflow categories and API modules, use different naming conventions.

Table 88: Names of Plug-In Components

Plug-In Name in the Configuration UI	Workflow Categories	API Module
Active Directory	Computer Configuration Organizational Unit User User Group	AD
AMQP	Configuration	AMQP
Auto Deploy	Answer Files Configuration Reprovision Host Rules Rule Set Compliance	AutoDeploy
Configuration	Configuration	Configurator
Dynamic Types	Configuration	DynamicTypes
Common enumerated types	None	Enums
HTTP-REST	Configuration	REST
Library	Locking Orchestrator Tagging	Not applicable.
Mail	Mail	Mail
Orchestrator Multi-Node	Servers Configuration Remote Execution	VCO

Table continued on next page

Continued from previous page

Plug-In Name in the Configuration UI	Workflow Categories	API Module
	Remote Management Tasks Workflows	
Net	None	Net
PowerShell	Configuration Generate Templates	PowerShell
SNMP	Device Management Query Management Trap Host Management	SNMP
SOAP	Configuration	SOAP
SQL	JDBC SQL	SQL
SSH	SSH	SSH
Support	None	Support
vAPI	VAPI	VAPI
vCenter	vCenter	VC
VMware Aria Automation	Configuration Infrastructure	VRA
vSphere Update Manager	Configuration	VUM
XML	XML	XML

Time Zone Codes

When implementing common enumerated types in workflows, you can use time zone codes as possible values for the Enums : MSTimeZone enumeration.

Time Zone Code	Time Zone Name	Description
000	Dateline Standard Time	(GMT-12:00) International Date Line West
001	Samoa Standard Time	(GMT-11:00) Midway Island, Samoa
002	Hawaiian Standard Time	(GMT-10:00) Hawaii
003	Alaskan Standard Time	(GMT-09:00) Alaska
004	Pacific Standard Time	(GMT-08:00) Pacific Time (US and Canada); Tijuana
010	Mountain Standard Time	(GMT-07:00) Mountain Time (US and Canada)
013	Mexico Standard Time 2	(GMT-07:00) Chihuahua, La Paz, Mazatlan
015	U.S. Mountain Standard Time	(GMT-07:00) Arizona
020	Central Standard Time	(GMT-06:00) Central Time (US and Canada)

Table continued on next page

Continued from previous page

Time Zone Code	Time Zone Name	Description
025	Canada Central Standard Time	(GMT-06:00) Saskatchewan
030	Mexico Standard Time	(GMT-06:00) Guadalajara, Mexico City, Monterrey
033	Central America Standard Time	(GMT-06:00) Central America
035	Eastern Standard Time	(GMT-05:00) Eastern Time (US and Canada)
040	U.S. Eastern Standard Time	(GMT-05:00) Indiana (East)
045	S.A. Pacific Standard Time	(GMT-05:00) Bogota, Lima, Quito
050	Atlantic Standard Time	(GMT-04:00) Atlantic Time (Canada)
055	S.A. Western Standard Time	(GMT-04:00) Caracas, La Paz
056	Pacific S.A. Standard Time	(GMT-04:00) Santiago
060	Newfoundland and Labrador Standard Time	(GMT-03:30) Newfoundland and Labrador
065	E. South America Standard Time	(GMT-03:00) Brasilia
070	S.A. Eastern Standard Time	(GMT-03:00) Buenos Aires, Georgetown
073	Greenland Standard Time	(GMT-03:00) Greenland
075	Mid-Atlantic Standard Time	(GMT-02:00) Mid-Atlantic
080	Azores Standard Time	(GMT-01:00) Azores

Configure Kerberos authentication for Automation Orchestrator plug-ins

You can use Kerberos authentication for Automation Orchestrator plug-ins.

Configure the krb5.conf file

1. Create or edit the `krb5.conf` file at `/data/vco/usr/lib/vco/app-server/conf/`.

A `krb5.conf` file has the following structure:

```
[libdefaults]
```

```
default_realm = YOURDOMAIN.COM
```

```
[realms]
```

```

YOURDOMAIN.COM = {
    kdc = dc.yourdomain.com
    default_domain = yourdomain.com
}
[domain_realm]
.yourdomain.com=YOURDOMAIN.COM
yourdomain.com=YOURDOMAIN.COM

```

The `krb5.conf` must contain specific configuration parameters with their values.

Kerberos configuration tags	Details
<code>default_realm</code>	The default Kerberos realm that a client uses to authenticate against an Active Directory server. Must be in uppercase letters.
<code>kdc</code>	The domain controller that acts as a Key Distribution Center (KDC) and issues Kerberos tickets.
<code>default_domain</code>	The default domain that is used to produce a fully qualified domain name. This tag is used for Kerberos 4 compatibility.

To allow ticket forwarding to other external systems, add the `forwardable = true` flag. For additional information, see [the Oracle documentation on the `krb5.conf` file](#).

By default, the Java Kerberos configuration uses the UDP protocol. To use only the TCP protocol, you must specify the `udp_preference_limit` parameter with a value 1.

NOTE

The Kerberos authentication requires a Fully Qualified Domain Name (FQDN) host address.

IMPORTANT

When you add or modify the `krb5.conf` file, you must restart the Automation Orchestrator server service.

If you have a clustered Automation Orchestrator environment, make sure that the `krb5.conf` file exists in all three appliances with the same configuration before you restart the Automation Orchestrator pods.

2. Change permissions.

```
chmod 644 krb5.conf
```

3. Redeploy the Automation Orchestrator pod.

```
kubectl -n prelude get pods
```

Look for an entry similar to `vco-app-<ID>`.

4. Destroy the pod.

```
kubectl -n prelude delete pod vco-app-<ID>
```

A new pod is automatically deployed to replace the pod you destroyed.

Enable Kerberos debug logging

You can troubleshoot Automation Orchestrator plug-in problems by modifying the Kerberos configuration file used by the plug-in.

The Kerberos configuration file is located in the `/data/vco/usr/lib/vco/app-server/conf/` directory of the Automation Orchestrator Appliance.

1. Log in to the Automation Orchestrator Appliance command line as **root**.
2. Run the `kubectl -n prelude edit deployment vco-app` command.
3. In the deployment file, locate and edit the `-Djava.security.krb5.conf=/usr/lib/vco/app-server/conf/krb5.conf` string.
`-Djava.security.krb5.conf=/usr/lib/vco/app-server/conf/krb5.conf`
`-Dsun.security.krb5.debug=true`
4. Save the changes and exit the file editor.
5. Run the `kubectl -n prelude get pods` command. Wait until all pods are running.
6. To monitor the Kerberos login, run the following command.
`tail -f /services-logs/prelude/vco-app/console-logs/vco-server-app.log`
7. Alternatively, you can enable debug logging in the Automation Orchestrator configurator by adding the `sun.security.krb5.debug = true` system property.

Using the Active Directory Plug-In

The Automation Orchestrator plug-in for Microsoft Active Directory allows interaction between Automation Orchestrator and Microsoft Active Directory. You can use the plug-in to run Automation Orchestrator workflows that automate Active Directory processes.

The Active Directory plug-in contains a set of standard workflows. You can also create custom workflows that implement the plug-in API to automate tasks in your Active Directory environment.

Configuring the Active Directory Plug-In

To connect to a Microsoft Active Directory instance by using the Active Directory plug-in, you must configure the connection parameters for the Microsoft Active Directory instance by running the configuration workflows included in the plug-in.

To access these workflows in the Automation Orchestrator Client, navigate to **Library > Workflows** and enter the `active_directory` and `configuration` tags in the workflow search box.

Workflow Name	Description
Add an Active Directory server	Adds a new Active Directory domain configuration.
Configure Active Directory plug-in options	Configures the search limitation options of the Active Directory plug-in.
Update an Active Directory server	Modifies an existing Active Directory server configuration.
Remove an Active Directory server	Removes an Active Directory server configuration.
Configure Active Directory server (Deprecated)	Creates or updates the default Active Directory server configuration. Use Update an Active Directory server.
Reset configuration (Deprecated)	Deletes the default Active Directory server configuration. Use Remove an Active Directory server.

Client-Side Load Balancing for the Active Directory Plug-In

You can use client-side load balancing and failover to improve the stability of your Active Directory plug-in configuration.

You can configure client-side load balancing when running the **Add an Active Directory server** and **Update an Active Directory server** workflows. Client-side load balancing is possible through the ServerSet Java class.

1. Log in to the Automation Orchestrator Client as an administrator.
2. Navigate to **Library > Workflows** and enter the `active_directory` and `configuration` tags in the workflow search box.
3. Run the **Add an Active Directory server** or **Update an Active Directory server** workflow.
4. Select the **Alternative hosts** tab.
5. From the drop-down menu, select **Single Server**, **Round-Robin DNS Server**, **Round-Robin**, or **Failover**.

Option	Description
Single Server	A server set implementation that connects to only one server.
Round-Robin DNS Server	A server set where server handles the case in which a given host name may resolve to multiple IP addresses. This server set does strictly require DNS server setup. The ordering mechanism for selecting an address is round-robin.
Round-Robin	A server set where load is distributed evenly between several directory servers. If a server is unavailable, the connection will move to the next server in the set.
Failover	A server set where server connections are established in order. This implementation can establish connections between separate server sets. Useful for providing high availability in complex environments.

6. When you finish configuring the workflow run, click **Run**.

Using the AMQP Plug-In

The AMQP plug-in allows you to interact with Advanced Message Queuing Protocol (AMQP) servers also known as brokers. You can define AMQP brokers and queue subscriptions as inventory objects by running configuration workflows, and perform AMQP operations on defined objects.

The plug-in contains a set of standard workflows related to managing AMQP brokers and calling AMQP operations.

Configuring the AMQP Plug-In

You can configure AMQP by running the configuration workflows included in the plug-in. The Configuration workflow category contains workflows that allow you to manage AMQP brokers.

To access these workflows in the Automation Orchestrator, navigate to **Library > Workflows** and enter the `amqp` and `configuration` tags in the workflow search box.

Workflow Name	Description
Add a broker	Adds an AMQP broker.
Remove a broker	Removes an AMQP broker.
Remove a subscription	Removes an AMQP message subscription.
Subscribe to queues	Creates a subscription element.

Table continued on next page

Continued from previous page

Workflow Name	Description
Update a broker	Updates broker properties.
Validate a broker	Validate a broker by attempting to start a connection.

TLS1.3 support in the AMQP plug-in

TLS1.3 support depends on the AMQP broker.

For RabbitMQ, see the list of supported versions at <https://www.rabbitmq.com/ssl.html#tls1.3>. If you follow the RabbitMQ guide, you must also add `ssl_options.password = <the_private_key_password>` to the Rabbit MQ configuration.

If you want to use TLS1.3 in the AMQP plug-in, add the following system parameter in the Automation Orchestrator Control Center:

key: o1ln.plugin.amqp.ssl-context-protocol

value: TLSv1.3

Add a Broker

You can run a workflow to add an AMQP broker.

1. Log in to the Automation Orchestrator Client as an administrator.
2. Navigate to **Library > Workflows** and enter the `amqp` and `configuration` tags in the workflow search box.
3. Locate the **Add a broker** workflow and click **Run**.
4. On the **AMQP broker properties** tab, enter the name of the broker.
5. On the **AMQP connection properties** tab, provide the information required for the broker connection.

Option	Action
Host	Enter the address of the host.
Port	Enter the port of the AMQP broker service. The default port is 5672.
Virtual host	Enter the address of the virtual host. The default value provided is /.
Use SSL	Select whether to use SSL certificates.
Accept all certificates	Select whether to accept all SSL certificates without validation.
User name	Enter the user name for the broker.
Password	Enter the password for the broker.

6. Click **Run**.

After the workflow runs successfully, the AMQP broker appears in the **Inventory** view.

You can run a Validate a broker workflow. If an error occurs, use the Update a broker workflow to change the properties of the broker before validating again.

Subscribe to Queues

You can run a workflow to create a new subscription element.

- Verify that you are logged in to the Automation Orchestrator Client as an administrator.
 - Verify that you have a connection to an AMQP broker from the **Inventory** view.
 - Verify that the AMQP broker has all queues included in the subscription declared.
1. Navigate to **Library > Workflows** and enter the `amqp` and `configuration` tags in the workflow search box.
 2. Locate the **Subscribe to queues** workflow and click **Run**.
 3. On the **Subscription** tab, enter the name of the queue to display.
 4. On the **AMQP Broker** tab, select the broker to which you want to add the subscription.
 5. On the **Queues** tab, select all the queues for message subscription.
 6. Click **Run**.

After the workflow runs successfully, a child of the broker appears in the **Inventory** view.

You can create a policy.

Update a Broker

You can run a workflow to update the broker properties.

- Verify that you are logged in to the Automation Orchestrator Client as an administrator.
- Verify that you have a connection to an AMQP broker from the **Inventory** view.

1. Navigate to **Library > Workflows** and enter the `amqp` and `configuration` tags in the workflow search box.
2. Locate the **Update a broker** workflow and click **Run**.
3. On the **AMQP Broker** tab, select the broker that you want to update.
Current properties of the broker appear on the **New AMQP connection properties** tab.
4. On the **New AMQP connection properties** tab, edit the properties that you want.
5. Click **Run**.

Using the AMQP plug-in workflow library

The AMQP workflow category contains workflows that allow you to run AMQP operations.

To access these workflows in the Automation Orchestrator Client, navigate to **Library > Workflows** and enter the `amqp` tag in the workflow search box.

Workflow Name	Description
Bind	Creates a binding in a specified broker.
Declare a queue	Adds a queue to a specified broker.
Declare an exchange	Adds an exchange to a specified broker.
Delete a queue	Deletes a queue from a specified broker.
Delete an exchange	Deletes an exchange from a specified broker.
Receive a text message	Receives a text message from a specified broker.
Send a test message	Sends a text message using a specified broker.
Unbind	Unbinds binding in a specified broker.

Declare a Binding

You can run a workflow to create a binding in a specified broker.

- Verify that you are logged in to the Automation Orchestrator Client as an administrator.
- Verify that you have a connection to an AMQP broker from the **Inventory** view.

1. Navigate to **Library > Workflows** and enter the `amqp` tag in the workflow search box.
2. Locate the **Bind** workflow and click **Run**.
3. On the **AMQP Broker** tab, select a broker in which you want to create a binding.
4. On the **Binding Properties** tab, provide information about the binding.

Option	Action
Queue name	Enter the name of the queue.
Exchange name	Enter the name of the exchange.
Routing key	Enter the routing key.

5. Click **Run**.

Declare a Queue

You can run a workflow to add a queue to a specified broker.

- Verify that you are logged in to the Automation Orchestrator Client as an administrator.
- Verify that you have a connection to an AMQP broker from the **Inventory** view.

1. Navigate to **Library > Workflows** and enter the `amqp` tag in the workflow search box.
2. Locate the **Declare a queue** workflow and click **Run**.
3. On the **AMQP Broker** tab, select a broker to which you want to add the queue.
4. On the **Queue Properties** tab, define the queue properties.
 - a) In the **Name** text box, enter the name of the queue to display.
 - b) Select whether the queue is durable.

Option	Description
Yes	The queue is removed after a broker restart.
No	The queue remains after a broker restart.

- c) Select whether an exclusive client is set for the specific queue.

Option	Description
Yes	Sets one client for this specific queue.
No	Sets more clients for this specific queue.

- d) Select whether to delete the queue with activated subscription automatically.

Option	Description
Yes	Automatically deletes the queue when no more clients are connected to it. The queue remains until at least one client subscribes to it.
No	Does not delete the queue.

5. Click **Run**.

Declare an Exchange

You can run a workflow to add an exchange in a specified broker.

- Verify that you are logged in to the Automation Orchestrator Client as an administrator.
- Verify that you have a connection to an AMQP broker from the **Inventory** view.

1. Navigate to **Library > Workflows** and enter the `amqp` tag in the workflow search box.
2. Locate the **Declare an exchange** workflow and click **Run**.
3. On the **AMQP Broker** tab, select a broker to which you want to add the exchange.
4. On the **Exchange Properties** tab, define the exchange properties.
 - a) In the **Name** text box, enter the name of the queue to display.
 - b) Select the exchange type.

Option	Description
direct	Makes a direct match between the routing key provided in the message and the routing criteria used when a queue is bound to this exchange.
fanout	Forwards any message sent to this exchange to all queues bound to it. Queues that are bound to this exchange contain no arguments.
headers	Queues are bound to this exchange with a table of arguments that can contain headers and values. A special argument named x-match determines the matching algorithm.
topic	Performs a wildcard match between the routing key and the routing pattern specified in the binding.

- c) Select whether the exchange is durable.

Option	Description
Yes	The exchange remains after a broker restart.
No	The exchange is removed after a broker restart.

- d) Select whether to delete the exchange with activated subscription automatically.

Option	Description
Yes	Automatically deletes the exchange when no more queues are bound to it. The exchange remains until at least one queue is bound to it.
No	Does not delete the exchange.

- Click **Run**.

Send a Text Message

You can run a workflow to send a text message using a specified broker.

- Verify that you are logged in to the Automation Orchestrator Client as an administrator.
- Verify that you have a connection to an AMQP broker from the **Inventory** view.

- Navigate to **Library > Workflows** and enter the `amqp` tag in the workflow search box.
- Locate the **Send a text message** workflow and click **Run**.
- On the **AMQP Broker** tab, select a broker from which you want to send a message.
- On the **Exchange** tab, specify the name of the exchange and the routing key.
- On the **Message** tab, enter the message you want to send.
- Click **Run**.

Delete a Binding

You can run a workflow to delete a binding in a specified broker.

- Verify that you are logged in to the Automation Orchestrator Client as an administrator.
- Verify that you have a connection to an AMQP broker from the **Inventory** view.

- Navigate to **Library > Workflows** and enter the `amqp` tag in the workflow search box.
- Locate the **Unbind** workflow and click **Run**.
- On the **AMQP Broker** tab, select a broker to remove the binding from.
- On the **Binding Properties** tab, enter the name of the queue, the name of the exchange, and the routing key.
- Click **Run**.

Using the Auto Deploy Plug-In

You can use the preinstalled Auto Deploy plug-in for VMware Aria Automation Orchestrator to manage the ESXi hosts on your vCenter Server. You use the plug-in to perform different operations associated with your vCenter ESXi hosts, such as applying image profiles and host profiles or changing the location where the host is stored.

An Image profile includes the vSphere Installation Bundles (VIBs) that define the installation and upgrade process for your ESXi host. Image profiles are managed through the vSphere Auto Deploy service and defined through the vSphere Image Builder service. For more information on image profiles, see [Image Profiles](#).

Image profiles and their associated VIBs are stored in software depots. A software depot is a hierarchy of files and folders and can be available through an HTTP or HTTPS URL address (online depot) or a ZIP file (offline depot).

A host profile includes the configuration profile used by a specific ESXi host. Host profiles can be extracted from one ESXi host and applied to a different host that you want to apply the same configuration to. For more information on host profiles, see [vSphere Host Profiles](#).

Configuring and the Auto Deploy Plug-In

You must configure the Auto Deploy plug-in before you can begin using it to manage your ESXi hosts.

- Enable the Auto Deploy service in vCenter.
 - Log in to vCenter and then navigate to **Home > Auto Deploy**. By default, only users with an administrator role have the privileges to use the **vCenter Auto Deploy Service**.
 - On the Auto Deploy page, click **Enable Auto Deploy and Image Builder** to activate the service. If the **Image Builder** service is already active, select the **Configure** tab and click **Enable Auto Deploy Service**.
- Add a vCenter to your Automation Orchestrator deployment.
Log in to the Automation Orchestrator Client and run the **Add a vCenter Server instance** workflow included with the vCenter plug-in for Automation Orchestrator.

NOTE

Each instance of the Auto Deploy plug-in is associated with a single vCenter instance.

1. Log in to the Automation Orchestrator Client.
2. Add a vCenter host and image profile depot.
 - a) Select the **Add an Auto Deploy host** workflow.
 - b) Select the vCenter that you have added to your Automation Orchestrator deployment and click **Run**.
 - c) Select the **Add a depot** workflow.
 - d) Enter a depot name, enter the depot URL address, and click **Run**.

You have added a depot to your Auto Deploy plug-in. You can view the image profiles hosted on the depot by navigating to the **Inventory** page and expanding the **Auto Deploy** entry.

Auto Deploy Plug-In Workflow Library

The Auto Deploy plug-in for VMware Aria Automation Orchestrator contains out-of-the-box workflows.

To access these workflows, navigate to **Library > Workflows** and enter the `auto_deploy` in the workflow search box.

Answer Files Workflows

Workflow	Description
Clear and answer file	Clears the content of an answer file associated with a specified ESXi host.
Get an answer file	Retrieves an answer file associated with a specific ESXi host.
Get answer file status	Retrieves the status of an answer file associated with a specific ESXi host. The possible states for the answer file are valid, invalid, and unknown.
Update an answer file	Updates an answer file from XML content. Creates an answer file when it is missing.

Configuration Workflows

Workflow	Description
Add an Auto Deploy host	Adds a new Auto Deploy host for an already configured vCenter instance.
Remove an Auto Deploy host	Removes an already configured Auto Deploy host.
Add a depot	Adds a public depot.
Remove a depot	Removes a public depot.
Update a depot	Updates a public depot.
Get deploy options	Retrieves the Auto Deploy global configuration options.
Reload plug-in configuration	Reloads the list of public depots. You can run this workflow after you import a package of public depots.
Set deploy option	Sets a value for an Auto Deploy global configuration option.

Re-provision Host Workflows

Workflow	Description
Apply image profile on hosts	Associates a specified image profile with the specified ESXi hosts.
Reprovision a host by a simple reboot	Reprovisions the host by repairing the rule set compliance and rebooting the host.
Reprovision a host with a host profile and an answer file	Reprovisions the ESXi host with a new host profile and an answer file. Validates the answer file before the ESXi host reboot.
Reprovision a host with an answer file	Reprovisions the host by updating or creating an answer file. Validates the answer file before remediating the rule set compliance, and rebooting the host.
Reprovision a host with a new image	Reprovisions the host by changing a specific deployment rule with a new image profile, repairing rule set compliance, and rebooting the host.
Reprovision a host with a new location	Reprovisions the host by changing a specific deploy rule with a new vCenter location, repairing the rule set compliance, and rebooting the host.

Rules Workflows

Workflow	Description
Activate a deploy rule and a working set	Activates a deploy rule by adding it to both working and active rule sets. All rules already in the working rule set are activated too.

Table continued on next page

Continued from previous page

Workflow	Description
Activate a working set	Activates all rules from a working rule set by moving them to an active set.
Add to working set	Adds a rule to a working rule set.
Copy a deploy rule	Replaces the original rule by creating a new copy and applying all the modifications. As a result, the old rule is hidden and the new modified rule takes the place of the original rule.
Create a deploy rule	Creates a new deploy rule.
Delete a deploy rule	Deletes a deploy rule from the Auto Deploy host.
Delete all hidden rules	Deletes all hidden rules from the rule engine.
Edit a deploy rule	Modifies a deploy rule on a specific Auto Deploy host.
Get deploy rules	Retrieves all deploy rules from the rule engine of the Auto Deploy server.
Get hidden rules	Retrieves all hidden rules from the rule engine of the Auto Deploy server.
Get host matching rules	Retrieves all rules which apply to a host.
Get rules from active set	Retrieves all rules from an active rule set.
Get rules from working set	Retrieves all rules from a working rule set.
Remove a rule from a rule set	Removes a rule from a rule set without deleting the rule.

Rule Set Compliance Workflows

Workflow	Description
Repair an active rule set compliance	Remediates the host to use the revised rule set the next time you boot the host. Updates the image profile, host profile, and location for the specified host in the vCenter inventory.
Test a rule set compliance	Checks whether the items associated with a specified ESXi host are in compliance with a rule set.

Other Workflows

Workflow	Description
Get host attributes	Retrieves the ESXi host attributes which are used when the Auto Deploy server evaluates the rules.

Using the Configuration Plug-In

In addition to configuring Automation Orchestrator by using Control Center, you can modify the Automation Orchestrator server configuration settings by running workflows from the Configuration plug-in.

With the Configuration plug-in, you can configure and manage the Automation Orchestrator server keystores and trusted certificates.

SSL Trust Manager Workflows

The SSL Trust Manager category contains workflows that you can use for deleting and importing SSL certificates.

To access these workflows in the Automation Orchestrator Client, navigate to **Library > Workflows** and enter the configuration and `ssl_trust_manager` tags in the workflow search box.

Workflow Name	Description
Delete a trusted certificate	Deletes an SSL certificate from the server trust store.
Import certificate from URL	Imports an SSL certificate from a URL into the server trust store.
Import a certificate from URL using authenticated proxy server	Imports an SSL certificate from a URL that is reachable through an authenticated proxy server.
Import certificate from URL using proxy server	Imports an SSL certificate from a URL that is reachable through a proxy server.
Import certificate from URL with certificate alias	Imports an SSL certificate from a URL into the server trust store.
Import trusted certificate from a file	Imports an SSL certificate from a file into the server trust store.

Keystore Workflows

To access these workflows in the Automation Orchestrator Client, navigate to **Library > Workflows** and enter the configuration and `keystores` tags in the workflow search box.

Workflow Name	Description
Add certificate	Adds a certificate to a keystore.
Add key	Adds a key.
Create a keystore	Creates a new keystore.
Delete a keystore	Deletes a keystore.
Delete certificate	Deletes a certificate from a keystore.
Delete entry	Deletes an entry.
Delete key	Deletes a key.

Using the Automation Orchestrator Plug-In for F5 BIG-IP

Using the F5 BIG-IP Plug-In

The VMware Aria Automation Orchestrator Plug-in for F5 BIG-IP replicates the entire F5 REST API, providing workflows and actions that enable users to automate and configure their F5 environments from Automation Orchestrator.

The VMware Aria Automation Orchestrator Plug-in for F5 BIG-IP provides nearly 200 out-of-the-box workflows for common F5 administrative tasks. For a full list of available workflows, see [F5 Plug-In Workflow Library](#).

System requirements

Before installing the plug-in on your Automation Orchestrator 8.x deployment, ensure your system meets the following requirements.

	F5 BIG-IP Requirements
Version	F5 BIG-IP 14.x, 15.x, 16.x
Connection	Hostname (Management IP or DNS name) of the F5 BIG-IP system
Credentials	User name and password with Administrative level access

Installing the F5 plug-in

Download the plug-in installation file from the [VMware Marketplace](#). For instructions how to install the plug-in, see [Install an plug-in](#).

Configuring the F5 plug-in

After the plug-in has been installed, you must configure the plug-in to an F5 BIG-IP instance. See [Run the Attach BIG-IP Workflow](#).

Accessing the F5 plug-in API

The VMware Aria Automation Orchestrator Plug-in for F5 BIG-IP also provides more than 900 scripting objects available for creating your own custom workflows. To view all of the available scripting objects that are available with the plug-in, navigate to the [API Explorer](#).

You can search by specific F5 object names and keywords, or scroll through the list to browse. Select a scripting object to view related properties.

Run the Attach BIG-IP Workflow

The **Attach BIG-IP** workflow configures an F5 BIG-IP endpoint to pull in the necessary F5 objects.

Download and install the VMware Aria Automation Orchestrator Plug-in for F5 BIG-IP. See [Using the](#)

1. Log in to the Automation Orchestrator Client.
2. Navigate to **Library > Workflows** and enter `Attach BIG-IP` in the workflow search box.
3. Locate the **Attach BIG-IP** workflow and click **Run**.
4. On the **General** tab, enter the following information.
 - The name of your F5 BIG-IP instance.
 - The hostname or IP address of your F5 BIG-IP instance.
 - The user name of your F5 BIG-IP instance.
 - The password associated with the user name of your F5 BIG-IP instance.
5. On the **Advanced Parameters** tab, configure the following settings.
 - Enter the interval length in minutes for data collection.
 - Enter the maximum number of threads that you want to be used during data collection.
 - Decide how SSL is used during collection. Select one of the following options.
 - • **No Verify**. Trust all server certificates.
 - **Verify**. Validate the certificate again the Java trust store.

- **No SSL.** Do not use SSL.
- Enter the timeout value in seconds for API requests.

6. On the **Collection Parameters** tab, set the modules for which you want configuration data collected to **true**.

7. Click **Run**.

After the workflow finishes, a green checkmark appears next to the workflow indicating it was successful.

NOTE

If the workflow fails, a red X appears next to the workflow, and errors are logged at the bottom of the screen.

- Verify the F5 Networks Inventory Tree. After your F5 BIG-IP instance is configured, click the **Inventory** tab to ensure that the F5 objects appear in the F5 Networks Inventory Tree.
- Run any of the other workflows provided with the plug-in. See [F5 Plug-In Workflow Library](#) for the full list of available workflows.

F5 Plug-In Workflow Library

The VMware Aria Automation Orchestrator Plug-in for F5 BIG-IP contains out-of-the-box workflows.

To access these workflows, navigate to **Library > Workflows** and enter the `f5_` tag in the workflow search box.

Category	Workflows
Asm	<ul style="list-style-type: none"> • ASM Activate Policy • ASM Assign Policy to VIP • ASM Blocking/Transparent Policy • ASM Export Policy • ASM Install Policy

Using the HTTP-REST Plug-In

The HTTP-REST plugin allows you to manage REST Web services by providing interaction between Automation Orchestrator and REST hosts. You can define REST services and their operations as inventory objects by running configuration workflows, and perform REST operations on the defined objects.

The plug-in contains a set of standard workflows related to managing REST hosts and invoking REST operations. You can also generate custom workflows to automate tasks in a REST environment.

Security Hardening

Sensitive information is considered internal to the corresponding HTTP-REST plug-in objects and intended for use only in scenarios involving these objects. Therefore, specific scripting properties and methods that might be used to access sensitive information are removed. Instead, you can store sensitive information in Automation Orchestrator configuration elements or external password vaults.

Persistent and Transient REST Hosts

The HTTP-REST plug-in supports two types of REST hosts that you can use to make requests to REST endpoints - persistent hosts and transient hosts.

Differences between persistent and transient hosts

The following table compares the two types of REST hosts.

Persistent Hosts	Transient Hosts
Stored in the Automation Orchestrator database.	Not stored in the Automation Orchestrator database. Transient hosts are virtual objects which reside in memory while a script is being executed.
Stored in the Automation Orchestrator inventory. Persistent hosts can also be viewed in form drop-down menus of the RESTHost type.	Not stored in the Automation Orchestrator inventory.
Available after restart, failover, and upgrade. When a workflow token gets interrupted, it can continue from where it left off if the workflow item takes a persistent REST host as input.	Not available after restart and failover. When a workflow gets interrupted, it can't restore a workflow item input which carries a transient REST host.
Use persistent hosts as inputs/outputs of workflow items. You can create them at the beginning of the scripting and delete them if you don't need them anymore.	Use transient hosts in scripting when you make isolated requests against a server which you otherwise don't use.
Can be exported and imported as resource elements.	Transferable across different Automation Orchestrator instances because they are created and managed entirely from scripting. Use transient hosts when you work on multiple environments with no need to migrate persistent hosts.
Each persistent host has a dedicated HTTP client that is used for managing requests to the endpoint.	Hosts reuse the same HTTP client instance.
Parallel requests are supported for persistent and transient hosts. <ul style="list-style-type: none"> If you activate parallel requests, each request is executed with a separate context, and the state, including cookies, is not preserved between requests. If support for parallel requests is deactivated, consecutive requests share the same HTTP context. 	

Considerations for transient hosts

When creating transient hosts, consider the following.

- Transient hosts passed between workflow items as input/output might not work in all cases. Transient hosts rely on workflow cache, which doesn't work when asynchronous workflows are started, for example. Nested workflows might also fail.
- Only `GET` and `HEAD` requests get redirected automatically. URL redirection uses the `default` strategy.
- Host name verification is not supported.
- Client certificate authentication is not supported.

Troubleshooting

If you use transient hosts without support for parallel requests, you might experience scripting regressions after upgrading your Automation Orchestrator environment or upgrading the HTTP-REST plug-in to version 2.4.1.19272162 or later. Using different transient host instances to run requests, which depend on one another for cookies, is not supported.

To avoid this problem, use one of the following methods.

- Instead of transient hosts, use persistent hosts and operations. You can create persistent REST hosts in one of two ways.
 - Create a REST host pointing to the server using the **Add a REST host** workflow. Instead of using transient hosts, use the REST host as input everywhere where you need to create a request to it.
 - Do not create transient operations pointing to this host. Create regular operations instead.
 - Support for parallel requests must be deactivated, otherwise cookies are not preserved.

This approach is not recommended if you make multiple requests in parallel to this host in your workflows.

- b. Create a REST host per workflow run from the scripting, and then delete it.

Use this method if you make parallel requests to the server. For example, if you have two parallel requests, create two different hosts.

1. Clone a workflow.
 2. Add a scripting element which creates the host that you want to use for future requests.
 3. Use the host as the output of the workflow and as input to all other scripting that makes requests to that host.
 4. To clean the state, add an element at the end of the scripting which deletes the host you created.
2. Use one transient host for all dependent requests in a given workflow and pass it between workflow items as input/output as needed.

Passing transient hosts between multiple workflow elements is not officially supported, but expected to work. Note that during restart, the workflow state might be lost and the workflow might not resume successfully.

If you use transient hosts and you want to make requests which depend on each other for cookies, you must use the same transient host instance for all requests. If the requests span multiple workflow items, create the host in the first workflow item and then pass it as input to the rest.

3. Use your current transient hosts, but modify the failing requests to include the necessary cookies by adding the respective headers.

You might have to parse the cookies from the previous response and use them in subsequent requests.

Configuring the HTTP-REST Plug-In

You can configure HTTP-REST by running the configuration workflows included in the plug-in. The Configuration workflow category contains workflows that help you to manage REST hosts.

To access these workflows in the Automation Orchestrator Client, navigate to **Library > Workflows** and enter the `http-rest` and `configuration` tags in the workflow search box.

Workflow Name	Description
Add a REST host	Adds a REST host to the plug-in inventory.
Add a REST host by Swagger spec as a string	Adds a REST host based on a Swagger spec web resource provided as a string.
Add a REST host by Swagger spec from a URL	Adds a REST host based on a Swagger spec available at a specific URL.
Add a REST operation	Adds an operation to a REST host.
Add schema to a REST host	Adds an XSD schema to a REST host.
Clone a REST host	Creates a clone of a REST host.
Clone a REST operation	Creates a clone of a REST operation.
Reload plug-in configuration	Refreshes the list of REST hosts in the plug-in inventory.
Remove a REST host	Removes a REST host from the plug-in inventory.
Remove a REST operation	Removes an operation from a REST host.
Remove schemas form a REST host	Removes all associated XSD schemas from a REST host.
Update a REST host	Updates a REST host in the plug-in inventory.
Update a REST operation	Updates an operation on a REST host.

Add a REST Host

You can run a workflow to add a REST host and configure the host connection parameters.

1. Log in to the Automation Orchestrator Client as an administrator.
2. Navigate to **Library > Workflows** and enter the `http-rest` and `configuration` tags in the workflow search box.
3. Locate the **Add a REST host** workflow and click **Run**.
4. On the **Host Properties** tab, enter the properties of the new host.
 - a) In the **Name** text box, enter the name of the host.
 - b) In the **URL** text box, enter the address of the host.

NOTE

The Kerberos authentication requires a Fully Qualified Domain Name (FQDN) host address.

- c) In the **Connection timeout** text box, enter the number of seconds before a connection times out.
- d) In the **Operation timeout** text box, enter the number of seconds before an operation times out.
- e) Select whether you want to accept the REST host certificate and add it to the Automation Orchestrator server trust store.
- f) Select whether you want to be able to run parallel requests.
- g) Select a redirect strategy.

Option	Description
defaultRedirect	Redirects only when the <code>HEAD</code> and <code>GET</code> methods are used.
alwaysRedirect	Redirects all HTTP methods, including <code>POST</code> , <code>PUT</code> , <code>DELETE</code> , and so on.
neverRedirect	Forbids all redirects and does not follow 3xx status codes with any HTTP method.

5. On the **Host Authentication** tab, select the authentication type.

Option	Description
None	No authentication is required.
OAuth 1.0	On the OAuth 1.0 tab, provide the required authentication parameters.
OAuth 2.0	<p>On the OAuth 2.0 tab, provide the authentication token and select a token sending strategy.</p> <ul style="list-style-type: none"> • If you select Authorization header, the token is sent in the authorization header of each request made to the host as a bearer token. • If you select Query parameter, the token is sent in the <code>oauth_token</code> query parameter of each request made to the host. <p>Alternatively, you can configure the authentication settings using the Automation Orchestrator scripting API. For instructions, see Using the Scripting API to Configure or Update a REST Host Authentication.</p>
Basic	<p>Provides basic access authentication.</p> <p>On the User credentials tab, select the session mode.</p>

Table continued on next page

Continued from previous page

Option	Description
	<ul style="list-style-type: none"> • If you select Shared Session, provide credentials for the shared session. • If you select Per User Session, the Automation Orchestrator client retrieves credentials from the user who is logged in.
Digest	<p>Provides digest access authentication that uses encryption.</p> <p>On the User credentials tab, select the session mode.</p> <ul style="list-style-type: none"> • If you select Shared Session, provide credentials for the shared session. • If you select Per User Session, the Automation Orchestrator client retrieves credentials from the user who is logged in.
NTLM	<p>Provides NT LAN Manager (NTLM) access authentication within the Window Security Support Provider (SSPI) framework.</p> <p>On the User credentials tab, select the session mode.</p> <ul style="list-style-type: none"> • If you select Shared Session, provide credentials for the shared session. • If you select Per User Session, the Automation Orchestrator client retrieves credentials from the user who is logged in. <p>On the NTLM tab, provide the NTLM settings.</p>
Kerberos	<p>Provides Kerberos access authentication.</p> <p>On the User credentials tab, select the session mode.</p> <ul style="list-style-type: none"> • If you select Shared Session, provide credentials for the shared session. • If you select Per User Session, the Automation Orchestrator client retrieves credentials from the user who is logged in.

6. On the **Proxy Settings** tab, select whether to use a proxy server.
 - a) Enter the address and the port of the proxy server.
 - b) Select the proxy authentication type.

Option	Description
None	No authentication is required.
Basic	<p>Provides basic access authentication.</p> <p>On the Proxy Credentials tab, select the session mode.</p>

Table continued on next page

Continued from previous page

Option	Description
	<ul style="list-style-type: none"> • If you select Shared Session, provide credentials for the shared session. • If you select Per User Session, the Automation Orchestrator client retrieves credentials from the user who is logged in.

7. On the **SSL** tab, select whether you want the target hostname to match the name stored in the server certificate.
8. Select a keystore entry to use to authenticate against the server. The keystore entry must be of the `PrivateKeyEntry` type.
9. Click **Run**.

After the workflow runs successfully, the REST host appears in the **Inventory** view.

You can add operations and XSD schema to the REST host. You can execute requests to the REST host based on the created REST operations using the default REST plug-in workflows, or using the Automation Orchestrator scripting.

Add a REST Operation

You can run a workflow to add an operation to a REST host from the plug-in inventory.

- Verify that you are logged in to the Automation Orchestrator Client as an administrator.
- Verify that you have a connection to a REST host from the **Inventory** view.

1. Navigate to **Library > Workflows** and enter the `http-rest` and configuration tags in the workflow search box.
2. Locate the **Add a REST operation** workflow and click **Run**.
3. Select the parent host to which you want to add the operation.
4. In the **Name** text box, enter the name of the operation.
5. In the **Template URL** text box, enter only the operation part of the URL.

You can include placeholders for parameters that are provided when you run the operation.

The following is an example URL syntax.

```
/customer/{id}/orders?date={date}
```

6. Select the HTTP method that the operation uses.
- If you select **POST** or **PUT**, you can provide a Content-Type request header for the method.
7. Click **Run**.

You can run workflows on the operation from the **Inventory** view.

Add a Schema to a REST Host

You can run a workflow to add an XSD schema to a REST host from the plug-in inventory.

- Verify that you are logged in to the Automation Orchestrator Client as an administrator.
- Verify that you have a connection to a REST host from the **Inventory** view.

The XSD schema describes the XML documents that are used as input and output content from Web services. By associating such a schema with a host, you can specify the XML element that is required as an input when you are generating a workflow from a REST operation.

1. Navigate to **Library > Workflows** and enter the `http-rest` and configuration tags in the workflow search box.
2. Locate the **Add a schema to a REST host** workflow and click **Run**.
3. On the **Host** tab, select the host to which you want to add the XSD schema.
4. On the **XSD Schema Details** tab, select whether to load the schema from URL.

Option	Action
Yes	Enter the URL of the schema.
No	Provide the schema content.

5. Click **Run**.

Generate a New Workflow from a REST Operation

You can create a custom workflow from a REST operation.

- Verify that you are logged in to the Automation Orchestrator Client as an administrator.
- Verify that you have a connection to a REST host from the **Inventory** view.

You can integrate custom-generated workflows into high-level workflows. For more information about workflow development, see the *Developing Workflows with Automation Orchestrator* guide.

1. Navigate to **Library > Workflows** and enter the `http-rest` tag in the workflow search box.
2. Locate the **Generate a new workflow from a REST operation** workflow and click **Run**.
3. Select the REST operation from the list of available operations.

If the operation takes input and XSD schemas are added to its host, you can specify the request input type.
4. In the **Name** text box, type the name of the workflow to generate.
5. Select the workflow folder in which to generate the new workflow.

You can select any existing folder from the workflow library.

6. Click **Run**.

Using the Library Plug-In

You can use the Library plug-in workflows as templates for customization and automation of client processes, and to troubleshoot Automation Orchestrator. The Library plug-in provides workflows in the **Locking**, **Orchestrator**, and **Tagging** workflow categories.

To access these workflows in the Automation Orchestrator Client, navigate to **Library > Workflows** and enter the tags in the workflow search box.

Locking Workflows

Use the `locking` tag.

Workflow Name	Description
Display all locks	Shows all locks.
Locking test	A test workflow that creates a lock.
Locking test (x5)	A test workflow that creates five locks.
Release all locks	Releases all locks.

Task Workflows

Use the `tasks` tag.

Workflow Name	Description
Create recurrent task	Creates a recurrent task and returns the newly created task.
Create task	Schedules a workflow to run at a later time and date, as a task.

Orchestrator Workflows

Use the `orchestrator` and `workflows` tags in the workflow search box.

Workflow Name	Description
Refresh stale workflow runs in waiting state	Processes all workflow runs that are in waiting state for the specified remote server and updates the workflow state according to the remote workflow run. You can use this workflow if there is data loss between the workflow runs, for example, when there is loss of connectivity between the Automation Orchestrator servers.
Start workflows in a series	Runs a workflow multiple times in a series, one instance after the other. You provide workflow parameters in an array. You also provide a property list, with one property per workflow input, for each instance of the workflow that starts. The number of properties in the array define the number of workflow runs.
Start workflows in parallel	Runs a workflow multiple times, with different parameters. You provide workflow parameters in an array. You also provide a property list, with one property per workflow input, for each instance of the workflow that starts. The number of properties in the array define the number of workflow runs.

Tagging Workflows

Use the `tagging` tag.

Workflow Name	Description
Find objects by tag	Finds objects by the tags assigned to them. You provide the names and values of the tags and the workflow returns a list of the objects to which these tags apply.

Table continued on next page

Continued from previous page

Workflow Name	Description
List workflow tags	Lists the tags assigned to the workflow you specified as an input parameter.
Tag workflow	Assigns a tag to a workflow. You must specify the workflow you want to tag and the tag name and value.
Tagging example	Demonstrates workflow tagging.
Untag workflow	Removes a tag from a workflow. You must specify the workflow you want to untag and the tag you want to remove from the workflow.

Using the Mail Plug-In

You can send email messages from workflows by using the Mail plug-in, which uses the Simple Mail Transfer Protocol (SMTP). For example, you can create a workflow to send an email to a given address if the workflow requires user interaction or when it completes its run.

Using the Mail plug-in sample workflows

You can call the sample workflows of the Mail plug-in from custom workflows to implement the email functionality to the custom workflows. You can run an example workflow to test the interaction between Automation Orchestrator and your SMTP server.

To access these workflows in the Automation Orchestrator Client, navigate to **Library > Workflows** and enter the `mail` tag in the workflow search box.

NOTE

Before you can access the workflows, verify that the user account that you are logged in with has the necessary permissions to run Mail workflows.

Workflow Name	Description
Configure mail	Defines the connection to the SMTP server, the SMTP authentication account, and the address and display name of the sender.
Retrieve messages	Retrieves the messages of a given email account by using the POP3 protocol.
Retrieve messages (via MailClient)	Retrieves the messages of a certain email account, without deleting them, by using the new scripting API provided by the <code>MailClient</code> class.
Send notification	Sends an email with specified content to a given email address. If optional parameters are not specified, the workflow uses the default values set through the Configure mail workflow.
Send notification to mailing list	Sends an email with specified content to a given email address list, CC list, and BCC list. If optional parameters are not specified, the workflow uses the default values set through the Configure mail workflow.

Define the default SMTP connection

You can set the default email account that can authenticate against an SMTP server to send and receive email notifications.

NOTE

Avoid load balancers when configuring mail in Automation Orchestrator. Otherwise, you might receive `SMTP_HOST_UNREACHABLE` error.

1. Log in to the Automation Orchestrator Client.
2. Navigate to **Library > Workflows** and enter the `mail` tag in the workflow search box.
3. Locate the **Configure mail** workflow and click **Run**.
4. On the **Host** tab, enter the IP address or domain name of your SMTP server and a port number to match your SMTP configuration.

The default SMTP port is 25.

5. On the **Credentials** tab, enter a user name and password for authentication.

Enter a valid email account and an associated password. Automation Orchestrator uses the email account to send emails.

6. On the **Email Content** tab, enter a sender's email address and name.

The sender information appears in all emails sent by Automation Orchestrator.

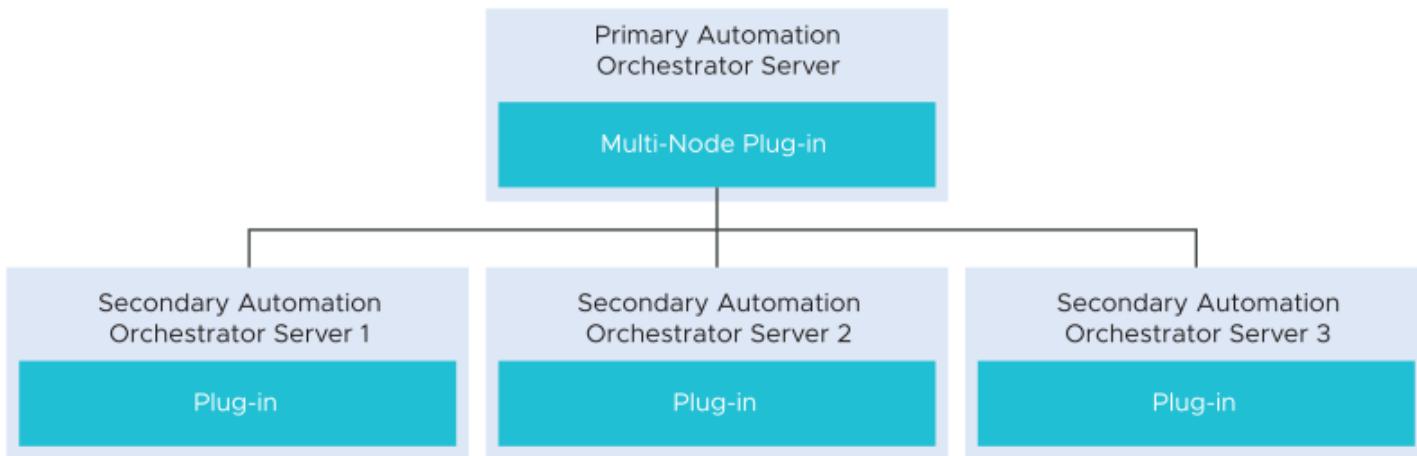

7. Click **Run**.

Using the Multi-Node plug-in

The Multi-Node plug-in workflow library contains workflows for hierarchical orchestration, management of Automation Orchestrator instances, and scale-out of Automation Orchestrator activities.

Multi-Node plug-in schema

The Multi-Node plug-in creates a primary-secondary relation between Automation Orchestrator servers, which extends in the areas of package management and workflow execution.

The plug-in contains a set of standard workflows for hierarchical orchestration, management of Automation Orchestrator instances, and scale-out of Automation Orchestrator activities.

Access the plug-in API

Automation Orchestrator provides an API Explorer to allow you to search the Multi-Node plug-in API and see the documentation for JavaScript objects that you can use in scripted elements.

Access the API Explorer from either the Automation Orchestrator Client or from the **Scripting** tabs of the workflow, policy, and action editors.

You can copy code from API elements and paste it into scripting boxes. For more information about API scripting, see *Developing with Automation Orchestrator*.

Using the Multi-Node plug-in inventory

The Multi-Node plug-in mirrors all inventories of the connected Automation Orchestrator servers in the **Inventory** view.

The inventory for a single remote server consists of two major parts, system objects and plug-in objects. Both objects are wrappers of the remote objects into locally usable types:

System object

System objects are under a top-level group called **System**. They contain configurations, packages, workflows, actions, and related folders. Remote system objects have individual wrapper types.

Plug-in objects

Plug-in objects mirror the inventories of all plug-ins attached to the remote Automation Orchestrator server. Remote plug-in objects are all wrapped into a single local type **VCO:RemotePluginObject**.

Remote management workflows

The Remote Management workflow category contains workflows that allow you to manage packages and workflows on remote Automation Orchestrator instances.

Remote Management Packages

To access these workflows, navigate to **Library > Workflows** and enter the `orchestrator`, `remote_management` and `packages` tags in the workflow search box.

Workflow Name	Description
Delete a package	Deletes a package and its contents from a remote Automation Orchestrator server.
Delete a package by name	Deletes a package and its contents by name on a remote Automation Orchestrator server.
Deploy a package from a local server	Deploys a package from a local Automation Orchestrator server to remote Automation Orchestrator servers.
Deploy a package from a remote server	Deploys a package from one remote Automation Orchestrator server to a list of remote Automation Orchestrator servers.
Deploy packages from a local server	Deploys packages from a local Automation Orchestrator server to remote Automation Orchestrator servers.

Remote Management Workflows

To access these workflows, navigate to **Library > Workflows** and enter the `orchestrator`, `remote_management` and `workflows` tags in the workflow search box.

Workflow Name	
Delete a remote workflow	Deletes a workflow from a remote Automation Orchestrator server.
Delete all finished workflow runs	Deletes all finished workflow runs from a remote workflow.
Deploy a workflow from a local server	Deploys a workflow from a local Automation Orchestrator server to a list of remote Automation Orchestrator servers.
Deploy a workflow from a remote server	Deploys a workflow from a remote Automation Orchestrator server to a list of other remote Automation Orchestrator servers.

Multi-Node plug-in use cases

The Multi-Node plug-in use cases include user scenarios such as importing a package from the local Automation Orchestrator server to the remote servers, using multi proxy actions, as well as information about maintenance of remote and proxy workflows.

Create a multi-proxy action

You can run the Create a multi-proxy action workflow to run a workflow on several servers.

You can create an action, so that you can run a workflow on a remote Automation Orchestrator server at a later stage.

1. Log in to the Automation Orchestrator Client as an administrator.
2. Navigate to **Library > Workflows** and enter the `orchestrator` and `remote_execution` tags in the workflow search box.
3. Locate the **Create a multi-proxy action** workflow and click **Run**.
4. On the **Action details** tab, enter the action name and module.

The action name must contain only alpha-numeric characters without spaces.

A new action is created even if another action with the same name exists.

5. On the **Workflow details** tab, select whether the workflow is local or remote.

Option	Description
Yes	Select the remote workflow that you want to use for this action.
No	Select the local workflow that you want to use for this action.

6. Click **Run**.

The generated action accepts the same parameters as the source workflow but promotes the parameters to an array in case of multi-selection of objects. The values in the array are indexed.

Maintenance of remote and proxy workflows

If the remote and proxy workflows change, you might want to update the proxies or to delete them if you do not need them anymore. For maintenance purposes, the Multi-Node plug-in provides workflows that allow you to update or delete proxy and remote workflow information.

To access the workflows for managing the proxy workflows in the Automation Orchestrator Client, navigate to **Library > Workflows** and enter the `orchestrator`, `remote_execution`, and `servers_proxies` tags in the workflow search box.

Workflow Name	Description
Refresh proxy workflows for an Orchestrator server	Regenerates all proxy workflows for the local Automation Orchestrator server from the remote server.
Delete proxy workflows for an Orchestrator server	Removes the proxy workflows for the local Automation Orchestrator server and deletes all generated workflows.

To access the workflows for further maintenance of the proxy workflows in the Automation Orchestrator Client, navigate to **Library > Workflows** and enter the `orchestrator`, `remote_management`, and `workflows` tags in the workflow search box.

Workflow Name	Description
Delete all finished workflow runs	Deletes all finished workflow runs from a remote workflow.
Delete a remote workflow	Deletes a workflow from a remote Automation Orchestrator server.
Deploy a workflow from a local server	Deploys a workflow from a local Automation Orchestrator server to a list of remote Automation Orchestrator servers.

Deploy a package from a local server

You can run a workflow to deploy a package from a local Automation Orchestrator server to remote Automation Orchestrator servers.

In this example, you can deploy a package from a local server to an array of remote servers.

1. Log in to the Automation Orchestrator Client as an administrator.
2. Navigate to **Library > Workflows** and enter the `orchestrator` and `remote_management` tags in the workflow search box.
3. Locate the **Deploy a package from a local server** workflow and click **Run**.
4. Select the package to deploy from the local storage.
5. Select the remote servers to deploy the package to.
6. Select whether you want to overwrite the remote server packages.

Option	Description
Yes	The packages on the remote server are replaced, discarding the version of the packaged elements.
No	A version check of the server and the deploying packages is performed. The packages are deployed after a successful check.

7. Click **Run**.

After running the workflow, the status information is displayed in the log view and in the inventory of the plug-in.

Using the Net Plug-In

You can use the Net plug-in to implement the Telnet, FTP, POP3, and IMAP protocols in workflows. The POP3 and IMAP implementations allow downloading and reading email. In combination with the Mail plug-in, the Net plug-in provides full email sending and receiving capabilities in workflows.

Using the PowerShell plug-in

The PowerShell plug-in allows interaction between Automation Orchestrator and Windows PowerShell. The PowerShell plug-in workflow library contains workflows that allow you to manage PowerShell hosts and run custom PowerShell operations.

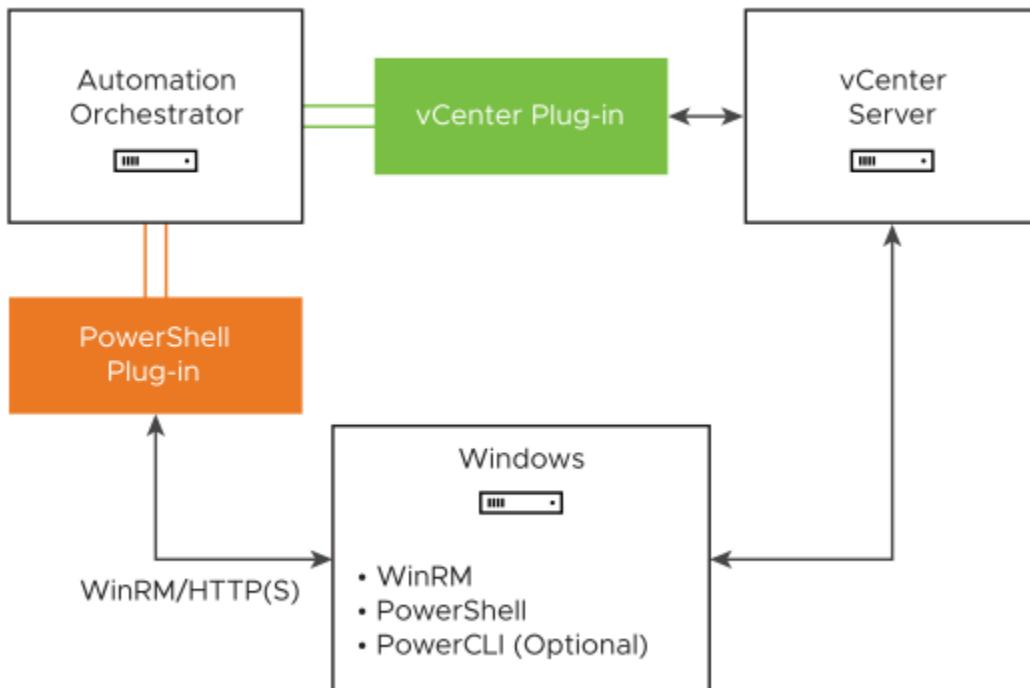

You use the plug-in to call PowerShell scripts and cmdlets from Automation Orchestrator actions and workflows, and to work with the result. In addition to the standard workflows that come with the plug-in, you can also create custom workflows that implement the plug-in API.

You can use the **Inventory** view in the Automation Orchestrator Client to manage the available PowerShell resources. You can use the scripting API of the plug-in to develop custom workflows.

PowerShell plug-in components

The PowerShell plug-in relies on a number of components to function properly.

Automation Orchestrator and Windows PowerShell provide the platform for the plug-in, and the plug-in provides interaction between those products. The PowerShell plug-in can also interact with other components, such as vCenter and vSphere PowerCLI.

The plug-in communicates with Windows PowerShell through the WinRM communication protocol. See [Configuring WinRM](#).

Optionally, you can integrate the PowerShell plug-in with vSphere PowerCLI and vCenter. See [PowerCLI Integration with the PowerShell Plug-In](#).

You can install all components on a local host. The usage, functionality, and communication protocol requirements of the PowerShell plug-in do not change if Automation Orchestrator and Windows PowerShell are installed on the same machine.

Access the PowerShell plug-in API

To access the API Explorer from the Automation Orchestrator Client, click **API Explorer** in the Automation Orchestrator Client navigation pane.

To access the API Explorer from the **Scripting** tabs of the workflow, policy, and action editors, click **Search API** on the left.

You can copy code from API elements and paste it into scripting boxes. For more information about API scripting, see *Developing with Automation Orchestrator*.

Using the PowerShell plug-in inventory

The PowerShell plug-in exposes all objects in the connected PowerShell hosts in the **Inventory** view.

Within the inventory of the plug-in, you can monitor PowerShell hosts and their snap-ins and cmdlets. Each remote host can contain snap-ins and each snap-in can contain cmdlets.

Configuring the PowerShell plug-in

You must use the Automation Orchestrator Client to configure the PowerShell plug-in.

Configuration Workflows

You use the workflows from the Configuration category to manage PowerShell hosts.

To access these workflows, navigate to **Library > Workflows** and enter the `powershell` and `configuration` tags in the workflow search box.

Workflow Name	Description
Add a PowerShell host	Adds a PowerShell host to the plug-in inventory.
Remove a PowerShell host	Removes a PowerShell host from the plug-in inventory.
Update a PowerShell host	Updates the specified PowerShell host in the plug-in inventory.
Validate a PowerShell host	Validates the configuration of the specified PowerShell host.

Sample Workflows

You use the workflows from the Samples category to test basic use cases.

To access these workflows in the workflows library, enter the `powershell` and `samples` tags in the workflow search box.

Workflow Name	Description
Invoke a script via API	Demonstrates how to call a PowerShell script through the available scripting API.
List directory content	Lists the contents of a directory on the PowerShell host file system.
Pipeline execution example	Demonstrates how you can run multiple cmdlets arranged into a pipe.

Table continued on next page

Continued from previous page

Workflow Name	Description
Toggle virtual machine state	Toggles the power state of a virtual machine.

Add a PowerShell host

You add a PowerShell host and configure the host connection parameters by running a workflow. You can set up a connection to a remote or a local PowerShell host.

Procedure

1. Log in to the Orchestrator client as an administrator.
2. Navigate to **Library > Workflows** and enter the `powershell` and `configuration` tags in the workflow search box.
3. Locate the Add a PowerShell host workflow and click **Run**.
4. In the **Name** text box, enter the name of the host.
5. In the **Host / IP** text box, enter the address of the host.

NOTE

The Kerberos authentication requires a Fully Qualified Domain Name (FQDN) host address.

6. In the **Port** text box, type the port of the host.
You use port 5985 for the HTTP or 5986 for the HTTPS protocol.
7. On the **Host Type** tab, specify the PowerShell host type that the plug-in connects to.
 - a. Select a transport protocol.

NOTE

If you use the HTTPS transport protocol, the certificate of the remote PowerShell host is imported into the Automation Orchestrator keystore.

- b. Select the authentication type.

IMPORTANT

If you want to use Kerberos authentication, you must enable it on the WinRM service.

8. On the **User Credentials** tab, select the type of session mode that the plug-in uses to connect to the PowerShell host.

Option	Description
Shared Session	The plug-in uses shared credentials to connect to the remote host. You must provide the PowerShell host credentials for the shared session. The PowerShell host credentials must belong to a member of the local administrators group.
Session per User	The Automation Orchestrator client retrieves credentials from the user who is logged in. You must log in with a <code>user@domain</code> format to Automation Orchestrator to use the Session per User mode.

9. On the **Advanced Options** tab, from the **Shell Code Page** drop-down menu, select the type of encoding that the PowerShell uses.
10. Click **Run**.

Results

After the workflow runs successfully, the PowerShell host appears in the **Inventory** view.

Troubleshooting

If the workflow fails with the Cannot Locate KDC (Dynamic Script Module name: addPowerShellHost#30) error, see [Troubleshooting the workflow Add a PowerShell host in VMware Aria Automation Orchestrator](#).

Working with PowerShell results

You can use objects from the PowerShell plug-in API to work with results that Windows PowerShell returns.

You can use the methods from the `PowerShellInvocationResult` class to retrieve information about a script that you run.

Method	Description
<code>getErrors()</code>	Returns a list of errors reported by the PowerShell engine during script invocation.
<code>getInvocationState()</code>	Status of the script. The possible values are <code>Completed</code> or <code>Failed</code> .
<code>getHostOutput()</code>	Output of the script as it appears on the PowerShell console.
<code>getResults()</code>	Objects returned by the PowerShell engine. The returned object is of type <code>PowershellRemotePSObject</code> .

`PowershellRemotePSObject` is a remote representation of objects returned by the PowerShell engine.

`PowershellRemotePSObject` contains XML serialization of the result that can be accessed by calling the `getXml()` method.

The PowerShell plug-in also provides an object model that wraps the XML result and provides easy access to particular object properties. The `getRootObject()` method provides access to the object model. In general, the `getRootObject()` method maps the PowerShell types to types available in Automation Orchestrator, by using the following rules.

- If the returned object is of a primitive PowerShell type, the object is mapped to the corresponding Orchestrator primitive type.
- If the returned object is of type `collection`, the object is represented as `ArrayList`.
- If the returned object is of type `dictionary`, the object is represented as `Hashtable`.
- If the returned object is of type `complex`, the object is represented as `PSObject`.

Scripting examples for common PowerShell tasks

You can cut, paste, and edit the JavaScript examples to write scripts for common PowerShell tasks.

For more information about scripting, see the *Automation Orchestrator Developer's Guide*.

Run a PowerShell Script Through the API

You can use JavaScript to run a PowerShell script through the plug-in API.

This example script performs the following actions.

- Opens a session to a PowerShell host.
- Provides a script to run.
- Checks invocation results.

- Closes the session.

```

var sess;
try {
    //Open session to PowerShell host
    var sess = host.openSession()
    //Set executed script
    var result = sess.invokeScript('dir')

    //Check for errors
    if (result.invocationState == 'Failed') {
        throw "PowerShellInvocationError: Errors found while executing script \n" +
        result.getErrors();
    }
    //Show result
    System.log( result.getHostOutput() );
} catch (ex) {
    System.error (ex)
} finally {
    if (sess) {
        //Close session
        host.closeSession( sess.getSessionId() );
    }
}

```

Work with Result

You can use JavaScript to work with the result of a PowerShell script run.

This example script performs the following actions.

- Checks the invocation state.
- Extracts a value from the result.
- Checks the **RemotePSObject** type.

```

var sess = host.openSession()
sess.addCommandFromString("dir " + directory)
var invResult = sess.invokePipeline();
//Show result

```

```

System.log( invResult.getHostOutput() ) ;

//Check for errors
if (invResult.invocationState == 'Failed'){
System.error(invResult.getErrors());
} else {
//Get PowerShellRemotePSObject
var psObject = invResult.getResults();
var directories = psObject.getRootObject();

var isList = directories instanceof Array
if ( isList ){
for (idx in directories){
var item = directories[idx];
if ( item.instanceOf('System.IO.FileInfo') ){//Check type of object
System.log( item.getProperty('FullName') );//Extract value from result
}
}
} else {
System.log( directories.getProperty('FullName') );//Extract value from
result
}
}

host.closeSession( sess.getSessionId() );

```

Connect with Custom Credentials

You can use JavaScript to connect to a PowerShell host with custom credentials.

```

var sess;
try {
sess = host.openSessionAs(userName, password);

var invResult = sess.invokeScript('$env:username');

```

```

//Check for errors

if (invResult.invocationState == 'Failed') {

    System.error(invResult.getErrors());

} else {

    //Show result

    System.log( invResult.getHostOutput() );

}

} catch (ex) {

    System.error (ex)

} finally {

    if (sess) {

        host.closeSession( sess.getSessionId());

    }

}

```

Troubleshooting

If you encounter problems when using the PowerShell plug-in, you can refer to a troubleshooting topic to understand the problem or solve it, if there is a workaround.

Activate Kerberos Event Logging

For troubleshooting purposes, you might want to activate Kerberos event logging on the Key Distribution Center (KDC) machine.

Back up the Windows registry.

1. Log in to the domain controller that acts as a Key Distribution Center (KDC).
2. Run the registry editor as an **administrator**.
3. In the registry window, expand
HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\Lsa\Kerberos\Parameters.
4. If a `LogLevel` registry key value does not exist, right-click to create it.
 - a) Right-click **Parameter**, select **New > DWORD (32-bit) Value**, and enter `LogLevel`.
 - b) Select **Parameter** and in the right pane, double-click `LogLevel` and enter `1` in the **Value data:** text box.

The new setting becomes effective without a reboot on Windows Server 2003 and later.

The Kerberos error event entries are recorded in the System Windows Event Log.

To deactivate Kerberos event logging, delete the `LogLevel` registry key value or change its value data to `0`.

Servers Not Found in Kerberos Database

After you add PowerShell servers with Kerberos authentication, the servers might not be found because they are not added correctly.

When you try to connect to a server, the server is not found in Kerberos database.

```
No valid credentials provided (Mechanism level: No valid
credentials provided (Mechanism level: Server not found in Kerberos
database (7)))
```

This error might be caused by several misconfigurations.

- The PowerShell host is not part of a domain.
- The host to realm mapping is not correct.
- The Service Principal Name of the PowerShell host is not built correctly.

NOTE

Kerberos authentication does not work when the destination is an IP address.

When you add a PowerShell host using the Kerberos authentication, enter a DNS or NetBIOS destination.

Unable to Obtain a Kerberos Ticket

When you provide wrong credentials, the plug-in fails to obtain a Kerberos ticket.

You are unable to add a host to the plug-in inventory and the result is the following error message.

```
Pre-authentication information was invalid (24)
```

You have provided wrong credentials.

Provide the correct credentials.

Kerberos Authentication Fails Due to Different Time Settings

Inconsistent time settings in the environment that uses Kerberos configuration might lead to authentication failure.

Attempts to use Kerberos for initial authentication of a host or for resource access fail, and the following error message appears.

```
Clock Skew
```

If the system time on the computers in the environment differs with more than 5 minutes from the domain controller, or from one another, the Kerberos authentication fails.

Synchronize the system times in the environment.

Kerberos Authentication Session Mode Fails

When you use Kerberos authentication with Shared Session or Session per User, adding the PowerShell host might fail.

When you attempt to add a PowerShell host to the plug-in inventory using Shared Session or Session per User, the workflow fails with the following error.

```
Null realm name (601) - default realm not specified (Dynamic Script Module name :
addPowerShellHost#16)
```

The default realm is not specified in the Kerberos configuration file `krb5.conf`, neither is provided as a part of the user name.

Provide a default realm in your Kerberos configuration file or include the realm in your user name when authenticating with Kerberos.

Unable to Reach a Key Distribution Center for a Realm

Any misspelling in the `krb5.conf` file might cause a failure when you add a host.

When you are adding a host, the Kerberos authentication is unable to reach a Key Distribution Center (KDC) for `yourrealm`.

```
Cannot get kdc for realm YOURREALM.COM
```

The `libdefaults` and `realms` sections in the `krb5.conf` file might be misspelled.

Verify that the `libdefaults` and `realms` sections in your `krb5.conf` file are spelled correctly.

Unable to Locate the Default Realm

Automation Orchestrator workflows that require Kerberos authentication might fail if the Kerberos configuration file does not have the correct format or encoding.

Kerberos authentication cannot identify the default realm.

```
Cannot locate default realm
```

The Kerberos configuration file `krb5.conf` that you upload to the Automation Orchestrator Appliance has been edited on a non-UNIX operating system. As a result, the format and the encoding might be incorrect.

In order for the Automation Orchestrator appliance to read the `krb5.conf` file, the format of the file must be UNIX and the character encoding must be ANSI as UTF-8.

Using the SNMP Plug-In

The SNMP plug-in allows Automation Orchestrator to connect and receive information from SNMP-enabled systems and devices. You can define SNMP devices as inventory objects by running workflows, and perform SNMP operations on the defined objects.

You can use the plug-in to connect to SNMP devices such as routers, switches, network printers, and UPS devices. The plug-in can also receive events from vCenter over the SNMP protocol.

The SNMP plug-in provides two methods of communication with the SNMP devices.

- Queries for the values of specific SNMP variables.
- Listening for events (SNMP traps) that are generated from the devices and pushed to the registered SNMP managers.

The plug-in contains a set of standard workflows related to managing SNMP devices, queries, the trap host, and performing SNMP operations. You can also create custom workflows to automate tasks in an SNMP environment.

Generic SNMP Request Workflows

The SNMP workflow category contains workflows that allow you to perform basic SNMP requests without having to create a query.

To access these workflows in the Automation Orchestrator Client, navigate to **Library > Workflows** and enter the `snmp` tag in the workflow search box.

Workflow Name	Description
Get bulk SNMP values	Runs a GET BULK query against an SNMP device.
Get next SNMP value	Runs a GET NEXT query against an SNMP device.
Get SNMP value	Runs a GET query against an SNMP device.
Send an SNMP trap	Sends an SNMP trap to a specified address.
Wait for a trap on all devices	Waits to receive an SNMP trap from all hosts that send traps to Automation Orchestrator.
Wait for a trap on an SNMP device	Waits to receive an SNMP trap from a specified device.

Using the SOAP plug-in

The SOAP plug-in allows you to manage SOAP Web services by providing interaction between Automation Orchestrator and SOAP hosts. You can define SOAP services as inventory objects by running configuration workflows, and perform SOAP operations on the defined objects.

The plug-in contains a set of standard workflows related to managing SOAP hosts and invoking SOAP operations. You can also generate custom workflows to automate tasks in a SOAP environment.

Invoke a SOAP Operation

You can call a SOAP operation directly, without generating a new workflow.

- Verify that you are logged in to the Automation Orchestrator Client as an administrator.
- Verify that you have a connection to a SOAP host from the **Inventory** view.

1. Navigate to **Library > Workflows** and enter the `soap` tag in the workflow search box.
2. Locate the **Invoke a SOAP operation** workflow and click **Run**.
3. Select the SOAP operation from the list of available operations.
4. Provide the input parameters that the SOAP operation requires.
5. Click **Run**.
6. In the **Logs** tab, review the list of available output parameters.

Using the SQL Plug-In

You can use the API that the SQL plug-in provides to implement connectivity to SQL databases and other tabular data sources, such as spreadsheets or flat files.

The SQL plug-in API, which is based on JDBC, provides a call-level API for SQL-based database access. The SQL plug-in also provides sample workflows that demonstrate how to use the API in workflows.

Configuring the SQL plug-in

You can use the workflows included in the SQL plug-in and run them from the Automation Orchestrator Client to configure the SQL plug-in and to add, update, or remove a database.

The Configuration workflow category of the SQL plug-in contains workflows that allow you to manage databases and database tables.

To access these workflows in the Automation Orchestrator Client, navigate to **Library > Workflows** and enter the `sql` and `configuration` tags in the workflow search box.

Workflow Name	Description
Add a database	Adds a database object to the SQL plug-in inventory.
Add tables to a database	Adds database tables to a database in the SQL plug-in inventory.
Remove a database	Removes a database object from the SQL plug-in inventory.
Remove a table from a database	Removes a database table from a database in the SQL plug-in inventory.
Update a database	Updates the configuration of a database object in the SQL plug-in inventory.
Validate a database	Validates a database in the SQL plug-in inventory.

Add a Database

You can run a workflow to add a database to the Automation Orchestrator server and configure the host connection parameters.

When you add a database that requires a secure connection, you must import the database SSL certificate. You can import the SSL certificate under the **Trusted Certificates** tab in Control Center.

NOTE

You might need to install a third party connector to use the database if it is not already installed. For more information, go to [Adding a JDBC connector for the SQL plug-in](#).

1. Log in to the Automation Orchestrator Client.
2. Navigate to **Library > Workflows** and enter the `sql` and `configuration` tags in the workflow search box.
3. Locate the **Add a database** workflow and click **Run**.
4. In the **Name** text box, enter the name of the database.
5. Select the type of the database.
6. In the **Connection URL** text box, enter the address of the database.

Database Type	Syntax
Oracle	<code>jdbc:oracle:thin:@database_url:port_number:SID</code>
Microsoft SQL (with SQL authentication)	<code>jdbc:jtds:sqlserver://database_url:port_number/database_name</code>
Microsoft SQL (with Windows account authentication)	<code>jdbc:jtds:sqlserver://database_url:port_number/database_name;useNTLMv2=true;domain=domain_name</code>
PostgreSQL	<code>jdbc:postgresql://database_url:port_number/database_name</code>
MySQL	<code>jdbc:mysql://database_url:port_number/database_name</code>

7. On the **User credentials** tab, select the session mode that the plug-in uses to connect to the database.

Option	Description
Shared Session	The plug-in uses shared credentials to connect to the database. You must provide the database credentials for the shared session.
Session Per User	<p>The Automation Orchestrator Client retrieves credentials from the user who is logged in.</p> <p>NOTE To use session per user mode, you must authenticate by using a user name only. Do not use <code>domain\user</code> or <code>user@domain</code> for authentication.</p>

8. Click **Run**.

After the workflow runs successfully, the database and all tables that belong to it appear in the **Inventory** view.

Add Tables to a Database

You can run a workflow to add tables to a database that is in the SQL plug-in inventory.

- Verify that you are logged in to the Automation Orchestrator Client as an administrator.
- Verify that you have a connection to a database from the **Inventory** view.

1. Navigate to **Library > Workflows** and enter the `sql` and `configuration` tags in the workflow search box.
2. Locate the **Add tables to a database** workflow and click **Run**.
3. Select a database to which to add tables.
4. Select the tables that you want to add.
5. Click **Run**.

After the workflow runs successfully, the added database tables appear in the **Inventory** view of the Automation Orchestrator Client.

Update a Database

You can run a workflow to update the configuration of a database that is in the SQL plug-in inventory.

1. Log in to the Automation Orchestrator Client.
2. Navigate to **Library > Workflows** and enter the `sql` and `configuration` tags in the workflow search box.
3. Locate the **Update a database** workflow and click **Run**.
4. Select the database that you want to update.
5. In the **Name** text box, enter the new name of the database.
The database appears in the **Inventory** view with the name that you entered.
6. Select the type of the database.
7. In the **Connection URL** text box, enter the new address of the database.
8. On the **User credentials** tab, select the session mode that the plug-in uses to connect to the database.

Option	Description
Shared Session	The plug-in uses shared credentials to connect to the database. You must provide the database credentials for the shared session.
Session Per User	<p>The Automation Orchestrator Client retrieves credentials from the user who is logged in.</p> <p>NOTE To use session per user mode, you must authenticate by using a user name only. Do not use <code>domain\user</code> or <code>user@domain</code> for authentication.</p>

9. Click **Run**.

Running the SQL Sample Workflows

You can run the SQL plug-in workflows to perform JDBC operations such as generating a JDBC URL, testing a JDBC connection, and managing rows in JDBC tables. You can also run the SQL plug-in workflows to manage databases and database tables, and to run SQL operations.

Generate a JDBC URL

You can run a workflow from the Automation Orchestrator Client to generate a JDBC connection URL.

Verify that the user account you are logged in with has the necessary permissions to run JDBC workflows.

1. Log in to the Automation Orchestrator Client.
2. Navigate to **Library > Workflows** and enter the `jdbc` tag in the workflow search box.
3. Locate the **JDBC URL generator** workflow and click **Run**.
4. On the **General** tab, select the type of database for which to generate a URL.

NOTE

If you use a Microsoft database, select the **Microsoft** tab and provide the database instance name and database user domain name.

5. Provide the required information to generate a database URL.
 - a) Enter a database server name or IP address.
 - b) Enter a database name.
 - c) Enter a database port number.

If you do not specify a port number, the workflow uses a default port number.

 - d) Enter a user name to access the database.
 - e) Enter a password to access the database.
6. Click **Run**.

Test a JDBC connection

You can run a workflow from the Automation Orchestrator Client to test the connection to a database.

Verify that the user account you are logged in with has the necessary permissions to run JDBC workflows.

1. Log in to the Automation Orchestrator Client.
2. Navigate to **Library > Workflows** and enter the `jdbc_examples` tag in the workflow search box.
3. Locate the **JDBC connection example** workflow and click **Run**.
4. Provide the required information to test a database connection.
 - a) Enter a user name to access the database.
 - b) Enter the URL to test.
 - c) Enter a password to access the database.
5. Click **Run**.

Create a table by using JDBC

You can run a workflow from the Automation Orchestrator Client to create a database.

Verify that the user account you are logged in with has the necessary permissions to run JDBC workflows.

1. Log in to the Automation Orchestrator Client.
2. Navigate to **Library > Workflows** and enter the `jdbc_examples` tag in the workflow search box.
3. Locate the **JDBC create table example** workflow and click **Run**.
4. Provide the required information, and click **Next**.
 - a) Type a password to access the database.
 - b) Type a database connection URL.
 - c) Type a user name to access the database.
5. Enter an SQL create statement.
Example syntax is:

```
CREATE TABLE "table_name"
("column1" "data_type_for_column1",
 "column2" "data_type_for_column2")
```
6. Click **Run**.

Insert a Row into a JDBC Table

You can run a workflow from the Automation Orchestrator Client to test the insertion of a row into a JDBC table.

Verify that the user account you are logged in with has the necessary permissions to run JDBC workflows.

1. Log in to the Automation Orchestrator Client.
2. Navigate to **Library > Workflows** and enter the `jdbc_examples` tag in the workflow search box.
3. Locate the **JDBC insert into table example** workflow and click **Run**.
4. On the **Database connection** tab, provide the required information.
 - a) Type a database connection URL.
 - b) Type a user name to access the database.
 - c) Type a password to access the database.
5. On the **SQL statement** tab, enter an SQL insert statement similar to the following example.

```
INSERT INTO "table_name" ("column1", "column2")
VALUES ("value1", "value2")
```
6. On the **Values to insert** tab, enter the values to insert into the row.
7. Click **Run**.

Select Rows from a JDBC Table

You can run a workflow from the Automation Orchestrator Client to select rows from a JDBC table.

Verify that the user account you are logged in with has the necessary permissions to run JDBC workflows.

1. Log in to the Automation Orchestrator Client.
2. Navigate to **Library > Workflows** and enter the `jdbc_examples` tag in the workflow search box.
3. Locate the **JDBC select from table example** workflow and click **Run**.
4. On the **Database connection tab**, provide the required information.
 - a) Type a database connection URL.
 - b) Type a user name to access the database.
 - c) Type a password to access the database.
5. On the **SQL statement** tab, type an SQL select statement similar to the following example.
Example syntax is:
`SELECT * FROM "table_name"`
6. Click **Run**.

Delete an Entry from a JDBC Table

You can run a workflow from the Automation Orchestrator Client to test the deletion of an entry from a JDBC table.

Verify that the user account you are logged in with has the necessary permissions to run JDBC workflows.

1. Navigate to **Library > Workflows** and enter the `jdbc_examples` tag in the workflow search box.
2. Locate the **JDBC delete entry from table example** workflow and click **Run**.
3. Provide the required information.
 - a) Enter the first name of the user entry to be deleted.
 - b) Type a user name to access the database.
 - c) Enter a JDBC connection URL.
 - d) Enter the last name of the user entry to be deleted.
 - e) Type a password to access the database.
4. Enter an SQL delete statement similar to the following example syntax.
`DELETE FROM "table_name" where ("column1" = ?, "column2" = ?)`
5. Click **Run**.

Delete All Entries from a JDBC Table

You can run a workflow from the Automation Orchestrator Client to delete all entries from a JDBC table.

Verify that the user account you are logged in with has the necessary permissions to run JDBC workflows.

1. Navigate to **Library > Workflows** and enter the `jdbc_examples` tag in the workflow search box.
2. Locate the **JDBC delete all from table example** workflow and click **Run**.
3. Provide the required information.
 - a) Type a database connection URL.
 - b) Type a user name to access the database.
 - c) Type a password to access the database.
4. Type an SQL delete statement similar to the following example syntax.
`DELETE FROM "table_name"`

5. Click **Run**.

Drop a JDBC Table

You can run a workflow from the Automation Orchestrator Client to test the dropping of a JDBC table.

Verify that the user account you are logged in with has the necessary permissions to run JDBC workflows.

1. Navigate to **Library > Workflows** and enter the `jdbc_examples` tag in the workflow search box.
2. Locate the **JDBC drop table example** workflow and click **Run**.
3. Provide the required information.
 - a) Type a password to access the database.
 - b) Type a database connection URL.
 - c) Type a user name to access the database.
4. Enter an SQL drop statement similar to the following example syntax.

```
DROP TABLE "table_name"
```

5. Click **Run**.

Run a Complete JDBC Cycle

You can run a workflow from the Automation Orchestrator Client to test all JDBC example workflows in one full cycle.

Verify that the user account you are logged in with has the necessary permissions to run JDBC workflows.

1. Navigate to **Library > Workflows** and enter the `jdbc_examples` tag in the workflow search box.
2. Locate the **Full JDBC cycle example** workflow and click **Run**.
3. Provide the required information.
 - a) Type a database connection URL.
 - b) Type a user name to access the database.
 - c) Type a password to access the database.
4. Enter the values to be used as entries in the database.
5. Click **Run**.

Running SQL Operations

You can use the SQL workflows to run SQL operations.

To access the SQL operations workflows in the Automation Orchestrator Client, navigate to **Library > Workflows** and enter the `sql` tag in the workflow search box.

Workflow Name	Description
Execute a custom query on a database	Runs a custom query on a specified database and returns the number of affected rows. You can run the workflow to update, delete, insert, and write queries.
Generate CRUD workflows for a table	Generates Create, Read, Update, and Delete workflows for a particular table.
Read a custom query from a database	Runs a custom query on a specified database and returns the result in an array of properties. You can run the workflow to select and read queries.

Generate CRUD Workflows for a Table

You can run a workflow to generate Create, Read, Update, and Delete workflows for a particular table.

- Verify that you are logged in to the Automation Orchestrator Client as an administrator.
- Verify that you have a connection to a database from the **Inventory** view.

1. Navigate to **Library > Workflows** and enter the `sql` tag in the workflow search box.
2. Locate the **Generate CRUD workflows for a table** workflow and click **Run**.
3. Select a table for which to generate the workflows.
4. Select the workflow folder in which to generate the workflows.
5. Select whether to overwrite any existing workflows.

Option	Description
Yes	The generated workflows overwrite existing workflows with the same name.
No	New workflows are not generated if workflows with the same name exist in the folder.

6. On the **Select read-only columns** tab, select columns that should not be populated.

You cannot edit the selected columns with the generated CRUD workflows.

7. Click **Run**.

After the workflow runs successfully, the CRUD workflows appear in the selected workflow folder.

You can run the generated workflows on the selected database table.

Adding a JDBC connector for the VMware Aria Automation Orchestrator SQL plug-in

This example demonstrates how you can add a MySQL connector for the VMware Aria Automation Orchestrator SQL plug-in.

The VMware Aria Automation Orchestrator SQL plug-in supports only certain database database types. Before adding a MySQL connector, verify that you are using one of the following database types:

- Oracle
- Microsoft SQL Server
- PostgreSQL
- MySQL

1. Add the MySQL connector.jar file to the VMware Aria Automation Orchestrator Appliance.

NOTE

For clustered VMware Aria Automation Orchestrator deployments, perform this operation on the appliances of all the nodes.

- a) Log in to the VMware Aria Automation Orchestrator Appliance command line over SSH as **root**.
- b) Navigate to the `/data/vco/var/run/vco` directory.

```
cd /data/vco/var/run/vco
```

- c) Create a `plugins/SQL/lib/` directory.

```
mkdir -p plugins/SQL/lib/
```

- d) Copy your MySQL connector.jar file from your local machine to the `/data/vco/var/run/vco/plugins/SQL/lib/` directory by running a secure copy (SCP) command.

```
scp ~/local_machine_dir/your_mysql_connector.jar root@orchestrator_FQDN_or_IP:/data/vco/var/run/vco/plugins/SQL/lib/
```

NOTE

You can also use alternative methods for copying your connector.jar file to the VMware Aria Automation Orchestrator Appliance, such as PSCP.

2. Add the new MySQL property to the Control Center.

- Log in to the Control Center as **root**.
- Select **System Properties**.
- Click **New**.
- Under **Key**, enter `o1ln.plugin.SQL.classpath`.
- Under **Value**, enter `/var/run/vco/plugins/SQL/lib/your_mysql_connector.jar`.

NOTE

The value text box can include multiple JDBC connectors. Each JDBC connector is separated by a semicolon (";"). For example:

```
/var/run/vco/plugins/SQL/lib/your_mysql_connector.jar;/var/run/vco/plugins/SQL/lib/your_mssql_connector.jar;/var/run/vco/plugins/SQL/lib/your_other_connector.jar
```

- Enter a description for the MySQL system property.
- Click **Add**, and wait for the VMware Aria Automation Orchestrator server to restart.

NOTE

Do not save your JDBC connector.jar file in another directory and do not set a different value to the `o1ln.plugin.SQL.classpath` property. Otherwise, the JDBC connector becomes unavailable to your VMware Aria Automation Orchestrator deployment.

Using the SSH Plug-In

You can use the SSH plug-in workflows to run SSH commands on a remote host that supports SSH and transfer files between a Automation Orchestrator server and a remote host through a secure connection.

Configuring the SSH Plug-In

You can run the SSH plug-in configuration workflows to manage the connections between Automation Orchestrator and SSH hosts.

To access these workflows in the Automation Orchestrator, navigate to **Library > Workflows** and enter the `ssh` and `configuration` tags in the workflow search box.

Workflow Name	Description
Add a Root Folder to SSH Host	Adds a root folder to an existing connection to an SSH host.
Add SSH Host	Adds a connection to an SSH host to the existing configuration.
Remove a Root Folder from SSH Host	Removes a root folder from an existing connection to an SSH host.
Remove SSH Host	Removes an existing connection to an SSH host from the existing configuration.
Update SSH Host	Updates an existing connection to an SSH host.

Add an SSH Host

You can set up the SSH plug-in to ensure encrypted connections.

1. Log in to the Automation Orchestrator Client.
2. Navigate to **Library > Workflows** and enter the `ssh` and `configuration` tags in the workflow search box.
3. Locate the **Add SSH host** workflow and click **Run**.
4. On the **General Information** tab, in the **Host name** text box, enter the name of the host that you want to access with SSH through Automation Orchestrator.
5. Enter the target port. The default SSH port is 22.
The host is added to the list of SSH connections.
6. Configure an entry path on the server.
 - a) Click **New root folder**.
 - b) Enter the new path and click **Insert value**.
7. On the **Authentication** tab, enter the user name for a user who has the necessary permissions to run SSH commands.
8. Select the authentication type.

Option	Action
Yes	To use password authentication, enter a password.
No	To use key authentication, enter the path to the private key and the private key passphrase.

9. Click **Run**.

The SSH host is available in the **Inventory** view of the Automation Orchestrator Client.

Running the SSH Plug-In Sample Workflows

You can run the SSH plug-in sample workflows from the Automation Orchestrator Client to test the connection between the Automation Orchestrator server and the SSH host.

Change the Key Pair Passphrase

You can run a workflow from the Automation Orchestrator Client to change the passphrase for the key pair that you generated most recently.

Verify that the user account you are logged in with has the necessary permissions to run SSH workflows.

1. Log in to the Automation Orchestrator Client.
2. Navigate to **Library > Workflows** and enter the `ssh` tag in the workflow search box.
3. Locate the **Change key pair passphrase** workflow and click **Run**.
4. On the **Change passphrase** tab, reset the key pair passphrase.
 - a) Enter the current passphrase.
 - b) Enter the new passphrase.
5. Click **Run**.

Register a Automation Orchestrator Public Key on an SSH Host

You can use a public key instead of a password. To register a Automation Orchestrator public key on an SSH host, you can run a workflow from the Automation Orchestrator client.

Verify that the user account you are logged in with has the necessary permissions to run SSH workflows.

1. Log in to the Automation Orchestrator Client.
2. Navigate to **Library > Workflows** and enter the `ssh` tag in the workflow search box.
3. Locate the **Register vCO public key on host** workflow and click **Run**.
4. On the **Register VS-O on Host** tab, provide the name of the SSH host, and the user name and password to log in to this host.

NOTE

You must provide credentials that are registered on the SSH host.

5. Click **Run**.

You can use public key authentication instead of password authentication when you connect to the SSH host as the registered user.

Run an SSH Command

You can run a workflow from the Automation Orchestrator Client to run SSH commands on a remote SSH server.

Verify that the user account you are logged in with has the necessary permissions to run SSH workflows.

1. Log in to the Automation Orchestrator Client.
2. Navigate to **Library > Workflows** and enter the `ssh` tag in the workflow search box.
3. Locate the **Run SSH command** workflow and click **Run**.
4. On the **Host selection** tab, enter an SSH host name or IP address.
5. On the **Command** tab, enter an SSH command to run.

NOTE

The default SSH command is `uptime`. It shows how long the server has been active and the user load for that period.

6. On the **Encoding** tab, specify the encoding method.
Leave this field empty to use the default system encoding.
7. On the **Authentication** tab, enter a user name.
8. Select the check box to use password authentication.

NOTE

The default option is to use key file authentication.

9. Enter a password if the authentication method requires a password. Otherwise, enter the path to the private key and enter the passphrase for the private key.
10. Click **Run**.

Copy a File from an SSH Host

You can run a workflow on the Automation Orchestrator Client to copy files from an SSH host to the Automation Orchestrator server.

Verify that the user account you are logged in with has the necessary permissions to run SSH workflows.

NOTE

Automation Orchestrator must have explicit write permissions to write in folders.

The SSH plug-in uses the Java JCraft library, which implements SFTP. The SCP get command workflow transfers files by using SFTP.

1. Log in to the Automation Orchestrator Client.
2. Navigate to **Library > Workflows** and enter the `ssh` tag in the workflow search box.
3. Locate the **SCP get command** workflow and click **Run**.
4. On the **Host** tab, enter the source host information.
 - a) Enter an SSH host name or IP address.
 - b) Enter the SSH user name and password.
5. On the **File** tab, enter the file information.
 - a) Enter the path to the file to get from the remote SSH host.
 - b) Enter the path to the directory on the Automation Orchestrator server into which to copy the file.
6. Click **Run**.

Copy a File to an SSH Host

You can run a workflow from the Automation Orchestrator Client to copy files from the Automation Orchestrator server to an SSH host.

Verify that the user account you are logged in with has the necessary permissions to run SSH workflows.

The SSH plug-in uses the Java JCraft library, which implements SFTP. The SCP put command workflow transfers files by using SFTP.

1. Navigate to **Library > Workflows** and enter the `ssh` tag in the workflow search box.
2. Locate the **SCP put command** workflow and click **Run**.
3. On the **Host** tab, enter the source host information.
 - a) Enter an SSH host name or IP address.
 - b) Enter the SSH user name and password.
4. On the **File** tab, enter the file information.
 - a) Enter the path to the file that you want to copy from the local Orchestrator server to the remote SSH host.
 - b) Enter the path to the directory on the remote SSH host into which to copy the file.
5. Click **Run**.

Using the vCenter plug-in

You can use the vCenter plug-in to manage multiple vCenter instances. You can create workflows that use the vCenter plug-in API to automate tasks in your vCenter environment.

vCenter Plug-In Scripting API

The vCenter plug-in maps the vCenter API to the JavaScript that you can use in workflows. The vCenter scripting API contains classes, with their respective attributes, methods, and constructors that allow interaction between Automation Orchestrator and vCenter.

The vCenter plug-in supports registering vCenter 6.5, 6.7, 7.0 instances as endpoints. Based on the vCenter version that you register, the plug-in exposes vSphere 6.5 and 6.7 API as SDK, and vSphere 7.0 API as scripting SDK. For information about vCenter scripting objects, navigate to the API Explorer in the Automation Orchestrator Client.

The vCenter plug-in provides a library of standard workflows that automate vCenter operations. For example, you can run workflows that create, clone, migrate, or delete virtual machines. The plug-in also provides actions that perform individual vCenter tasks that you can include in workflows. You can use the API to develop custom workflows.

Most vCenter plug-in workflows communicate only with the vCenter. However, some guest operations workflows require communication with the ESXi host managed by vCenter. Before you run these workflows, you must import the ESXi host certificate through the Automation Orchestrator Control Center. For more information, see *Manage Automation Orchestrator Certificates* in *Installing and Configuring Automation Orchestrator*.

The vCenter plug-in includes the Policy-Based Management (PBM) and the Storage Monitoring Service (SMS) APIs as scripting objects in the Automation Orchestrator scripting API. The Storage Policy-Based Management policies and components appear in the **Inventory** page of the Automation Orchestrator Client.

Using the vCenter Plug-In Inventory

The vCenter plug-in exposes all objects of the connected vCenter instances in the Inventory view.

To display the workflows that are available for a vCenter inventory object, navigate to **Administration > Inventory > vSphere vCenter Plug-in** in the Automation Orchestrator Client.

Performance Considerations for Querying

With the vCenter plug-in for Automation Orchestrator, you can query the vCenter inventory for specific objects.

Querying Methods

For querying, you can either use the `vCSearchIndex` managed object, or the object finder methods that are included in the plug-in inventory, such as `getAllDatastores()`, `getAllVirtualMachines()`, `findAllForType()`, and others.

Performance

By default, both methods return the queried objects without including any of their properties, unless you specify a set of properties as an argument for the method parameters in the search query.

NOTE

You must always use query expressions with the `getAll...()` and `findAll...()` finder objects to prevent the Automation Orchestrator Client from filtering large sets of returned objects, which might affect the overall performance of the Automation Orchestrator server.

You can use two types of expressions for querying the vCenter inventory.

Type of Expression	Description
Name expressions	<p>You can specify a name as an argument for a query parameter.</p> <p>NOTE The objects are filtered by the specified name argument according to the name of the plug-in object as it appears in the vCenter plug-in inventory.</p>
XPath expressions	<p>You can use expressions based on the XPath query language. For more information, see Using XPath Expressions with the Plug-In.</p>

When you invoke a vCenter inventory object with custom properties, each reference to this object, in a workflow or an action, sends a query to the vCenter, which generates a noticeable performance overhead. To optimize performance and avoid serializing and deserializing the object multiple times within a workflow run, it is best to use a shared resource to store the object, instead of storing it as a workflow attribute, an input, or an output parameter. Such shared resource can be a configuration element or a resource element.

vCenter Plug-In Workflow Library

The vCenter plug-in workflow library contains workflows that you can use to run automated processes related to the management of vCenter.

Batch Workflows

Batch workflows populate configuration elements or run workflows on a selected vCenter object.

To access these workflows, navigate to **Library > Workflows** and enter the `vccenter` and `batch` tags in the workflow search box.

Workflow Name	Description
Fill batch configuration elements	<p>Populates the configuration elements that the Run a workflow on a selection of objects workflow uses. Performs the following tasks:</p> <ul style="list-style-type: none"> • Resets the <code>BatchObject</code> and <code>BatchAction</code> configuration elements. • Fills the <code>BatchObject</code> configuration element with all the workflows that have only one input parameter. • Fills the <code>BatchAction</code> configuration element with all the actions that have no input parameters or one input parameter and that have an array as the <code>returnType</code>.
Run a workflow on a selection of objects	<p>Runs a workflow on a selection of vCenter objects, taking one action as input. This is the action that retrieves the list of objects on which to run the workflow. To return the objects without running the selected workflow, run the workflow in simulation mode.</p>

Cluster and Compute Resource Workflows

With the cluster and compute resource workflows, you can create, rename, or delete a cluster. You can also activate or deactivate high availability, Distributed Resource Scheduler, and vCloud Distributed Storage on a cluster.

To access these workflows, navigate to **Library > Workflows** and enter the `vcenter` and `cluster_and_compute_resource` tags in the workflow search box.

Workflow Name	Description
Add DRS virtual machine group to cluster	Adds a DRS virtual machine group to a cluster.
Add virtual machines to DRS group	Adds a virtual machine list to an existing DRS virtual machine group.
Create cluster	Creates a cluster in a host folder.
Delete cluster	Deletes a cluster.
Disable DRS on cluster	Deactivates DRS on a cluster.
Disable HA on cluster	Deactivates high availability on a cluster.
Disable vCloud Distributed Storage on cluster	Deactivates vCloud Distributed Storage on a cluster.
Enable DRS on cluster	Activates DRS on a cluster.
Enable HA on cluster	Activates high availability on a cluster.
Enable vCloud Distributed Storage on cluster	Activates vCloud Distributed Storage on a cluster.
Remove virtual machine DRS group from cluster	Removes a DRS virtual machine group from a cluster.
Remove virtual machines from DRS group	Removes virtual machines from a cluster DRS group.
Rename cluster	Renames a cluster.

Configuration Workflows

The Configuration workflow category of the vCenter plug-in contains workflows that let you manage the connections to vCenter instances.

You can access these workflows from **Library > vCenter > Configuration** in the **Workflows** view of the Automation Orchestrator client.

Workflow Name	Description
Add a vCenter instance	Configures Automation Orchestrator to connect to a new vCenter instance so that you can run workflows over the objects in the vSphere infrastructure.
List the Orchestrator extensions of vCenter	Lists all Automation Orchestrator extensions of vCenter.
Register Orchestrator as a vCenter extension	Registers the Automation Orchestrator instance as a vCenter extension.
Remove a vCenter instance	Removes a vCenter instance from the Automation Orchestrator inventory. You cannot orchestrate this vCenter instance any longer.
Update a vCenter instance	Updates the connection to a vCenter instance. For example, if the certificate or the IP address of your vCenter system changes, you must update the connection parameters to the vCenter instance so that you can manage your vSphere inventory with Automation Orchestrator.
Unregister a vCenter extension	Unregisters a vCenter extension.

Custom Attributes Workflows

With custom attributes workflows, you can add custom attributes to virtual machines or get a custom attribute for a virtual machine.

To access these workflows, navigate to **Library > Workflows** and enter the `vcenter` and `custom_attributes` tags in the workflow search box.

Workflow Name	Description
Add custom attribute to a virtual machine	Adds a custom attribute to a virtual machine.
Add custom attribute to multiple virtual machines	Adds a custom attribute to a selection of virtual machines.
Get custom attribute	Gets a custom attribute for a virtual machine in vCenter.

Datacenter Workflows

With datacenter workflows, you can create, delete, reload, rename, or rescan a datacenter.

To access these workflows, navigate to **Library > Workflows** and enter the `vcenter` and `datacenter` tags in the workflow search box.

Workflow Name	Description
Create datacenter	Creates a data center in a data center folder.
Delete datacenter	Deletes a data center.
Reload datacenter	Forces vCenter to reload data from a data center.
Rename datacenter	Renames a data center and waits for the task to complete.
Rescan datacenter HBAs	Scans the hosts in a data center and initiates a rescan on the host bus adapters to discover new storage.

Datastore and Files Workflows

With the datastore and files workflows, you can delete a list of files, find unused files in a datastore, and so on.

To access these workflows, navigate to **Library > Workflows** and enter the `vcenter` and `datastore_and_files` tags in the workflow search box.

Workflow Name	Description
Delete all files	Deletes a list of files.
Delete all unused datastore files	Searches all datastores in the vCenter environment and deletes all unused files.
Export unused datastore files	Searches all datastores and creates an XML descriptor file that lists all unused files.
Find unused files in datastores	Searches the vCenter environment for all unused disks (*.vmdk), virtual machines (*.vmx), and template (*.vmtx) files that are not associated with any vCenter instances registered with Orchestrator.
Get all configuration, template, and disk files from virtual machines	Creates a list of all virtual machine descriptor files and a list of all virtual machine disk files, for all datastores.

Table continued on next page

Continued from previous page

Workflow Name	Description
Log all datastore files	Creates a log for every virtual machine configuration file and every virtual machine file found in all datastores.
Log unused datastore files	Searches the vCenter environment for unused files that are registered on virtual machines and exports a log of the files in a text file.
Upload file to datastore	Uploads a file to an existing folder on a specific datastore. The uploaded file overwrites any existing file with the same name in the same destination folder.

Datacenter Folder Management Workflows

With datacenter folder management workflows, you can create, delete, or rename a datacenter folder.

To access these workflows, navigate to **Library > Workflows** and enter the `vcenter` and `datacenter_folder` tags in the workflow search box.

Workflow Name	Description
Create datacenter folder	Creates a data center folder.
Delete datacenter folder	Deletes a data center folder and waits for the task to complete.
Rename datacenter folder	Renames a data center folder and waits for the task to complete.

Host Folder Management Workflows

With host folder management workflows, you can create, delete, or rename a host folder.

To access these workflows, navigate to **Library > Workflows** and enter the `vcenter` and `host_folder` tags in the workflow search box.

Workflow Name	Description
Create host folder	Creates a host folder.
Delete host folder	Deletes a host folder and waits for the task to complete.
Rename host folder	Renames a host folder and waits for the task to complete.

Virtual Machine Folder Management Workflows

With virtual machine folder management workflows, you can create, delete, or rename a virtual machine folder.

To access these workflows, navigate to **Library > Workflows** and enter the `vcenter` and `vm_folder` tags in the workflow search box.

Workflow Name	Description
Create virtual machine folder	Creates a virtual machine folder.

Table continued on next page

Continued from previous page

Workflow Name	Description
Delete virtual machine folder	Deletes a virtual machine folder and waits for the task to complete.
Rename virtual machine folder	Renames a virtual machine folder and waits for the task to complete.

Guest Operation Files Workflows

With the guest operation files workflows, you can manage files in a guest operating system.

To access these workflows, navigate to **Library > Workflows** and enter the `vcenter`, `guest_operations` and `files` tags in the workflow search box.

Workflow Name	Description
Check for directory in guest	Verifies that a directory exists in a guest virtual machine.
Check for file in guest	Verifies that a file exists in a guest virtual machine.
Copy file from guest to Orchestrator	Copies a specified file from a guest file system to an Orchestrator server.
Copy file from Orchestrator to guest	Copies a specified file from an Orchestrator server to a guest file system.
Create directory in guest	Creates a directory in a guest virtual machine.
Create temporary directory in guest	Creates a temporary directory in a guest virtual machine.
Create temporary file in guest	Creates a temporary file in a guest virtual machine.
Delete directory in guest	Deletes a directory from a guest virtual machine.
Delete file in guest	Deletes a file from a guest virtual machine.
List path in guest	Shows a path in a guest virtual machine.
Move directory in guest	Moves a directory in a guest virtual machine.
Move file in guest	Moves a file in a guest virtual machine.

Guest Operation Processes Workflows

With guest operation processes workflows, you can get information and control the running processes in a guest operating system.

To access these workflows, navigate to **Library > Workflows** and enter the `vcenter`, `guest_operations` and `processes` tags in the workflow search box.

Workflow Name	Description
Get environment variables from guest	Returns a list with environmental variables from a guest. An interactive session returns the variables of the user who is currently logged in.
Get processes from guest	Returns a list with the processes running in the guest operating system and the recently completed processes started by the API.
Kill process in guest	Terminates a process in a guest operating system.
Run program in guest	Starts a program in a guest operating system.

Power Host Management Workflows

With power host management workflows you can reboot or shut down a host.

To access these workflows, navigate to **Library > Workflows** and enter the `vcenter`, `host_management` and `power` tags in the workflow search box.

Workflow Name	Description
Reboot host	Reboots a host. If the Orchestrator client is connected directly to the host, it loses the connection to the host and does not receive an indication of success in the returned task.
Shut down host	Shuts down a host. If the Orchestrator client is connected directly to the host, it loses the connection to the host and does not receive an indication of success in the returned task.

Basic Host Management Workflows

With the basic host management workflows, you can put a host into maintenance mode and make a host exit maintenance mode. You can also move a host to a folder or a cluster, and reload data from a host.

To access these workflows, navigate to **Library > Workflows** and enter the `vcenter`, `host_management` and `basic` tags in the workflow search box.

Workflow Name	Description
Enter maintenance mode	Puts the host into maintenance mode. You can cancel the task.
Exit maintenance mode	Exits maintenance mode. You can cancel the task.
Move host to cluster	Moves an existing host to a cluster. The host must be part of the same data center, and if the host is part of a cluster, the host must be in maintenance mode.
Move host to folder	Moves a host into a folder as a standalone host. The host must be part of a <code>ClusterComputeResource</code> in the same data center and the host must be in maintenance mode.
Reload host	Forces vCenter to reload data from a host.

Host Registration Management Workflows

With the host registration management workflows, you can add a host to a cluster, disconnect, or reconnect a host from a cluster, and so on.

To access these workflows, navigate to **Library > Workflows** and enter the `vcenter`, `host_management` and `registration` tags in the workflow search box.

Workflow Name	Description
Add host to cluster	Adds a host to the cluster. This workflow fails if it cannot authenticate the SSL certificate of the host.

Table continued on next page

Continued from previous page

Workflow Name	Description
Add standalone host	Registers a host as a standalone host.
Disconnect host	Disconnects a host from the vCenter instance.
Reconnect host	Reconnects a disconnected host by providing only the host information.
Reconnect host with all information	Reconnects a disconnected host by providing all information about the host.
Remove host	Removes a host and unregisters it from the vCenter instance. If the host is part of a cluster, you must put it in maintenance mode before attempting to remove it.

Networking Workflows

With networking workflows you can add a port group to distributed virtual switch, create a distributed virtual switch with a port group, and so on.

To access these workflows, navigate to **Library > Workflows** and enter the `vcenter` and `networking` tags in the workflow search box.

Workflow Name	Description
Add port group to distributed virtual switch	Adds a new distributed virtual port group to a specified distributed virtual switch.
Attach host system to distributed virtual switch	Adds a host to a distributed virtual switch.
Create distributed virtual switch with port group	Creates a new distributed virtual switch with a distributed virtual port group.

Distributed Virtual Port Group Workflows

With the distributed virtual port group workflows, you can update or delete a port group, and reconfigure the port group.

To access these workflows, navigate to **Library > Workflows** and enter the `vcenter`, `networking` and `distributed_virtual_port_group` tags in the workflow search box.

Workflow Name	Description
Connect virtual machine NIC number to distributed virtual port group	Reconfigures the network connection of the specified virtual machine NIC number to connect to the specified distributed virtual port group. If no NIC number is specified, the number zero is used.
Delete distributed virtual port group	Deletes a specified distributed virtual port group.
Set teaming options	Provides an interface to manage the teaming options for a distributed virtual port group.
Update distributed virtual port group	Updates the configuration of a specified distributed virtual port group.

Distributed Virtual Switch Workflows

With distributed virtual switch workflows, you can create, update or delete a distributed virtual switch, and create, delete, or update a private VLAN.

To access these workflows, navigate to **Library > Workflows** and enter the `vcenter`, `networking` and `distributed_virtual_switch` tags in the workflow search box.

Workflow Name	Description
Create distributed virtual switch	Creates a distributed virtual switch in the specified network folder with a name and uplink port names that you specify. You must specify at least one uplink port name.
Create private VLAN	Creates a VLAN on the specified distributed virtual switch.
Delete distributed virtual switch	Deletes a distributed virtual switch and all associated elements.
Delete private VLAN	Deletes a VLAN from a specified distributed virtual switch. If a secondary VLAN exists, you must first delete the secondary VLAN.
Update distributed virtual switch	Updates the properties of a distributed virtual switch.
Update private VLAN	Updates a VLAN on the specified distributed virtual switch.

Standard Virtual Switch Workflows

With the standard virtual switch workflows you can create, update, or delete a standard virtual switch, and create, delete, or update port groups in standard virtual switches.

To access these workflows, navigate to **Library > Workflows** and enter the `vcenter`, `networking` and `standard_virtual_switch` tags in the workflow search box.

Workflow Name	Description
Add port group in standard virtual switch	Adds a port group in a standard virtual switch.
Create standard virtual switch	Creates a standard virtual switch.
Delete port group from standard virtual switch	Deletes a port group from a standard virtual switch
Delete standard virtual switch	Deletes a standard virtual switch from a host network configuration.
Retrieve all standard virtual switches	Retrieves all standard virtual switches from a host.
Update port group in standard virtual switch	Updates the properties of a port group in a standard virtual switch.
Update standard virtual switch	Updates the properties of a standard virtual switch.
Update VNIC for port group in standard virtual switch	Updates a virtual NIC associated with a port group in a standard virtual switch.

Networking Virtual SAN Workflows

With Virtual SAN workflows, you can configure Virtual SAN network traffic.

To access these workflows, navigate to **Library > Workflows** and enter the `vcenter`, `networking` and `vsan` tags in the workflow search box.

Workflow Name	Description
Set a cluster's VSAN traffic network	Sets a Virtual SAN traffic network of the cluster.
Set a host's VSAN traffic network	Sets a Virtual SAN traffic network of the host.

Resource Pool Workflows

With the resource pool workflows you can create, rename, reconfigure or delete a resource pool, and get resource pool information.

To access these workflows, navigate to **Library > Workflows** and enter the `vcenter` and `resource_pool` tags in the workflow search box.

Workflow Name	Description
Create resource pool	Creates a resource pool with the default CPU and memory allocation values. To create a resource pool in a cluster, the cluster must have VMware DRS enabled.
Create resource pool with specified values	Creates a resource pool with CPU and memory allocation values that you specify. To create a resource pool in a cluster, the cluster must have VMware DRS enabled.
Delete resource pool	Deletes a resource pool and waits for the task to complete.
Get resource pool information	Returns CPU and memory information about a given resource pool.
Reconfigure resource pool	Reconfigures CPU and memory allocation configuration for a given resource pool.
Rename resource pool	Renames a resource pool and waits for the task to complete

Storage Workflows

With the storage workflows, you can perform storage-related operations.

To access these workflows, navigate to **Library > Workflows** and enter the `vcenter` and `storage` tags in the workflow search box.

Workflow Name	Description
Add datastore on iSCSI/FC/local SCSI	Creates a datastore on a Fibre Channel, iSCSI or local SCSI disk. Only disks that are not currently in use by an existing VMFS are applicable to new datastore creation. The new datastore allocates the maximum available space of the specified disk.
Add datastore on NFS	Adds a datastore on an NFS server.
Add iSCSI target	Adds iSCSI targets to a vCenter host. The targets can be of type <code>Send</code> or <code>Static</code> .
Create VMFS for all available disks	Creates a VMFS volume for all available disks of a specified host.
Delete datastore	Deletes datastores from a vCenter Server host.
Delete iSCSI target	Deletes already configured iSCSI targets. The targets can be of type <code>Send</code> or <code>Static</code> .
Disable iSCSI adapter	Deactivates the software iSCSI adapter of a specified host.
Display all datastores and disks	Displays the existing datastores and available disks on a specified host.
Enable iSCSI adapter	Activates an iSCSI adapter.
List all storage adapters	Lists all storage adapters of a specified host.

Storage DRS Workflows

With the storage DRS workflows, you perform storage-related operations, such as creating and configuring a datastore cluster, removing a datastore from cluster, adding storage to a cluster, and others.

To access these workflows, navigate to **Library > Workflows** and enter the `vcenter` and `storage_drs` tags in the workflow search box.

Workflow Name	Description
Add datastore to cluster	Adds datastores to a datastore cluster. Datastores must be able to connect to all hosts to be included in the datastore cluster. Datastores must have the same connection type to reside within a datastore cluster.
Change Storage DRS per virtual machine configuration	Sets Storage DRS settings for each virtual machine.
Configure datastore cluster	Configures datastore cluster setting values for automation and runtime rules.
Create simple datastore cluster	Creates a simple datastore cluster with default configuration. The new datastore cluster contains no datastores.
Create Storage DRS scheduled task	Creates a scheduled task for reconfiguring a datastore cluster. Only automation and runtime rules can be set.
Create virtual machine anti-affinity rule	Creates an anti-affinity rule to indicate that all virtual disks of certain virtual machines must be kept on different datastores.
Create VMDK anti-affinity rule	Creates a VMDK anti-affinity rule for a virtual machine that indicates which of its virtual disks must be kept on different datastores. The rule applies to the virtual disks of the selected virtual machine.
Remove datastore cluster	Removes a datastore cluster. Removing a datastore cluster also removes all the settings and the alarms for the cluster from the vCenter system.
Remove datastore from cluster	Removes a datastore from a datastore cluster and puts the datastore in a datastore folder.
Remove Storage DRS scheduled task	Removes a scheduled Storage DRS task.
Remove virtual machine anti-affinity rule	Removes a virtual machine anti-affinity rule for a given datastore cluster.
Remove VMDK anti-affinity rule	Removes a VMDK anti-affinity rule for a given datastore cluster.

Storage VSAN Workflows

With the Virtual SAN workflows, you can manage non-SSD disks and disk groups in a Virtual SAN cluster.

To access these workflows, navigate to **Library > Workflows** and enter the `vcenter`, `storage` and `vsan` tags in the workflow search box.

Workflow Name	Description
Add disks to a disk group	Adds non-SSD disks to a Virtual SAN disk group.

Table continued on next page

Continued from previous page

Workflow Name	Description
Claim disks into disk groups	Claims disks for use by the Virtual SAN system and automatically creates disk groups and distributes the disks into existing disk groups.
Create a disk group	Creates a Virtual SAN disk group.
List hosts, disk groups and disks	Lists all hosts in a cluster, their disk groups and disks, used or eligible for use by the Virtual SAN system.
Remove disk groups	Removes Virtual SAN disk groups.
Remove disks from disk groups	Removes non-SSD disks from Virtual SAN disk groups.

Basic Virtual Machine Management Workflows

With the basic virtual machine management workflows, you can perform basic operations on virtual machines, for example, create, rename or delete a virtual machine, upgrade virtual hardware, and others.

To access these workflows, navigate to **Library > Workflows** and enter the `vcenter`, `virtual_machine_management` and `basic` tags in the workflow search box.

Workflow Name	Description
Create custom virtual machine	Creates a virtual machine with the specified configuration options and additional devices.
Create simple dvPortGroup virtual machine	Creates a simple virtual machine. The network used is a Distributed Virtual Port Group.
Create simple virtual machine	Creates a virtual machine with the most common devices and configuration options.
Delete virtual machine	Removes a virtual machine from the inventory and datastore.
Get virtual machines by name	Returns a list of virtual machines from all registered vCenter instances that match the provided expression.
Mark as template	Converts an existing virtual machine to a template, not allowing it to start. You can use templates to create virtual machines.
Mark as virtual machine	Converts an existing template to a virtual machine, allowing it to start.
Move virtual machine to folder	Moves a virtual machine to a specified virtual machine folder.
Move virtual machine to resource pool	Moves a virtual machine to a resource pool. If the target resource pool is not in the same cluster, you must use the migrate or relocate workflows.
Move virtual machines to folder	Moves several virtual machines to a specified virtual machine folder.
Move virtual machines to resource pool	Moves several virtual machines to a resource pool.
Register virtual machine	Registers a virtual machine. The virtual machine files must be placed in an existing datastore and must not be already registered.
Reload virtual machine	Forces vCenter to reload a virtual machine.

Table continued on next page

Continued from previous page

Workflow Name	Description
Rename virtual machine	Renames an existing virtual machine on the vCenter system or host and not on the datastore.
Set virtual machine performance	Changes performance settings such as shares, minimum and maximum values, shaping for network, and disk access of a virtual machine.
Unregister virtual machine	Removes an existing virtual machine from the inventory.
Upgrade virtual machine hardware (force if required)	Upgrades the virtual machine hardware to the latest revision that the host supports. This workflow forces the upgrade to continue, even if VMware Tools is out of date. If the VMware Tools is out of date, forcing the upgrade to continue reverts the guest network settings to the default settings. To avoid this situation, upgrade VMware Tools before running the workflow.
Upgrade virtual machine	Upgrades the virtual hardware to the latest revision that the host supports. An input parameter allows a forced upgrade even if VMware Tools is out of date.
Wait for task and answer virtual machine question	Waits for a vCenter task to complete or for the virtual machine to ask a question. If the virtual machine requires an answer, accepts user input and answers the question.

Clone Workflows

With clone workflows, you can clone virtual machines with or without customizing the virtual machine properties.

To access these workflows, navigate to **Library > Workflows** and enter the `vcenter`, `virtual_machine_management` and `clone` tags in the workflow search box.

Workflow Name	Description
Clone virtual machine from properties	Clones virtual machines by using properties as input parameters.
Clone virtual machine, no customization	Clones a virtual machine without changing anything except the virtual machine UUID.
Customize virtual machine from properties	Customizes a virtual machine by using properties as input parameters.

Linked Clone Workflows

With the linked clone workflows, you can perform linked clone operations such as restoring a virtual machine from a linked clone, creating a linked clone, or others.

To access these workflows, navigate to **Library > Workflows** and enter the `vcenter`, `virtual_machine_management` and `linked_clone` tags in the workflow search box.

Workflow Name	Description
Linked clone, Linux with multiple NICs	Creates a linked clone of a Linux virtual machine, performs the guest operating system customization, and configures up to four virtual network cards.
Linked clone, Linux with single NIC	Creates a linked clone of a Linux virtual machine, performs the guest operating system customization, and configures one virtual network card.
Linked clone, no customization	Creates the specified number of linked clones of a virtual machine.
Linked clone, Windows with multiple NICs and credential	Creates a linked clone of a Windows virtual machine and performs the guest operating system customization. Configures up to four virtual network cards and a local administrator user account.
Linked clone, Windows with single NIC and credential	Creates a linked clone of a Windows virtual machine and performs the guest operating system customization. Configures one virtual network card and a local administrator user account.
Restore virtual machine from linked clone	Removes a virtual machine from a linked clone setup.
Set up virtual machine for linked clone	Prepares a virtual machine to be link cloned.

Linux Customization Clone Workflows

With Linux customization workflows, you can clone a Linux virtual machine and customize the guest operating system.

To access these workflows, navigate to **Library > Workflows** and enter the `vcenter`, `virtual_machine_management`, `clone` and `linux_customization` tags in the workflow search box.

Workflow Name	Description
Clone, Linux with multiple NICs	Clones a Linux virtual machine, performs the guest operating system customization, and configures up to four virtual network cards.
Clone, Linux with a single NIC	Clones a Linux virtual machine, performs the guest operating system customization, and configures one virtual network card.

Tools Clone Workflows

With the tools clone workflows, you can obtain customization information about the operating system of the virtual machine, information required to update a virtual device, and others.

To access these workflows, navigate to **Library > Workflows** and enter the `vcenter`, `virtual_machine_management`, `clone` and `tools` tags in the workflow search box.

Workflow Name	Description
Get a VirtualEthernetCard to change the network	Returns a new ethernet card to update a virtual device. Contains only the device key of the given virtual device and the new network.
Get Linux customization	Returns the Linux customization preparation.

Table continued on next page

Continued from previous page

Workflow Name	Description
Get multiple VirtualEthernetVard device changes	Returns an array of <code>VirtualDeviceConfigSpec</code> objects for add and remove operations on <code>VirtualEthernetCard</code> objects.
Get NIC setting map	Returns the setting map for a virtual network card by using <code>VimAdapterMapping</code> . Changes NIC information for workflows that clone and reconfigure virtual machines. Other clone workflows call this workflow.
Get Windows customization, Sysprep with credentials	Returns customization information about the Microsoft Sysprep process, with credentials. Workflows for cloning Windows virtual machines use this workflow.
Get Windows customization, Sysprep with <code>Unattended.txt</code>	Returns customization information about the Microsoft Sysprep process by using an <code>Unattended.txt</code> file. Workflows for cloning Windows virtual machines use this workflow.
Get Windows customizations for Sysprep	Returns customization information about the Microsoft Sysprep process. Workflows for cloning Windows virtual machines use this workflow.

Windows Customization Clone Workflows

With the Windows customization clone workflows, you can clone Windows virtual machines and customize the guest operating system.

To access these workflows, navigate to **Library > Workflows** and enter the `vcenter`, `virtual_machine_management`, `clone` and `windows_customization` tags in the workflow search box.

Workflow Name	Description
Clone thin provisioned, Windows with single NIC and credential	Clones a Windows virtual machine performing the guest operating system customization. Specifies virtual disk thin provisioning policy and configures one network card and a local administrator user account. Sysprep tools must be available on vCenter system.
Clone, Windows Sysprep with single NIC and credential	Clones a Windows virtual machine performing the guest operating system customization. Configures one virtual network card and a local administrator user account. Sysprep tools must be available on vCenter system.
Clone, Windows with multiple NICs and credential	Clones a Windows virtual machine performing the guest operating system customization. Configures the local administrator user account and up to four virtual network cards. Sysprep tools must be available on the vCenter system.
Clone, Windows with single NIC	Clones a Windows virtual machine performing the guest operating system customization and configures one virtual network card. Sysprep tools must be available on the vCenter system.
Clone, Windows with single NIC and credential	Clones a Windows virtual machine performing the guest operating system customization. Configures one virtual

Table continued on next page

Continued from previous page

Workflow Name	Description
	network card and a local administrator user account. Sysprep tools must be available on the vCenter system.
Customize, Windows with single NIC and credential	Performs guest operating system customization, configures one virtual network card and a local administrator user account on a Windows virtual machine.

Device Management Workflows

With the device management workflows, you can manage the devices that are connected to a virtual machine or to a host datastore.

To access these workflows, navigate to **Library > Workflows** and enter the `vcenter`, `virtual_machine_management` and `device_management` tags in the workflow search box.

Workflow Name	Description
Add CD-ROM	Adds a virtual CD-ROM to a virtual machine. If the virtual machine has no IDE controller, the workflow creates one.
Add disk	Adds a virtual disk to a virtual machine.
Change RAM	Changes the amount of RAM of a virtual machine.
Convert disks to thin provisioning	Converts thick-provisioned disks of virtual machines to thin-provisioned disks.
Convert independent disks	Converts all independent virtual machine disks to normal disks by removing the independent flag from the disks.
Disconnect all detachable devices from a running virtual machine	Disconnects floppy disks, CD-ROM drives, parallel ports, and serial ports from a running virtual machine.
Mount CD-ROM	Mounts the CD-ROM of a virtual machine. If the virtual machine has no IDE controller and/or CD-ROM drive, the workflow creates them.
Mount floppy disk drive	Mounts a floppy disk drive FLP file from the ESX datastore.

Move and Migrate Workflows

With the move and migrate workflows, you can migrate virtual machines.

To access these workflows, navigate to **Library > Workflows** and enter the `vcenter`, `virtual_machine_management` and `move_and_migrate` tags in the workflow search box.

Workflow Name	Description
Mass migrate virtual machines with storage vMotion	Uses Storage vMotion to migrate a single virtual machine, a selection of virtual machines, or all available virtual machines.
Mass migrate virtual machines with vMotion	Uses vMotion, Storage vMotion, or both vMotion and Storage vMotion to migrate a single virtual machine, a selection of virtual machines, or all available virtual machines.

Table continued on next page

Continued from previous page

Workflow Name	Description
	NOTE vCenter Server does not allow storage vMotion and vMotion in the same pass for a powered on virtual machine. You must power off the virtual machine to use storage vMotion and vMotion in the same pass.
Migrate virtual machine with vMotion	Migrates a virtual machine from one host to another by using the <code>MigrateVM_Task</code> operation from the vSphere API.
Move virtual machines to another vCenter Server	Moves a list of virtual machines to another vCenter system.
Quick migrate multiple virtual machines	Suspends the virtual machines if they are powered on and migrates them to another host using the same storage.
Quick migration of virtual machine	Suspends the virtual machine if it is powered on and migrates it to another host using the same storage.
Relocate virtual machine disks	Relocates virtual machine disks to another host or datastore while the virtual machine is powered off by using the <code>RelocateVM_Task</code> operation from the vSphere API.

Other workflows

With the workflows from the Others category, you can activate and deactivate Fault Tolerance (FT), extract virtual machine information, and find orphaned virtual machines.

To access these workflows, navigate to **Library > Workflows** and enter the `vcenter`, `virtual_machine_management` and `others` tags in the workflow search box.

Workflow Name	Description
Disable FT	Deactivates Fault Tolerance for a specified virtual machine.
Enable FT	Activates Fault Tolerance for a specified virtual machine.
Extract virtual machine information	Returns the virtual machine folder, host system, resource pool, compute resource, datastore, hard drive sizes, CPU and memory, network, and IP address for a given virtual machine. Might require VMware Tools.
Find orphaned virtual machines	Lists all virtual machines in an orphaned state in the Automation Orchestrator inventory. Lists the VMDK and VMTX files for all datastores in the Automation Orchestrator inventory that have no association with any virtual machines in the inventory. Sends the lists by email (optional).
Get VM by Name and BIOS UUID	Searches virtual machines by name and then filters the result with particular universally unique identifier (UUID) in order to identify a unique virtual machine.

Table continued on next page

Continued from previous page

Workflow Name	Description
	<p>NOTE</p> <p>This workflow is needed when DynamicOps calls Automation Orchestrator workflows having input parameters of <code>VC:VirtualMachine</code> type in order to make the correspondence between a particular DynamicOps and Automation Orchestrator virtual machine.</p>
Get VM by Name and UUID	<p>Searches virtual machines by name and then filters the result with particular universally unique identifier (UUID) in order to identify a unique virtual machine.</p> <p>NOTE</p> <p>This workflow is needed when DynamicOps calls Automation Orchestrator workflows having input parameters of <code>VC:VirtualMachine</code> type in order to make the correspondence between a particular DynamicOps and Automation Orchestrator virtual machine.</p>
Get VM UUID	<p>Searches virtual machines by name and then filters the result with particular universally unique identifier (UUID) in order to identify a unique virtual machine.</p> <p>NOTE</p> <p>This workflow is needed when DynamicOps calls Automation Orchestrator workflows having input parameters of <code>VC:VirtualMachine</code> type in order to make the correspondence between a particular DynamicOps and Automation Orchestrator virtual machine.</p>

Power Management Workflows

With the power management workflows, you can power on and off virtual machines, reboot the guest operating system of a virtual machine, suspend a virtual machine, and others.

To access these workflows, navigate to **Library > Workflows** and enter the `vcenter`, `virtual_machine_management` and `power_management` tags in the workflow search box.

Workflow Name	Description
Power off virtual machine and wait	Powers off a virtual machine and waits for the process to complete.
Reboot guest OS	Reboots the guest operating system of the virtual machine. Does not reset nonpersistent virtual machines. VMware Tools must be running.
Reset virtual machine and wait	Resets a virtual machine and waits for the process to complete.

Table continued on next page

Continued from previous page

Workflow Name	Description
Resume virtual machine and wait	Resumes a suspended virtual machine and waits for the process to complete.
Set guest OS to standby mode	Sets the guest operating system to standby mode. VMware Tools must be running.
Shut down and delete virtual machine	Shuts down a virtual machine and deletes it from the inventory and disk.
Shut down guest OS and wait	Shuts down a guest operating system and waits for the process to complete.
Start virtual machine and wait	Starts a virtual machine and waits for VMware Tools to start.
Suspend virtual machine and wait	Suspends a virtual machine and waits for the process to complete.

Snapshot Workflows

With snapshot workflows, you can perform snapshot-related operations.

To access these workflows, navigate to **Library > Workflows** and enter the `vcenter`, `virtual_machine_management` and `snapshot` tags in the workflow search box.

Workflow Name	Description
Create a snapshot	Creates a snapshot.
Create snapshots of all virtual machines in a resource pool	Creates a snapshot of each virtual machine in a resource pool.
Remove all snapshots	Removes all existing snapshots without reverting to a previous snapshot.
Remove excess snapshots	Finds virtual machines with more than a given number of snapshots and optionally deletes the oldest snapshots. Sends the results by email.
Remove old snapshots	Gets all snapshots that are older than a given number of days and prompts the user to select which ones to delete.
Remove snapshots of a given size	Gets all snapshots that are larger than a given size and prompts the user to confirm deletion.
Revert to current snapshot	Reverts to the current snapshot.
Revert to snapshot and wait	Reverts to a specific snapshot. Does not delete the snapshot.

VMware Tools Workflows

With VMware Tools workflows, you can perform VMware Tools-related tasks on virtual machines.

To access these workflows, navigate to **Library > Workflows** and enter the `vcenter`, `virtual_machine_management` and `vmware_tools` tags in the workflow search box.

Workflow Name	Description
Mount tools installer	Mounts the VMware Tools installer on the virtual CD-ROM.
Set console screen resolution	Sets the resolution of the console window. The virtual machine must be powered on.
Turn on time synchronization	Turns on time synchronization between the virtual machine and the ESX server in VMware Tools.
Unmount tools installer	Unmounts the VMware Tools CD-ROM.
Update tools on Windows virtual machine without rebooting	Updates VMware Tools on a Windows virtual machine without performing a reboot.
Upgrade tools	Upgrades VMware Tools on a virtual machine.
Upgrade tools at next reboot	Deprecated: use the workflow Update tools on Windows virtual machine without rebooting

Using the Automation Orchestrator Plug-In for vSphere Web Client

Using the vCOIN Plug-In

You can use the Automation Orchestrator plug-in for vSphere Web Client (also known as the vCOIN plug-in) to perform operations on certain Automation Orchestrator content from your vSphere Client.

The content that the plug-in exposes in the vSphere Client includes workflows, workflow runs, scheduled workflows, and workflows waiting for input. In the vSphere Client, users can see workflow details, run or schedule workflows, and manage workflow runs.

Context Actions

You can add Automation Orchestrator workflows as context actions in the vSphere Web Client. With context actions, you can map a particular workflow to a specific vSphere item and run or schedule the workflow directly from the vSphere inventory.

When you use the vCOIN plug-in for the first time, a configuration element is created in Automation Orchestrator. You must not change or edit the location and any configuration items in that location because they are managed by the vCOIN service.

Group Assignments

Administrators can use group assignments to assign context actions to specific Automation Orchestrator groups. Users in these groups can then use context actions in vSphere. Users can run only the workflows that are assigned to their group.

When a user logs into the vSphere Client, they have the same views and/or permissions in the vCOIN plug-in as in Automation Orchestrator. For example, if a user has the Viewer role in Automation Orchestrator, they can't run workflows in the vSphere Client.

To use group assignments, you must have at least one group defined in Automation Orchestrator. If you want to leverage specific user roles, such as **Designer** or **Administrator**, your Automation Orchestrator environment must use a VMware Cloud Foundation license.

When you assign context actions to a group, all of the mapped workflows are added as group items in the assigned group, along with the configuration item.

Functional Requirements for the vCOIN Plug-In

The Automation Orchestrator plug-in for vSphere Web Client supports the following:

- Standalone Automation Orchestrator environments only. The plug-in is not supported for instances of Automation Orchestrator that are embedded in VMware Aria Automation.
- The vCOIN plug-in is available only with Automation Orchestrator. To upgrade the plug-in, you must upgrade Automation Orchestrator.
- vSphere 7.0 U1 and later. Versions 7.0 and earlier are not supported.
- Maximum one vCOIN can be registered per vCenter Server.
- In vSphere deployments with multiple vCenters (in Enhanced Linked Mode), you can register a single vCOIN plug-in with multiple vCenters (maximum one plug-in installation per vCenter), or you can register multiple vCOINs with multiple vCenter servers.
- Before you can use the plug-in, you must configure the plug-in by enabling the service on the Automation Orchestrator appliance. See [Configure the vCOIN plug-in](#).

Create a context action

The vSphere Client provides an inventory of vSphere items that are available for management. You can define context actions for specific vSphere inventory objects and run Automation Orchestrator workflows on those objects from the vSphere inventory.

1. Log in to the vSphere Web Client.
2. On the Automation Orchestrator home page, click the **Context Actions** tab.
3. Click **Add**.
4. In the search box, enter the name of the workflow that you want to add as a context action.
5. Select the workflow in the results table.
6. In the **Type of object** dropdown menu, select which vSphere object you want to associate with the context action, such as a vCenter server, for example.
7. Click **Assign**.
You added a Automation Orchestrator workflow as a context action.
8. Run the workflow on the vCenter server that you associated with the action.
 - a) In the vSphere Client, right click the vCenter server.
 - b) Select **Orchestrator > Run Workflow**.
 - c) Select the context action workflow to run on the vCenter server.
The workflow input form appears. If the workflow has as an input parameter of the particular inventory type over which you initiated the context action, the form is prepopulated.
 - d) Click **Run**.

Using the vCloud Suite API (vAPI) Plug-In

The vCloud Suite API plug-in provides the ability to consume API exposed by any vCloud Suite API provider. The vCloud Suite API provides a service-oriented architecture for accessing resources in the virtual environment by issuing requests to vCenter, through the vCloud Suite Endpoint.

The plug-in contains a set of standard workflows and example workflows. You can also create custom workflows that implement the plug-in to automate tasks in your virtual environment. For information about vCloud Suite API, see [VMware vCloud Suite SDKs Programming Guide](#).

Access the vCloud Suite API Plug-In API

Automation Orchestrator provides an API Explorer to allow you to search the vCloud Suite API plug-in API and see the documentation for JavaScript objects that you can use in scripted elements.

To access the API Explorer from the Automation Orchestrator Client, click **API Explorer** in the Automation Orchestrator Client navigation pane.

To access the API Explorer from the **Scripting** tabs of the workflow, policy, and action editors, click **Search API** on the left.

You can copy code from API elements and paste it into scripting boxes. For more information about API scripting, see *Developing with Automation Orchestrator*.

Using the Automation Orchestrator Plug-In for VMware Aria Automation

Using the Automation Plug-In

The VMware Aria Automation Orchestrator™ Plug-in for VMware Aria Automation™ integrates Automation Orchestrator with VMware Aria Automation. With the plug-in, you can run Automation Orchestrator workflows from your VMware Aria Automation instance. You can use the workflows that are provided with the plug-in to deploy and manage VMware Aria Automation resources.

Role of Automation Orchestrator with the Automation plug-in

Automation Orchestrator powers the Automation plug-in. You use the Automation Orchestrator Client to run and create workflows and access the Automation plug-in API.

You can use either the embedded Automation Orchestrator instance in your VMware Aria Automation deployment, or an external Automation Orchestrator server.

Installing the Automation plug-in

Depending on your Automation Orchestrator setup, you must either download and install the Automation plug-in yourself, or the plug-in might come preinstalled on your VMware Aria Automation environment.

The following table provides more information about each scenario.

Automation Orchestrator deployment	VMware Aria Automation version	Out of the box plug-in availability	What to do
Embedded	VMware Aria Automation 8.18.x	Yes	<ol style="list-style-type: none"> Configure vRealize Automation hosts. Start building your infrastructure.
External	VMware Aria Automation 8.18.x	No	<ol style="list-style-type: none"> Download the plug-in from the VMware Marketplace. Install the plug-in on your Automation Orchestrator instance.
Extensibility Appliance	VMware Aria Automation SaaS	No	<ol style="list-style-type: none"> Verify that you have a Automation Orchestrator integration in Automation Assembler. See Configure an Automation Orchestrator integration in Automation Assembler. Download the plug-in from the VMware Marketplace. Install the plug-in on your cloud-enabled Automation Orchestrator.

The Automation plug-in supports out-of-the-box proxy-based connection configurations on the VMware Aria Automation extensibility appliance. You can connect an external proxy with the VMware Aria Automation host connection object without any additional configuration changes.

Using the default Automation plug-in workflows and actions

The Automation plug-in provides out-of-the-box workflows for common tasks, such as [host configuration workflows](#) and [infrastructure workflows](#). For a full list of available workflows, navigate to **Library > Workflows** in the Automation Orchestrator Client.

The plug-in library also contains predefined actions that you can use to build your own custom workflows. To access these actions, navigate to **Library > Actions**, and enter `com.vmware.library.vra` in the action search box.

Using the Automation plug-in inventory

The Automation Orchestrator inventory supports objects for hosts, cloud accounts, cloud zones, disks, machines, machine disks and snapshots, networks, projects, and other entities that are required as lookups for create/update workflows, such as tags, data collectors, regions, NSX-T, and NSX-V cloud accounts.

To display all available inventory objects, navigate to **Administration > Inventory > VMware Aria Automation** in the Automation Orchestrator Client.

Accessing the Automation plug-in API

In the Automation Orchestrator API Explorer, you can search the Automation plug-in API and see the documentation for JavaScript objects that you can use in scripted elements. You can copy code from API elements and paste it into scripting boxes.

In the Automation Orchestrator API Explorer, click the **VRA** module in the left pane to expand the hierarchical list of Automation plug-in API scripting objects.

To access the API reference for your VMware Aria Automation version, go to <https://VMware-Aria-Automation-hostname/automation-ui/api-docs>.

For up-to-date VMware Aria Automation API documentation, see the [VMware Aria Automation 8.18 API Programming Guide](#).

Configuring VMware Aria Automation hosts

Host configuration workflows

You can manage VMware Aria Automation hosts by running the default workflows provided with the plug-in.

To access these workflows in the Automation Orchestrator Client, navigate to **Library > Workflows**, and enter the `vra` or `vra-cloud` tag in the workflow search box.

Workflow	Description
Add vRA Host	Adds a VMware Aria Automation on-prem host to the plug-in inventory. See Add a vRealize Automation host .

Table continued on next page

Continued from previous page

Workflow	Description
	<p>NOTE</p> <p>If you use the plug-in in an embedded Automation Orchestrator instance, a default host is created in the plug-in inventory. The logged-in user session is used to execute operations on the default host.</p> <p>When you perform operations on the default host from Automation Consumption, the Automation Orchestrator Gateway service token is used to execute the operation.</p>
Add vRA Cloud Host	Adds a VMware Aria Automation SaaS host to the plug-in inventory. When running this workflow, you must select only a relevant region-specific cloud host. See Add a vRealize Automation Cloud host .
Update vRA Host	Updates a VMware Aria Automation SaaS or on-prem host in the plug-in inventory.
Update vRA Cloud Host	
Remove Host	Removes a VMware Aria Automation SaaS or on-prem host from the plug-in inventory.
Validate Host	Validates the configuration of the VMware Aria Automation SaaS or on-prem host.

Multi-tenancy support

You can configure the Automation plug-in to work with your multi-tenant environment.

- For on-premises connections, you must add a dedicated VMware Aria Automation host for each tenant, using the tenant FQDN as the host name.
- If you use the plug-in with a Automation Orchestrator instance that is embedded in VMware Aria Automation, the default connection does not use a tenant-specific URL. Instead, it uses the default VMware Aria Automation host name.
- For cloud connections, the plug-in uses the API token to differentiate between the tenants.

Invoking REST operations on hosts

The Automation Orchestrator plug-in for VMware Aria Automation supports generic REST operations on dynamically created hosts. You can run the default plug-in workflows to invoke any public VMware Aria Automation APIs.

The plug-in supports the following REST operations.

Workflow	Description
Get operation	Generic REST client support for HTTP GET operation.
Put operation	Generic REST client support for HTTP PUT operation.
Post operation	Generic REST client support for HTTP POST operation.
Patch operation	Generic REST client support for HTTP PATCH operation.
Delete operation	Generic REST client support for HTTP DELETE operation.

Add a VMware Aria Automation host

You add a VMware Aria Automation on-prem host and configure the connection parameters by running a Automation Orchestrator workflow.

1. Log in to Automation Orchestrator as an administrator.
2. Navigate to **Library > Workflows** and enter the `vra` and configuration tags in the workflow search box.
3. Locate the **Add vRA host** workflow and click **Run**.
4. Enter a unique name for the host.
5. Enter the URL address of the host.

For example: `https://VMware-Aria-Automation-hostname`.

6. Select whether to install the SSL certificates automatically without user confirmation.
7. On the **User credentials** tab, select the type of connection to the host.

Option	Actions
Shared Session	Connect using the credentials for a VMware Aria Automation user that you provide in the Authentication User Name and Authentication Password text boxes.
Per User Session	Connect using the credentials of the user that is currently logged in. You must be logged in to the Automation Orchestrator Client with the credentials of the VMware Aria Automation administrator.

8. Click **Run**.

You have added a VMware Aria Automation on-prem host.

Add a VMware Aria Automation SaaS host

You add a VMware Aria Automation SaaS host and configure the connection parameters by running a Automation Orchestrator workflow.

- Verify that you have a Automation Orchestrator integration in Automation Assembler. See [Configure an Automation Orchestrator integration in Automation Assembler](#).
- Verify that you have an API access token. See [Generate API Tokens](#).

1. Log in to the Automation Orchestrator Client as an administrator.
2. Navigate to **Library > Workflows** and enter the `vra-cloud` and configuration tags in the workflow search box.
3. Locate the **Add vRA Cloud Host** workflow and click **Run**.
4. Enter a unique name for the host in the **vRA Cloud Host Name** text box.
5. Select the URL address of the VMware Aria Automation SaaS host that contains the cloud region for which you want to configure the host.
6. Select whether to install the SSL certificates automatically without user confirmation.
7. On the **User credentials** tab, provide the API access token.
8. Click **Run**.

You have added a VMware Aria Automation SaaS host.

Using the VMware Aria Automation plug-in infrastructure administration workflows

Infrastructure workflows

You can use the infrastructure administration workflows to manage cloud accounts, cloud zones, machines, and projects.

Cloud Accounts Workflows

The Cloud Accounts category contains workflows that you can use for managing vSphere cloud accounts.

To access these workflows in the Automation Orchestrator Client, navigate to **Library > Workflows**, and enter the `vsphere_cloud_accounts` tag in the workflow search box.

Workflow Name	Description
Create vSphere Cloud Account	Adds a vCenter cloud account in VMware Aria Automation and to the plug-in inventory in Automation Orchestrator. See Add a cloud account .
Create vSphere Cloud Account Async	Creates a cloud account asynchronously with the selected configuration. On request submission, the workflow returns a <code>RequestTracker</code> object. You can get the status of the requested cloud account by using the <code>RequestService</code> and <code>RequestTracker</code> objects and the <code>getRequestTrackerById</code> action.
Delete vSphere Cloud Account	Removes a vCenter cloud account in VMware Aria Automation and from the plug-in inventory in Automation Orchestrator.
Update vSphere Cloud Account	Updates a vCenter cloud account in VMware Aria Automation and in the plug-in inventory in Automation Orchestrator.
Update vSphere Cloud Account Async	Requests to update a cloud account asynchronously with the selected configuration. On request submission, the workflow returns a <code>RequestTracker</code> object. You can get the status of the requested cloud account by using the <code>RequestService</code> and <code>RequestTracker</code> objects and the <code>getRequestTrackerById</code> action.

Cloud Zones Workflows

To access the Cloud Zones workflows in the Automation Orchestrator Client, navigate to **Library > Workflows**, and enter the `cloud_zones` tag in the workflow search box.

Workflow Name	Description
Create Cloud Zone	Adds a cloud zone in VMware Aria Automation and to the plug-in inventory in Automation Orchestrator. See Add a cloud zone .
Delete Cloud Zone	Removes a cloud zone in VMware Aria Automation and from the plug-in inventory in Automation Orchestrator.
Update Cloud Zone	Updates a cloud zone in VMware Aria Automation and in the plug-in inventory in Automation Orchestrator.

Disks Workflows

To access the Disks workflows in the Automation Orchestrator Client, navigate to **Library > Workflows**, and enter the **disks** tag in the workflow search box.

Workflow Name	Description
Create Disk	Creates a disk (block device) synchronously and adds it to the plug-in inventory in Automation Orchestrator. See Add a disk .
Delete Disk	Requests to delete a disk (block device) with the selected configuration asynchronously. On request submission, the workflow returns a <code>RequestTracker</code> object. You can get the status of the requested machine disk by using the <code>RequestService</code> and <code>RequestTracker</code> objects.

In addition to the default workflows, the Automation plug-in supports the Promote disk and Resize block device operations.

Machines Workflows

To access the Machines workflows in the Automation Orchestrator Client, navigate to **Library > Workflows**, and enter the **machines** tag in the workflow search box.

Workflow Name	Description
Create Machine	Creates a virtual machine in VMware Aria Automation and adds it to the plug-in inventory in Automation Orchestrator. See Add a machine .
Create Machine Async	Asynchronously creates a virtual machine with the selected configuration. On request submission, the workflow returns a <code>RequestTracker</code> object. You can get the status of the requested machine by using the <code>RequestService</code> and <code>RequestTracker</code> objects and the <code>getRequestTrackerById</code> action.
Delete Machine	Removes a virtual machine from VMware Aria Automation and from the plug-in inventory in Automation Orchestrator. On request submission, the workflow returns a <code>RequestTracker</code> object. You can get the status of the requested machine by using the <code>RequestService</code> and <code>RequestTracker</code> objects and the <code>getRequestTrackerById</code> action.
Resize Machine	Resizes a VMware Aria Automation machine asynchronously. On request submission, the workflow returns a <code>RequestTracker</code> object. You can get the status of the requested machine by using the <code>RequestService</code> and <code>RequestTracker</code> objects. Note that the Resize Machine workflow does not validate the maximum value for the CPU Count, Core Count, and

Table continued on next page

Continued from previous page

Workflow Name	Description
	Memory inputs. The Automation Orchestrator API does not support fetching the maximum configured values for these machine attributes.
Update Machine Custom Properties	Updates virtual machine custom properties.
Update Machine Tags	Updates virtual machine tags.

In addition to the default workflows, the Automation plug-in supports various machine power operations, including Power On/Off, Reset, Reboot, Resize, Shutdown.

To access these actions, navigate to **Library > Actions**, and search for the `com.vmware.library.vra.infrastructure.machine.power` tag in the action search box.

Note that the power operation action fails if you run an unsupported operation or if the target criteria is not met.

Machine Disks Workflows

To access the Machine Disks workflows in the Automation Orchestrator Client, navigate to **Library > Workflows**, and enter the `machines and disks` tags in the workflow search box.

Workflow Name	Description
Attach Machine Disk	Attaches a VMware Aria Automation machine disk (block device) asynchronously.
Detach Machine Disk	Dettaches a VMware Aria Automation machine disk (block device) asynchronously.

On request submission, the Machine Disks workflows return a `RequestTracker` object. You can get the status of the requested machine disks by using the `RequestService` and `RequestTracker` objects.

Machine Snapshots Workflows

To access the Machine Snapshots workflows in the Automation Orchestrator Client, navigate to **Library > Workflows**, and enter the `machines and snapshots` tags in the workflow search box.

Workflow Name	Description
Create Machine Snapshot	Requests to create a machine snapshot with the selected configuration asynchronously.
Delete Machine Snapshot	Requests to delete a machine snapshot with the selected configuration asynchronously.
Revert Machine Snapshot	Reverts a VMware Aria Automation machine snapshot asynchronously.

On request submission, the Machine Snapshots workflows return a `RequestTracker` object. You can get the status of the requested machine snapshots by using the `RequestService` and `RequestTracker` objects.

Networks Workflows

To access the Networks workflows in the Automation Orchestrator Client, navigate to **Library > Workflows**, and enter the `networks` tag in the workflow search box.

Workflow Name	Description
Create Network	Creates a network asynchronously. See Add a network .
Delete Network	Requests to delete a network with the selected configuration asynchronously. On request submission, the workflow returns a <code>RequestTracker</code> object. You can get the status of the requested network operation by using the <code>RequestService</code> and <code>RequestTracker</code> objects.

Projects Workflows

To access the Projects workflows in the Automation Orchestrator Client, navigate to **Library > Workflows**, and enter the `projects` tag in the workflow search box.

Workflow Name	Description
Create Project	Adds a project in VMware Aria Automation and to the plug-in inventory in Automation Orchestrator. See Add a project .
Delete Project	Removes a project in VMware Aria Automation and from the plug-in inventory in Automation Orchestrator.
Update Project	Updates a project in VMware Aria Automation and in the plug-in inventory in Automation Orchestrator.
Update Project Resource Metadata	Updates the resource metadata, such as tags, that are associated with a project.

Add a vSphere cloud account

You add a vSphere cloud account and configure its parameters by running a Automation Orchestrator workflow.

- To configure and work with cloud accounts in VMware Aria Automation, verify that you have the necessary credentials. See [Credentials required for working with cloud accounts in VMware Aria Automation](#).
- For information about creating vSphere cloud accounts, see [Create a vCenter cloud account in VMware Aria Automation](#).

1. Log in to the Automation Orchestrator Client as an administrator.
2. Navigate to **Library > Workflows** and enter the `cloud_accounts` tag in the workflow search box.
3. Locate **Create vSphere Cloud Account** workflow and click **Run**.
4. Select a VMware Aria Automation host for which you want to configure a vSphere cloud account.
5. Enter a name for the cloud account.
6. Configure the **vCenter** credentials.
 - a) Enter the IP address or fully-qualified domain name of your **vCenter** server.
 - b) Select whether to accept self-signed certificates automatically without user confirmation.
 - c) Provide the **vCenter** server user name and password.
7. If you want to add tags to support a tagging strategy, add capability tags.
You can add tags now, or later when you edit the cloud account. For information about tagging, see [How do I use tags to manage Automation Assembler resources and deployments](#).
8. Click **Run**.

You have added a vSphere cloud account.

Configure a cloud zone within the cloud account you just created. See [Add a cloud zone](#).

Add a cloud zone

You add a cloud zone and configure its parameters by running a Automation Orchestrator workflow.

- Verify that you configured at least one cloud account. See [Add a cloud account](#).
- For information about cloud zones, see [Learn more about Automation Assembler cloud zones](#).

1. Log in to the Automation Orchestrator Client as an administrator.
2. Navigate to **Library > Workflows** and enter the `cloud_zones` tag in the workflow search box.
3. Locate **Create Cloud Zone** workflow and click **Run**.
4. On the **Summary** tab, configure the cloud zone properties.

Option	Description
Host	Select the VMware Aria Automation host for which you want to configure a cloud zone.
Region	Select a cloud region.
Name	Enter a name for the cloud zone.
Description	Add a description.
Placement policy	<p>Placement policy drives host selection for deployments within the specified cloud zone.</p> <p>Apply one of the following placement strategies:</p> <ul style="list-style-type: none"> • DEFAULT. Places compute resources on random hosts. • BINPACK. Places compute resources on the most loaded host that has enough resources to run the given compute. • SPREAD. Provisions compute resources, at a deployment level, to the cluster or host with the least number of virtual machines. For vSphere, Distributed Resource Scheduler (DRS) distributes the virtual machines across the hosts.

5. On the **Capabilities** tab, add capability tags if you want to support a tagging strategy.

You can add tags now, or later when you edit the cloud account. For information about tagging, see [How do I use tags to manage Automation Assembler resources and deployments](#).

6. Click **Run**.

You have added a cloud zone.

Configure a project and add your cloud zones to it. See [Add a project](#).

Add a disk

You create a disk and configure its parameters by running a Automation Orchestrator workflow.

1. Log in to the Automation Orchestrator Client as an administrator.
2. Navigate to **Library > Workflows** and enter the `disks` tag in the workflow search box.
3. Locate **Create Disk** workflow and click **Run**.

4. Select a VMware Aria Automation host for which you want to configure a disk.
5. Enter a name for the disk.
6. Add a description for the disk.
7. Select a project to which to add the disk.
8. On the **Specification** tab, define the capacity of the disk in gigabytes.
9. Configure any additional settings for the disk, such as tags, constraints, and custom properties.
10. Click **Run**.

You have added a disk in VMware Aria Automation and to the Automation Orchestrator plug-in inventory.

Add a machine

You add a virtual machine and configure its parameters by running a Automation Orchestrator workflow.

1. Log in to the Automation Orchestrator Client as an administrator.
2. Navigate to **Library > Workflows** and enter the `machines` tag in the workflow search box.
3. Locate **Create Machine** workflow and click **Run**.
4. Select a VMware Aria Automation host for which you want to configure a machine.
5. Enter a name for the machine.
6. Define how many machines you want to provision.
7. Select a project to which to add the machine.
8. Go to the **Flavors and Images** tab.
 - a) Select the type of image used for the machine.
 - b) Select the direct image reference used for the machine.

This setting is required if you have multiple zones of the same cloud connection configured under image mapping.

- c) Select the flavor of the machine.

If multi-zone cloud accounts are attached to a project, machines are created for AWS, GCP, and Azure only if the flavor reference is not attached to the machine specification object.
- d) Select the provider-specific flavor reference for the machine.

This setting is required if you have multiple zones of the same cloud connection configured under flavor mapping.
9. Configure any additional settings for the machine, such as tags, custom properties, remote access, and others.

Keep in mind the following considerations:

- When you configure disk specifications, you must select a block device. The block device must be a data disk and must be available to attach to the machine.
You can create a block device using the `createBlockDevice` method. For more information about this method, go to **Plugins > VRA > Objects > VraDiskService** in the Automation Orchestrator API Explorer.
- When you configure network specifications, you must select a fabric network. Do not specify a Network ID. Network ID and fabric network can't be passed at the same time.

For more information about these settings, consult the signpost help.

10. Click **Run**.

You have added a machine in VMware Aria Automation and to the Automation Orchestrator plug-in inventory.

Add a network

You create a network and configure its parameters by running a Automation Orchestrator workflow.

Before you add a network in Automation Orchestrator, make sure that you have an on-demand network isolation policy set up under Network Profiles in VMware Aria Automation. See [Learn more about network profiles in VMware Aria Automation](#).

1. Log in to the Automation Orchestrator Client as an administrator.
2. Navigate to **Library > Workflows** and enter the `networks` tag in the workflow search box.
3. Locate the **Create Network** workflow and click **Run**.
4. Select a VMware Aria Automation host for which you want to configure a network.
5. Enter a name for the network.
6. Add a description for the network.
7. Select a project to which to add the network.
8. On the **Specification** tab, configure the following settings.
 - a) Select whether you want to activate or deactivate outbound access.
By default, outbound access is activated, which creates an outbound network.
 - b) Select whether you want to create a gateway in the network.
 - c) Enter the deployment ID of your VMware Aria Automation instance.
9. Configure any additional settings for the network, such as tags, constraints, and custom properties. For example:
 - a) Use constraints to select a network policy defined in VMware Aria Automation.
 - b) Use custom properties to select the Network type in the workflow request, for example, `networkType:private`.
The Automation plug-in supports the `private`, `routed`, and `outbound` network types.
10. Click **Run**.

You have added a network in VMware Aria Automation and to the Automation Orchestrator plug-in inventory.

Add a project

You add a project and configure its parameters by running a Automation Orchestrator workflow.

- Verify that you configured at least one cloud account. See [Add a cloud account](#).
- Verify that you configured at least one cloud zone. See [Add a cloud zone](#).
- For information about projects, see [Adding and managing Automation Assembler projects](#).

1. Log in to the Automation Orchestrator Client as an administrator.
2. Navigate to **Library > Workflows** and enter the `projects` tag in the workflow search box.
3. Locate **Create Project** workflow and click **Run**.
4. On the **Summary** tab, select the VMware Aria Automation host for which you want to configure a project, and enter a name for the project.
5. On the **Provisioning: Zones** tab, add one or more cloud zones.
 - a) Configure the cloud zone properties.
 - b) Select a placement policy.
6. Go to the **Provisioning: Resource Tags & Constraints** tab, add tags and constraints for your project.
7. Go to the **Provisioning: Custom Properties, Custom Naming & Request Timeout** tab.
 - a) Add custom properties that you want added to all requests in the project.

- b) Specify the naming template for machines, networks, security groups, and disks in the project.
 - c) If the workloads requested for this project take more than two hours to deploy, enter a longer value for the **Timeout**. The default value is 2 hours.
8. Click **Run**.

You have added a project.

Using the Automation Orchestrator plug-in for vSphere Update Manager

Using the VUM Plug-In

The Automation Orchestrator plug-in for VMware vSphere® Update Manager™ allows interaction between Automation Orchestrator and VMware vSphere Update Manager/vSphere Lifecycle Manager. You can use the plug-in to run Automation Orchestrator workflows that automate vSphere Update Manager processes. The plug-in contains a set of standard workflows. You can also create custom workflows that implement the plug-in API to automate tasks in your vSphere environment.

Role of Automation Orchestrator with the vSphere Update Manager Plug-in

Automation Orchestrator powers the vSphere Update Manager plug-in.

You can use the plug-in to run Automation Orchestrator workflows that interact with vSphere Update Manager to perform automated tasks in the vSphere infrastructure. vSphere Update Manager enables centralized, automated patch and version management for VMware vSphere, and offers support for VMware ESX/ESXi hosts and virtual machines.

With the vSphere Update Manager plug-in, you can perform the following tasks:

- Upgrade and patch ESX/ESXi hosts.
- Install and update third-party software on hosts.
- Upgrade virtual machine hardware and VMware Tools.

To learn more about vSphere Update Manager, see the [vSphere Update Manager Installation and Administration Guide](#).

Functional Prerequisites for the vSphere Update Manager Plug-In

vSphere Update Manager requires network connectivity with VMware vCenter™. Each installation of vSphere Update Manager must be associated with a single vCenter instance. For instructions about configuring a vCenter connection, see [Connect the plug-in to](#).

vSphere Update Manager Plug-In Scripting API

The vSphere Update Manager plug-in supports the following:

- vSphere API versions 6.7, 7.0, 7.0 U1, 7.0 U2.
- vSphere Update Manager API version 6.0 to 8.0.

The vSphere Update Manager plug-in scripting API contains classes, with their respective attributes and methods, that allow interaction between Automation Orchestrator and vSphere Update Manager. You can use the API to develop custom workflows that interact with vSphere Update Manager.

In the Automation Orchestrator API Explorer, click the **VUM** module in the left pane to expand the hierarchical list of vSphere Update Manager plug-in API scripting objects. You can search the plug-in API and see the documentation for JavaScript objects that you can use in scripted elements. You can copy code from API elements and paste it into scripting boxes.

Using the vSphere Update Manager Plug-In Inventory

The vSphere Update Manager plug-in exposes all objects in the connected vSphere Update Manager instance in the Inventory view in the Automation Orchestrator Client. You can use the Inventory view to add authorization elements or to run workflows on vSphere objects.

To display all available inventory objects, navigate to **Administration > Inventory > VMware Update Manager** in the Automation Orchestrator Client.

Access the vSphere Update Manager Plug-In Workflow Library

The vSphere Update Manager plug-in workflow library contains workflows that you can use to run automated processes related to the management of vSphere objects in the inventory of the vCenter with which vSphere Update Manager is registered.

You can integrate standard workflows from the workflow library to create custom workflows.

For a full list of available workflows, navigate to **Library > Workflows > vCenter Update Manager** in the Automation Orchestrator Client. See [Plug-In Workflow Library](#).

Connect the vSphere Update Manager plug-in to vCenter

Connect the VUM Plug-In to vCenter

Before you start running the vSphere Update Manager plug-in workflows, you must associate the plug-in with a vCenter instance.

1. Log in to the Automation Orchestrator Client as an administrator.
2. Navigate to **Library > Workflows**, and enter the `vcenter` and `configuration` tags in the workflow search box.
3. To add a vCenter instance, run the **Add a vCenter server instance** workflow. For detailed instructions about running this workflow, see [Configure the Connection to a Instance](#).
 - If you add a single vCenter server, it is set as the default vCenter for the vSphere Update Manager plug-in. That server is pre-selected for all vSphere Update Manager plug-in workflows that you run.
 - If you add more than one vCenter server, all instances are registered with the vSphere Update Manager plug-in. No server is pre-selected as the default for the workflows that you run. To set a default server, you must run the **Set a default vCenter with Update Manager** workflow.
4. To select a default vCenter to work with, run the **Set a default vCenter with Update Manager** workflow. The default vCenter server that you set is pre-selected for all other workflows that you run.
If you call the REST API directly, instead of run workflows from the Automation Orchestrator Client, you must set a default host by running the **Set a default vCenter with Update Manager** workflow.
5. Depending on the version of vCenter that you use, you might have to accept and import the vSphere Update Manager certificates.
 - If you have vCenter instances that are version 6.x, you must import a vSphere Update Manager server certificate for each vCenter connection by running the **Import a certificate from URL** workflow. The URL must follow the `https://vCenter-Server-IP-address:8084` format.
 - If you have vCenter instances that are 7.x and later, no further configuration is required because vCenter and vSphere Update Manager use the same certificate.

You can browse the vSphere Update Manager plug-in inventory, or run some of the workflows that are provided with the plug-in. For a full list of available workflows, see [Plug-In Workflow Library](#).

vSphere Update Manager Plug-In Workflow Library

VUM Plug-In Workflow Library

The vCenter Update Manager workflow category contains a set of standard workflows that cover the most common tasks that you can perform with vSphere Update Manager. You can use the workflows as building blocks for creating complex custom workflows. By combining standard workflows, you can automate multi-step processes in your vSphere environment.

You can manage baselines, patches, and inventory objects by running the default workflows provided with the plug-in.

To access these workflows in the Automation Orchestrator Client, navigate to **Library > Workflows**, and enter the `vcenter_update_manager` tag in the workflow search box.

Baseline Workflows

Workflow	Description
Attach a baseline	<p>Attaches baselines to a selected vSphere object. The object can be a template, virtual machine, vApp, ESX/ESXi host, folder, cluster, or a data center.</p> <p>Attaching a baseline to a container object, such as a folder or data center, transitively attaches the baseline to all objects in the container.</p>
Create a patch baseline	<p>Creates a new patch baseline. You can apply patch baselines to hosts or virtual machines.</p> <p>Depending on the patch criteria that you select, patch baselines can be dynamic or static (fixed). You can explicitly select the patches to include in the baseline by using the <code>includePatch</code> parameter. You can also use the <code>searchSpec</code> attribute to filter the patches that you want to include. You can filter by product, vendor, severity, and release date. Patches that have been excluded by using the <code>excludePatch</code> parameter will not be included in the baseline, even if they correspond to the filter criteria defined by the <code>searchSpec</code> attribute.</p>
Detach a baseline	Detaches baselines from the selected vSphere inventory objects. To detach inherited baselines, you must detach them from the parent object.
Export baselines	Detaches baselines from the selected vSphere inventory objects. To detach inherited baselines, you must detach them from the parent object.
Filter baselines	Filters baselines depending on the provided filter parameters.
Filter baselines with no user interaction	You can manually select a baseline from the filtered list to include it as a workflow result.
Get attached entities	Selects entities attached to baselines or baseline groups.
Import baselines	Imports baselines from the .xml file that the Export baselines workflow generates.
Update a patch baseline	Modifies the properties of an existing patch baseline.
Remove baselines	Deletes the baselines you select. Before deletion, the baselines are detached from all vSphere objects that they are attached to.

Patch Workflows

Workflow	Description
Download all patches	Check for new patches and updates and depending on the availability, download the new patches to the plug-in repository.
Download all patches asynchronously	
Filter patches	Filter patches and allow you to select a subset of the filtered patch for further processing.
Filter patches without user interaction	
Stage	Stage patches to hosts. Staging allows you to download patches and extensions from the vSphere Update Manager/vSphere Lifecycle Manager repository to ESX/ESXi hosts, without applying the patches and extensions immediately. You can stage patches to hosts or container objects such as clusters or data centers. This way, the remediation process is faster because the patches and extensions are already available locally on the hosts.
Stage asynchronously	The Stage asynchronously workflow returns an array with task keys for all of the started vCenter tasks.

Compliance and Inventory Workflows

Workflow	Description
Export compliance report	<p>Exports the compliance report to an external file format (CSV, PDF, or HTML).</p> <p>Run this workflow with a selected entity, baseline and compliance status to verify that the upgraded host is compliant against the baseline.</p> <p>Alternatively, you can run this workflow before you create a new patch baseline to discover which hosts are not compliant and need an upgrade.</p> <p>To run the workflow, you select relevant vSphere objects, a set of baselines that you want to check compliance against, a file location, and a file format. After you run the workflow, you can find the report at /data/vco/var/run/vco/.</p>
Get compliance	Retrieves compliance data for the specified object. The object can be a template, virtual machine, vApp, host, cluster, folder or datacenter. The workflow returns information about the compliance state of the vSphere object against the baselines that are attached to it. If the vSphere object is a container, you receive compliance data for all objects in the container.
Remediate	Remediates an inventory object against the specified baselines. You can remediate vSphere objects such as templates, virtual machines, vApps, hosts, folders, clusters, and data centers.
Remediate asynchronously	

Table continued on next page

Continued from previous page

Workflow	Description
	The Remediate asynchronously workflow returns an array of vCenter task keys.
Scan inventory asynchronously	Scans vSphere objects for applicable patches and updates that are included in the attached baselines. You can scan vSphere objects such as templates, virtual machines, vApps, hosts, folders, clusters, and data centers. If the objects are different types, the workflow starts a separate vCenter task for each object type.
Set a default vCenter with Update Manager	Set a default vCenter to use with vSphere Update Manager. The default vCenter instance is pre-selected for all vSphere Update Manager plug-in workflows that you run. If you have a single vCenter instance it will automatically be set as default.

Using the XML Plug-In

You can use the XML plug-in to run workflows that create and modify XML documents.

The XML plug-in adds an implementation of a Document Object Model (DOM) XML parser to the Automation Orchestrator JavaScript API. The XML plug-in also provides some sample workflows to demonstrate how you can create and modify XML documents from workflows.

Alternatively, you can use the ECMAScript for XML (E4X) implementation in the Automation Orchestrator JavaScript API to process XML documents directly in JavaScript. For an E4X scripting example, see *Developing Workflows with Automation Orchestrator*.

For information about E4X, go to the website of the organization that maintains the ECMA-357 standard.

Running the XML Plug-In Sample Workflows

You can run the XML plug-in sample workflows from the Automation Orchestrator Client to create and modify XML documents for testing purposes.

The workflows can create, read, or modify files, so you must have sufficient access rights to the working directory.

Orchestrator has read, write, and execute rights to a folder named `orchestrator`, at the root of the server system. Although workflows have permission to read, write, and execute in this folder, you must create the folder on the server system. If you use the Orchestrator Appliance, the folder is named `vco` and is located at `/var/run/vco`.

You can allow access to other folders by changing the settings for server file system access from workflows and JavaScript. See *Installing and Configuring Automation Orchestrator*, *Setting Server File System Access from Workflows and Actions*.

Create a Simple XML Document

You can run a workflow from the Automation Orchestrator Client to create a simple XML document for testing purposes.

- Verify that the user account you are logged in with has the necessary permissions to run XML workflows.
- Verify that you created the `c:/orchestrator` folder at the root of the Orchestrator server system or set access rights to another folder.

1. Log in to the Automation Orchestrator Client.
2. Navigate to **Library > Workflows** and enter the `xml` and `samples_xml_(simple)` tags in the workflow search box.
3. Locate the **Create a simple XML document** workflow and click **Run**.
4. Enter the filepath to the XML document to create.
For example, `c:/orchestrator/filename.xml`.
5. Click **Run**.

The workflow creates an XML document that contains a list of users. The attributes for each entry are `user_ID` and `name`.

Find an Element in an XML Document

You can run a workflow from the Automation Orchestrator Client to find an element in the XML created by the Create a simple XML document workflow.

- Verify that the user account you are logged in with has the necessary permissions to run XML workflows.
- Verify that you created the `c:/orchestrator` folder at the root of the Orchestrator server system or set access rights to another folder.

1. Log in to the Automation Orchestrator Client.
2. Navigate to **Library > Workflows** and enter the `xml` and `samples_xml_(simple)` tags in the workflow search box.
3. Locate the **Find element in document** workflow and click **Run**.
4. Type the filepath to the XML document.
For example, `c:/orchestrator/filename.xml`.
5. Click **Run**.
The workflow searches for an element and displays the result in the system log.

To view the result, select the completed workflow run in the Automation Orchestrator Client and click **Logs** on the **Schema** tab.

Modify an XML Document

You can run a workflow from the Automation Orchestrator Client to modify the XML that the Create a simple XML document workflow creates.

- Verify that the user account you are logged in with has the necessary permissions to run XML workflows.
- Verify that you created the `c:/orchestrator` folder at the root of the Orchestrator server system or set access rights to another folder.

1. Log in to the Automation Orchestrator Client.
2. Navigate to **Library > Workflows** and enter the `xml` and `samples_xml_(simple)` tags in the workflow search box.
3. Locate the **Modify XML document** workflow and click **Run**.
4. Provide the input and output filepaths.
 - a) Type the filepath to the XML document to modify.
For example, `c:/orchestrator/filename.xml`.
 - b) Type the filepath to the modified XML document.
For example, `c:/orchestrator/filename.xml`.

NOTE

If you type the same filepath in both fields, the workflow overwrites the original file with the modified file. If you type an output filepath to a file that does not exist, the workflow creates a modified file.

5. Click **Run**.

The workflow searches for an element and modifies the entry where the element is found.

Create an Example Address Book from XML

You can run a workflow from the Automation Orchestrator Client to create an address book for testing purposes.

- Verify that the user account you are logged in with has the necessary permissions to run XML workflows.
- Verify that you created the `c:/orchestrator` folder at the root of the Orchestrator server system or set access rights to another folder.

1. Log in to the Automation Orchestrator Client.

2. Navigate to **Library > Workflows** and enter the `xml` and `samples_xml_(address_book)` tags in the workflow search box.

3. Locate the **Full address book test** workflow and click **Run**.

4. Type the path to the address book folder.

For example, `c:/orchestrator/foldername`.

The workflow automatically creates the folder if it does not exist.

5. Click **Run**.

The workflow creates a DTD, an XML, and a CSS file, appends the stylesheet, and stores the files in the specified folder.

VMware Aria Automation Reference Architecture

The Reference Architecture describes the structure and configuration of typical VMware Aria Automation deployments.

The Reference Architecture also provides information about high availability, scalability, port requirements, and deployment profiles for these components:

- VMware Aria Suite Lifecycle
- VMware Identity Manager
- VMware Aria Automation

For software requirements, installation, and support platforms, refer to the individual product documentation.

Deployment and Configuration Recommendations

Configuring Deployments

Deploy and configure all VMware Aria Automation components in accordance with VMware recommendations.

The clocks for VMware Aria Suite Lifecycle, VMware Identity Manager, VMware Aria Automation, and Automation Orchestrator components must be synced to the same timezone. UTC+0 is recommended.

Install VMware Aria Suite Lifecycle, VMware Identity Manager, VMware Aria Automation, and Automation Orchestrator components on the same management cluster. Machines should then be provisioned on a separate cluster to keep user and server workloads isolated.

Authenticating VMware Aria Automation 8

VMware Aria Automation 8 requires an external VMware Identity Manager instance.

You can use an existing VMware Identity Manager instance or deploy a new one by using VMware Aria Suite Lifecycle. For information on how to deploy a new VMware Identity Manager instance, refer to [Deployment of VMware Identity Manager](#).

Configuring Load Balancers

VMware Aria Automation 8 requires a configured load balancer to direct and manage traffic.

If you are deploying a large VMware Aria Automation 8 instance, you must configure two load balanced VIPs. However, no session persistence is required.

For detailed configuration information, refer to the [Load Balancing Guide for VMware Aria Automation](#).

VMware Aria Automation and VMware Identity Manager appliances require and use these ports:

- VMware Aria Automation
 - Port: 443
 - Health Monitor Port: 8008
 - Health Monitor URL: /health
- VMware Identity Manager
 - Port: 443
 - Health Monitor Port: 443
 - Health Monitor URL: /SAAS/API/1.0/REST/system/health/heartbeat

Configuring Automation Orchestrator

VMware Aria Automation 8 requires a configured Automation Orchestrator instance for extensibility functionality.

VMware Aria Automation 8 supports both an external and embedded Automation Orchestrator instance. For optimized performance with VMware Aria Automation 8, configure an embedded Automation Orchestrator instance.

Configuring High Availability

You can configure high availability on VMware components by deploying clusters full stop. However, not all VMware components support high availability.

Table 89: Component High Availability

Product	High Availability Support
VMware Aria Suite Lifecycle	VMware Aria Suite Lifecycle does not support a highly available deployment.
VMware Identity Manager	Content is replicated in a VMware Identity Manager cluster. Deploy a cluster behind a load balancer to enable high availability.
VMware Aria Automation	Content is replicated in a VMware Aria Automation cluster. Deploy a cluster behind a load balancer to enable high availability.

Hardware Requirements

Use these hardware specifications when configuring your system.

Table 90: Hardware Requirements

Component	vCPU	Memory (GB)	Storage (GB)
VMware Aria Suite Lifecycle	2	6	78
VMware Identity Manager	8	16	100

Table continued on next page

Continued from previous page

Component	vCPU	Memory (GB)	Storage (GB)
VMware Aria Automation	Medium profile: 12 XL profile: 24	Medium profile: 54 XL Profile: 96	Medium profile: 246 XL profile: 246

For more information, see [System Requirements](#).

Scalability and Concurrency Maximums

The scalability and concurrency limit tables outline the recommended maximums on VMware Aria Automation HA multi-tenant (clustered) deployments.

Table 91: Scalability Maximums

Component	Scale Targets	
	Medium Profile	XL Profile
Tenants	20	50
Cloud Accounts: Private Endpoints - vCenter, NSX, and NSXT	50	100
Cloud Accounts: Public Endpoints - AWS, Azure, GCP, and VMC	50	300
Compute resources - ESXi hosts on a single vCenter	600	2000
Compute resources - ESXi Hosts across 50 vCenters	2,000	10,000
Cloud Zones (for all endpoints)	400	1000
Cloud Zones for a single endpoint	20	100
Data collected machines (includes private and public cloud)	200,000	280,000
Images collected	150,000	150,000
Image and Flavor Mapping	150	150
Cloud Zones and images per Image Mapping	100	124
Cloud Zone and Flavors per Flavor Mapping	100	124
VPZ created from single endpoint by provider tenant	50	50
VPZ created across endpoints by provider tenant	300	300
VPZ assignment per tenant	60	60
Resources per deployment	100	300
Cloud Template	8,000	10,000
Catalog items	8,000	10,000
Catalog - content sources	1,000	2,000
Projects across tenants	5,000	13,000

Table continued on next page

Continued from previous page

Component	Scale Targets	
Non-admin users for all projects	All 5,000 projects can have a maximum of 50 users each.	All 13,000 projects can have a maximum of 200 users each.
Non-admin users per single project	A single project can have 5,000 non-admin users. The maximum number of projects that can contain 5,000 non-admin users is 50.	A single project can have 5,000 non-admin users. The maximum number of projects that can contain 5,000 non-admin users is 50.
Custom Roles per User	100	500
Subscriptions	3,000	3,000
Subscriptions per deployment	40	40
Blocking subscription per event topic	50	50
Non-Blocking subscription per event topic	50	50
Approval policies	4,500	4,500
Pipelines	3,000	5,000
ABX Actions - AWS lambda and Azure function providers	1,000	2,000
ABX Actions - On-prem provider	150	150
HCMP Active Alerts	70,000	70,000
Maximum RTT Latency for Private Endpoints (ms)	300	300
Maximum Disks per vSphere managed Virtual Machine	59	59

Table 92: Concurrency Maximums

Action	Medium Profile Sustain Load	XL Profile Sustain Load
Concurrent Cloud Template resource provisioning, Day 2 actions on deployments, Provisioned Resources, ABX Action and vRO workflow. Additional Requests stay in the queue.	250 Active Requests	750 Active Requests
Concurrent pipeline executions	20/minute	50/minute
Bulk-Imported machines using workload on-boarding - Multiple plans	19,000/hour	30,000/hour
Bulk-Imported machines using workload on-boarding - Single Plan	3,500/hour	6,000/hour
Enforcement time taken by a single Day2 Actions Policy	25 minutes for 10,000 deployments 12 minutes for 5,000 deployments	15 minutes for 10,000 deployments 6 minutes for 5,000 deployments

Table continued on next page

Continued from previous page

Action	Medium Profile Sustain Load	XL Profile Sustain Load
Enforcement time taken for Content Sharing Policies (1 policy per Project for an overall of 4,000 projects)	12 minutes for 4,000 Day 0 policies 12 minutes for 4,000 Day 2 policies	12 minutes for 4,000 Day 0 policies 13 minutes for 4,000 Day 2 policies

Network and Port Communication

Network Requirements

Use these network requirements with your VMware Aria Automation 8 components.

All VMware Aria Automation 8 components must be deployed layer 2 adjacent. VMware Aria Automation 8 cannot be deployed with an IP address or access external services with IP addresses in these ranges. Reserve these network ranges for intra-service communication:

- 10.244.0.0/22
- 10.244.4.0/22

Port Requirements

The inbound and outbound ports for VMware components with VMware Aria Automation are outlined in the Port Requirements table.

Table 93: Port Requirements

Component	Inbound Ports	Outbound Ports
VMware Identity Manager Load Balanced VIP	User <ul style="list-style-type: none"> • HTTPS 443 VMware Aria Automation Appliance <ul style="list-style-type: none"> • HTTPS 443 VMware Aria Suite Lifecycle Appliance <ul style="list-style-type: none"> • HTTPS 443 	VMware Identity Manager <ul style="list-style-type: none"> • HTTPS 443
VMware Aria Automation Appliance Load Balanced VIP	User <ul style="list-style-type: none"> • HTTPS 443 	VMware Aria Automation <ul style="list-style-type: none"> • HTTPS 443 • Health Monitor 8008
VMware Identity Manager Appliance	User <ul style="list-style-type: none"> • *HTTPS 443 VMware Identity Manager Load Balanced VIP <ul style="list-style-type: none"> • HTTPS 443 VMware Aria Automation Appliance	VMware Identity Manager Load Balancer <ul style="list-style-type: none"> • **HTTPS 443

Table continued on next page

Component	Inbound Ports	Outbound Ports
	• ** SSH 22	
* Direct access only. Required only in deployments that are not load balanced.		
** Intra-cluster communication.		

Deployment Configurations

The components and communication ports in your deployment depend on the deployment's size.

Small deployments require these components:

- 1 VMware Aria Suite Lifecycle Appliance
- 1 VMware Identity Manager Appliance
- 1 VMware Aria Automation Appliance

NOTE

Small deployments do not require load balancers.

Large deployments require these components:

- 1 VMware Aria Suite Lifecycle Appliance
- 3 VMware Identity Manager Appliances
- 3 VMware Aria Automation Appliances

NOTE

A Load Balancer VIP is required for the 3 VMware Identity Manager Appliances and the 3 VMware Aria Automation Appliances.

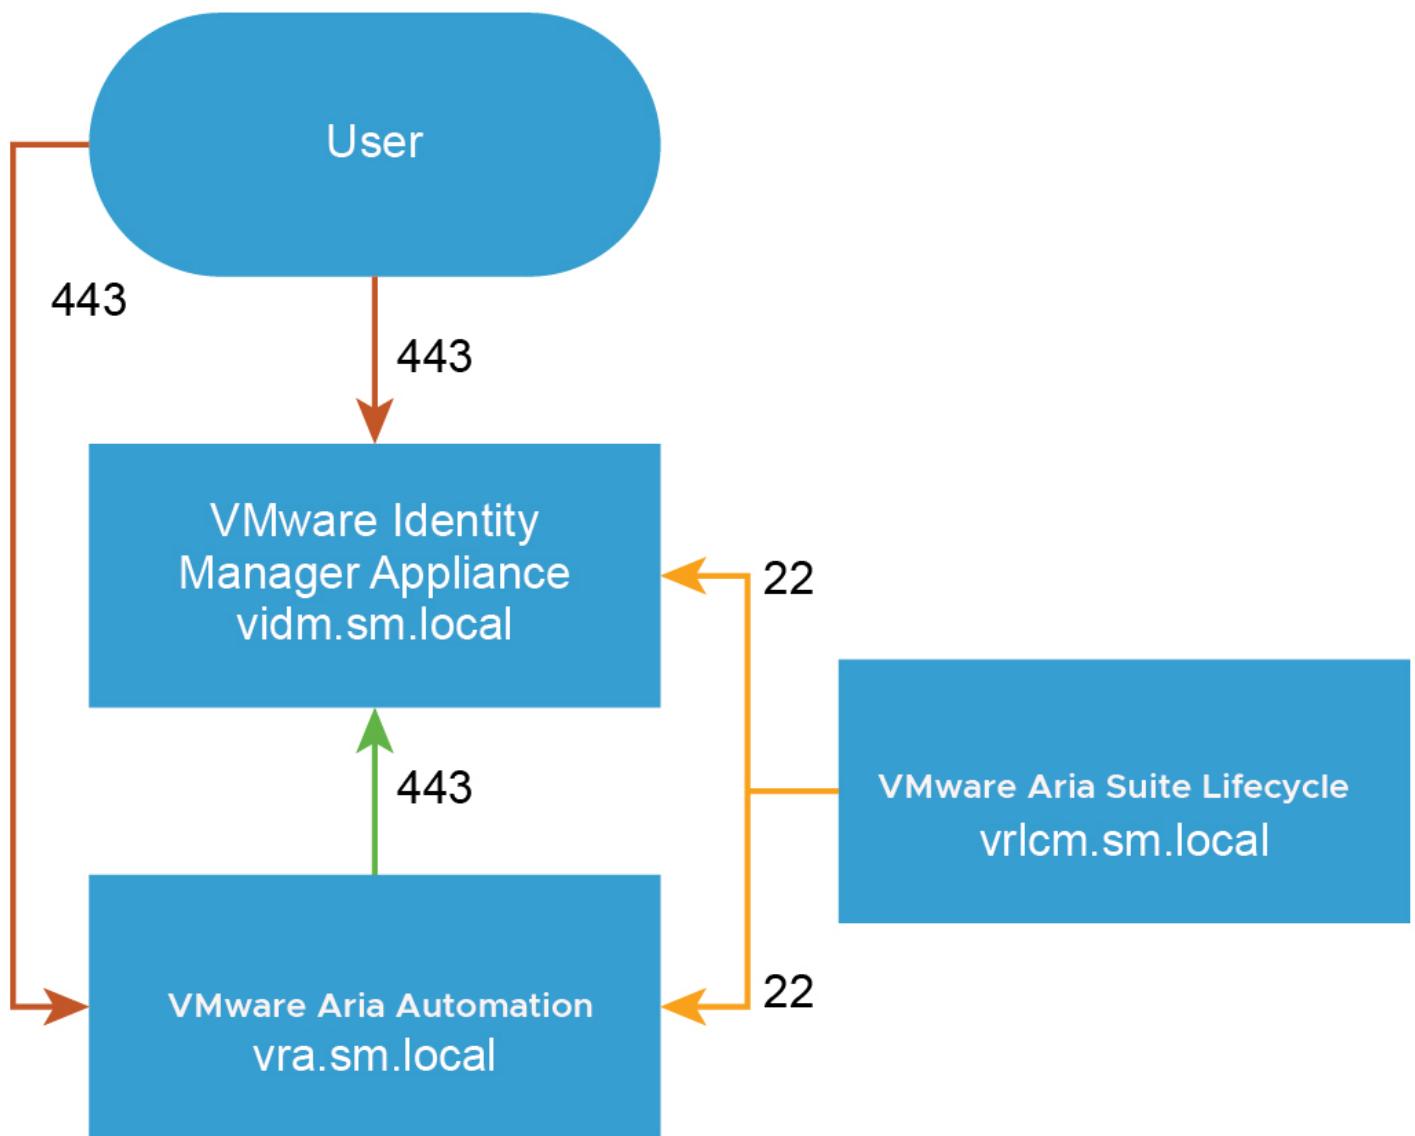

Small Deployment Configuration

Table 94: Small Deployment Hostnames

Component	Hostname
VMware Aria Suite Lifecycle Appliance	vrlcm.sm.local
VMware Identity Manager Appliance	vidm.sm.local
VMware Aria Automation Appliance	vra.sm.local

Table 95: Certificates

Server Role	Common Name or Subject Alt Name
VMware Identity Manager	Common name contains the hostname vidm.sm.local
VMware Aria Suite Lifecycle	Common name contains the hostname vrlcm.sm.local
VMware Aria Automation	Common name contains the hostname vra.sm.local

Large (Clustered) Deployment Configuration

Large (clustered) deployments include several component types and communication ports.

Large (clustered) deployments are comprised of these components:

- Identity Manager Appliance Load Balanced VIP
- VMware Aria Automation Appliance Load Balanced VIP
- VMware Aria Suite Lifecycle Appliance
- VMware Identity Manager Appliance x3
- VMware Aria Automation Appliance x3

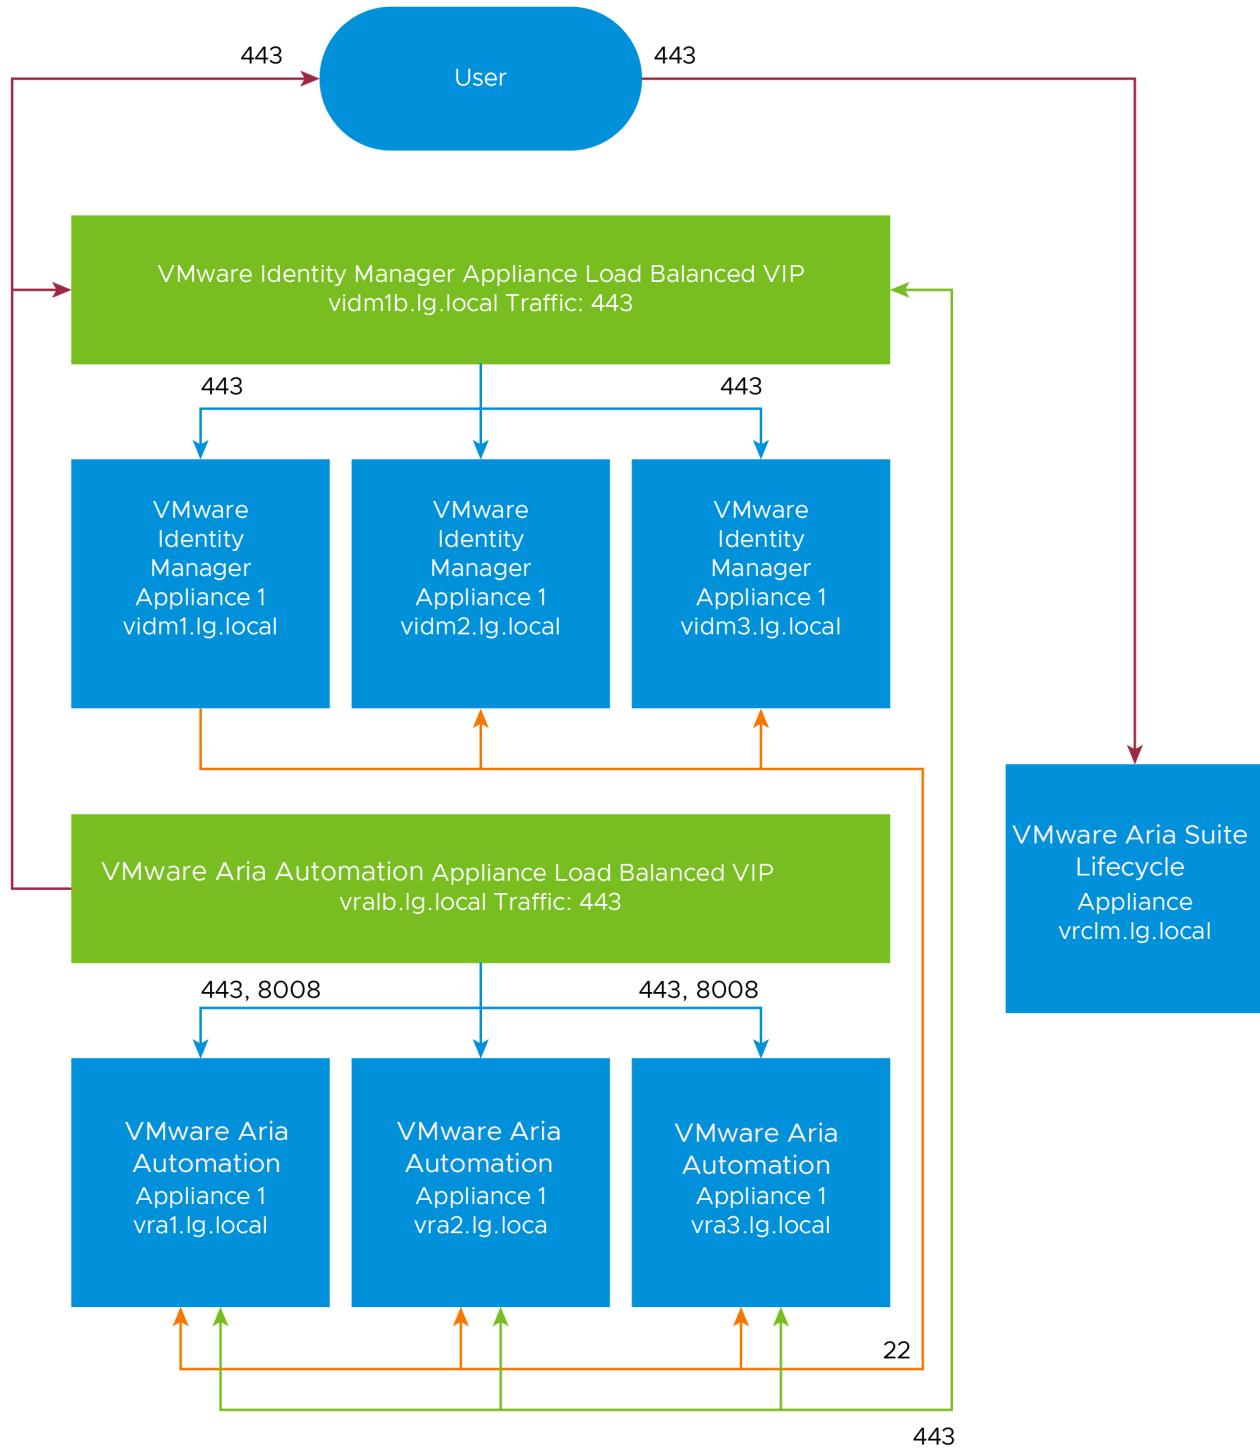

Table 96: Large Deployment Hostnames

Components	Hostname
Identity Manager Appliance Load Balanced VIP	vidmlb.lg.local
VMware Aria Automation Appliance Load Balanced VIP	vralb.lg.local
VMware Aria Suite Lifecycle Appliance	vrlcm.lg.local
VMware Identity Manager Appliance	<ul style="list-style-type: none"> • vidm1.lg.local • vidm2.lg.local • vidm3.lg.local
VMware Aria Automation Appliance	<ul style="list-style-type: none"> • vra1.lg.local • vra2.lg.local • vra3.lg.local

Table 97: Certificates

Server Role	Common Name or Subject Alt Name
VMware Identity Manager Appliance	Subject Alt name contains the hostnames: <ul style="list-style-type: none"> • vidmlb.lg.local • vidm1.lg.local • vidm2.lg.local • vidm3.lg.local
VMware Aria Suite Lifecycle	Common name contains the hostname vrlcm.lg.local
VMware Aria Automation	Subject Alt name contains the hostnames: <ul style="list-style-type: none"> • vralb.lg.local • vra1.lg.local • vra2.lg.local • vra3.lg.local

The diagram outlines the communication ports between large deployment components.

Administering VMware Aria Automation

This guide describes how to monitor and manage critical infrastructure and user management aspects of a VMware Aria Automation deployment.

The tasks described herein are vital to keeping a VMware Aria Automation deployment operating appropriately. These tasks include user and group management, and monitoring system logs.

In addition, it describes how to configure and manage multi-organization deployments.

While some VMware Aria Automation administration tasks are completed from within VMware Aria Automation, others require the use of related products such as VMware Aria Suite Lifecycle and Workspace ONE Access. Users should familiarize themselves with these products and their functionality before completing applicable tasks.

For example, for information about backup, restore, and disaster recovery, see the **Backup and Restore, and Disaster Recovery > 2019** section of [vRealize Suite product documentation](#).

NOTE

Disaster recovery is supported in VMware Aria Automation.

For information about working with VMware Aria Suite Lifecycle installation, upgrade, and management, see [VMware Aria Suite Lifecycleproduct documentation](#).

Administering Users and Groups in VMware Aria Automation

Administering users

VMware Aria Automation uses Workspace ONE Access, the VMware-supplied identity management application to import and manage users and groups. After users and groups are imported or created, you can manage the role assignments for single tenant deployments using the **Identity & Access Management** page.

VMware Aria Automation is installed using VMware Aria Suite Lifecycle. When installing VMware Aria Automation you must import an existing Workspace ONE Access instance, or deploy a new one to support identity management. These two scenarios define your management options.

- If you deploy a new Workspace ONE Access instance, you can manage users and groups by using VMware Aria Suite Lifecycle. During installation, you can set up an Active Directory connection using Workspace ONE Access. Alternatively, you can view and edit some aspects of users and groups within VMware Aria Automation using the **Identity & Access Management** page as described herein.
- If you use an existing Workspace ONE Access instance, you import it for use with VMware Aria Automation by using VMware Aria Suite Lifecycle during installation. In this case, you can continue to use Workspace ONE Access to manage users and groups, or you can use the management functions in VMware Aria Suite Lifecycle.

See [Logging in to tenants and adding users in VMware Aria Automation](#) for more information about managing users under a multi-organization deployment.

VMware Aria Automation users must be assigned roles. Roles define access to features within the application. When VMware Aria Automation is installed with a Workspace ONE Access instance, a default organization is created and the installer is assigned the Organization Owner role. All other VMware Aria Automation roles are assigned by the Organization Owner.

There are three types of roles in VMware Aria Automation: organization roles, service roles, and project roles. For Automation Assembler, Automation Service Broker and Automation Pipelines, user-level roles can typically use resources whereas admin-level roles are required to create and configure resources. Organizational roles define permissions within the tenant; organizational owners have admin-level permissions while organizational members have user-level permissions. Organization owners can add and manage other users.

Organization Roles	Service Roles
<ul style="list-style-type: none"> • Organization Owner • Organization Member 	<ul style="list-style-type: none"> • Automation Assembler Administrator • Automation Assembler User • Automation Assembler Viewer • Automation Service Broker Administrator • Automation Service Broker User • Automation Service Broker Viewer • Automation Pipelines Administrator • Automation Pipelines User • Automation Pipelines Viewer

There are also project-level roles not shown in the table. These roles are assigned automatically on a per project basis in Automation Assembler. These roles are somewhat fluid. The same user can be an administrator on one project and a user on another project. For more information, see [What are the user roles](#).

How do I enable Active Directory groups in VMware Aria Automation for projects

How do I enable Active Directory groups for projects

If a group is not available on the **Add Groups** page when you are adding users to projects, check the **Identity & Access Management** page and add the group if it is available. If the group is not listed on the **Identity & Access Management** page in VMware Aria Automation, the group may not be synchronized in your Workspace ONE Access instance. You can verify that it has been synchronized and then use this procedure to add the group as shown herein.

If the groups are not synchronized, they are not available when you try to add them to a project. Verify that you synchronized your Active Directory groups with your VMware Aria Suite Lifecycle instance.

To add members of an Active Directory group to a project, you must ensure that the group is synchronized with your Workspace ONE Access instance and that the group is added to the organization.

1. Log in to VMware Aria Automation as a user from the same Active Directory domain that you are adding. For example, @mycompany.com
2. In Automation Assembler, click **Identity & Access Management** in the header right navigation.
3. Click **Enterprise Groups**, and then click **Assign Roles**.
4. Use the search function to find the group that you are adding and select it.
5. Assign an organization role.

At a minimum, the group must have an Organization Member role. See [What are the VMware Aria Automation user roles](#) for more information.

6. Click **Add Service Access**, add one or more services, and select a role for each.
7. Click **Assign**.

You can now add the Active Directory group to a project.

How do I remove users in VMware Aria Automation

You can remove users as needed in VMware Aria Automation.

All users are listed by default and you cannot add users with the Identity and Access Management page. You can delete users.

1. Select the Active Users tab on the Identity & Access Management page.
2. Locate and select the users that you want to delete.

3. Click **Remove Users**.

The selected users are removed.

How do I edit user roles in VMware Aria Automation

You can edit roles assigned to Workspace ONE Access users that have been imported into VMware Aria Automation.

1. In Automation Assembler, click **Identity & Access Management** in the header right navigation.
2. Select the desired user on the **Active Users** tab and click **Edit Roles**.
3. You can edit the organization and service roles for the user.
 - Select the drop down beside the **Assign Organization Roles** heading to change the user's relationship with the organization.
 - Click **Add Service Access** to add new service roles for the user.
 - To remove user roles, click the **X** beside the applicable service.
4. Click **Save**.

The user role assignment is updated as specified.

How do I edit group role assignments in VMware Aria Automation

You can edit role assignments for groups in VMware Aria Automation

Users and groups have been imported from a valid Workspace ONE Access instance that is associated with your VMware Aria Automation deployment.

1. In Automation Assembler, click **Identity & Access Management** in the header right navigation.
2. Select the **Enterprise Groups** tab.
3. Enter the name of the group for which you want to edit role assignments in the search field.
4. Edit the role assignments for the selected group. You have two options.
 - Assign Organization Roles
 - Assign Service Roles
5. Click **Assign**.

Role assignments are updated as specified.

What are the VMware Aria Automation user roles

As a organization owner, you can assign users organization roles and service roles in VMware Aria Automation. The roles determine what users can do or see. Then, in the services, the service administrator can assign project roles. To determine the role that you want to assign, evaluate the tasks in the following tables.

Assembler Service Roles

The Automation Assembler service roles determine what you can see and do in Automation Assembler. These service roles are defined in the console by an organization owner.

Table 98: Automation Assembler Service Role Descriptions

Role	Description
Assembler Administrator	A user who has read and write access to the entire user interface and API resources. This is the only user role that can see and do everything, including add cloud accounts, create new projects, and assign a project administrator.
Assembler User	A user who does not have the Assembler Administrator role. In an Automation Assembler project, the administrator adds users to projects as project members, administrators, or viewers. The administrator can also add a project administrator.
Assembler Viewer	A user who has read access to see information but cannot create, update, or delete values. This is a read-only role across all projects in all the services. Users with the viewer role can see all the information that is available to the administrator. They cannot take any action unless you make them a project administrator or a project member. If the user is affiliated with a project, they have the permissions related to the role. The project viewer would not extend their permissions the way that the administrator or member role does.

In addition to the service roles, Automation Assembler has project roles. Any project is available in all of the services.

The project roles are defined in Automation Assembler and can vary between projects.

In the following tables, which tells you what the different service and project roles can see and do, remember that the service administrators have full permission on all areas of the user interface.

The descriptions of project roles will help you decide what permissions to give your users.

- Project administrators leverage the infrastructure that is created by the service administrator to ensure that their project members have the resources they need for their development work.
- Project members work within their projects to design and deploy cloud templates. Your projects can include only resources that you own or resources that are shared with other project members.
- Project viewers are restricted to read-only access, except in a few cases where they can do non-destructive things like download cloud templates.
- Project supervisors are approvers in Automation Service Broker for their projects where an approval policy is defined with a project supervisor approver. To provide the supervisor with context for approvals, consider also granting them the project member or viewer role.

Table 99: Automation Assembler service roles and project roles

Service Broker Service Roles

The Automation Service Broker service roles determine what you can see and do in Automation Service Broker. These service roles are defined in the console by an organization owner.

Table 100: Service Broker Service Role Descriptions

Role	Description
Service Broker Administrator	Must have read and write access to the entire user interface and API resources. This is the only user role that can perform all tasks, including creating a new project and assigning a project administrator.
Service Broker User	Any user who does not have the Automation Service Broker Administrator role. In an Automation Service Broker project, the administrator adds users to projects as project members, administrators, or viewers. The administrator can also add a project administrator.
Service Broker Viewer	A user who has read access to see information but cannot create, update, or delete values. This is a read-only role across all projects in all the services. Users with the viewer role can see all the information that is available to the administrator. They cannot take any action unless you make them a project administrator or a

Table continued on next page

Continued from previous page

Role	Description
	project member. If the user is affiliated with a project, they have the permissions related to the role. The project viewer would not extend their permissions the way that the administrator or member role does.

In addition to the service roles, Automation Service Broker has project roles. Any project is available in all of the services.

The project roles are defined in Automation Service Broker and can vary between projects.

In the following tables, which tells you what the different service and project roles can see and do, remember that the service administrators have full permission on all areas of the user interface.

Use the following descriptions of project roles will help you as you decide what permissions to give your users.

- Project administrators leverage the infrastructure that is created by the service administrator to ensure that their project members have the resources they need for their development work.
- Project members work within their projects to design and deploy cloud templates. In the following table, Your projects can include only resources that you own or resources that are shared with other project members.
- Project viewers are restricted to read-only access.
- Project supervisors are approvers in Automation Service Broker for their projects where an approval policy is defined with a project supervisor approver. To provide the supervisor with context for approvals, consider also granting them the project member or viewer role.

Table 101: Service Broker Service Roles and Project Roles

UI Context	Task	Service Broker Administrator	Service Broker Viewer	Service Broker User User must be a project administrator to see and do project-related tasks.			
				Project Administrator	Project Member	Project Viewer	Project Supervisor
Access Service Broker							
Console	In the console, you can see and open Service Broker	Yes	Yes	Yes	Yes	Yes	Yes
Infrastructure							
	See and open the Infrastructure tab	Yes	Yes				
Administration - Projects	Create projects	Yes					
	Update, or delete values	Yes

Active Directory sync and authentication with multiple domains

When adding a directory, you must choose whether to use the SAM Account Name and the User Principal Name (UPN) as an Active Directory attribute that contains the user name, and there are implications to either choice that users should consider.

The following list outlines important issues that you should understand regarding syncing multiple domains with Active Directory.

- When an Active Directory is synced by SAM Account Name, usernames are in the format "USERNAME"
- When an Active Directory is synced by User Principal Name (UPN), the usernames are in the format "USERNAME@DOMAIN". A UPN consists of a UPN prefix (the user account name) and an UPN suffix (a DNS domain name). The prefix is joined with the suffix using the @ symbol. For example, someone@example.com.
- By convention, User Principal Name (UPN) matches the email of the user, but there might be exceptions: The UPN might be jsmith@example.com but the email field can be john@example.com. The username and email fields are mapped to different attributes from the Active Directory.

No matter what format you choose, the same account is specified.

Consider the following issues when choosing the SAM Account Name as the attribute for the username: It is possible to explicitly configure a user in different domains with the same SAM Account Name, but with a different User Principal Name (UPN) name. As a consequence, in order to ensure that the SAM Account Name is working in a multi-domain environment, you must ensure that the attribute is unique within all of the domains (and not just unique in the specific domain). On the other side, a configuration having a User Principal Name (UPN) will support a multi-domain environment without any issues.

Display full names of users

By default, users in VMware Aria Automation are identified with user IDs, such as Active Directory SAM Account Names or User Principal Names (UPN). You can expose the personal names (first and last name) of your users on different pages across the organization, such as Resources, Deployments, and Policies.

To be legally compliant with regulations such as the California Consumer Privacy Act (CCPA), the General Data Protection Regulation (GDPR) and others, you must provide explicit consent to data compliance when you expose the names of users.

If you deactivate the feature, you revoke consent and the names of your users will no longer be displayed in the VMware Aria Automation user interface.

IMPORTANT

VMware Aria Automation employs a data at rest policy, which means that storing personal user data is necessary for performance and low latency requirements of the application, so storing the data is considered legally data compliant with or without explicit user consent.

For more information, see the [Privacy and Data Protection](#) policies.

1. Log in as an administrator.
2. Go to **Infrastructure > Settings**, and click **Show names of users**.
3. Toggle the feature on or off.
4. Click **Save**.

Enable Department of Defense Notice and Consent Banner

For some government customers, an administrator must configure the standard Department of Defense (DoD) notice and consent banner in Workspace ONE Access to allow users to access VMware Aria Automation.

The Standard Mandatory DoD Notice and Consent Banner text is as follows:

You are accessing a U.S. Government (USG) Information System (IS) that is provided for USG-authorized use only. By using this IS (which includes any device attached to this IS) you consent to the following conditions:

- The USG routinely intercepts and monitors communications on this IS for purposes including, but not limited to, penetration testing, COMSEC monitoring, network operations and defense, personnel misconduct (PM), law enforcement (LE), and counterintelligence (CI) investigations.
- At any time, the USG may inspect and seize data stored on this IS.
- Communications using, or data stored on, this IS are not private, are subject to routine monitoring, interception, and search, and may be disclosed or used for any USG-authorized purpose.

The following steps describe how to configure this banner in Workspace ONE Access. For more information, see the Workspace ONE Access administrative console documentation.

1. Log in to the Workspace ONE Access administrative console as an administrator.
2. In the Workspace ONE Access console, click the **Identity and Access Management** tab.
3. Click **Setup** and then click the **Connectors** tab.
4. Click the **Worker** link for each connector that you want to configure.
5. Click the **Auth Adapters** tab and then **CertificateAuthAdapter**.
6. Click the **Enable Consent Form before Authentication** check box.
7. Paste the Standard Mandatory DoD Notice and Consent Banner text into the **Consent Form Content** box.
8. Save your changes.

Maintaining your VMware Aria Automation appliance

Maintaining your appliance

As a system administrator, you might need to perform various tasks to ensure the proper functioning of your installed VMware Aria Automation application.

If you are just getting started with VMware Aria Automation, these are not required tasks. Knowing how to perform these tasks is useful if you need to resolve performance or product behavior issues.

Starting and stopping VMware Aria Automation

Observe the proper procedures when starting or shutting down VMware Aria Automation.

The recommended procedure to shut down and start VMware Aria Automation components is to use the Power OFF and ON functionality provided in **Lifecycle Operations > Environments** section of VMware Aria Suite Lifecycle. The following procedures outline manual methods to shut down and start VMware Aria Automation components in case VMware Aria Suite Lifecycle is not available for some reason.

Shut down VMware Aria Automation

To preserve data integrity, shut down the VMware Aria Automation services before powering off the virtual appliances. Using SSH or VMRC, you can shut down or start all nodes from any individual appliance.

NOTE

Avoid using `vracli reset vdm` commands if at all possible. This command resets all configurations of Workspace ONE Access and breaks the association between users and provisioned resources.

1. Log in to the console of any VMware Aria Automation appliance using either SSH or VMRC.
2. To shut down the VMware Aria Automation services on all cluster nodes, run the following set of commands.

NOTE

If you copy any of these commands to run and they fail, paste them into notepad first, and then copy them again before running them. This procedure strips out any hidden characters and other artifacts that might exist in the documentation source.

```
/opt/scripts/deploy.sh --shutdown
```

3. Shut down the VMware Aria Automation appliances.

Your VMware Aria Automation deployment is now shut down.

Start VMware Aria Automation

Following an unplanned shutdown, a controlled shutdown, or a recovery procedure, you must restart VMware Aria Automation components in a specific order. VMware Aria Suite Lifecycle is a non-critical component, so you can start it at any time. Workspace ONE Access components must be started before you start VMware Aria Automation.

NOTE

Verify that applicable load balancers are running before starting VMware Aria Automation components.

1. Power on all VMware Aria Automation appliances and wait for them to start.
2. Log into the console for any appliance using SSH or VMRC and run the following command to restore the services on all nodes.

```
/opt/scripts/deploy.sh
```

- Verify that all services are up and running with the following command.

```
kubectl get pods --all-namespaces
```

NOTE

You should see three instances of every service, with a status of either Running or Completed.

When all services are listed as Running or Completed, VMware Aria Automation is ready to use.

Restart VMware Aria Automation

You can restart all VMware Aria Automation services centrally from any of the appliances in your cluster. Follow the preceding instructions to shut down VMware Aria Automation, and then use the instructions to start VMware Aria Automation. Before restarting VMware Aria Automation, verify that all applicable load balancer and Workspace ONE Access components are running.

When all services are listed as Running or Completed, then VMware Aria Automation is ready to use.

Run the following command to verify that all services are running:

```
kubectl -n prelude get pods
```

Scale out VMware Aria Automation from one to three nodes

Scale out from one node to three nodes

As needs expand, you can scale out a VMware Aria Automation deployment from one node to three nodes.

This procedure assumes that you already have a functioning single node VMware Aria Automation deployment.

You must use features of VMware Aria Suite Lifecycle to complete many steps of this procedure. For information about working with VMware Aria Suite Lifecycle installation, upgrade, and management, see [VMware Aria Suite Lifecycle product documentation](#).

If you are using a three node clustered deployment, VMware Aria Automation can typically withstand the failure of one node and still function. The failure of two nodes in a three node cluster will render VMware Aria Automation non-functional.

- Shut down all VMware Aria Automation appliances.

To shut down the VMware Aria Automation services on all cluster nodes, run the following set of commands.

```
/opt/scripts/svc-stop.sh
sleep 120
/opt/scripts/deploy.sh --onlyClean
```

Now you can shut down the VMware Aria Automation appliances.

- Take a deployment snapshot.

Use the **Create Snapshot** option in VMware Aria Suite Lifecycle by selecting **Lifecycle Operations** > **Environments** > **vRA** > **View Details**.

NOTE

Online snapshots, taken without shutting down VMware Aria Automation nodes, are supported.

- Power on the VMware Aria Automation appliance and bring up all containers.

4. Using the **Locker** functionality located in VMware Aria Suite Lifecycle at **Locker > Certificates**, generate or import VMware Aria Automation certificates for all components, including VMware Aria Automation node FQDNs and the VMware Aria Automation load balancer FQDN.
- Add the names of all three appliances in the **Subject Alternative Names**.
5. Import the new certificate into VMware Aria Suite Lifecycle.
6. Replace the existing VMware Aria Automation certificate with the one generated in the previous step using the **Lifecycle Operations > Environments > vRA > View Details > Replace Certificate** option in VMware Aria Suite Lifecycle.
7. Scale out VMware Aria Automation to three nodes using the **Add Components** option in VMware Aria Suite Lifecycle by selecting **Lifecycle Operations > Environments > vRA > View Details**.

NOTE

If your VMware Aria Automation deployment is patched, refer to the workaround in [KB 96619](#).

VMware Aria Automation has been scaled to a three node deployment.

Configure an anti-affinity rule and virtual machine group for a clustered Workspace ONE Access instance in VMware Aria Automation

Configure an anti-affinity rule and virtual machine group for a clustered Workspace ONE Access instance. If your VMware Aria Automation environment uses a clustered Workspace ONE Access instance, you can create an anti-affinity rule and machine cluster to ensure proper vSphere High Availability workflow.

To protect any clustered Workspace ONE Access nodes from a host-level failure, you can configure an anti-affinity rule to run virtual machines that exist on different hosts in the default vSphere management cluster. To define the desired machine start-up order, create an anti-affinity rule to configure a virtual machine group. By using a defined machine start-up order, you can ensure that vSphere High Availability powers on the clustered Workspace ONE Access nodes in the correct order.

For general information about creating datastore anti-affinity rules for VMs, see [Create VM anti-affinity rules](#).

For information about how to configure anti-affinity rules for a VMware Aria Automation appliance, see [Configure anti-affinity rules for appliances](#).

Configure anti-affinity rules for VMware Aria Automation appliances

Configure anti-affinity rules

Create an anti-affinity rule to ensure that each VMware Aria Automation appliance runs on a different ESXi host. This ensures that if an ESXi host fails, the VMware Aria Automation appliance remains available and operational on one or more other hosts.

1. In a web browser, log in to the management domain or VI workload domain vCenter at `https://vcenter_server_fqdn/ui`.
2. Select **Menu > Hosts and Clusters**.
3. In the inventory, expand **vCenter Server > Datacenter**.
4. Select the VMware Aria Automation appliance or appliances and click the **Configure** tab.
5. Select **VM/Host rules** and click **Add**.
6. Enter the following rule details:

- **Name** - Enter a new rule name.
 - **Enable rule** - Toggle this option on.
 - **Type** - Select **Separate Virtual Machines**.
 - **Members** - Click **Add**, select the VMware Aria Automation appliance or appliances, and click **OK**.
7. Click **OK** on the **Create VM/Host rule** page.

Configure anti-affinity rule and virtual machine group for a clustered VMware Aria Automation instance

Configure an anti-affinity rule and virtual machine group for a clustered VMware Aria Automation instance. If your VMware Aria Automation environment is clustered, you can create an anti-affinity rule and machine cluster to ensure proper vSphere High Availability workflow.

To protect any clustered VMware Aria Automation nodes from a host-level failure, configure an anti-affinity rule to run virtual machines that exist on different hosts in the default vSphere management cluster. After you create an anti-affinity rule, configure a virtual machine group to define the desired machine start-up order. By using a defined machine start-up order, you can ensure that vSphere High Availability powers on the clustered VMware Aria Automation nodes in the correct order for your environment.

For information about how to configure anti-affinity rules for a manager cluster, see [Create Anti-Affinity Rule for Global Manager Cluster in VMware Cloud Foundation](#) in the VMware Cloud Foundation Product Documentation.

For general information about creating anti-affinity rules for VMs, see [Create VM Anti-Affinity Rules](#).

Replacing a VMware Aria Automation appliance node

Replacing an appliance node

When a VMware Aria Automation appliance in a multiple-node, high availability (HA) configuration has failed, you might need to replace the faulty node.

CAUTION

Before proceeding, VMware recommends that you contact technical support to troubleshoot the HA issue and verify that the problem is isolated to one node.

If technical support determines that you need to replace the node, take the following steps.

1. In vCenter, take backup snapshots of every appliance in the HA configuration.
In the backup snapshots, don't include virtual machine memory.
2. Shut down the faulty node.
3. Make note of the faulty node VMware Aria Automation software build number, and network settings.
Note the FQDN, IP address, gateway, DNS servers, and especially MAC address. Later, you assign the same values to the replacement node.
4. Check the status of the primary database node. From a root command line on any healthy node, run the following:

```
> kubectl get pod `vracli status | jq -r '.databaseNodes[] | select(.["Role"] == "primary") | .["Node name"]' | cut -d '.' -f 1` -n prelude -o wide --no-headers=true
```

```
primary-db-node-name 1/1 Running 0 39h 12.123.2.14 vc-vm-224-84.company.com <none>
<none>
```

IMPORTANT

The primary database node must be one of the healthy nodes.

If the primary database node is faulty, contact technical support instead of proceeding.

5. From the root command line of the healthy node, remove the faulty node.

```
vracli cluster remove faulty-node-FQDN
```

6. Use vCenter to deploy a new, replacement VMware Aria Automation node.

Deploy the same VMware Aria Automation software build number, and apply the network settings from the faulty node. Include the FQDN, IP address, gateway, DNS servers, and especially MAC address that you noted earlier.

7. Power on the replacement node.

8. Log in as root to the command line of the replacement node.

9. Verify that the initial boot sequence has finished by running the following command.

```
vracli status first-boot
```

Look for a First boot complete message.

10. From the replacement node, join the VMware Aria Automation cluster.

NOTE

If your VMware Aria Automation deployment is patched, refer to the workaround in [KB 96619](#).

```
vracli cluster join primary-DB-node-FQDN
```

11. Log in as root to the command line of the primary database node.

12. Deploy the repaired cluster by running the following script:

```
/opt/scripts/deploy.sh
```

Increase VMware Aria Automation appliance disk space

You might need to increase VMware Aria Automation appliance disk space for purposes such as log file storage.

1. Use vSphere to expand the VMDK on the VMware Aria Automation appliance.
2. Log in to the command line of the VMware Aria Automation appliance as a root user.
3. From the command prompt, run the following VMware Aria Automation command:

```
vracli disk-mgr resize
```

If VMware Aria Automation resizing fails, see [Knowledge Base article 79925](#).

Update the DNS assignment for VMware Aria Automation

Update the DNS assignment

An administrator can update the DNS assignments for VMware Aria Automation.

1. Log in to the console for any VMware Aria Automation appliance using either SSH or VMRC.
2. Run the following command.

```
vracli network dns set --servers DNS1,DNS2
```

3. Verify that the new DNS servers were properly applied to all VMware Aria Automation nodes with `vracli network dns status` command.

4. Run the following set of commands to shut down the VMware Aria Automation services on all cluster nodes.

For related information about shutting down VMware Aria Automation, see [Starting and stopping VMware Aria Automation](#).

```
/opt/scripts/svc-stop.sh
sleep 120
/opt/scripts/deploy.sh --onlyClean
```

5. Restart the VMware Aria Automation nodes and wait for them to start completely.

For related information about restarting VMware Aria Automation, see [Starting and stopping VMware Aria Automation](#).

6. Log in to each VMware Aria Automation node with SSH and verify that the new DNS servers are listed in `/etc/resolv.conf`.
7. On one of the VMware Aria Automation nodes, run the following command to start the VMware Aria Automation services: `/opt/scripts/deploy.sh`

The VMware Aria Automation DNS settings are changed as specified.

Change IP addresses of VMware Aria Automation node or cluster

Change the IP address of a node or cluster

You can change the IP address of a VMware Aria Automation node or cluster.

For example, you might want to migrate your deployed VMware Aria Automation environment to a more convenient vCenter or to support VMware Aria Automation fail-over.

As a VMware Aria Automation administrator, you can use the following procedure to set a new IP address for the VMware Aria Automation node or cluster and then redeploy services to the new IP address.

NOTE

Before you proceed with changing the IP of a VMware Aria Automation node or cluster, you must verify that the node or cluster is in a healthy state. Attempting to run this procedure on a node or cluster that is not in a healthy state can create problems that are very challenging to resolve.

In this procedure, you will restart VMware Aria Automation in a specific and sequential manner. For related information about shutting down and restarting VMware Aria Automation, see [Starting and stopping VMware Aria Automation](#).

1. Verify that the VMware Aria Automation node or cluster is in a healthy state by using the following command.
`vracli service status`
2. When VMware Aria Automation is in healthy state, set the alternative IP of the node or cluster appliance(s) by using the following command.
`vracli network alternative-ip set --dns DNSIPaddress1,DNSIPaddress2 IPV4_addressGateway_IPV4_address`
If you are working with a cluster, set the alternative IP of each applicable node in the cluster.
3. Shut down the services by using the following command.
`/opt/scripts/deploy.sh -shutdown`
4. If needed, perform a VMware Aria Automation fail-over or migration operation. See information about [VMware Site Recovery Manager](#) and your own internal procedures and practices.
5. Change the IP of VMware Aria Automation by using the following command.
`vracli network alternative-ip swap`

If you are using a VMware Aria Automation cluster, you must change the IP address of each node in the cluster.

- Reboot VMware Aria Automation by using the following command.

```
shutdown -r now
```

If you are using a VMware Aria Automation cluster, you must reboot each node in the cluster.

- Redeploy VMware Aria Automation services by using the following command.

```
/opt/scripts/deploy.sh
```

After you reboot VMware Aria Automation and the redeploy services are running, VMware Aria Automation should be available at the new IP address.

How do I enable time synchronization of VMware Aria Automation

How do I enable time synchronization

You can enable time synchronization on your VMware Aria Automation deployment by using the VMware Aria Automation appliance command line.

You can configure time synchronization for your standalone or clustered VMware Aria Automation deployment by using the Network Time Protocol (NTP) networking protocol. VMware Aria Automation supports two, mutually exclusive, NTP configurations:

NTP configuration	Description
ESXi	<p>This configuration can be used when the ESXi server hosting the VMware Aria Automation is synchronized with an NTP server. If you are using a clustered deployment, all ESXi hosts must be synchronized with an NTP server. For more information about configuring NTP for ESXi, see KB article 57147 Configuring Network Time Protocol (NTP) on an ESXi host using the vSphere Web Client.</p> <p>NOTE If your VMware Aria Automation deployment is migrated to a ESXi host that is not synchronized to an NTP server, you can experience clock drift.</p>
systemd	<p>This configuration uses the <code>systemd-timesyncd</code> daemon to synchronize the clocks of your VMware Aria Automation deployment.</p> <p>NOTE By default, the <code>systemd-timesyncd</code> daemon is enabled, but configured with no NTP servers. If the VMware Aria Automation appliance uses a dynamic IP configuration, the appliance can use any NTP servers received by the DHCP protocol.</p>

- Log in to the VMware Aria Automation appliance command line as **root**.

- Enable NTP with ESXi.

- Run the `vracli ntp esxi` command.

- To confirm the status of the NTP configuration, run the `vracli ntp status` command.

You can also reset the NTP configuration to the default state by running the `vracli ntp reset` command.

- Enable NTP with `systemd`.

- Run the `vracli ntp systemd --set FQDN_or_IP_of_NTP_server` command.

NOTE

You can add multiple `systemd` NTP servers by separating their network addresses with a comma. Each network address must be placed inside single quotation marks. For example, `vracli ntp systemd --set 'ntp_address_1', 'ntp_address_2'`.

- b) To confirm the status of the NTP configuration, run the `vracli ntp status` command.

You have enabled time synchronization for your VMware Aria Automation appliance deployment.

The NTP configuration can fail if there is a time difference of above 10 minutes between the NTP server and the VMware Aria Automation deployment. To resolve this problem, reboot the VMware Aria Automation appliance.

How do I reset the root password for VMware Aria Automation

How do I reset the root password

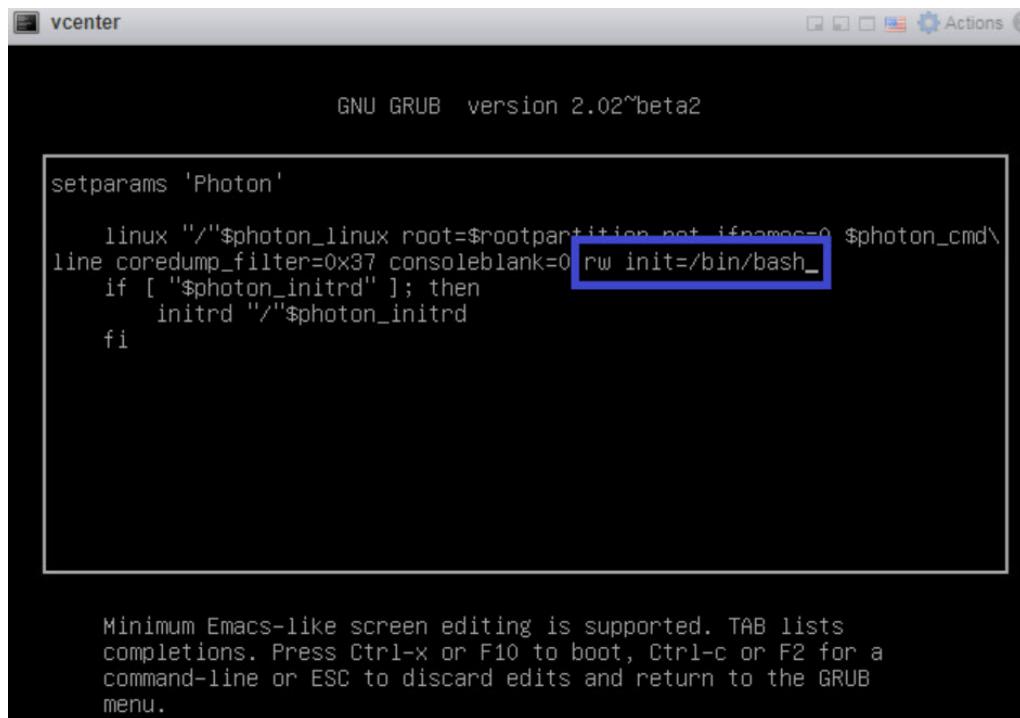

You can reset a lost or forgotten VMware Aria Automation root password.

This process is for VMware Aria Automation administrators and requires the credentials needed to access the host vCenter appliance.

For related information about password management in VMware Aria Suite Lifecycle, see [KB 92245](#).

In this procedure, you use a command line window on the host vCenter appliance to reset your organization's VMware Aria Automation root password.

1. Shut down and start up VMware Aria Automation by using the procedure described in [Starting and stopping VMware Aria Automation](#).
2. When the Photon operating system command line window appears, enter `e` and press the **Enter** key to open the GNU GRUB boot menu editor.
3. In the GNU GRUB editor, enter `rw init=/bin/bash` at the end of the line that begins with `linux "/"$photon_linux root=rootpartition` as shown below:

4. Click the **F10** key to push your change and restart VMware Aria Automation.
5. Wait for VMware Aria Automation to restart.
6. At the `root [/]#` prompt, enter `passwd` and press the **Enter** key.
7. At the `New password:` prompt, enter your new password and press the **Enter** key.
8. At the `Retype new password:` prompt, reenter your new password and press the **Enter** key.
9. At the `root [/]#` prompt, enter `reboot -f` and press the **Enter** key to complete the root password reset process.

```
root [/]# passwd
New password:
Retype new password:
passwd: password updated successfully
root [/]# reboot -f_
```

As a VMware Aria Automation administrator, you can now log in to VMware Aria Automation with the new root password.

To remediate passwords outside of VMware Aria Suite Lifecycle , see [KB 92253](#).

Using multi-organization tenant configurations in VMware Aria Automation

VMware Aria Automation enables IT providers to set up multiple tenants, or organizations, within each deployment. Providers can set up multiple tenant organizations and allocate infrastructure within each deployment and also manage users for tenants.

In a VMware Aria Automation multi-organization configuration, providers can create multiple organizations, and each tenant organization manages its own projects, resources and deployments. While providers cannot manage tenant infrastructure remotely, they can log in to tenants and manage infrastructure within their tenants.

Multi-tenancy relies on coordination and configuration of three different VMware products as outlined below:

- Workspace ONE Access - This product provides the infrastructure support for multi-tenancy and the Active Directory domain connections that provide user and group management within tenant organizations.
- VMware Aria Suite Lifecycle - This product supports the creation and configuration of tenants for supported products, such as VMware Aria Automation. In addition, it provides some certificate management capabilities.
- VMware Aria Automation - Providers and users log in to VMware Aria Automation to access tenants in which they create and manage deployments.

When configuring multi-tenancy, users should be familiar with all three of these products and their associated documentation.

For more information about working VMware Aria Suite Lifecycle and Workspace ONE Access, see the following:

- [VMware Aria Suite Lifecycle product documentation](#)
- [VMware Workspace ONE Access product documentation](#)

Administrators with VMware Aria Suite Lifecycle privileges create and manage tenants using the VMware Aria Suite Lifecycle tenants page located under the **Identity and Tenant Management** service. Tenants are constructed by using an Active Directory IWA or LDAP connection. They are supported by the associated Workspace ONE Access instance that is required for VMware Aria Automation deployments.

When configuring multi-tenancy, you start with a base, or master tenant. This tenant is the default tenant that is created when the underlying Workspace ONE Access application is deployed. Other tenants, known as sub-tenants, can be based upon the master tenant. VMware Aria Automation currently supports up to 20 tenant organizations with the standard three node deployment.

Before enabling VMware Aria Automation for multi-tenancy, you must first install the application in a single organization configuration, and then use VMware Aria Suite Lifecycle to set up a multi-organization configuration. A Workspace ONE Access deployment supports the management of tenants and the associated Active Directory domain connections.

When you initially set up multi-tenancy, a provider administrator is designated in VMware Aria Suite Lifecycle. You can change this designation or add administrators later if desired. Under multi-organization configurations, VMware Aria Automation users and groups are managed primarily through Workspace ONE Access.

After organizations are created, authorized users can log in to their applications to create or work with projects and resources and create deployments. Administrators can manage user roles in VMware Aria Automation.

Setting up for a multi-organization configuration

You can enable a multi-organization deployment after completing a VMware Aria Automation installation. When setting up a multi-organization configuration, you must configure your external Workspace ONE Access for multi-tenancy use and then use Lifecycle manager to create and configure tenants. This applies to both new and existing deployments. As an initial step to setting up tenants, you must use VMware Aria Suite Lifecycle to set an alias for the master tenant that was created by default on Workspace ONE Access. Sub-tenants that you create based on this master tenant inherit the Active Directory domain configurations from this master tenant.

In Lifecycle Manager, you assign tenants to a product, such as VMware Aria Automation, and to a specific environment. When setting up a tenant, you must also designate a tenant administrator. By default, multi-tenancy is enabled based on tenant hostname. Users can elect to manually configure tenant name by DNS name. During this procedure you must set several flags to support multi-tenancy, and you must configure the load balancer as well.

If you use a clustered instance, both the Workspace ONE Access and VMware Aria Automation tenant based hostnames will point to the load balancer.

If your clustered VMware Aria Automation and Workspace ONE Access load balancers do not use wildcard certificates, then users must add tenant hostnames as SAN entries on the certificates for every new tenant that is created.

You cannot delete tenants in VMware Aria Automation or in VMware Aria Suite Lifecycle. If you need to add tenants to an existing multi-tenancy deployment, you can do this using VMware Aria Suite Lifecycle, but it will require downtime of three to four hours.

Refer to the documentation links at the beginning of this topic for more information about using VMware Aria Suite Lifecycle/Workspace ONE Access.

Hostnames and multi-tenancy

In prior versions of VMware Aria Automation, users accessed tenants with URLs that were based on directory path. In the current multi-tenancy implementation, users access tenants based on hostname.

Also, the hostname format that VMware Aria Automation users will use to access tenants differs from the format that is used to access tenants within Workspace ONE Access. For example, a valid hostname would look like the following: `tenant1.example.eng.vmware.com` as opposed to `vidm-node1.eng.vmware.com`.

Multi-tenancy and certificates

You must create certificates for all components involved in a multi-organization configuration. You will need one or more certificates for Workspace ONE Access, VMware Aria Suite Lifecycle, and VMware Aria Automation, depending on whether you are using a single node configuration or a clustered configuration.

When configuring certificates, you can use either wildcard with the SAN names or dedicated names. Using wild cards will simplify certificate management somewhat as certificates must be updated whenever you add new tenants. If your VMware Aria Automation and Workspace ONE Access load balancer do not use wildcard certificates, then you must add tenant hostnames as SAN entries on the certificates for every new tenant that is created. Also, if you use SAN, certificates must be updated manually if you add or delete hosts or change a hostname. You must also update DNS entries for tenants.

Note that VMware Aria Suite Lifecycle does not create separate certificates for each tenant. Instead it creates a single certificate with each tenant hostname listed. For basic configurations, the tenant's CNAME uses the following format: `tenantname.vrahostname.domain`. For high availability configurations, the name uses the following format: `tenantname.vralBhostname.domain`.

If you are using a clustered Workspace ONE Access configuration, note that Lifecycle Manager cannot update the load balancer certificate, so you must update it manually. Also, if you need to re-register products or services that are external to VMware Aria Suite Lifecycle, this is a manual process.

Set up multi-organization tenancy for VMware Aria Automation

Set up multi-organization tenancy

You can set up multi-organization tenancy for VMware Aria Automation by using VMware Aria Suite Lifecycle.

- Install and configure Workspace ONE Access.
- Install and configure VMware Aria Suite Lifecycle.

The following is a high level description of the procedure to set up multi-tenancy for VMware Aria Automation including configuring DNS and certificates. It focuses on a single node deployment but includes notes for a clustered configuration. For related information and a video demonstration of configuring VMware Aria Automation multi-organization multi-tenancy, see this [VMware blog](#).

1. Create the required A and CNAME Type DNS records.

- For your primary tenant and each sub-tenant, you must create and apply a SAN certificate.
- For single node deployments, the VMware Aria Automation FQDN points to the VMware Aria Automation appliance, and the Workspace ONE Access FQDN points to the Workspace ONE Access appliance.

- For clustered deployments, both the Workspace ONE Access and VMware Aria Automation tenant-based FQDNs must point to their respective load balancers. Workspace ONE Access is configured with SSL Termination, so the certificate is applied on both the Workspace ONE Access cluster and load balancer. The VMware Aria Automation load balancer uses SSL passthrough, so the certificate is applied only on the VMware Aria Automation cluster.

See [Managing certificates and DNS configuration under single-node multi-organization deployments](#) and [Managing certificate and DNS configuration in clustered VMware Aria Automation deployments](#) for more details.

- Create or import the required multi-domain (SAN) certificates for both Workspace ONE Access and VMware Aria Automation.

You can create certificates in VMware Aria Suite Lifecycle by using the Locker service. The Locker service allows you to create certificates, licenses, and passwords. Alternatively, you can use a CA server or some other mechanism to generate certificates.

If you need to add or create additional tenants, you must recreate and apply your VMware Aria Automation and Workspace ONE Access tenants.

After you create your certificates, you can apply them within VMware Aria Suite Lifecycle by using the Lifecycle Operations feature. You must select the environment and product and then select the **Replace Certificate** option. Then you can select the product. When you replace a certificate, you must re-trust all associated products in your environment.

Wait for the certificate to be applied and all services to restart before proceeding to the next step.

See [Managing certificates and DNS configuration under single-node multi-organization deployments](#) and [Managing certificate and DNS configuration in clustered VMware Aria Automation deployments](#) for more details.

- Apply the Workspace ONE Access SAN certificate on the Workspace ONE Access instance or cluster.
- In VMware Aria Suite Lifecycle, run the Enable Tenancy wizard to enable multi-tenancy and create an alias for the default primary tenant.

Enabling tenancy requires that you create an alias for the provider organization primary tenant or default tenant. After you enable tenancy, you can access Workspace ONE Access via the primary tenant FQDN.

For example, if the existing Workspace ONE Access FQDN is `idm.example.local` and you create an alias of `default-tenant`, after tenancy is enabled, the Workspace ONE Access FQDN changes to `default-tenant.example.local`, and all clients communicating with Workspace ONE Access would now communicate through `default-tenant.example.local`.

- Apply the VMware Aria Automation SAN certificates on the VMware Aria Automation instance or cluster.

You can apply SAN certificates through the VMware Aria Suite Lifecycle Lifecycle Operations service. Display details of the environment and then select **Replace Certificates**. You must wait for the certificate replacement task to complete before adding tenants. As part of certificate replacement, VMware Aria Automation services will restart.

- In VMware Aria Suite Lifecycle, run the **Add Tenants** wizard to configure the desired tenants.

You add tenants by using the VMware Aria Suite Lifecycle **Tenant Management** page located under **Identity and Tenant Management**. You can only add tenants for which you have previously configured certificates and DNS settings.

When creating a tenant, you must designate a tenant administrator and you can select the Active Directory connections for this tenant. Available connections are based on those configured in your default or primary tenant. You must also select the product or product instance to which the tenant will be associated.

After you create tenants, you can use the VMware Aria Suite Lifecycle **Tenant Management** page located under **Identity and Tenant Management** to change or add tenant administrators, add Active Directory directories to the tenant and change product associations for the tenant.

You can also log in to your Workspace ONE Access instance to view and validate your tenant configuration.

Managing certificates and DNS configuration under single-node multi-organization deployments

Multi-organization tenancy VMware Aria Automation configurations rely on a coordinated configuration between several products, and you must ensure that DNS settings and certificates are configured correctly in order for your multi-organization tenancy configuration to function.

This multi-organization configuration assumes single node deployments for the following components:

- VMware Aria Suite Lifecycle
- Workspace ONE Access Identity Manager
- VMware Aria Automation

Also, it assumes that you are starting with a default tenant, which is your provider organization, and creating two sub-tenants, called tenant-1 and tenant-2.

You can create and apply certificates using the Locker service in VMware Aria Suite Lifecycle or you can use another mechanism. VMware Aria Suite Lifecycle also enables you to replace or re-trust certificates on VMware Aria Automation or Workspace ONE Access.

DNS Requirements

You must create both main A type records and CNAME type records for system components as described below.

- Create both main A type records for each system component and for each of the tenants that you will create when you enable multi-tenancy.
- Create multi-tenancy A type records for each of the tenants you will create as well as for the primary tenant.
- Create multi-tenancy CNAME type records for each of the tenants you will create, not including the primary tenant.

Certificate requirements for single node multi-tenancy deployment

You must create two Subject Alternative Name (SAN) certificates, one for Workspace ONE Access and one for VMware Aria Automation.

- The VMware Aria Automation certificate lists the hostname of the VMware Aria Automation server and the names of the tenants you will create.
- The Workspace ONE Access certificate lists the hostname of the Workspace ONE Access server and the tenant names you are creating.
- If you use dedicated SAN names, certificates must be updated manually when you add or delete hosts or change a hostname. You must also update DNS entries for tenants. As an option to simplify configuration, you can use wildcards for the Workspace ONE Access and VMware Aria Automation certificates. For example, *.example.com and *.vra.example.com.

NOTE

VMware Aria Automation supports wildcard certificates only for DNS names that match the specifications in the Public Suffix list at <https://publicsuffix.org>. For example, *.myorg.com is a valid name while *.myorg.local is invalid.

Note that VMware Aria Suite Lifecycle does not create separate certificates for each tenant. Instead it creates a single certificate with each tenant hostname listed. For basic configurations, the tenant's CNAME uses the following format: *tenantname.vrahostname.domain*. For high availability configurations, the name uses the following format: *tenantname.vraLBhostname.domain*.

Summary

The following table summarizes DNS and certificate requirements for a single node Workspace ONE Access and single node VMware Aria Automation deployment.

DNS Requirements	SAN Certificate Requirements
Main A Type Records lcm.example.com WorkspaceOne.example.com vra.example.com	Workspace ONE AccessCertificate Host Name: WorkspaceOne.example.com, default-tenant.example.com, tenant-1.vra.example.com, tenant-2.vra.example.com
Multi-tenancy A Type Records default-tenant.example.com tenant-1.example.com tenant-2.example.com	
Multi-Tenancy CNAME Type Records tenant-1.vra.example.com tenant-2.vra.example.com	VMware Aria Automation Certificate Host Name: vra.example.com, tenant-1.vra.example.com, tenant-2.vra.example.com

Managing certificate and DNS configuration in clustered VMware Aria Automation deployments

You must coordinate the certificate and DNS configuration between all applicable components to set up a multi-organization clustered VMware Aria Automation deployment.

In a typical clustered configuration, there are three Workspace ONE Access appliances and three VMware Aria Automation appliances as well as a single VMware Aria Suite Lifecycle appliance.

This configuration assumes clustered deployments for the following components:

- Workspace ONE Access Identity Manager appliances:
 - idm1.example.com
 - idm2.example.com
 - idm3.example.com
 - idm-lb.example.com
- VMware Aria Automation appliances:
 - vra-1.example.com
 - vra-2.example.com
 - vra-3.example.com
 - vra-lb.example.com
- VMware Aria Suite Lifecycle appliance

DNS Requirements

You must create both main A type records for each component and for each of the tenants that you will create when you enable multi-tenancy. In addition, you must create multi-tenancy CNAME type records for each of the tenants you will create, not including the master tenant. Finally, you must also create Main A Type records for the Workspace ONE Access and VMware Aria Automation load balancers.

- Create A type records for the three Workspace ONE Access appliances, and for the VMware Aria Automation appliances that point to their respective FQDNs.
- In addition, create A type records for the Workspace ONE Access load balancer and the VMware Aria Automation load balancer that point to their respective FQDNs.

- Create multi-tenancy A Type records for the default tenant and for tenant-1 and tenant-2 that point to the IP address of the Workspace ONE Access load balancer.
- Create CNAME records for tenant-1 and tenant-2 that point to the IP address of the VMware Aria Automation load balancer.

Subject Alternative Name (SAN) Certificate Requirements

You must create two Workspace ONE Access certificates, one that applies on the cluster appliances and one that applies on the load balancer. In addition, create a certificate that applies to the VMware Aria Automation appliances, the tenants you are creating, excluding the default tenant, and the load balancer.

- Create a certificate for the Workspace ONE Access appliances that list the FQDNs of the Workspace ONE Access appliances as well as the default tenant and other tenants you create. This certificate should include the IP addresses of the Workspace ONE Access appliances.
- As a best practice, create an SSL termination on the load balancer. To support this capability, create a certificate for the Workspace ONE Access load balancer that lists the FQDN of the Workspace ONE Access load balancer as well as the default tenant and all other tenants you create. This certificate should include the IP address of the load balancer.
- You must create a certificate for VMware Aria Automation that lists the host names of the three VMware Aria Automation appliances as well as the related load balancer and the tenants you are creating. In addition, it should list the IP addresses of the three VMware Aria Automation appliances.
- As an option, to simplify configuration, you can use wildcards for the Workspace ONE Access and VMware Aria Automation certificates. For example, *.example.com, *.vra.example.com, and *.vra-lb.example.com.

NOTE

VMware Aria Automation supports wildcard certificates only for DNS names that match the specifications in the Public Suffix list at <https://publicsuffix.org>. For example, *.myorg.com is a valid name.

If you are using a clustered Workspace ONE Access configuration, note that VMware Aria Suite Lifecycle cannot update the load balancer certificates, so you must update them manually. Also, if you need to re-register products or services that are external to VMware Aria Suite Lifecycle, this is a manual process.

Summary of DNS entries and certificates for a clustered multi-organization configuration

The following tables outlines DNS Main A Type Records and C Name Type records and certificate requirements for a clustered Workspace ONE Access and clustered VMware Aria Automation multi-organization deployment.

DNS Requirements	SAN Certificate Requirements
Main A Type Records <ul style="list-style-type: none"> • lcm.example.com • WorkspaceOne-1.example.com • WorkspaceOne-2.example.com • WorkspaceOne-3.example.com • Workspace.One-lb.example.com • vra-1.example.com • vra-2.example.com • vra-3.example.com • vra-lb.example.com 	Workspace ONE Access Certificate Host Name: <ul style="list-style-type: none"> • WorkspaceOne-1.example.com • WorkspaceOne-2.example.com • WorkspaceOne-3.example.com • default-tenant.example.com • tenant-1.example.com • tenant-2.example.com
Multi-Tenancy A Type Records <ul style="list-style-type: none"> • default-tenant.example.com • tenant-1.vra.example.com 	Workspace ONE Access LB Certificate (LB Terminated) Host Name:

Table continued on next page

Continued from previous page

DNS Requirements	SAN Certificate Requirements
<ul style="list-style-type: none"> tenant-2.vra.example.com <p>NOTE All of the multi-tenancy A Type records must point to the vIDM/WS1A load balancer IP address.</p>	<ul style="list-style-type: none"> WorkspaceOne-lb.example.com default-tenant.example.com tenant-1.example.com tenant-2.example.com
Multi-Tenancy CNAME Type Records <ul style="list-style-type: none"> tenant-1.vra-lb.example.com - vra-lb.example.com tenant-2.vra-lb.example.com - vra-lb.example.com 	VMware Aria Automation Certificate Host Name: <ul style="list-style-type: none"> vra-1.example.com vra-2.example.com vra-3.example.com vra-lb.example.com tenant-1.example.com tenant-2.example.com <p>No certificate is required on the VMware Aria Automation load balancer as it uses SSL passthrough.</p>

NOTE

Each additional tenant that you add must be listed separately in the VMware Aria Automation Certificate, Multi-tenancy CNAME records, Multi-tenancy Type A records, Workspace ONE Access Certificate and Workspace ONE Access LB Certificate.

NOTE

The *.com file names are for example use only. They may not be applicable to most business environments.

Logging in to tenants and adding users in VMware Aria Automation

After you have created tenants for VMware Aria Automation in VMware Aria Suite Lifecycle, you can log in to Workspace ONE Access to view your tenants and add users.

You can view tenants created for a VMware Aria Automation deployment by logging in to the associated Workspace ONE Access instance. The URL to use is `https://default-tenant name.domainname.local` or, for a non-clustered deployment, `https://idm.domainname.local` which will direct you back to the default tenant Workspace ONE Access URL.

You can validate specific tenants in Workspace ONE Access by using the following URL: `https://tenant-1.domainname.local`. This URL opens a page that shows the users for the specified tenant. You can click **Add User** to create additional users.

Authorized users can log in to the main provider organization in VMware Aria Automation by using `https://vra.domainname.local`. This view provides access to all VMware Aria Automation related services.

Authorized users can log in to applicable tenants in VMware Aria Automation by using `https://tenantname.vra.domainname.local`.

For more information about managing users, see [VMware Workspace ONE Access product documentation](#).

Adding local users

You can add local users to your deployment using the associated Workspace ONE Access instance. Local users are users that are not stored in any external identity provider.

Using VMware Aria Automation Orchestrator with VMware Aria Automation multi-organization deployments

You can use VMware Aria Automation Orchestrator with VMware Aria Automation multi-organization tenancy deployments.

The default tenant supports integration with the embedded VMware Aria Automation Orchestrator integration out of the box. VMware Aria Automation Orchestrator is available pre-configured on the **Integrations** page of the default tenant. Subtenants do not have any pre-registered VMware Aria Automation Orchestrator integration. They have several options to add a VMware Aria Automation Orchestrator integration.

- Subtenants can add an integration with the embedded VMware Aria Automation Orchestrator by navigating to **Infrastructure > Connections > Integrations**.

NOTE

If the embedded VMware Aria Automation Orchestrator is added as an integration to multiple tenants, all the VMware Aria Automation Orchestrator content, including the plug-in inventory, is shared among these tenants.

- Subtenants can add an external VMware Aria Automation Orchestrator instance that uses the multi-organization VMware Aria Automation as an Auth Provider.

Any VMware Aria Automation Orchestrator instance that uses a VMware Aria Automation multi-organization deployment as an Auth Provider can be registered to any of the tenants by creating a new integration and providing the VMware Aria Automation Orchestrator FQDN without providing any credentials.

Working with logs in VMware Aria Automation

Working with logs

You can use the supplied `vracli` command line utility to create and use logs in VMware Aria Automation.

You can use logs directly in VMware Aria Automation or you can instead forward all logs to VMware Aria Operations for Logs.

How do I work with logs and log bundles in VMware Aria Automation

How do I work with logs and log bundles

Various services generate logs automatically. You can generate log bundles in VMware Aria Automation. You can also configure your environment to send logs to VMware Aria Operations for Logs.

Use the `--help` argument in the `vracli` command line (for example, `vracli log-bundle --help`) for information about the `vracli` command line utility.

For related information about using VMware Aria Operations for Logs, see [How do I configure log forwarding to VMware Aria Operations for Logs in VMware Aria Automation](#).

Log bundle commands

You can create a log bundle to contain all the logs that are generated by the services that you run. A log bundle contains all your service logs. You can use a log bundle for troubleshooting.

In a clustered environment (high availability mode), run the `vracli log-bundle` command on only one node. Logs are pulled from all nodes in the environment. However, in the event of a networking or other cluster issue, logs are pulled from as many nodes as can be reached. For example, if one node is disconnected in a cluster of three nodes, logs are only

collected from the two healthy nodes. Output from the `vracli log-bundle` command contains information about any issues found and their workaround steps.

- To create a log bundle, SSH to any node and run the following `vracli` command:
`vracli log-bundle`
- To change the timeout value for collecting logs from each node, run the following `vracli` command:
`vracli log-bundle --collector-timeout $CUSTOM_TIMEOUT_IN_SECONDS`

For example, if your environment contains large log files, slow networking, or high CPU usage, you can set the timeout to greater than the 1000 second default value.

- To determine the disk space being consumed by a specific service log such as `ebs` or `vro`, run the following `vracli` command and examine the command output:
`vracli disk-mgr`
- To configure other options, such as assembly timeout and buffer location, use the following `vracli help` command:
`vracli log-bundle --help`

Log bundle structure

The log bundle is a timestamped tar file. The name of the bundle matches the pattern `log-bundle-<date>T<time>.tar` file, for example `log-bundle-20200629T131312.tar`. Typically the log bundle contains logs from all nodes in the environment. In case of an error, it contains as many logs as possible. It minimally contains logs from the local node.

The log bundle consists of the following content:

- Environment file

The environment file contains the output of various Kubernetes maintenance commands. It supplies information about current resource usage per nodes and per pods. It also contains cluster information and description of all available Kubernetes entities.

- Host logs and configuration

The configuration of each host (for example, its `/etc` directory) and the host-specific logs (for example, `journald`) are collected in one directory for each cluster node or host. The directory name matches the host name of the node. The internal contents of the directory match the file system of the host. The number of directories matches the number of cluster nodes.

- Services logs

Logs for Kubernetes services are located in the following folder structure:

- `<hostname>/services-logs/<namespace>/<app-name>/file-logs/<container-name>.log`
- `<hostname>/services-logs/<namespace>/<app-name>/console-logs/<container-name>.log`

An example file name is `my-host-01/services-logs/prelude/vco-app/file-logs/vco-server-app.log`.

- `hostname` is the host name of the node on which the application container is or was running. Typically, there is one instance for each node for each service. For example, 3 nodes = 3 instances.
- `namespace` is the Kubernetes namespace in which the application is deployed. For user-facing services, this value is `prelude`.
- `app-name` is the name of the Kubernetes application that produced the logs (for example, `provisioning-service-app`).
- `container-name` is the name of the container that produced the logs. Some apps consist of multiple containers. For example, the `vco-app` container includes the `vco-server-app` and `vco-controlcenter-app` containers.

- (Legacy) Pod logs

While you can continue to generate pod logs in the bundle by using the `vracli log-bundle --include-legacy-pod-logs` command, doing so is not advised as all log information already resides in each services' logs. Including pod logs can unnecessarily increase the time and space required to generate the log bundle.

Reducing the size of the log bundle

To generate a smaller log bundle, use either of the following `vracli log-bundle` commands:

- `vracli log-bundle --since-days n`

Use this command to collect only the log files that were generated over the past number of days. Otherwise, logs are retained and collected for the past 2 days. For example:

```
vracli log-bundle --since-days 1
```

- `vracli log-bundle --services service_A,service_B,service_C`

Use this command to collect only the logs for the named provided services. For example:

```
vracli log-bundle --services ebs-app,vco-app
```

- `vracli log-bundle --skip-heap-dumps`

Use this command to exclude all heap dumps from the generated log bundle.

Displaying logs

You can output the logs of a service pod or app by using the `vracli logs <pod_name>` command.

The following command options are available:

- `--service`

Displays a merged log for all nodes of the app instead of a single pod

Example: `vracli logs --service abx-service-app`

- `--tail n`

Displays the last *n* lines of the log. The default *n* value is 10.

Example: `vracli logs --tail 20 abx-service-app-8598fcd4b4-tjwhk`

- `--file`

Displays only the specified file. If a file name is not provided, all files are shown.

Example: `vracli logs --file abx-service-app.log abx-service-app-8598fcd4b4-tjwhk`

Understanding log rotation

Regarding log rotation, recognize the following service log considerations:

- All services produce logs. Service logs are stored in a dedicated `/var/log/services-logs` disk.
- All logs are rotated regularly. Rotation occurs either hourly or when a certain size limit is reached.
- All old log rotations are eventually compressed.
- There is no per-service quota for log rotations.
- The system retains as many logs as possible. Automation regularly checks the used disk space for logs. When the space becomes 70% full, older logs are purged until the disk space for logs reaches 60% full.
- You can resize your logs disk if you need more space. See [Increase appliance disk space](#).

To check the logs disk space, run the following `vracli` commands. The free space of `/dev/sdc(/var/log)` should be near 30% or more for each node.

```
# vracli cluster exec -- bash -c 'current_node; vracli disk-mgr; exit 0'
sc1-10-182-1-103.eng.vmware.com
/dev/sda4(/):
    Total size: 47.80GiB
    Free: 34.46GiB (72.1%)
```

```
Available(for non-superusers): 32.00GiB(66.9%)
SCSI ID: (0:0)

/dev/sdb(/data):
Total size: 140.68GiB
Free: 116.68GiB(82.9%)
Available(for non-superusers): 109.47GiB(77.8%)
SCSI ID: (0:1)

/dev/sdc(/var/log):
Total size: 21.48GiB
Free: 20.76GiB(96.6%)
Available(for non-superusers): 19.64GiB(91.4%)
SCSI ID: (0:2)

/dev/sdd(/home):
Total size: 29.36GiB
Free: 29.01GiB(98.8%)
Available(for non-superusers): 27.49GiB(93.7%)
SCSI ID: (0:3)
```

How do I configure log forwarding to VMware Aria Operations for Logs in VMware Aria Automation

How do I configure log forwarding to VMware Aria Operations for Logs

To take advantage of more robust log analysis and report generation, you can forward logs from VMware Aria Automation to VMware Aria Operations for Logs.

VMware Aria Automation contains a [fluentd-based](#) logging agent. The agent collects and stores logs so that they can be included in a log bundle and examined later. The agent can forward a copy of the logs to a VMware Aria Operations for Logs server by using the VMware Aria Operations for Logs REST API. The API allows other programs to communicate with VMware Aria Operations for Logs.

For more information about VMware Aria Operations for Logs, including documentation for the REST API, see [VMware Aria Operations for Logs](#) documentation.

To forward all VMware Aria Automation logs to VMware Aria Operations for Logs, use `vracli` configuration commands.

You can examine each log line in VMware Aria Operations for Logs. Each log line contains a host name and an environment tag. In a high availability (HA) environment, logs contain tags with different host names depending on the node from which they originated. The environment tag is configurable by using the `--environment ENV` option as described in the *Configure or update integration of VMware Aria Operations for Logs* section. In a high availability (HA) environment, the environment tag has the same value for all log lines.

To display information about how to use the `vracli` command line utility, use the `--help` argument in the `vracli` command line. For example, `vracli vrli --help`. For a user-friendly response, begin the command with `vracli -j vrli`.

NOTE

You can only configure a single remote logging integration. VMware Aria Operations for Logs has priority when a VMware Aria Operations for Logs server and a `syslog` server are available.

Check existing configuration of VMware Aria Operations for Logs

Command

```
vracli vrli
```

Arguments

There are no command line arguments.

Output

The current configuration for VMware Aria Operations for Logs integration is output in JSON format.

Exit codes

The following exit codes are possible:

- 0 - Integration with VMware Aria Operations for Logs is configured.
- 1 - An exception error occurred. Examine the error message for details.
- 61 - Integration with VMware Aria Operations for Logs is not configured. Examine the error message for details.

Example - check integration configuration

```
$ vracli vrli
```

No vRLI integration configured

```
$ vracli vrli
```

```
{
```

```
  "agentId": "0",
  "environment": "prod",
  "host": "my-vrli.local",
  "port": 9543,
  "scheme": "https",
  "sslVerify": false
```

```
}
```

Configure or update integration of VMware Aria Operations for Logs

Command

```
vracli vrli set [options] FQDN_OR_URL
```

NOTE

After you run the command, it can take up to 2 minutes for the logging agent to apply your specified configuration.

Arguments

- **FQDN_OR_URL**

Specifies the FQDN or URL address of the VMware Aria Operations for Logs server to use for posting logs. Port 9543 and https are used by default. If any of these settings must be changed, you can use a URL instead.

```
vracli vrli set <options> https://FQDN:9543
```

NOTE

You can set a different host scheme (the default is HTTPS) and port (default for https is 9543, default for http is 9000) to use for sending the logs, as shown in the following samples:

```
vracli vrli set https://HOSTNAME:9543
```

```
vracli vrli set --insecure HOSTNAME
```

```
vracli vrli set http://HOSTNAME:9000
```

Ports 9543 for https and 9000 for http are used by the VMware Aria Operations for Logs ingestion REST API as described in the [Administering VMware Aria Operations for Logs topic Ports and External Interfaces in VMware Aria Operations for Logs documentation](#).

• Options

- **--agent-id SOME_ID**

Sets the id of the logging agent for this appliance. The default is 0. Used to identify the agent when posting logs to VMware Aria Operations for Logs by using the VMware Aria Operations for Logs REST API.

- **--environment ENV**

Sets an identifier for the current environment. It will be available in VMware Aria Operations for Logs logs as a tag for each log entry. The default is `prod`.

- **--ca-file /path/to/server-ca.crt**

Specifies a file that contains the certificate of the certificate authority (CA) that was used to sign the certificate of the VMware Aria Operations for Logs server. This forces the logging agent to trust the specified CA and enable it to verify the certificate of the VMware Aria Operations for Logs server if it was signed by an untrusted authority. The file may contain a whole certificate chain to verify the certificate. In the case of a self-signed certificate, pass the certificate itself.

- **--ca-cert CA_CERT**

Definition is identical to that of `--ca-file` as above, but instead passes the certificate (chain) inline as string.

- **--insecure**

Deactivates SSL verification of the server certificate. This forces the logging agent to accept any SSL certificate when posting logs.

• Advanced options

- **--request-max-size BYTES**

Multiple log events are ingested with a single API call. This argument controls the maximum payload size, in bytes, for each request. Valid values are between 4000 and 4000000. The default value is 256000. For related information for allowed values, see VMware Aria Operations for Logs events ingestion in the VMware Aria Operations for Logs REST API documentation. Setting this value too low can cause logging events that are larger than the allowed size to be dropped.

- **--request-timeout SECONDS**

A call to the API can hang for a number of reasons including problems with the remote, networking issues, and so on. This parameter controls the number of seconds wait for each operation to complete, such as opening a connection, writing data, or awaiting a response, before the call is recognized as failed. The value cannot be less than 1 second. The default is 30.

- **--request-immediate-retries RETRIES**

Logs are buffered in aggregated chunks before they are sent to VMware Aria Operations for Logs (see `--buffer-flush-thread-count` below). If an API request fails, the log is retried immediately. The default number of immediate retries is 3. If none of the retries is successful, then the whole log chunk is rolled back and is retried again later.

– `--request-http-compress`

To lower network traffic volumes, you can apply gzip compression to requests that are sent to the VMware Aria Operations for Logs server. If this parameter is not specified, no compression is used.

– `--buffer-flush-thread-count THREADS`

For better performance and to limit networking traffic, logs are buffered locally in chunks before they are flushed and sent to the log server. Each chunk contains logs from a single service. Depending on your environment, chunks can grow large and time-consuming to flush. This argument controls the number of chunks that can be flushed simultaneously. The default is 2.

NOTE

When configuring integration over https, if the VMware Aria Operations for Logs server is configured to use an untrusted certificate such as a self-signed certificate or a certificate that was signed by an untrusted authority, you must use one of the `--ca-file`, `--ca-cert` or `--insecure` options or the logging agent fails to validate the server identity and does not send logs. When using `--ca-file` or `--ca-cert`, the VMware Aria

Operations for Logs server certificate must be valid for the server's host name. In all cases, verify the integration by allowing a few minutes for processing and then checking that VMware Aria Operations for Logs received the logs.

Output

No output is expected.

Exit codes

The following exit codes are possible:

- 0 - The configuration was updated.
- 1 - An exception occurred as part of the execution. Examine the error message for details.

Examples – Configure or update integration configuration

The following example statements are shown in separate command lines, however the arguments can be combined in a single command line. For example, you can include multiple arguments when using `vracli vqli set {somehost}` or `vracli vqli set --ca-file path/to/server-ca.crt` to modify the default agent ID or environment values. For related information, see the online command help at `vracli vqli --help`.

```
$ vracli vqli set my-vqli.local
$ vracli vqli set 10.20.30.40
$ vracli vqli set --ca-file /etc/ssl/certs/ca.crt 10.20.30.40
$ vracli vqli set --ca-cert "$(cat /etc/ssl/certs/ca.crt)" 10.20.30.40
$ vracli vqli set --insecure http://my-vqli.local:8080
$ vracli vqli set --agent-id my-vqli-agent my-vqli.local
$ vracli vqli set --request-http-compress
$ vracli vqli set --environment staging my-vqli.local
$ vracli vqli set --environment staging --request-max-size 10000 --request-timeout 120 --request-immediate-retries 5 --buffer-flush-thread-count 4 my-vqli.local
```

Clear integration of VMware Aria Operations for Logs

Command

```
vracli vqli unset
```

NOTE

After you run the command, it can take up to 2 minutes for the logging agent to apply your specified configuration.

Arguments

There are no command line arguments.

Output

Confirmation is output in plain text format.

Exit codes

The following exit codes are available:

- 0 - The configuration was cleared or no configuration existed.
- 1 - An exception occurred as part of the execution. Examine the error message for details.

Examples - Clear integration

```
$ vracli vqli unset
```

Clearing vRLI integration configuration

```
$ vracli vqli unset
```

No vRLI integration configured

How do I create or update a syslog integration in VMware Aria Automation

How do I create or update a syslog integration

You can configure VMware Aria Automation to send your logging information to remote syslog servers.

Configure a remote syslog server.

The **vracli remote-syslog set** command is used to create a syslog integration or overwrite existing integrations. VMware Aria Automation remote syslog integration supports the following connection types:

- Over UDP.
- Over TCP without TLS.

NOTE

To create a syslog integration without using TLS, add the **--disable-ssl** flag to the **vracli remote-syslog set** command.

- Over TCP with TLS.

NOTE

You can only configure a single remote logging integration. VMware Aria Operations for Logs is prioritized in the event that both a VMware Aria Operations for Logs server and a syslog server are available.

For information on configuring logging integration with VMware Aria Operations for Logs, see [How do I configure log forwarding to VMware Aria Operations for Logs in VMware Aria Automation](#).

1. Log in to the VMware Aria Automation appliance command line as **root**.
2. To create an integration to a syslog server, run the **vracli remote-syslog set** command.

```
vracli remote-syslog set -id name_of_integration protocol_type://
syslog_URL_or_FQDN:syslog_port
```

NOTE

If you do not enter a port in the `vracli remote-syslog set` command, the port value defaults to 514.

NOTE

You can add a certificate to the syslog configuration. To add a certificate file, use the `--ca-file` flag. To add a certificate as plaintext, use `--ca-cert` flag.

- To overwrite an existing syslog integration, run the `vracli remote-syslog set` and set the `-id` flag value to the name of the integration you want to overwrite.

NOTE

By default, the VMware Aria Automation appliance requests that you confirm that you want to overwrite the syslog integration. To skip the confirmation request, add the `-f` or `--force` flag to the `vracli remote-syslog set` command.

To review the current syslog integrations in the appliance, run the `vracli remote-syslog` command.

How do I delete a syslog integration for logging in VMware Aria Automation

How do I delete a syslog integration for logging

You can delete syslog integrations from your VMware Aria Automation appliance by running the `vracli remote-syslog unset` command.

Create one or more syslog integrations in the VMware Aria Automation appliance. See [How do I create or update a syslog integration in VMware Aria Automation](#).

- Log in to the VMware Aria Automation appliance command line as `root`.
- Delete syslog integrations from the VMware Aria Automation appliance using either of the following methods:
 - To delete a specific syslog integration, run the `vracli remote-syslog unset -id Integration_name` command.
 - To delete all syslog integrations on the VMware Aria Automation appliance, run the `vracli remote-syslog unset` command without the `-id` flag.

NOTE

By default, the VMware Aria Automation appliance requests that you confirm that you want to delete all syslog integrations. To skip the confirmation request, add the `-f` or `--force` flag to the `vracli remote-syslog unset` command.

How do I work with VMware Aria Automation content packs

Content packs are hosted in Log Insight and contain dashboards, extracted fields, saved queries, and alerts that are related to a specific product or set of logs. You can install community supported content packs from the VMware Sample Exchange and other content packs from the Content Pack Marketplace.

VMware Aria Operations for Logs delivers automated log management through aggregation, analytics and search, enabling operational intelligence and enterprise-wide visibility in dynamic hybrid cloud environments. Content packs are plug-ins to VMware Aria Operations for Logs that provide pre-defined knowledge about specific types of events such as log messages.

To download a content pack, from VMware Aria Operations for Logs navigate to **Content Packs > Marketplace**. You can also import content packs by clicking **+ Import Content Pack**.

VMware Aria Automation Content Pack

The VMware Aria Automation content pack provides a consolidated summary of log events across all VMware Aria Automation environment components. It includes several dashboards that provide a general overview, insight on errors and operations, and overall health of your VMware Aria Automation instance. These dashboards are listed on the **Dashboard** tab along with all other VMware Aria Operations for Logs dashboards. Once loaded, it can take up to 30 seconds for the dashboards to populate with metrics.

The VMware Aria Automation content pack includes these dashboards:

- General - Overview: Captures an overview of high level metrics for VMware Aria Automation.
- General - Problems:
- Service - Provision: Captures issues related to the provisioning service.
- Service - Catalog: Captures issues related to the catalog service.
- Service - EBS: Captures issues related to the event broker service.
- Service - Templates: Captures errors and metrics related to Automation Assembler cloud templates, custom resources, and resource actions.
- Service - Approval: Captures errors and metrics related to approvals.
- Infra - Health: Captures when pods are restarted over time. This dashboard is essential to detect outages due to resource limits.
- Infra - Active Ping: Captures the health check URL over time.

Some dashboards contain widgets that provide more focused analytics. To view the type of analysis that is performed in each widget, click the information  icon.

As a VMware Aria Automation administrator, you can follow this general content pack workflow to identify errors and troubleshoot.

Participating in the Customer Experience Improvement Program for VMware Aria Automation

Participating in the Customer Experience Improvement Program

This product participates in VMware's Customer Experience Improvement Program (CEIP). The CEIP provides VMware with information that allows VMware to improve its products and services, to fix problems, and to advise you on how best to deploy and use our products.

Details regarding the data collected through CEIP, and the purposes for which it is used by VMware, are described on the [Customer Experience Improvement Program](#) page.

How do I join or leave the Customer Experience Improvement Programs for VMware Aria Automation

How do I join or leave the customer experience improvement programs (CEIP and Pendo CEIP)

VMware Aria Automation participates in VMware's original Customer Experience Improvement Program (CEIP) and also the Pendo Customer Experience Program (Pendo CEIP) for supported services.

You can separately join or leave the VMware original Customer Experience Improvement Program (CEIP) and the Pendo Customer Experience Program (Pendo CEIP). Each program collects somewhat different types of customer interaction data, as described below.

- Original CEIP

The original CEIP provides VMware with information that helps VMware designers and engineers improve products and services and fix problems. It collects usage and data that helps gauge system stability and consumption levels of different features. This information also helps determine what should be build next based on which use-cases and features are being used.

You can join this CEIP when you install VMware Aria Automation with Workspace ONE Access. After installation, VMware Aria Automation administrators and enabled users can also join or leave the program by using `vracli ceip` command line options.

- **Pendo CEIP**

Pendo is an integrated third-party tool that collects user activities and provides analytics to VMware Aria Automation product development. The Pendo CEIP collects workflow data based on your interaction with the user interface. This information helps VMware designers and engineers develop data-driven improvements to the usability of products and services.

You can join or leave the Pendo CEIP by using `vracli ceip pendo` command line options. Enabled users can also join or leave the Pendo CEIP by using options in their VMware Aria Automation user interface.

Details regarding the data collected through the original VMware CEIP, and the purposes for which that data is used by VMware, are described at <http://www.vmware.com/trustvmware/ceip.html>. Details regarding the Pendo CEIP for supported services are described on the **Cookie Usage** page in VMware Aria Automation.

Join or leave the VMware CEIP by using VMware Aria Automation appliance command line options

You can join or leave the original **Customer Experience Improvement Program (CEIP)** by using the following procedures.

Join the program by using the following appliance command line sequence:

1. Log in to the VMware Aria Automation appliance command line as **root**.
2. Run the `vracli ceip on` command.
3. Review the **Customer Experience Improvement Program information** and run the `vracli ceip on --acknowledge-ceip` command.
4. Restart the VMware Aria Automation services by running the `/opt/scripts/deploy.sh` command.

Leave the program by using the following command line sequence:

1. Log in to the VMware Aria Automation appliance command line as **root**.
2. Run the `vracli ceip off` command.
3. Restart the VMware Aria Automation services by running the `/opt/scripts/deploy.sh` command.

Join or leave the Pendo CEIP by using VMware Aria Automation appliance command line options

You can join, leave, or verify the **Pendo Customer Experience Improvement Program (Pendo CEIP)** by using the following procedures.

Join the program by using the following command line sequence:

1. Log in to the VMware Aria Automation appliance command line as root.
2. Run the `vracli ceip pendo on` command.
3. Restart VMware Aria Automation services by running the `/opt/scripts/deploy.sh` command.

Leave the program by using the following command line sequence:

1. Log in to the VMware Aria Automation appliance command line as root.
2. Run the `vracli ceip pendo off` command.
3. Restart VMware Aria Automation services by running the `/opt/scripts/deploy.sh` command.

Verify the program status by using the following command line sequence:

1. Log in to the VMware Aria Automation appliance command line as root.
2. Run the `vracli ceip pendo status` command.

Join or leave the Pendo CEIP by using on-screen options in VMware Aria Automation

You can join or leave the program by using the following on-screen interaction sequence in VMware Aria Automation.

1. From the active VMware Aria Automation service, click the question mark toggle (?) in the upper-right area of the screen. Alternately and if visible, you can click **Cookie Usage** in the cookie banner. If you clicked the ? icon, click **Cookie Usage** in the lower right area of the subsequent **Help** page.
2. Review the **Cookie Usage** and **How to opt-out** content.

Cookie Usage

VMware and its service providers use cookies and other tracking technologies to provide you with a better user experience, improving the service and user experience. [How to opt-out](#)

Some of these cookies are essential for the provision of the functionality of the services, such as recognizing returning users and being used by tracking how you interact with the services and applications.

How to opt-out

Below are some of the third-party tools VMware utilizes that help us provide a better user experience. You can elect to opt-out of these third-party cookies (and others) by clicking the links below. You can also opt-out of other cookies used by VMware. Details are provided in VMware's [Privacy Notices](#). Each time you visit our website, we will ask you to review these details and choose which cookies to ensure they are not used in connection with your visit.

pendo

We use Pendo to provide a better user experience for you and collect data used to diagnose issues and improve user experience. Pendo collects data based on your interaction with our Service Offering(s). This data is used to understand the way you use our Service(s) in order to improve our products and services and design them better. If you would like to opt-out, please click the link below.

[OPT OUT](#)

3. Click **Opt-in** or **Opt-out**.

If you click **Opt-in**, the program sends your user interaction cookies to VMware. If you click **Opt-out**, the program does not send your user interaction cookies to VMware.

How do I configure the data collection time for the Customer Experience Improvement Program for VMware Aria Automation

How do I configure the data collection time for the program?

You can set the day and time when the Customer Experience Improvement Program (CEIP) sends data to VMware.

1. Log in to the VMware Aria Automation appliance command line as **root**.
2. Open the following file in a text editor.
`/etc/telemetry/telemetry-collector-vami.properties`
3. Edit the properties for day of week (dow) and hour of day (hod).

Property	Description
frequency.dow=<day-of-week>	Day when data collection occurs.
frequency.hod=<hour-of-day>	Local time of day when data collection occurs. Possible values are 0–23.

4. Save and close `telemetry-collector-vami.properties`.
5. Apply the settings by entering the following command.

```
vcac-config telemetry-config-update --update-info
```

Changes are applied to all nodes in your deployment.

Turning on the in-product feedback form in VMware Aria Automation

Turning on the in-product feedback form

You can enable your users to provide feedback to the VMware Aria Automation development team. Your feedback is important to our development process.

What is the feedback form

The feedback form is located in the support panel on a tab labeled **Feedback**. To open the form, click the **?** button and then click **Feedback** in the upper right corner of the page.

How do I make the feedback form available to my users

The feedback form requires that your VMware Aria Automation host has Internet access and that the following base URLs are included in your allowed list of Internet URLs.

- <https://lumos.vmware.com/>
- <https://feedback.esp.vmware.com/>

If the host does not have Internet access, the form is not available in the help pane.

Installing VMware Aria Automation with Easy Installer

The VMware Aria Suite Easy Installer for VMware Aria Automation and VMware Identity Manager helps you install VMware Aria Automation and Workspace ONE Access in less time than it would take to install individual products.

The procedures in this guide provide the step-by-step process for installing and deploying VMware Aria Automation, VMware Aria Suite Lifecycle, and Workspace ONE Access by using the VMware Aria Suite Easy Installer.

The screenshot shows the 'vRealize Easy Installer for vRA and vIDM' interface. On the left, a sidebar lists steps from 1 to 10: Introduction, End User License Agreement, Appliance Deployment Target, Select a Storage Location, Network Configuration, Password Configuration, Lifecycle Manager Configuration, Identity Manager Configuration, vRealize Automation Configuration, and Summary. The main panel displays the 'Introduction' step, which includes a brief description of the tool, three icons representing vRealize Automation, vRealize Suite Lifecycle Manager, and VMware Identity Manager, and a bulleted list of features for each product. At the bottom right are 'CANCEL' and 'NEXT' buttons.

10 Summary

Introduction

vRealize Easy Installer for vRA and vIDM is a single pane of glass which enables you to install vRealize Automation, vRealize Suite Lifecycle Manager and VMware Identity Manager.

vRealize Automation

vRealize Suite Lifecycle Manager

VMware Identity Manager

- **VMware vRealize® Automation™** provides a secure portal where authorized administrators, developers or business users can request new IT services and manage specific cloud and IT resources, while ensuring compliance with business policies. Requests for IT service, including infrastructure, applications, desktops, and many others, are processed through a common service catalog to provide a consistent user experience despite underlying heterogeneous infrastructure.
- **vRealize® Suite Lifecycle Manager™** automates install, configuration, upgrade, patch, configuration management, drift remediation and health from within a single pane of glass, thereby freeing IT Managers/Cloud admin resources to focus on business-critical initiatives, while improving time to value (TTV), reliability and consistency.
- **VMware Identity Manager™** enables quickly and easily provision apps, apply conditional access controls, and enable secure single sign-on (SSO) to SaaS, web, cloud and native mobile apps using a self-service catalog.

CANCEL **NEXT**

VMware Aria Automation

VMware Aria Automation is a modern infrastructure automation platform that enables private and multi-cloud environments on VMware Cloud infrastructure. It delivers self-service automation, DevOps for infrastructure, configuration management and network automation capabilities that help you increase business and IT agility, productivity, and efficiency. Integrate, streamline, and modernize traditional, cloud-native, and multi-cloud infrastructures with VMware Aria Automation and simplify IT while preparing for the future of your business.

VMware Aria Automation is installed, configured, managed, and upgraded only through VMware Aria Suite Lifecycle.

VMware Aria Suite Lifecycle

VMware Aria Suite Lifecycle delivers a comprehensive application lifecycle and content management solution for the Aria Suite, accelerating time to value, minimizing ongoing management, and improving end-user productivity.

The VMware Aria Suite Easy Installer also allows you to migrate VMware Aria Suite Lifecycle instances.

VMware Identity Manager

VMware Identity Manager (also known as Workspace One) integrates access control, application management and multi-platform endpoint management into a single platform and is available as a cloud service or on-premises deployment.

NOTE

You can skip the individual installations of Workspace ONE and VMware Aria Automation by selecting the Skip Installation button at the top of their Configuration tabs.

System Requirements

The following system resources are required to install VMware Aria Automation and VMware Identity Manager.

VMware Aria Suite Easy Installer supports

- VMware Aria Automation 8.0.0 and later.
- VMware Aria Suite Lifecycle 8.0.0 and later
- VMware Identity Manager 3.3.1 (for import only) and later.

NOTE

VMware Aria Automation 8 does not support nested virtual environments, such as ESX > ESX > Aria Automation.

Requirements	VMware Aria Suite Lifecycle	VMware Identity Manager	VMware Aria Automation	
			Medium Profile	Extra Large Profile
Total Disk Size	78 GB	100 GB	246 GB (Only for single node Installation)	246 GB (Only for single node Installation)
Virtual CPU	2	8	12	24
Memory/RAM Size	6 GB	16 GB	54 GB	96 GB
Maximum Network Latency			5 ms between each cluster node	5 ms between each cluster node
Maximum Storage Latency			20 ms for each disk IO operation from any VMware Aria Automation node	20 ms for each disk IO operation from any VMware Aria Automation node

NOTE

The system requirements for VMware Aria Automation are for single node environments. For 3 node HA VMware Aria Automation environments, multiply the requirement by 3.

Automation Orchestrator Considerations

Scaling the heap memory of the Automation Orchestrator Appliance is only applicable for standalone Automation Orchestrator instances and is not supported for embedded Automation Orchestrator instances in VMware Aria Automation.

NOTE

To modify the heap memory of an embedded Automation Orchestrator instance, you must increase the VMware Aria Automation profile size through the VMware Aria Suite Lifecycle.

Hardware Requirements

Specifications for Workspace ONE Access are based on the number of users in the directories. For more information, see [System and Network Configurations Requirements](#).

NOTE

To learn more about the hardware resizing of Workspace ONE Access through VMware Aria Suite Lifecycle, see [Resize hardware resources deployed for VMware Lifecycle Manager](#).

Load Balancer Requirements

The Load Balancing guide includes information on these configurations:

- NSX LB
- F5 LB
- Citrix NetScaler LB

For more information, see [VMware Aria Automation Load Balancing](#).

Network Requirements

VMware Aria Automation requires:

- Single, static IPv4 and Network Address
- Reachable DNS server set manually
- Valid, Fully qualified domain name, set manually that can be resolved both forward and in reverse through the DNS server

Ports and Protocols Requirements

VMware Aria Automation is accessed over port 443. The 443 port is secured with a self-signed certificate that is generated during the installation. When using an external load balancer, it must be set up to balance on port 443. The table provides an overview of the Ports and Port number used for VMware Aria Automation. For more information on Ports and Protocols for VMware Aria Automation where you can view port information of various VMware products in a single dashboard and also export an offline copy of the selected data, see [VMware Ports and Protocols](#).

Protocol	Port Number
TCP	80
TCP	443
TCP	2379
TCP	2380
TCP	6443
TCP	8008
TCP	10250
TCP	16000
TCP	20849
TCP	30333
TCP	30821
TCP	31090
UDP	500
UDP	4500
UDP	8285
ESP	

Table continued on next page

Continued from previous page

Protocol	Port Number
AH	

Table 102: Requirement for Ports for Product and Integration Communications

Product or Integration	TCP Port Number
VMware Aria Automation Appliance	5480, 443, 22
Identity Manager Appliances	8443, 443, 5432 9999, 9898, 9000, 9694 (Use these for a cluster)
vCenter Server Instances	443
ESXi Host Instances	443

For more information on ports, see [VMware Aria Suite Lifecycle Ports](#).

How to run the VMware Aria Suite Lifecycle Easy Installer for vRealize Automation and VMware Identity Manager (vIDM)

The VMware Aria Suite Lifecycle VMware Aria Suite Easy Installer for vRealize Automation and VMware Identity Manager (vIDM) is downloadable from the Broadcom Support Portal.

1. Log in to the [Broadcom Support Portal](#) and from the **My Dashboard** view, select **VMware Cloud Foundation**.
 - a) Go to **My Downloads** and select **VMware Aria Universal** > **VMware Aria Universal Enterprise**. Click **Subscription**.
 - b) From the list of primary downloads that appears, select the **View Group** link on the line for VMware Aria Suite Lifecycle.
 - c) From the list of primary downloads that appears, click the cloud icon to download the binary for VMware Aria Suite Easy Installer.
2. After you download the file, mount the `vra-lcm-installer.iso` file.
3. Browse to the folder `vrlcm-ui-installer` inside the CD-ROM.
4. The folder contains three subfolders for three operating systems. Based on your operating system, browse to the corresponding operating system folder inside the `vrlcm-ui-installer` folder.
5. Click the installer file in the folder.

Operating System	File Path
Windows	<code>lcm-installer\vrlcm-ui-installer\win32</code>
Linux	<ol style="list-style-type: none"> 1. Log in to Linux VM. 2. Run <code>apt-get install p7zip-full</code>. 3. Run <code>7z x vra-lcm-installer.iso</code>. 4. Run <code>chmod +x vrlcm-ui-installer/lin64/installer</code> 5. Run <code>chmod +x ./vrlcm/ovftool/lin64/ovftool*</code>

Table continued on next page

Continued from previous page

Operating System	File Path
	6. Run <code>apt install libnss3</code> (required only if the libnss3 component is not installed.) 7. Run <code>vrlcm-ui-installer/lin64/installer</code> .
Mac	<code>vrlcm-ui-installer/mac/Installer</code>

The VMware Aria Suite LifecycleVMware Aria Suite Easy Installer for vRealize Automation and VMware Identity Manager (vIDM) is specific to the operating system. Ensure that you are using the valid UI folder path to run the installer.

You can now install your applications using the VMware Aria Suite LifecycleVMware Aria Suite Easy Installer for vRealize Automation and VMware Identity Manager (vIDM).

If the VMware Aria Suite LifecycleVMware Aria Suite Easy Installer for vRealize Automation and VMware Identity Manager (vIDM) fails to launch, and you see this error message A problem occurred during installation. Check the installer logs and retry, it is because:

- A host rebooted during installation. Select the host to return to a healthy state.
- The datastore was 100% full during installation. Clear the datastore memory and retry launching the VMware Aria Suite Easy Installer.
- The VMware Aria Suite LifecycleVMware Aria Suite Easy Installer for vRealize Automation and VMware Identity Manager (vIDM) could not connect to the ESXI host. Add the target vCenter and all cluster associated ESXI servers DNS FQDN entries to the system host file: `C:\Windows\System32\drivers\etc\hosts`. For Linux and Mac, use `/etc/hosts`.

Installing VMware Aria Suite Lifecycle with Easy Installer for vRealize Automation and vIDM

You can install VMware Aria Suite Lifecycle using VMware Aria Suite Lifecycle Easy Installer for vRealize Automation and vIDM.

You must meet these prerequisites before you can install VMware Aria Suite Lifecycle:

- Ensure you have a vCenter set up and access to the credentials.
- Ensure you have the network configuration details for vRealize Automation
- Ensure you know the VMware Aria Suite Lifecycle VA deployment details

Watch the VMware Aria Suite Lifecycle[Installation with Easy Installer](#) video.

1. Click **Install** on the **Easy Installer** window.
2. Click **Next** after reading the introduction.
3. Accept the License Agreement and click **Next**. Read the **Customer Experience Improvement Program** and select the checkbox to join the program.
4. To specify vCenter details, enter these details on the Appliance Deployment Target tab.
 - a) Enter the **vCenter Server Hostname**.
 - b) Enter the **HTTPs Port** number.
 - c) Enter the **vCenter Server Username**, and **Password**.
5. Click **Next** and you are prompted with a certificate warning, click **Accept** to proceed.

6. You must specify a location to deploy virtual appliances.
 - a) Expand the vCenter tree.
 - b) Expand to any data center and map your deployment to a specific VM folder.
7. Specify a resource cluster on the **Select a Compute Resource** tab.
 - a) Expand the data center tree to an appropriate resource location and click **Next**.
8. On the **Select a Storage Location** tab, select a datastore to store your deployment and click **Next**.
9. On the **Network Configuration** and **Password Configuration** tabs, set up your **Network** and **Password configuration** by entering the required fields, and clicking **Next**.
 - a) For a VMware Aria Suite Lifecycle VM, enter the **NTP Server** for the appliance and click **Next**.

The network configurations provided for all products are a one time entry for your configuration settings. The password provided is also common for all products and you need not enter the password again while you are installing the products.

Password should have minimum one upper case, one lower case, one number and one special character. Special characters can be !@#\$%^&*().
10. Set up VMware Aria Suite Lifecycle configuration settings,
 - a) Enter a **Virtual Machine Name**, **IP Address**, and **Hostname**.
 - b) Provide configuration information. Enter the **Data Center Name**, **vCenter Name** and **Increase the Disk Space** fields.
 - c) Enable or disable the **FIPS Mode Compliance**, as required.
 - d) Click **Next**.

You can now start installing VMware Aria Suite Lifecycle.

How do I set up a VMware Aria Suite Lifecycle instance on VMware Cloud

Using the easy installer, you can set up an VMware Aria Suite Lifecycle instance on a VMware Cloud, such as AWS.

By default, VMware Cloud includes one vCenter with clusters and objects. You can use the easy installer to set up an VMware Aria Suite Lifecycle instance on your VMC. You can use VMware cloud to set up a software defined data center. By default, only the Compute-ResourcePool, and the Management VMs and Workloads folders are available. To deploy VMs, configure all deployments under the Workloads folder and on the WorkloadDatastore.

NOTE

The Easy Installer does not support migration for VMware Aria Suite Lifecycle to 8.2 on a VMC vCenter. You must install and configure a new VMware Aria Suite Lifecycle instance.

1. Navigate to the Appliance Deployment Target tab of the easy installer.
2. Enter the details of your VMC vCenter, using the cloud admin account as your username click **Next**.

NOTE

The required user role and privileges are highlighted on screen.

1 Introduction 2 End User License Agreement 3 Appliance Deployment Target 4 Select a Storage Location 5 Network Configuration 6 Password Configuration 7 Lifecycle Manager Configuration	<div style="border-bottom: 1px solid #ccc; margin-bottom: 10px;"> Appliance Deployment Target Specify the vCenter Server details <small>(Refer link to check required permission for vCenter user - vCenter Permission)</small> </div> <div style="display: flex; justify-content: space-between;"> <div style="width: 45%;"> vCenter Server Hostname <input type="text" value="vccenter.sddc-44-233-210-244.vmwarevmc.com"/> </div> <div style="width: 45%;"> HTTPS Port <input type="text" value="443"/> </div> </div> <div style="display: flex; justify-content: space-between;"> <div style="width: 45%;"> Username <input type="text" value="cloudadmin@vmc.local"/> </div> <div style="width: 45%;"> Password <input type="password" value="*****"/> </div> </div>
---	---

NOTE

By default, the VMC vCenter cloud admin account is the only user account with access the vCenter inventory.

3. On the Select a Location tab, select Workloads and click **Next**.
4. Select a cluster under Select a Compute Resource and click **Next**.
5. Select WorkloadDatastore as the storage location and click **Next**.
6. On the Network Configuration and Password Configuration tabs, set up your **Network** and **Password configuration** by entering the required fields, and clicking **Next**.
 - a) For a VMware Aria Suite Lifecycle VM, enter the **NTP Server** for the appliance and click **Next**.
The network configurations provided for all products are a one time entry for your configuration settings. The password provided is also common for all products and you need not enter the password again while you are installing the products.
Password should have minimum one upper case, one lower case, one number, and one special character. Special characters can be !@#\$%^&*(). Colon(:) is not supported in the password for VMware Aria Automation 8.0 and 8.0.1.
7. Set up VMware Aria Suite Lifecycle configuration settings,
 - a) Enter a **Virtual Machine Name, IP Address**, and **Hostname**.
 - b) Provide configuration information. Enter the **Data Center Name**, **vCenter Name** and **Increase the Disk Space** fields.
 - c) Enable or disable the **FIPS Mode Compliance**, as required.
 - d) Click **Next**.

A VMware Aria Suite Lifecycle instance is successfully configured on VMC. However, if configuration fails ensure these settings are correct and retry configuration:

- User role and permissions are not correct. Refer to [vCenter Permissions](#) for information on what roles and permissions are required.
- The selected resources are not correct. You can only select and use ComputeResourcePool, the Workload folder, and Workload Datastore in your configuration.

Install and configure VMware Identity Manager in VMware Aria Suite Lifecycle

Install and configure VMware Identity Manager

You can install a new instance of VMware Identity Manager (vIDM) or import an existing instance when you are configuring VMware Aria Suite LifecycleVMware Aria Suite Easy Installer for vRealize Automation and VMware Identity Manager (vIDM).

Verify that you have a static IP address before you begin your configuration.

The terms VMware Identity Manager and VMware Identity Manager (vIDM) are used interchangeably in VMware Aria Suite Lifecycle.

If you want to customize your VMware Identity Manager (vIDM) configuration, which can include deployment of VMware Identity Manager (vIDM) in a standard or a cluster mode, customized mode of network, storage, you can skip the installation of VMware Identity Manager (vIDM). If you have skipped, you are still prompted to configure the VMware Identity Manager (vIDM) on the VMware Aria Suite Lifecycle UI. With VMware Aria Suite LifecycleVMware Aria Suite Easy Installer for vRealize Automation and VMware Identity Manager (vIDM), you either import an existing VMware Identity Manager (vIDM) into VMware Aria Suite Lifecycle or a new instance of VMware Identity Manager (vIDM) can be deployed.

For more information on hardware re-sizing for VMware Identity Manager (vIDM), see [Resize hardware resources deployed for VMware Lifecycle Manager](#).

For information about product and version compatibility, see this [sample page](#) in the [VMware Interoperability Matrix](#).

1. To install a new instance, select the **Install new VMware Identity Manager (vIDM)** option.

2. Enter the required text boxes under **Virtual Machine Name, IP Address, Hostname, and Default Configuration Admin.**

NOTE

The VMware Aria Suite LifecycleVMware Aria Suite Easy Installer for vRealize Automation and VMware Identity Manager (vIDM) creates the default configuration admin user as a local user in VMware Identity Manager (vIDM) and the same user is used to integrate products with VMware Identity Manager (vIDM).

3. To import an existing instance, select **Import Existing vIDM**.

- Enter the **Hostname, Admin Password, System Admin Password, SSH User Password, Root Password, Default Configuration Admin, and Default Configuration Password**.
- Select the **Sync group members to the Directory** when user want to sync group member while adding a group for the global configuration of VMware Identity Manager (vIDM).

With VMware Aria Suite Easy Installer for vRealize Automation and VMware Identity Manager (vIDM)	VMware Identity Manager (vIDM) supported version
New installation of VMware Aria Suite Lifecycle	3.3.7
Import VMware Aria Suite Lifecycle	3.3.7
Deploy vRealize Automation	3.3.7

NOTE

VMware Identity Manager (vIDM) is supported for single or cluster instance with embedded Postgres database.

NOTE

VMware Identity Manager (vIDM) is not supported for the following scenarios:

- Single or cluster instance having external database (Postgres/MSSQL and so on).
- Single or cluster instance with additional connectors (Windows and external connectors) other than the embedded ones.
- VMware Identity Manager (vIDM) version 3.3.0 and earlier.

NOTE

If the older version of VMware Aria Suite Lifecycle does not have VMware Identity Manager (vIDM), it can either be installed or imported. VMware Identity Manager (vIDM) and extended day-2 functionalities are not supported from the VMware Aria Suite Lifecycle and extended day-2 functionalities are not supported from the VMware Aria Suite Lifecycle if the imported VMware Identity Manager (vIDM) not in supported form factor.

Upgrade support from an older VMware Identity Manager (vIDM) version (3.3.0 and earlier) to the latest is only available if it is a single instance or a node VMware Identity Manager (vIDM) with embedded postgres database. Otherwise, you can upgrade outside VMware Aria Suite Lifecycle. After upgrade, it can be reimplemented by starting an Inventory Sync in VMware Aria Suite Lifecycle.

4. Click **Next**.

If you cannot deploy VMware Aria Suite Lifecycle, VMware Identity Manager (vIDM), or vRealize Automation in VMware Cloud on AWSvCenter by using VMware Aria Suite LifecycleVMware Aria Suite Easy Installer for vRealize

Automation and VMware Identity Manager (vIDM), then use the vCenter that has an administrator privilege to deploy products.

Install and Configure VMware Aria Automation

The VMware Aria Suite Easy Installer provides you with an option to install VMware Aria Automation with minimum steps. Installation of VMware Aria Automation is an optional procedure and you can skip this step if you do not want to install a new instance of VMware Aria Automation.

- Verify that you have the static IP address of the VM, host name, and VM name. VMware Aria Automation requires Workspace ONE Access 3.3.6 for an import or a new installation. Manual installation of VMware Aria Automation through OVA is not supported.
- Verify that you have an external load balancer configured for cluster deployments.

To upgrade VMware Aria Automation using VMware Aria Suite Lifecycle, see [Upgrade Aria Automation 8.x using Aria Suite Lifecycle](#).

NOTE

VMware Aria Automation license downgrade is not supported.

The easy installer provides you with minimal or a clustered deployment options before you start your VMware Aria Automation configuration.

NOTE

Starting with 8.1, you have the option to skip the installation of Workspace ONE Access. If you have skipped, then you cannot configure VMware Aria Automation. To configure VMware Aria Automation, you can either go back and configure Workspace ONE Access or complete the installation and configure VMware Aria Automation in VMware Aria Suite Lifecycle UI.

VMware Aria Automation installation is optional and it can be deployed in a standard or a cluster mode. Standard supports a single node VMware Aria Automation and cluster mode supports three node VMware Aria Automation installation.

1. Enter the VMware Aria Automation**Environment Name**.
2. Under the VMware Aria Automation license, enter the **License Key**.

Enter a license key only if you are using a legacy license. If you are using a VCF Solution license, leave the text box empty. The VCF Solution license is automatically retrieved by the vCenter server connected to VMware Aria Automation.

If your license expires, you have a grace period before you lose access to VMware Aria Automation functionality. You can review your current license status by logging into the VMware Aria Automation appliance and running the `vracli license --detailed` command.

3. After configuring your Workspace ONE Access settings, you have the option to install VMware Aria Automation. For a standard deployment with a master node, enter the **Virtual Machine Name**, **IP Address**, and **FQDN Hostname** of VMware Aria Automation. Skip to step 6.
4. For a cluster deployment with three nodes, you are required to enter the **Load Balancer IP address** and **FQDN**.

NOTE

If the SSL is terminated at load-balancer, select the **SSL terminated at load-balancer** check box.

Deselect the check box, if the SSL pass-through is enabled in the load-balancer. If a wrong value is provided for the property, then VMware Aria Automation deployment fails.

5. For a cluster deployment, create a master node by using step 2 as a guideline.
6. For a cluster deployment, create secondary nodes, enter the required text boxes, and proceed.
7. (Optional) In the Advanced Configuration for VMware Aria Automation section, you can manually enter K8S Cluster and Service IP ranges by selecting Configure internal pods and service subnets (For example, 10.221.0.0/22 and

10.221.21.0/22). If left unselected, VMware Aria Automation uses the default values: 10.244.0.0/22 and 10.244.4.0/22.

8. Click **Next**.
9. Read the Summary page with the entered data and click **Submit**.

For example, the installation time depends on copying binaries from the source machine to VMware Aria Suite Lifecycle VA for Workspace ONE Access and Automation deployment, which varies based on the network speed.

After submitting your details, the installer takes about 30 minutes to install the VMware Aria Suite Lifecycle, copy binaries, and then start the installation process which depends on the network speed. After the VMware Aria Automation installation, you can also start configuring VMware Aria Operations for Logs. For more information, see [How do I configure log forwarding to Aria Operations for Logs](#).

Migrate VMware Aria Suite Lifecycle

Using the Easy Installer you can migrate your VMware Aria Suite Lifecycle.

Watch the VMware Aria Suite Lifecycle Migration with Easy Installer video:

Migration of Aria Suite Lifecycle with Easy Installer

1. Click **Install** on the **Easy Installer** window.
2. Click **Next** after reading the introduction.
3. Accept the License Agreement and click **Next**. Read the **Customer Experience Improvement Program** and select the check box to join the program.
4. To specify vCenter Server details, enter these details on the Appliance Deployment Target tab.
 - a) Enter the **vCenter Server Hostname**.
 - b) Enter the **HTTPs Port** number.
 - c) Enter the **vCenter Server Username**, and **Password**.
5. Click **Next** and you are prompted with a Certificate Warning, click **Accept** to proceed.
6. You must select a location to deploy virtual appliances.
 - a) Expand the vCenter Server tree.
 - b) Expand to any data center and map your deployment to a specific VM folder.
7. Specify a resource cluster on the Select a Compute Resource tab.
 - a) Expand the data center tree to an appropriate resource location and click **Next**.
8. On the Select a Storage Location tab, select a datastore to store your deployment, and click **Next**.
9. On the Network Configuration and Password Configuration tabs, set up your **Network** and **Password configuration** by entering the required fields, and clicking **Next**.
 - a) For a VMware Aria Suite Lifecycle VM, enter the **NTP Server** for the appliance and click **Next**.
10. Set up VMware Aria Suite Lifecycle configuration settings,
 - a) Enter a **Virtual Machine Name**, **IP Address**, and **Hostname**.
 - b) Provide configuration information. Enter the **Data Center Name**, **vCenter Name** and **Increase the Disk Space** fields.
 - c) Click **Next**.
11. One the Migration Details tab, provide your source environment details and click **Next**
12. Select either **Install New VMware Identity Manager** or **Import Existing VMware Identity Manager**.
 - a) If installing a new VMware Identity Manager, enter the VMware Identity Manager configuration and click **Next**.
 - b) If importing an existing VMware Identity Manager, review the notes about using an existing VMware Identity Manager and click **Next**.

NOTE

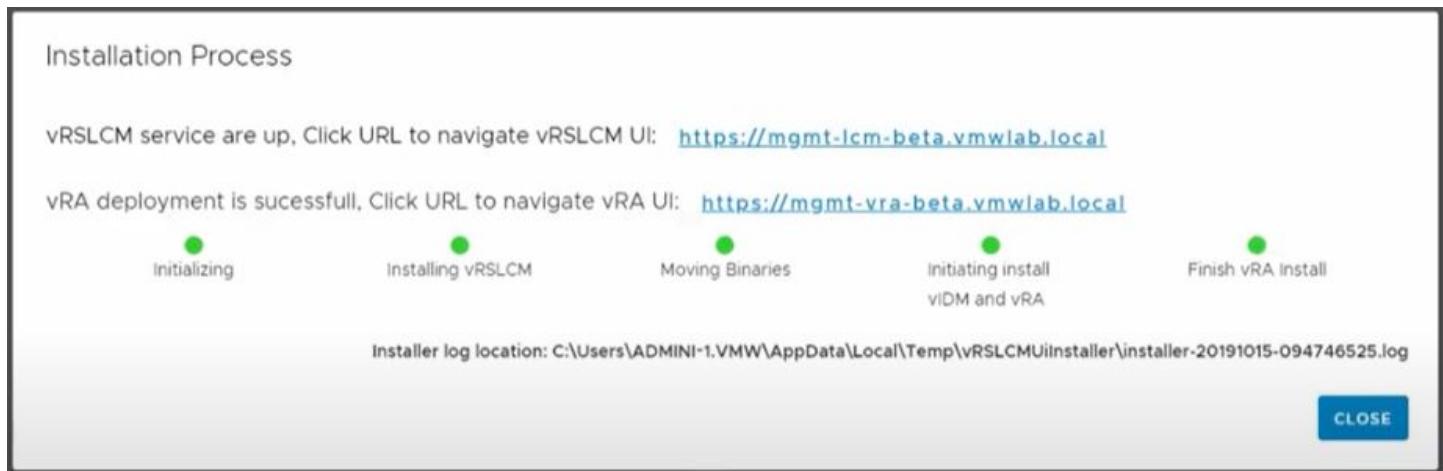

After importing your existing VMware Identity Manager, you must upgrade it to version 3.3.2 to make it compatible with VMware Aria Automation 8.2 components.

13. Review the Summary and click **Submit**.

Your VMware Aria Suite Lifecycle is migrated.

How do I launch my installed applications

After using the easy installer to install your applications, you can view the deployed applications and their dashboards.

You can open the VMware Aria Suite Lifecycle and VMware Aria Automation applications by clicking the IP addresses on the installation process window.

NOTE

If the Easy Installer was launched with a Linux OS, clicking the links in the Installation Process window might not open a browser. Manually copy and paste the url into a browser to access the desired application.

VMware Aria Suite Lifecycle

The screenshot shows the vRealize Suite Lifecycle Manager dashboard. At the top, there's a header with the title 'vRealize Suite Lifecycle Manager' and a user dropdown for 'admin@local'. Below the header is a 'Dashboard' section with a 'My Services' heading. Five service tiles are displayed: 'Lifecycle Operations' (cloud icon), 'Locker' (padlock icon), 'User Management' (people icon), 'Content Management' (triangle icon), and 'Marketplace' (shopping cart icon). Underneath these tiles is a 'Service Widgets' section with a message stating 'No widgets are available at the moment'.

After clicking the IP address from the installation process window, login using the same credentials that you entered in the VMware Aria Suite Easy Installer. To view requests, click **Lifecycle Operations** and click on the request to open its details. At the request level, you can view the different stages of the request along with the time each stage took.

To view information on your Workspace ONE Access and VMware Aria Automation applications, click **Environments** and select the appropriate application tile.

The screenshot shows the 'Environments' page within the vRealize Suite Lifecycle Manager. The top navigation bar includes the title 'vRealize Suite Lifecycle Manager' and the current section 'Lifecycle Operations'. Below the navigation is a breadcrumb trail 'Home > Environments' and a main heading 'Environments'. A filter bar at the top right shows 'COMPLETED (2)', 'IN PROGRESS (0)', and 'FAILED (0)'. Two environment cards are listed: 'globalenvironment' (Default_datacenter) and 'vRealize Automation' (Default_datacenter). Each card has a 'Products' section with a circular icon and a 'VIEW DETAILS' button. The 'globalenvironment' card also has a '...' button next to its name.

You can also monitor request statuses from VMware Aria Suite Lifecycle by clicking **Request** from the left pane. If an application request fails, click the failed status to view more details. After identifying and correcting reasons for failure, click **Retry** to retry request or **Redeploy** to redeploy the environment.

Post-Installation Tasks

After installing your applications using the VMware Aria Suite Easy Installer, you can perform these post-installation tasks in VMware Aria Suite Lifecycle.

Depending on the needs and configuration of your system, you might have to perform these post-installation tasks:

- Configure VMware Aria Automation license.
- Generate a certificate for products deployed in VMware Aria Suite Lifecycle.
- Configure Active Directory Groups in VMware Aria Suite Lifecycle.
- Configure VMware Aria Suite Lifecycle appliance root password outside VMware Aria Suite Easy Installer.
- Configure and replace license for VMware Aria Automation.
- Perform an Inventory Sync after installing VMware Aria Automation to identify the current state of VMware Aria Automation deployment.

Installing and Configuring Automation Orchestrator

Installing and configuring VMware Aria Automation Orchestrator provides information and instructions about installing and configuring VMware Aria Automation Orchestrator.

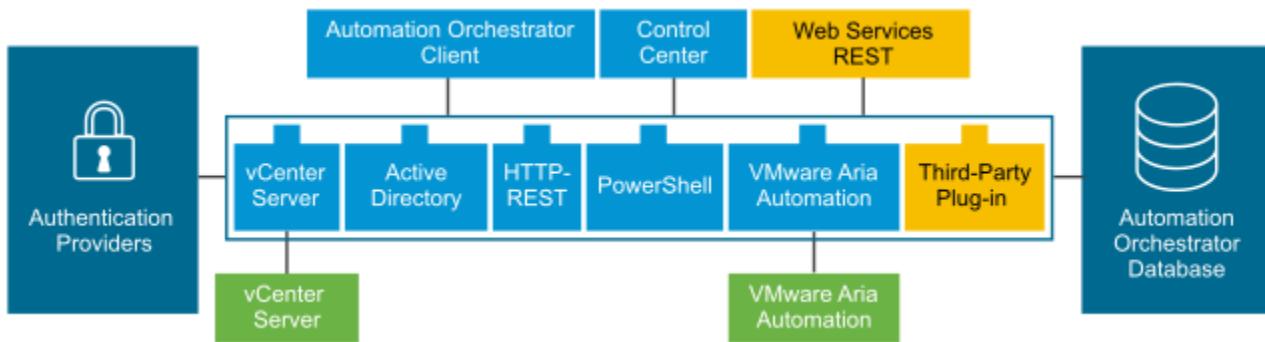

What is VMware Aria Automation Orchestrator

VMware Aria Automation Orchestrator is a development- and process-automation platform that provides a library of extensible workflows to allow you to create and run automated, configurable processes to manage VMware products as well as other third-party technologies.

VMware Aria Automation Orchestrator automates management and operational tasks of both VMware and third-party applications such as service desks, change management systems, and IT asset management systems.

VMware Aria Automation Orchestrator architecture

VMware Aria Automation Orchestrator contains a workflow library and a workflow engine to allow you to create and run workflows that automate orchestration processes. You run workflows on the objects of different technologies that VMware Aria Automation Orchestrator accesses through a series of plug-ins.

VMware Aria Automation Orchestrator provides a standard set of plug-ins, including plug-ins for vCenter and VMware Aria Automation, to allow you to orchestrate tasks in the different environments that the plug-ins expose. VMware Aria Automation Orchestrator also presents an open architecture for plugging in external third-party applications to the orchestration platform. You can run workflows on the objects of the plugged-in technologies that you define yourself.

VMware Aria Automation Orchestrator connects to an authentication provider to manage user accounts and to a preconfigured PostgreSQL database to store information from the workflows that it runs.

You can access VMware Aria Automation Orchestrator, the objects it exposes, and the VMware Aria Automation Orchestrator workflows through the Automation Orchestrator Client, or through Web services. Monitoring and configuration of VMware Aria Automation Orchestrator workflows and services is done through the Automation Orchestrator Client and Control Center.

VMware Aria Automation Orchestrator plug-ins

Plug-ins allow you to use VMware Aria Automation Orchestrator to access and control external technologies and applications. By exposing an external technology in an VMware Aria Automation Orchestrator plug-in, you can incorporate objects and functions in workflows that access the objects and functions of that external technology.

The external technologies that you can access by using plug-ins include virtualization management tools, email systems, databases, directory services, and remote-control interfaces.

For more information about the VMware Aria Automation Orchestrator plug-ins, see [Using the Automation Orchestrator Plug-Ins](#).

For more information about third-party VMware Aria Automation Orchestrator plug-ins, see [VMware Marketplace](#).

Intended Audience

This information is intended for advanced vSphere administrators and experienced system administrators who are familiar with virtual machine technology and data center operations.

Key features of the VMware Aria Automation Orchestrator platform

VMware Aria Automation Orchestrator is composed of three distinct layers: an orchestration platform that provides the common features required for an orchestration tool, a plug-in architecture to integrate control of subsystems, and a library of workflows. VMware Aria Automation Orchestrator is an open platform that can be extended with new plug-ins and content, and can be integrated into larger architectures through a REST API.

VMware Aria Automation Orchestrator includes several key features that help with running and managing workflows.

Persistence

A production-grade PostgreSQL database is used to store relevant information, such as processes, workflow states, and the VMware Aria Automation Orchestrator configuration.

Central management

VMware Aria Automation Orchestrator provides a central tool to manage your processes. The application server-based platform, with full version history, can store scripts and process-related primitives in the same storage location. This way, you can avoid scripts without versioning and proper change control on your servers.

Check-pointing

Every step of a workflow is saved in the database, which prevents data-loss if you must restart the server. This feature is especially useful for long-running processes.

Control Center

Control Center is a web-based portal that increases the administrative efficiency of VMware Aria Automation Orchestrator instances by providing a centralized administrative interface for runtime operations, workflow monitoring, and correlation between the workflow runs and system resources.

NOTE

Starting with Automation Orchestrator 8.18, the Control Center service is deprecated and is removed in Automation Orchestrator 8.18.1 and later.

Versioning

All VMware Aria Automation Orchestrator platform objects have an associated version history. Version history is useful for basic change management when distributing processes to project stages or locations.

Git integration

With the Automation Orchestrator Client, you can integrate a Git repository to further improve version and source control of your VMware Aria Automation Orchestrator content. With Git, you can manage workflow development across multiple VMware Aria Automation Orchestrator instances. See *Using Git with the Automation Orchestrator Client* in the *Using Automation Orchestrator* guide.

Scripting engine

The Mozilla Rhino JavaScript engine provides a way to create building blocks for the Automation Orchestrator Client platform. The scripting engine is enhanced with basic version control, variable type checking, name space management, and exception handling. The engine can be used in the following building blocks:

- Actions
- Workflows
- Policies

In addition to JavaScript, you can also use Python, Node.js, and PowerShell/PowerCLI runtimes as a way of creating workflows and actions. For more information, go to [Core Concepts for Python, Node.js, and PowerShell Scripts](#).

Workflow engine

The workflow engine is used by VMware Aria Automation Orchestrator for core processes such as:

- Processing the workflow schema
- Performs the workflow and action runs
- Manages user interactions
- Creates checkpoints for VMware Aria Automation Orchestrator objects

The capabilities to manage VMware Aria Automation Orchestrator content are provided by the Orchestrator platform and Automation Orchestrator Client.

Users, other workflows, schedules, or policies can start workflows.

Policy engine

You can use the policy engine to monitor and generate events to react to changing conditions in the Automation Orchestrator Client server or a plugged-in technology. Policies can aggregate events from the platform or the plug-ins, which helps you to handle changing conditions on any of the integrated technologies.

Automation Orchestrator Client

Create, run, edit, and monitor workflows with the Automation Orchestrator Client. You can also use the Automation Orchestrator Client to manage action, configuration, policy, and resource elements. See [Using Automation Orchestrator](#).

Development and resources

The VMware Aria Automation Orchestrator landing page provides quick access to resources to help you develop your own plug-ins, for use in VMware Aria Automation Orchestrator. You will also find information about using the VMware Aria Automation Orchestrator REST API to send requests to the VMware Aria Automation Orchestrator server.

Security

VMware Aria Automation Orchestrator provides the following advanced security functions:

- Public Key Infrastructure (PKI) to sign and encrypt content imported and exported between servers.
- Digital Rights Management (DRM) to control how exported content can be viewed, edited, and redistributed.
- Transport Layer Security (TLS) to provide encrypted communications between the Automation Orchestrator Client, VMware Aria Automation Orchestrator server, and HTTPS access to the Web front end.
- Advanced access rights management to provide control over access to processes and the objects manipulated by these processes.

Encryption

VMware Aria Automation Orchestrator uses a FIPS-compliant Advanced Encryption Standard (AES) with a 256-bit cipher key for encryption of strings. The cipher key is randomly generated and is unique across appliances that are not part of a cluster. All nodes in a cluster share a cipher key.

VMware Aria Automation Orchestrator user roles

User roles

VMware Aria Automation Orchestrator provides different capabilities based on the specific responsibilities of the users. In VMware Aria Automation Orchestrator, you can have users with full rights (**administrators**), users who create and develop new content (**workflow designers**), and troubleshooting users (**viewers**).

VMware Aria Automation Orchestrator user roles are managed in the **Roles Management** menu of the Automation Orchestrator Client. For more information on configuring user roles in the Automation Orchestrator Client, go to [Assign Roles in the Automation Orchestrator Client](#).

NOTE

For VMware Aria Automation Orchestrator deployments authenticated with VMware Aria Automation, or using a VMware Cloud Foundation license, user roles are assigned with the Identity and Access Management service of the VMware Aria Automation platform. Go to [Configure Automation Orchestrator Client Roles in VMware Aria Automation](#).

User Role	Description
Administrator	<p>This user has full access to all VMware Aria Automation Orchestrator platform capabilities and content, including content created by specific groups. Primary administrator user responsibilities include:</p> <ul style="list-style-type: none"> • Installing and configuring VMware Aria Automation Orchestrator. • Adding users to the Automation Orchestrator Client, assigning roles, and creating and deleting groups. Go to Create Groups in the Automation Orchestrator Client. • Creating an integration with a Git repository for the developers in their VMware Aria Automation Orchestrator environment. Go to Configure a Connection to a Git Repository. • Troubleshooting their VMware Aria Automation Orchestrator environment through features like workflow validation and debugging workflow scripts.
Workflow Designer	<p>This user can extend the VMware Aria Automation Orchestrator platform functionality by creating and editing objects. Workflow designers do not have access to the administrative and troubleshooting features of the Automation Orchestrator Client. Primary workflow designer responsibilities include:</p> <ul style="list-style-type: none"> • Creating, editing, running, and deleting VMware Aria Automation Orchestrator objects like workflows, actions, policies, and configuration elements. • Scheduling workflow runs. Go to Schedule Workflows in the Automation Orchestrator Client.

Table continued on next page

Continued from previous page

User Role	Description
	<ul style="list-style-type: none"> Adding content created by the workflow developer to groups they are assigned to. Pushing local changes to the remote Git repository in the active branch defined by an administrator. Go to Push Changes to a Git Repository.
Viewer	<p>This user has read-only access to all Automation Orchestrator Client, including all groups and group content. This user can view but cannot create, edit, or run content, or export workflow runs, workflow run logs, or packages. Viewers are not limited by group permissions.</p> <p>NOTE The viewer role is supported only for VMware Aria Automation Orchestrator instances authenticated with VMware Aria Automation. This role is not mapped to a VMware Aria Automation role by default so it must be explicitly assigned to users.</p>
Users with limited rights	<p>Users with no assigned role can still log in to the Automation Orchestrator Client by directly entering the URL, but have limited access to client features and content. If they are assigned to a group, this user can view and run content included in that group. Users who are not assigned to a group can only view their own workflow runs through the available integrations to VMware Aria Automation.</p>

Installing VMware Aria Automation Orchestrator

VMware Aria Automation Orchestrator consists of a virtual appliance that can be either standalone or an internal appliance as a part of VMware Aria Automation.

To use VMware Aria Automation Orchestrator, you must deploy the Automation Orchestrator Appliance and configure the VMware Aria Automation Orchestrator server.

You can change the default VMware Aria Automation Orchestrator configuration settings by using the VMware Aria Automation Orchestrator Control Center.

NOTE

Starting with Automation Orchestrator 8.18, the Control Center service is deprecated and is removed in Automation Orchestrator 8.18.1 and later.

Download and Deploy the Automation Orchestrator Appliance

Before you can access the VMware Aria Automation Orchestrator content and services, you must download and deploy the Automation Orchestrator Appliance.

- Verify that you have a running vCenter instance. The vCenter version must be 6.0 or later.

- Verify that the host on which you are deploying the Automation Orchestrator Appliance meets the minimum hardware requirements. See [Hardware requirements](#).
- If your system is isolated and without Internet access, you must download the .ova file for the appliance from the VMware website.

- Log in to the vSphere Web Client as an **administrator**.
- Select an inventory object that is a valid parent object of a virtual machine, such as a data center, folder, cluster, resource pool, or host.
- Select **Actions > Deploy OVF Template**.
- Enter the file path or the URL to the .ova file and click **Next**.
- Enter a name and location for the Automation Orchestrator Appliance, and click **Next**.
- Select a host, cluster, resource pool, or vApp as a destination on which you want the appliance to run, and click **Next**.
- Review the deployment details, and click **Next**.
- Accept the terms in the license agreement and click **Next**.
- Select the storage format you want to use for the Automation Orchestrator Appliance.

Format	Description
Thick Provisioned Lazy Zeroed	Creates a virtual disk in a default thick format. The space required for the virtual disk is allocated when the virtual disk is created. If any data remains on the physical device, it is not erased during creation, but is zeroed out on demand later on first write from the virtual machine.
Thick Provisioned Eager Zeroed	Supports clustering features such as Fault Tolerance. The space required for the virtual disk is allocated when the virtual disk is created. If any data remains on the physical device, it is zeroed out when the virtual disk is created. It might take much longer to create disks in this format than to create disks in other formats.
Thin Provisioned Format	Saves hard disk space. For the thin disk, you provision as much datastore space as the disk requires based on the value that you select for the disk size. The thin disk starts small and, at first, uses only as much datastore space as the disk needs for its initial operations.

- Click **Next**.
 - Configure the network settings and enter the **root** password.
- When configuring the network settings of the Automation Orchestrator Appliance, you must use the IPv4 protocol. For both DHCP and Static network configurations, you must add a fully qualified domain name (FQDN) for your Automation Orchestrator Appliance. If the host name displayed in the shell of the deployed Automation Orchestrator Appliance is *photon-machine*, the preceding network configuration requirements are not met.
- Configure additional network settings for the Automation Orchestrator Appliance, such as enabling SSH access.

NOTE

When configuring a Kubernetes network, the values of the internal cluster CIDR and internal service CIDR must allow for at least 1024 hosts. Because of this requirement, the network mask value must be 22 or less. Network mask values higher than 22 are invalid. The Kubernetes network properties have the following default values:

Kubernetes network property	Default value	Property description
Kubernetes internal cluster CIDR	10.244.0.0/22	The CIDR used for pods running inside the Kubernetes cluster.
Kubernetes internal service CIDR	10.244.4.0/22	The CIDR used for Kubernetes services inside the Kubernetes cluster.

NOTE

You can also change the Kubernetes CIDR network properties after deployment. See [Configure Kubernetes CIDR](#).

- To enable FIPS mode for the Automation Orchestrator Appliance, set **FIPS Mode** to strict.

NOTE

FIPS 140-2 enablement is supported only for new VMware Aria Automation Orchestrator environments. If you want to enable FIPS mode on your environment, you must do so during installation.

- Click **Next**.

- Review the **Ready to complete** page and click **Finish**.

The Automation Orchestrator Appliance is successfully deployed.

Log in to the Automation Orchestrator Appliance command line as **root** and confirm that you can perform a forward or reverse DNS lookup.

- To perform a forward DNS lookup, run the `nslookup your_orchestrator_FQDN` command. The command must return the Automation Orchestrator Appliance IP address.
- To perform a reverse DNS lookup, run the `nslookup your_orchestrator_IP` command. The command must return the Automation Orchestrator Appliance FQDN.

NOTE

If you have not enabled SSH during deployment, you can also perform DNS lookups from the virtual machine console in the vSphere Web Client.

If you encounter problems with your Automation Orchestrator Appliance, go to [KB 93142](#).

Power on the Automation Orchestrator Appliance and Open the Home Page

To use the standalone Automation Orchestrator Appliance, you must first power it on.

- Log in to the vSphere Web Client as an **administrator**.
- Right-click the Automation Orchestrator Appliance and select **Power > Power On**.
- In a Web browser, navigate to the host address of your Automation Orchestrator Appliance virtual machine that you configured during the OVA deployment.
`https://your_orchestrator_FQDN/vco`.

Activate or Deactivate SSH Access to the Automation Orchestrator Appliance

You can activate or deactivate SSH access to the Automation Orchestrator Appliance.

- Download and deploy the Automation Orchestrator Appliance.
- Verify that the Automation Orchestrator Appliance is up and running.

1. Log in to the Automation Orchestrator Appliance command line as **root**.
2. To activate SSH access, run the `/usr/bin/toggle-ssh enable` command.
3. To deactivate SSH access, run the `/usr/bin/toggle-ssh disable` command.

You can configure the SSH settings of the Automation Orchestrator Appliance by editing the `/etc/ssh/sshd_config` file. By editing this file, you can remove any ciphers or MACs that you do not consider safe.

Initial Configuration

Before you begin automating tasks and managing systems and applications with VMware Aria Automation Orchestrator, you must use the VMware Aria Automation Orchestrator Control Center to configure an external authentication provider. You can also use the VMware Aria Automation Orchestrator Control Center for additional configuration tasks such as managing license and certificate information, installing plug-ins, and monitoring the state of your VMware Aria Automation Orchestrator cluster. You can also configure your VMware Aria Automation Orchestrator deployment through the command line interface.

Configuring Automation Orchestrator with the command line interface

Starting with VMware Aria Automation Orchestrator 8.18.1, the Control Center is removed and you must use command line interface to perform most configurations.

Configuring the Automation Orchestrator Appliance authentication provider with the command line interface

You can now configure your VMware Aria Automation Orchestrator options such as the authentication provider with the Automation Orchestrator Appliance command line interface (CLI). This does not replace the existing configuration options in the Control Center. To use these commands, you must log in to the Automation Orchestrator Appliance as a **root** user. After making any authentication changes, you must run the `/opt/scripts/deploy.sh` script so the change to the Automation Orchestrator Appliance is applied.

Retrieving the current authentication provider

You can retrieve the current authentication provider by running the following command:

```
vracli vro authentication
```

Configure the authentication provider by using a guided wizard

To configure the authentication provider by using a guided configuration wizard, run the following command:

```
vracli vro authentication wizard
```

After running the authentication wizard command, you are prompted to provide the necessary authentication provider information such as the type of authentication provider, hostname, and password.

Configure the authentication provider by using predefined parameters

To configure the authentication provider by using predefined configuration parameters, run the `vracli vro authentication set` command. The command can have the following parameters:

Parameter	Importance	Description
<code>-p</code> or <code>--provider</code>	Required	This parameter defines the authentication provider type. The parameter value can be either <code>vsphere</code> or <code>vra</code> depending on the authentication provider you want to configure: vSphere or VMware Aria Automation.
<code>-hn</code> or <code>--hostname</code>	Required	The hostname or URL of the authentication provider you want to configure. Both options are applicable.
<code>-u</code> or <code>--username</code>	Required	The username of the administrator associated with the authentication provider.
<code>--password-file</code>	Optional	<p>The path to a file containing the password of the administrator account for the authentication provider. If left empty, you receive a prompt for adding the password data. The password file must be stored inside the <code>/data/vco/usr/lib/vco</code> directory of the Automation Orchestrator</p> <p>Appliance. When adding the parameter in the command, exclude the <code>/data/vco</code> part of the filepath.</p>
<code>--admin-group</code>	Required for vSphere authentication providers. Ignored for VMware Aria Automation authentication providers.	Parameter for adding the VMware Aria Automation Orchestrator administrators group of the specified vSphere deployment.
<code>--admin-group-domain</code>	Required for vSphere authentication providers. Ignored for VMware Aria Automation authentication providers.	This parameter defines the administrator group domain.
<code>-k</code> or <code>--ignore-certificate</code>	Optional	Using this parameter, the authentication process is configured to automatically trust the certificate of the authentication provider.
<code>-f</code> or <code>--force</code>	Optional	Using this parameter, you are not prompted for confirmation if the specified authentication provider is already configured.
<code>--fqdn</code>	Optional	This parameter defines the external address of the VMware Aria Automation Orchestrator server.

Table continued on next page

Continued from previous page

Parameter	Importance	Description
		<p>NOTE You can retrieve the FQDN address for your environment by running the <code>nslookup <your_orchestrator_IP></code> command.</p>

Example authentication configurations

```
echo "my-pass" > /data/vco/usr/lib/vco/password_file

vracli vro authentication set -p vra -hn https://my-aria-automation.local -u
administrator@domain.local --password-file /usr/lib/vco/password_file

vracli vro authentication set -p vsphere -hn https://my-vsphere.local -u
administrator@vsphere.local --tenant vsphere.local --admin-group Administrators --admin-
group-domain vsphere.local
```

Unregister an authentication provider

You can unregister the current authentication provider by running the `vracli vro authentication unregister` command. This command can have the following parameters:

Parameter	Importance	Description
<code>-u</code> or <code>--username</code>	Required	The username of the administrator associated with the authentication provider.
<code>--password-file</code>	Optional	The path to a file containing the password of the administrator account for the authentication provider. If left empty, you receive a prompt for adding the password data. The password file must be stored inside the <code>/data/vco/usr/lib/vco</code> directory of the appliance. When including the parameter in the command, exclude the <code>/data/vco</code> part of the filepath.

CLI command logs

VMware Aria Automation Orchestrator CLI commands print their logs in the `/services-logs/prelude/vco-app/file-logs/vco-server-app_cfg-cli.log` file. When a command returns a result different than zero and the standard output does not show a specific error, the exception is visible in this file.

Additional configuration options

Aside from configuring the authentication provider of your VMware Aria Automation Orchestrator deployment, you can use CLI commands for:

- License configuration

- System properties configuration
- Extension configuration
- Troubleshooting
- Retrieving system information
- Logging configuration

For more information on these additional configuration options, go to [Additional command line interface configuration options](#).

Additional command line interface configuration options

Aside from configuring your authentication provider, you can also use command line interface commands to configure other VMware Aria Automation Orchestrator options. To use these commands, you must log in to the Automation Orchestrator Appliance as a **root** user.

Aside from configuring the authentication provider of your VMware Aria Automation Orchestrator deployment, you can use command line interface (CLI) commands for:

- License configuration
- System properties configuration
- Extension configuration
- Troubleshooting
- Retrieving system information
- Logging configuration

For information on configuring the authentication provider with CLI commands, go to [Configuring the Automation Orchestrator Appliance authentication provider with the command line interface](#)

License configuration

You can retrieve the current VMware Aria Automation Orchestrator license configuration by running the following command:

```
vracli vro license
```

You can set a new license key by running the following command:

```
vracli vro license set <license_key>
```

You can reset the current license to the default license of the authentication provider by running the following command:

```
vracli vro license default
```

System property configuration

You can retrieve a list of all configured VMware Aria Automation Orchestrator system properties, as a JSON file, by running the following command:

```
vracli vro properties
```

You can set a system property by running the following command:

```
vracli vro properties set
```

This system property command has the following properties:

Property	Importance	Description
<code>-k</code> or <code>--key</code>	Required	This property defines the name of the system property you want to set.
<code>-v</code> or <code>--value</code>	Required	This property defines the value of the system property.
<code>-n</code> or <code>--noRestart</code>	Optional	This property defines if the set system property requires a restart of the VMware Aria Automation Orchestrator service. By default, setting any new system property performs a restart of the service.

The following is an example of this system property command:

```
vracli vro properties set -k com.vmware.o1ln.property -v true
```

You can remove existing system properties by running the following command:

```
vracli vro properties remove -k <key_value>
```

NOTE

The `-k` or `--key` property must include the name of the system property you want to remove.

You can retrieve the name, value, and description of the most commonly used system properties by running the following command:

```
vracli vro properties advanced
```

Extension configuration

You can retrieve a list of all configured VMware Aria Automation Orchestrator extensions by running the following command:

```
vracli vro extensions
```

You can activate an extension by running the following command:

```
vracli vro extensions <extension_name> activate
```

You can deactivate an extension by running the following command:

```
vracli vro extensions <extension_name> deactivate
```

You can list all the configuration properties of a specific extension by running the following command:

```
vracli vro extensions <extension_name> list
```

You can set a extension property by running the following command:

```
vracli vro extensions <extension> set
```

This extension property command can have the following properties:

Property	Importance	Description
-k or --key	Required	This property defines the ID of the extension property.
-v or --value	Required	This property defines the value of the extension property.

For example, the workflow of activating an extension, listing all its properties, and setting a system property could look similar to this:

```
vracli vro extensions tokenreplay activate
vracli vro extensions tokenreplay list
vracli vro extensions tokenreplay set -k recordScripting -v true
```

Troubleshooting

You can cancel all active workflow runs by running the following command:

```
vracli vro cancel executions
```

You can cancel a specific workflow run by adding its ID to the following command:

```
vracli vro cancel workflow <workflow_id>
```

You can suspend all active scheduled tasks by running the following command:

```
vracli vro cancel tasks
```

You can retrieve a list of all trusted certificates by running the following command:

```
vracli vro keystore list
```

System information

You can retrieve the current system information of your VMware Aria Automation Orchestrator deployment by running the following command:

```
vracli vro info
```

NOTE

You can add the optional property of -d or --details to the system information command to all check the health status API of the VMware Aria Automation Orchestrator server.

Logging configuration

You can retrieve the current VMware Aria Automation Orchestrator logging configuration by running the following command:

```
vracli vro logs
```

You can configure the VMware Aria Automation Orchestrator logging server by running the following command:

```
vracli vro logs configure
```

The logging server command can have the following parameters

Parameter	Importance	Description
<code>-l</code> or <code>--level</code>	Optional	This parameter defines the server logging level.
<code>-sc</code> or <code>--scripting-count</code>	Optional	This parameter defines the number of saved scripting log rotations.
<code>-sl</code> or <code>--scripting-level</code>	Optional	This parameter defines the scripting log level.
<code>-ss</code> or <code>--scripting-size</code>	Optional	This parameter defines the scripting log size in megabytes (MB).

NOTE

The valid level values are ALL, TRACE, DEBUG, INFO, WARN, ERROR, FATAL and OFF.

CLI command logs

VMware Aria Automation Orchestrator CLI commands print their logs in the `/services-logs/prelude/vco-app/file-logs/vco-server-app_cfg-cli.log` file. When a command returns a result different than zero and the standard output does not show a specific error, the exception is visible in this file.

Configuring a Standalone VMware Aria Automation Orchestrator Server

Although the Automation Orchestrator Appliance is a preconfigured Photon-based virtual machine, you must configure an authentication provider before you access the full functionality of the VMware Aria Automation Orchestrator Control Center and Automation Orchestrator Client.

Configure a standalone VMware Aria Automation Orchestrator server with VMware Aria Automation authentication**Authenticating with VMware Aria Automation**

To prepare the Automation Orchestrator Appliance for use, you must configure the host settings and the authentication provider. You can configure VMware Aria Automation Orchestrator to authenticate with VMware Aria Automation.

- Download and deploy the latest version of the Automation Orchestrator Appliance. Go to [Download and Deploy the](#).
- Install and configure VMware Aria Automation and verify that your VMware Aria Automation server is running. See the VMware Aria Automation documentation.

IMPORTANT

The product version of the VMware Aria Automation authentication provider must match the product version your VMware Aria Automation Orchestrator deployment.

- If you plan to create a cluster, set up a load balancer to distribute traffic among multiple instances of Automation Orchestrator. Go to [Load Balancing Guide](#).
- Starting with VMware Aria Automation Orchestrator 8.18, the Control Center service is deprecated and is removed in VMware Aria Automation Orchestrator 8.18.1 and later. For VMware Aria Automation Orchestrator 8.18.1 and later, use the command line interface to configure your authentication provider. For more information, go to [Configuring the authentication provider with the command line interface](#).

- Access the Control Center to start the configuration wizard.
 - Navigate to `https://your_Automation-Orchestrator_FQDN/vco-controlcenter`.
 - Log in as **root** with the password you entered during OVA deployment.
- Configure the authentication provider.
 - On the **Configure Authentication Provider** page, select **VMware Aria Automation** from the **Authentication mode** drop-down menu.

- b) In the **Host address** text box, enter your VMware Aria Automation host address and click **Connect**.

The format of the VMware Aria Automation host address must be `https://your_Vmware-Aria-Automation_hostname`.

- c) Click **Accept Certificate**.
 d) Enter the credentials of the VMware Aria Automation organization owner under which VMware Aria Automation Orchestrator will be configured. Click **Register**.
 e) Click **Save Changes**.
 A message indicates that your configuration is saved successfully.

You have successfully finished the VMware Aria Automation Orchestrator server configuration.

Verify that the node is configured properly at the **Validate Configuration** page.

NOTE

Following the configuration of the authentication provider, the VMware Aria Automation Orchestrator server restarts automatically after 2 minutes. Verifying the configuration immediately after authentication can return an invalid configuration status.

Configure a standalone Automation Orchestrator server with vSphere authentication

Authenticating with vSphere

You register the Automation Orchestrator server with a vCenter Single Sign-On server by using the vSphere authentication mode. Use vCenter Single Sign-On authentication with vCenter 7.0 and later.

- Download and deploy the latest version of the Automation Orchestrator Appliance. See [Download and Deploy the](#).
- Install and configure a vCenter with vCenter Single Sign-On running. See the [vSphere documentation](#).
- If you plan to create a cluster, set up a load balancer to distribute traffic among multiple instances of Automation Orchestrator. Go to [Load Balancing Guide](#).
- Starting with VMware Aria Automation Orchestrator 8.18, the Control Center service is deprecated and is removed in VMware Aria Automation Orchestrator 8.18.1 and later. For VMware Aria Automation Orchestrator 8.18.1 and later, use the command line interface to configure your authentication provider. For more information, go to [Configuring the authentication provider with the command line interface](#).

Depending on the configuration of the vCenter server being used to authenticate Automation Orchestrator, your authentication uses either the built-in identity provider or VMware Single Sign-On (VMware SSO). VMware SSO allows you to use an external identity provider to sign in to your vCenter server hosts.

NOTE

You can configure VMware SSO in vSphere 8.0 Update 3 or later. For more information on configuring VMware SSO, go to [Configure VMware Single Sign-On](#).

If both the built-in and external identity providers are available in the vCenter server used for authentication, the external identity provider is the preferred method.

1. Access the Control Center to start the configuration wizard.

NOTE

You can also configure the authentication provider from the command line interface. For more information, go to [Configuring the Automation Orchestrator Appliance authentication provider with the command line interface](#).

- a) Navigate to `https://your_orchestrator_FQDN/vco-controlcenter`.
- b) Log in as **root** with the password you entered during OVA deployment.

2. Configure the authentication provider.

- a) On the **Configure Authentication Provider** page, select **vSphere** from the **Authentication mode** drop-down menu.
- b) In the **Host address** text box, enter the fully qualified domain name or IP address of the vCenter Server instance that contains the vCenter Single Sign-On and click **Connect**.

NOTE

If you use an external vCenter Server or multiple vCenter Server instances behind a load balancer, you must manually import the certificates of all vCenter Server that share a vCenter Single Sign-On domain.

NOTE

To integrate a different vSphere Client with your configured Automation Orchestrator environment, you must configure vSphere to use the same vCenter Server registered to VMware Aria Automation Orchestrator. For High Availability VMware Aria Automation Orchestrator environments, you must replicate the vCenter Server instances behind the VMware Aria Automation Orchestrator load balancer server.

- c) Review the certificate information of the authentication provider and click **Accept Certificate**.
- d) Enter the credentials of the local administrator account for the vCenter Single Sign-On domain. Click **REGISTER**.

For the built-in identity provider, the default account is `administrator@vsphere.local` and the name of the default tenant is `vsphere.local`. The credentials for external identity provider depend on the specific provider which your vSphere environment is using.

- e) In the **Admin group** text box, enter the name of an administrators group and click **Search**.
For example, `vsphere.local\vcoadmins`

NOTE

When using a external identity provider, local groups such as `vsphere.local` are not supported. You can only select groups coming from the external identity provider.

- f) Select the administration group you want to use. The administration group you select receives administrator privileges in Automation Orchestrator.
- g) Click **Save changes**.
A message indicates that your configuration is saved successfully.

You have successfully finished the VMware Aria Automation Orchestrator server configuration.

Verify that the node is configured properly at the **Validate Configuration** page.

NOTE

Following the configuration of the authentication provider, the VMware Aria Automation Orchestrator server restarts automatically after 2 minutes. Verifying the configuration immediately after authentication can return an invalid configuration status.

VMware Aria Automation Orchestrator feature enablement with licenses

Feature enablement with licenses

Access to certain VMware Aria Automation Orchestrator features is based on the license applied to your VMware Aria Automation Orchestrator deployment.

After authentication, your VMware Aria Automation Orchestrator instance is assigned a license based on the license edition of the authentication provider. Licenses control access to the following VMware Aria Automation Orchestrator features:

- Git integration
- Role management
- Multi-language support (Python, Node.js, and PowerShell)

You can view the details of your currently applied license, such as the license expiry date, by logging in to the Automation Orchestrator Client, navigating to **Administration > Licensing** and selecting the **Overview** tab. To manually change the license of the VMware Aria Automation Orchestrator deployment, select the **Manual License** tab.

Core VMware Aria Automation Orchestrator operations such as running workflows, actions, scheduling tasks, and running policies are restricted and cannot be started if your VMware Aria Automation Orchestrator deployment does not have a valid license entitlement. In such a scenario, operations started by users will fail.

NOTE

There is no limit to the number of VMware Aria Automation Orchestrator deployments to which you can apply the same license, regardless of the license type. For VMware Aria Automation licenses, having a deployed and configured VMware Aria Automation environment is not required.

Authentication	Current licensing	Legacy licensing	Git Integration	Role management	Multi-language support
vSphere	VMware vSphere Standard VMware vSphere Foundation	vSphere vCloud Suite Standard	No	No	No
vSphere	Manually added VMware Cloud Foundation license	VMware Aria Automation VMware Aria Suite Advanced or Enterprise vCloud Suite Advanced or Enterprise	Yes	Yes	Yes
VMware Aria Automation	VMware Cloud Foundation	VMware Aria Automation VMware Aria Suite Advanced or Enterprise vCloud Suite Advanced or Enterprise	Yes	Roles are managed from the VMware Aria Automation instance used to authenticate VMware Aria Automation Orchestrator.	Yes

NOTE

Legacy licenses such as vSphere and VMware Aria Automation continue to be valid. However, if your deployment is uses a VMware Cloud Foundation or VMware vSphere Foundation license, the older license becomes irrelevant.

You will receive a notification message in your Automation Orchestrator Client when there is an upcoming change to your licenses, such as a license expiry. In case your license expires, you will have a set grace period of 60 days during which you must renew your license or risk losing access to VMware Aria Automation Orchestrator functionality.

VMware Aria Automation Orchestrator Database Connection

The VMware Aria Automation Orchestrator server requires a database for storing data.

The deployed Automation Orchestrator Appliance includes a preconfigured PostgreSQL database used by the VMware Aria Automation Orchestrator server to store data.

The PostgreSQL database is not accessible for users.

Manage VMware Aria Automation Orchestrator certificates

Issued for a particular server and containing information about the server public key, the certificate allows you to sign all elements created in VMware Aria Automation Orchestrator and guarantee authenticity. When the client receives an element from your server, typically a package, the client verifies your identity and decides whether to trust your signature.

You can manage the VMware Aria Automation Orchestrator certificates from the **Certificates** page in the VMware Aria Automation Orchestrator Control Center or with the Automation Orchestrator Client, by using the *ssl_trust_manager* tagged workflows .

NOTE

Starting with VMware Aria Automation Orchestrator 8.18, the Control Center service is deprecated and is removed in VMware Aria Automation Orchestrator 8.18.1 and later.

Import a certificate to the VMware Aria Automation Orchestrator trust store

VMware Aria Automation Orchestrator Control Center uses a secure connection to communicate with vCenter, relational database management system (RDBMS), LDAP, Single Sign-On, and other servers. You can import the required TLS certificate from a URL or a PEM-encoded file. Each time you want to use a TLS connection to a server instance, you must import the corresponding certificate from the **Trusted Certificates** tab on the **Certificates** page and import the corresponding TLS certificate.

You can load the TLS certificate in VMware Aria Automation Orchestrator from a URL address or a PEM-encoded file.

Option	Description
Import from URL or proxy URL	The URL of the remote server: <code>https://your_server_IP_address or your_server_IP_address:port</code>
Import from file	Path to the PEM-encoded certificate file. NOTE You can also import a trusted certificate by running the Import a trusted certificate from a file workflow in the Automation Orchestrator Client. The file imported through this workflow must be DER-encoded.

For more information on importing a certificate, see [Import a Trusted Certificate with the Control Center](#).

Package signing certificate

Packages exported from an VMware Aria Automation Orchestrator server are digitally signed. Import, export, or generate a new certificate to be used for signing packages. Package signing certificates are a form of digital identification that is used to guarantee encrypted communication and a signature for your VMware Aria Automation Orchestrator packages.

The Automation Orchestrator Appliance includes a package signing certificate that is generated automatically, based on the network settings of the appliance. If the network settings of the appliance change, you must generate a new package signing certificate manually. After generating a new package signing certificate, all future exported packages are signed with the new certificate.

Generate a custom TLS certificate for VMware Aria Automation Orchestrator

Generate a custom TLS certificate

You can use the Automation Orchestrator Appliance to generate a new TLS certificate for your environment or set an existing custom certificate.

Verify that SSH access for the Automation Orchestrator Appliance is enabled. See [Activate or Deactivate SSH Access to the](#).

The Automation Orchestrator Appliance includes a Trusted Layer Security (TLS) certificate that is generated automatically, based on the network settings of the appliance. If the network settings of the appliance change, you must generate a new certificate manually. You can create a certificate chain to guarantee encrypted communication and provide a signature for your packages. However, the recipient cannot be sure that the self-signed package is in fact a package issued by your server and not a third party claiming to be you. To prove the identity of your server, use a certificate signed by a Certificate Authority (CA).

VMware Aria Automation Orchestrator generates a server certificate that is unique to your environment. The private key is stored in the `vmo_keystore` table of the VMware Aria Automation Orchestrator database.

NOTE

To configure your Automation Orchestrator Appliance to use an existing custom TLS certificate, see [Set a custom TLS certificate for](#).

1. Log in to the Automation Orchestrator Appliance command line over SSH as **root**.
2. Run the `vracli certificate ingress --generate auto --set stdin` command.
3. To apply the custom certificate to your Automation Orchestrator Appliance, run the deployment script.

a) Navigate to the `/opt/scripts/` directory.

```
cd /opt/scripts/
```

b) Run the `./deploy.sh` script.

IMPORTANT

Do not interrupt the deployment script. You receive the following message when the script finishes running:

Prelude has been deployed successfully.

To access, go to `your_orchestrator_address`

To confirm that the new certificate chain is applied, run the `vracli certificate ingress --list` command.

Set a custom TLS certificate for VMware Aria Automation Orchestrator

Set a custom TLS certificate

Set a custom TLS Certificate for your Automation Orchestrator Appliance.

- Verify that SSH access for the Automation Orchestrator Appliance is enabled. See [Activate or Deactivate SSH Access to the](#).
- Verify that the PEM file containing the TLS certificate contains the following components in the set order:
 - The private key for the certificate.
 - The primary certificate.
 - If applicable, the Certificate Authority (CA) intermediate certificate or certificates.
 - The root CA certificate.

For example, the TLS certificate can have the following structure:

```
-----BEGIN RSA PRIVATE KEY-----
<Private Key>
-----END RSA PRIVATE KEY-----
-----BEGIN CERTIFICATE-----
<Primary TLS certificate>
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
<Intermediate certificate>
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
<Root CA certificate>
-----END CERTIFICATE-----
```

The Automation Orchestrator Appliance includes a Trusted Layer Security (TLS) certificate that is generated automatically, based on the network settings of the appliance.

You can configure your Automation Orchestrator Appliance to use an existing custom TLS certificate. You can set the certificate by importing the relevant PEM file from your local machine into the Automation Orchestrator Appliance. You can also set your custom TLS certificate by copying the certificate chain directly into the Automation Orchestrator Appliance. Both procedures require you to run the `./deploy.sh` script before the new TLS certificate can be used in your VMware Aria Automation Orchestrator deployment.

For information on generating a new custom TLS certificate, see [Generate a custom TLS certificate for](#).

- Set the certificate by importing the PEM file into the Automation Orchestrator Appliance.
 - Import the certificate PEM from your local machine by running a secure copy (SCP) command from an SSH shell.
For Linux, you can use a terminal SCP command:
`scp ~/PEM_local_filepath/your_cert_file.PEM root@orchestrator_FQDN_or_IP:/PEM_orchestrator_filepath/your_cert_file.PEM`
For Windows, you can use a PuTTY client PSCP command:
`pscp C:\PEM_local_filepath\your_cert_file.PEM root@<orchestrator_FQDN_or_IP>:/PEM_orchestrator_filepath\your_cert_file.PEM`
 - Log in to the Automation Orchestrator Appliance command line over SSH as **root**.
 - Run the `vracli certificate ingress --set your_cert_file.PEM` command.
- Set the certificate by copying the certificate chain directly into the appliance.
 - Log in to the Automation Orchestrator Appliance command line over SSH as **root**.

- b) Run the `vracli certificate ingress --set stdin` command.
- c) Copy and paste the certificate chain, and press Ctrl+D.
- 3. To apply the new TLS certificate, run the deployment script.

- a) Navigate to the `/opt/scripts/` directory.

```
cd /opt/scripts/
```

- b) Run the `./deploy.sh` script.

IMPORTANT

Do not interrupt the deployment script. You receive the following message when the script finishes running:

Prelude has been deployed successfully.

To access, go to `https://your_orchestrator_FQDN`

You have set custom TLS certificate for your Automation Orchestrator Appliance.

To confirm that the new certificate chain is applied, run the `vracli certificate ingress --list` command.

Import a Trusted Certificate with the Control Center

To communicate with other servers securely, the VMware Aria Automation Orchestrator server must be able to verify their identity. For this purpose, you might need to import the TLS certificate of the remote entity to the VMware Aria Automation Orchestrator trust store. To trust a certificate, you can import it to the trust store either by establishing a connection to a specific URL, or directly as a PEM-encoded file.

Starting with VMware Aria Automation Orchestrator 8.18, the Control Center service is deprecated and is removed in VMware Aria Automation Orchestrator 8.18.1 and later.

1. Log in to Control Center as `root`.
2. Go to the **Certificates** page.
3. Select **Trusted Certificates** and click **Import**.
4. To import the certificate from a file, select **Import from a PEM-encoded file**.
5. Browse to the certificate file and click **Import**.
6. To import the certificate from a URL address, select **Import from URL**.
7. Enter the URL address where your certificate is stored and click **Import**.

You have successfully imported a remote server certificate to the VMware Aria Automation Orchestrator trust store.

Activate the certificate path validation algorithm

By adding a system property, you can activate the certificate path validation algorithm for your trusted certificates.

VMware Aria Automation Orchestrator uses an enhanced public-key infrastructure X.509 (PKIX) certification path when working with certificates for establishing an SSL or TLS connection with a host. VMware Aria Automation Orchestrator must work uninterrupted when establishing a connection with a host with an updated certificate issued by a trusted certificate authority (CA) included in the VMware Aria Automation Orchestrator trust store.

If the subject certificate or some of the intermediate certificates are renewed, the algorithm makes an informed trust decision on whether it can trust any certificate that is not already explicitly trusted.

NOTE

Activating the `com.vmware.o11n.certPathValidator` system property makes certificate validation stricter and done according to [RFC5280](#). After activating the certificate validation algorithm, some workflows associated with a host with a trusted but outdated certificate start to fail. To resolve this certificate issue, renew the specific host to use a valid and up to date certificate and add it to the VMware Aria Automation Orchestrator trust store again.

1. Log in to the Control Center as **root**.
2. Select **System Properties**, and click **New**.
3. In the **Key** text-box, enter `com.vmware.o11n.certPathValidator`.
4. In the **Value** text-box, enter `true`.
5. Add a description for the system property.
6. Click **Add**.
A pop-up window appears.
7. To finish adding the new system property, click **Save changes** from the pop-up window.
8. Wait for the server to automatically restart so the changes are applied.

The certificate validation algorithm is now active. For more information on managing VMware Aria Automation Orchestrator certificates, see [Manage certificates](#).

If your VMware Aria Automation Orchestrator deployment uses vSphere as an authentication provider and you change the vCenter certificate, you must restart the VMware Aria Automation Orchestrator pod so the environment can use the new certificate. To restart your pod, use the following procedure:

1. Log in to the Automation Orchestrator Appliance as **root**.
2. Run the following commands:

```
kubectl -n prelude scale deployment vco-app --replicas=0
kubectl -n prelude scale deployment vco-app --replicas=1
```

NOTE

For clustered VMware Aria Automation Orchestrator deployments, replace the second command with the following:

```
kubectl -n prelude scale deployment vco-app --replicas=3
```

Configuring the VMware Aria Automation Orchestrator plug-ins

The Automation Orchestrator Appliance provides access to a library of preinstalled default plug-ins. The default VMware Aria Automation Orchestrator plug-ins are configured with plug-in specific workflows run in VMware Aria Automation Orchestrator.

The default VMware Aria Automation Orchestrator plug-ins come with configuration workflows. You can run these workflows from VMware Aria Automation Orchestrator to register endpoints for management.

The configuration workflows have the `configuration` tag. For example, to access workflows that are used to manage AMQP brokers and subscriptions, enter the tags `AMQP` and `Configuration` in the search text box of the workflow library.

For more information about the VMware Aria Automation Orchestrator plug-ins, go to the [Using VMware Aria Automation Orchestrator Plug-Ins](#) guide.

VMware Aria Automation Orchestrator High Availability

To increase the availability of the VMware Aria Automation Orchestrator services, start multiple VMware Aria Automation Orchestrator server instances in a cluster with a shared database. VMware Aria Automation Orchestrator works as a single instance until it is configured to work as part of a cluster.

Multiple VMware Aria Automation Orchestrator server instances with identical server and plug-ins configurations work together in a cluster and share one database.

All VMware Aria Automation Orchestrator server instances communicate with each other by exchanging heartbeats. Each heartbeat is a timestamp that the node writes to the shared database of the cluster at a certain time interval. Network problems, an unresponsive database server, or overload might cause an VMware Aria Automation Orchestrator cluster node to stop responding. If an active VMware Aria Automation Orchestrator server instance fails to send heartbeats within the failover timeout period, it is considered non-responsive. The failover timeout is equal to the value of the heartbeat interval multiplied by the number of the failover heartbeats. It serves as a definition for an unreliable node and can be customized according to the available resources and the production load.

An VMware Aria Automation Orchestrator node enters standby mode when it loses connection to the database, and remains in this mode until the database connection is restored. The other nodes in the cluster take control of the active work, by resuming all interrupted workflows from their last unfinished items, such as scriptable tasks or workflow invocations.

You can monitor the state of your VMware Aria Automation Orchestrator cluster from the **System** tab of the Automation Orchestrator Client dashboard. To configure the cluster heartbeat, number of failover heartbeats, and the number of active nodes, navigate to the **Orchestrator Cluster Management** page of the VMware Aria Automation Orchestrator Control Center.

NOTE

Starting with VMware Aria Automation Orchestrator 8.18, the Control Center service is deprecated and is removed in VMware Aria Automation Orchestrator 8.18.1 and later.

For information about scalability maximums, go to [system requirements](#).

Configure an VMware Aria Automation Orchestrator cluster

You can configure your new VMware Aria Automation Orchestrator deployment to run in high availability by deploying three nodes and connecting them as a cluster.

- Download and deploy three standalone VMware Aria Automation Orchestrator instances. Go to [Download and Deploy the](#) .

NOTE

A clustered VMware Aria Automation Orchestrator environment can consist of three nodes.

- Verify that SSH access is enabled for all VMware Aria Automation Orchestrator nodes. Go to [Activate or Deactivate SSH Access to the](#) .
- Configure a load balancer server. Go to [Load Balancing Guide](#).

An VMware Aria Automation Orchestrator cluster consists of three VMware Aria Automation Orchestrator instances that share a common PostgreSQL database. The database of the configured VMware Aria Automation Orchestrator cluster can only run in asynchronous mode.

To create an VMware Aria Automation Orchestrator cluster, you must select one VMware Aria Automation Orchestrator instance to be the primary node of the cluster. After configuring the primary node, you join the secondary nodes to it. The VMware Aria Automation Orchestrator cluster you created is pre-configured with automatic failover.

NOTE

Failure of the automatic failover can lead to loss of database data.

1. Configure the primary node.

- a) Log in to the Automation Orchestrator Appliance command line of the primary node over SSH as **root**.
 - b) To configure the cluster load balancer server, run the **vracli load-balancer setload_balancer_FQDN** command.
 - c) Log in to the Control Center of the primary node and select **Host Settings**.
 - d) Click **Change** and set the host address of the connected load balancer server.
 - e) Configure the authentication provider. Go to [Configuring a Standalone Server](#).
2. Join secondary nodes to primary node.
 - a) Log in to the Automation Orchestrator Appliance command line of the secondary node over SSH as **root**.
 - b) To join the secondary node to the primary node, run the **vracli cluster join primary_node_hostname_or_IP** command.
 - c) Enter the root password of the primary node.
 - d) Repeat the procedure for other secondary node.
 3. If your primary node uses a custom certificate, you must either set the certificate in the appliance or generate a new certificate. Go to [Generate a custom TLS certificate for](#) .

NOTE

The file containing the certificate chain must be PEM-encoded.

4. Finish the cluster deployment.
 - a) Log in to the Automation Orchestrator Appliance command line of the primary node over SSH as **root**.
 - b) To confirm that all nodes are in a ready state, run the **kubectl -n prelude get nodes** command.
 - c) Run the **/opt/scripts/deploy.sh** script and wait for the deployment to finish.

You have created an VMware Aria Automation Orchestrator cluster. After creating the cluster, you can access your VMware Aria Automation Orchestrator environment only from the FQDN address of your load balancer server.

NOTE

Because you can only access the Control Center of the cluster with the root password of the load balancer, you cannot edit the configuration of a cluster node if it has a different root password. To edit the configuration of this node, remove it from the load balancer, edit the configuration in the Control Center, and add the node back to the load balancer.

To monitor the state of the VMware Aria Automation Orchestrator cluster, log in to the Automation Orchestrator Client and navigate to the **System** tab of the dashboard. Go to [Monitoring an cluster](#).

Remove an VMware Aria Automation Orchestrator cluster node

You can delete an VMware Aria Automation Orchestrator so you can reduce your cluster capacity.

Create an VMware Aria Automation Orchestrator cluster. See [Configure an cluster](#).

After removing a node from your VMware Aria Automation Orchestrator cluster, that node will no longer be functional. If you want to use this node again, you must delete its Automation Orchestrator Appliance from your vCenter and deploy it again. See [Download and Deploy the](#) .

1. Log in to the Automation Orchestrator Appliance command line of the node you want to remove as **root**.
2. To remove the node from your VMware Aria Automation Orchestrator, run the **vracli cluster leave** command.
3. Log in to the Automation Orchestrator Appliance command line of one of the remaining nodes as **root**.
4. Run the **kubectl -n prelude get nodes** command and confirm that the removed node is no longer part of the cluster.

Scale out a standalone VMware Aria Automation Orchestrator deployment

You can increase the availability and scalability of your configured VMware Aria Automation Orchestrator deployment by scaling it out.

- Download, deploy, and configure an VMware Aria Automation Orchestrator instance. Go to [Download and Deploy the](#) and [Configuring a Standalone Server](#).
- Download and deploy two additional VMware Aria Automation Orchestrator instances. Go to [Download and Deploy the](#).
- Configure a load balancer server. Go to [Load Balancing Guide](#).

1. Configure the primary node.

- a) Log in to the Control Center of your configured VMware Aria Automation Orchestrator deployment as **root**.
- b) Select **Configure Authentication Provider** and unregister your authentication provider.
- c) Select **Host Settings** and enter the host name of the load balancer server.
- d) Select **Configure Authentication Provider** and register your authentication provider again.
- e) Log in to the Automation Orchestrator Appliance command line of the configured instance as **root**.
- f) To stop all the services of the VMware Aria Automation Orchestrator instance, run the `/opt/scripts/deploy.sh --onlyClean` command.
- g) To set the load balancer, run `vracli load-balancer setload_balancer_FQDN`.
- h) If your VMware Aria Automation Orchestrator instance uses a custom certificate, run the `vracli certificate ingress --set your_cert_file.pem` command.

NOTE

The file containing the certificate chain must be PEM-encoded.

2. Join secondary nodes to the configured instance.

NOTE

If your VMware Aria Automation Orchestrator deployment is patched, refer to the workaround in [KB 96619](#).

- a) Log in to the Automation Orchestrator Appliance command line of the secondary node as **root**.
- b) To join the secondary node to the configured instance, run the `vracli cluster join primary_node_hostname_or_IP` command.
- c) Repeat for the other secondary node.

3. Finish the scale-out process.

- a) Log in to the Automation Orchestrator Appliance command line of the configured instance as **root**.
- b) Run `/opt/scripts/deploy.sh` and wait for the script to finish.

You have scaled out your VMware Aria Automation Orchestrator deployment.

NOTE

For a deployment with three VMware Aria Automation Orchestrator instances, the scaled out deployment can withstand one instance failing and still function. Two instances failing renders the VMware Aria Automation Orchestrator deployment non-functional.

Monitoring an VMware Aria Automation Orchestrator cluster

Monitoring a cluster

You can monitor your existing VMware Aria Automation Orchestrator cluster through the **System** tab of the Automation Orchestrator Client dashboard.

The recommended method for monitoring the configuration synchronization states of the VMware Aria Automation Orchestrator instances is through the **System** tab of the Automation Orchestrator Client dashboard.

NOTE

If you are unable to access the Automation Orchestrator Client dashboard, you can also monitor the states of your VMware Aria Automation Orchestrator instances by running the `kubectl get pods -n prelude` command from the Automation Orchestrator Appliance command line.

Configuration Synchronization State	Description
RUNNING	The VMware Aria Automation Orchestrator service is available and can accept requests.
STANDBY	The VMware Aria Automation Orchestrator service cannot process requests because: <ul style="list-style-type: none"> The node is part of a High Availability (HA) cluster and remains in a standby mode until the primary node fails. The service cannot verify the configuration prerequisites, like a valid connection to the database, authentication provider, and the VMware Aria Automation Orchestrator instance license.
Failed to retrieve the service's health status	The VMware Aria Automation Orchestrator server service cannot be contacted because it is either stopped or a network issue is present.
Pending restart	Control Center detects a configuration change and the VMware Aria Automation Orchestrator server restarts automatically.

Recovering a Cluster Node

Restoring a VMware Aria Automation Orchestrator node can cause issues with the Kubernetes service.

To recover a problematic node in your VMware Aria Automation Orchestrator cluster, you must locate the node, remove it from the cluster, and then add it to the cluster again.

- Identify the primary node of your VMware Aria Automation Orchestrator cluster.
 - Log in to the Automation Orchestrator Appliance command line of one of your nodes over SSH as **root**.
 - Find the node with the **primary** role by running the `kubectl -n prelude exec postgres-0` command.

```
kubectl -n prelude exec postgres-0 - chpst -u postgres repmgr cluster show --terse --compact
```
 - Retrieve the name of the pod in which the primary node is located.
 In most cases, the name of the pod is `postgres-0.postgres.prelude.svc.cluster.local`.
 - Find the FQDN address of the primary node by running the `kubectl -n prelude get pods` command.

```
kubectl -n prelude get pods -o wide
```

- e) Find the database pod with the name you retrieved and get the FQDN address for the corresponding node.
2. Locate the problematic node by running the `kubectl -n prelude get node` command.

The problematic node has a `NotReady` status.

3. Log in to the Automation Orchestrator Appliance command line of the primary node over SSH as `root`.
4. Remove the problematic node from the cluster by running the `vracli cluster remove <NODE-FQDN>` command.
5. Log in to the Automation Orchestrator Appliance command line of the problematic node over SSH as `root`.
6. Add the node to the cluster again by running the `vracli cluster join <MASTER-DB-NODE-FQDN>` command.

Configuring the Automation Orchestrator Appliance authentication provider with the command line interface

You can now configure your VMware Aria Automation Orchestrator options such as the authentication provider with the Automation Orchestrator Appliance command line interface (CLI). This does not replace the existing configuration options in the Control Center. To use these commands, you must log in to the Automation Orchestrator Appliance as a `root` user. After making any authentication changes, you must run the `/opt/scripts/deploy.sh` script so the change to the Automation Orchestrator Appliance is applied.

Retrieving the current authentication provider

You can retrieve the current authentication provider by running the following command:

```
vracli vro authentication
```

Configure the authentication provider by using a guided wizard

To configure the authentication provider by using a guided configuration wizard, run the following command:

```
vracli vro authentication wizard
```

After running the authentication wizard command, you are prompted to provide the necessary authentication provider information such as the type of authentication provider, hostname, and password.

Configure the authentication provider by using predefined parameters

To configure the authentication provider by using predefined configuration parameters, run the `vracli vro authentication set` command. The command can have the following parameters:

Parameter	Importance	Description
<code>-p</code> or <code>--provider</code>	Required	This parameter defines the authentication provider type. The parameter value can be either <code>vsphere</code> or <code>vra</code> depending on the authentication provider you want to configure: vSphere or VMware Aria Automation.
<code>-hn</code> or <code>--hostname</code>	Required	The hostname or URL of the authentication provider you want to configure. Both options are applicable.

Table continued on next page

Continued from previous page

Parameter	Importance	Description
<code>-u</code> or <code>--username</code>	Required	The username of the administrator associated with the authentication provider.
<code>--password-file</code>	Optional	<p>The path to a file containing the password of the administrator account for the authentication provider. If left empty, you receive a prompt for adding the password data. The password file must be stored inside the <code>/data/vco/usr/lib/vco</code> directory of the Automation Orchestrator Appliance. When adding the parameter in the command, exclude the <code>/data/vco</code> part of the filepath.</p>
<code>--admin-group</code>	Required for vSphere authentication providers. Ignored for VMware Aria Automation authentication providers.	Parameter for adding the VMware Aria Automation Orchestrator administrators group of the specified vSphere deployment.
<code>--admin-group-domain</code>	Required for vSphere authentication providers. Ignored for VMware Aria Automation authentication providers.	This parameter defines the administrator group domain.
<code>-k</code> or <code>--ignore-certificate</code>	Optional	Using this parameter, the authentication process is configured to automatically trust the certificate of the authentication provider.
<code>-f</code> or <code>--force</code>	Optional	Using this parameter, you are not prompted for confirmation if the specified authentication provider is already configured.
<code>--fqdn</code>	Optional	<p>This parameter defines the external address of the VMware Aria Automation Orchestrator server.</p> <p>NOTE You can retrieve the FQDN address for your environment by running the <code>nslookup <your_orchestrator_IP></code> command.</p>

Example authentication configurations

```

echo "my-pass" > /data/vco/usr/lib/vco/password_file

vracli vro authentication set -p vra -hn https://my-aria-automation.local -u
administrator@domain.local --password-file /usr/lib/vco/password_file

vracli vro authentication set -p vsphere -hn https://my-vsphere.local -u
administrator@vsphere.local --tenant vsphere.local --admin-group Administrators --admin-
group-domain vsphere.local

```

Unregister an authentication provider

You can unregister the current authentication provider by running the `vracli vro authentication unregister` command. This command can have the following parameters:

Parameter	Importance	Description
<code>-u</code> or <code>--username</code>	Required	The username of the administrator associated with the authentication provider.
<code>--password-file</code>	Optional	The path to a file containing the password of the administrator account for the authentication provider. If left empty, you receive a prompt for adding the password data. The password file must be stored inside the <code>/data/vco/usr/lib/vco</code> directory of the appliance. When including the parameter in the command, exclude the <code>/data/vco</code> part of the filepath.

CLI command logs

VMware Aria Automation Orchestrator CLI commands print their logs in the `/services-logs/prelude/vco-app/file-logs/vco-server-app_cfg-cli.log` file. When a command returns a result different than zero and the standard output does not show a specific error, the exception is visible in this file.

Additional configuration options

Aside from configuring the authentication provider of your VMware Aria Automation Orchestrator deployment, you can use CLI commands for:

- License configuration
- System properties configuration
- Extension configuration
- Troubleshooting
- Retrieving system information
- Logging configuration

For more information on these additional configuration options, go to [Additional command line interface configuration options](#).

Additional command line interface configuration options

Aside from configuring your authentication provider, you can also use command line interface commands to configure other VMware Aria Automation Orchestrator options. To use these commands, you must log in to the Automation Orchestrator Appliance as a **root** user.

Aside from configuring the authentication provider of your VMware Aria Automation Orchestrator deployment, you can use command line interface (CLI) commands for:

- License configuration
- System properties configuration
- Extension configuration
- Troubleshooting
- Retrieving system information
- Logging configuration

For information on configuring the authentication provider with CLI commands, go to [Configuring the Automation Orchestrator Appliance authentication provider with the command line interface](#)

License configuration

You can retrieve the current VMware Aria Automation Orchestrator license configuration by running the following command:

```
vracli vro license
```

You can set a new license key by running the following command:

```
vracli vro license set <license_key>
```

You can reset the current license to the default license of the authentication provider by running the following command:

```
vracli vro license default
```

System property configuration

You can retrieve a list of all configured VMware Aria Automation Orchestrator system properties, as a JSON file, by running the following command:

```
vracli vro properties
```

You can set a system property by running the following command:

```
vracli vro properties set
```

This system property command has the following properties:

Property	Importance	Description
-k or --key	Required	This property defines the name of the system property you want to set.
-v or --value	Required	This property defines the value of the system property.
-n or --noRestart	Optional	This property defines if the set system property requires a restart of the VMware Aria Automation Orchestrator service. By default, setting any new system property performs a restart of the service.

The following is an example of this system property command:

```
vracli vro properties set -k com.vmware.o1ln.property -v true
```

You can remove existing system properties by running the following command:

```
vracli vro properties remove -k <key_value>
```

NOTE

The -k or --key property must include the name of the system property you want to remove.

You can retrieve the name, value, and description of the most commonly used system properties by running the following command:

```
vracli vro properties advanced
```

Extension configuration

You can retrieve a list of all configured VMware Aria Automation Orchestrator extensions by running the following command:

```
vracli vro extensions
```

You can activate an extension by running the following command:

```
vracli vro extensions <extension_name> activate
```

You can deactivate an extension by running the following command:

```
vracli vro extensions <extension_name> deactivate
```

You can list all the configuration properties of a specific extension by running the following command:

```
vracli vro extensions <extension_name> list
```

You can set a extension property by running the following command:

```
vracli vro extensions <extension> set
```

This extension property command can have the following properties:

Property	Importance	Description
-k or --key	Required	This property defines the ID of the extension property.
-v or --value	Required	This property defines the value of the extension property.

For example, the workflow of activating an extension, listing all its properties, and setting a system property could look similar to this:

```
vracli vro extensions tokenreplay activate
vracli vro extensions tokenreplay list
vracli vro extensions tokenreplay set -k recordScripting -v true
```

Troubleshooting

You can cancel all active workflow runs by running the following command:

```
vracli vro cancel executions
```

You can cancel a specific workflow run by adding its ID to the following command:

```
vracli vro cancel workflow <workflow_id>
```

You can suspend all active scheduled tasks by running the following command:

```
vracli vro cancel tasks
```

You can retrieve a list of all trusted certificates by running the following command:

```
vracli vro keystore list
```

System information

You can retrieve the current system information of your VMware Aria Automation Orchestrator deployment by running the following command:

```
vracli vro info
```

NOTE

You can add the optional property of `-d` or `--details` to the system information command to all check the health status API of the VMware Aria Automation Orchestrator server.

Logging configuration

You can retrieve the current VMware Aria Automation Orchestrator logging configuration by running the following command:

```
vracli vro logs
```

You can configure the VMware Aria Automation Orchestrator logging server by running the following command:

```
vracli vro logs configure
```

The logging server command can have the following parameters

Parameter	Importance	Description
<code>-l</code> or <code>--level</code>	Optional	This parameter defines the server logging level.
<code>-sc</code> or <code>--scripting-count</code>	Optional	This parameter defines the number of saved scripting log rotations.
<code>-sl</code> or <code>--scripting-level</code>	Optional	This parameter defines the scripting log level.
<code>-ss</code> or <code>--scripting-size</code>	Optional	This parameter defines the scripting log size in megabytes (MB).

NOTE

The valid level values are ALL, TRACE, DEBUG, INFO, WARN, ERROR, FATAL and OFF.

CLI command logs

VMware Aria Automation Orchestrator CLI commands print their logs in the `/services-logs/prelude/vco-app/file-logs/vco-server-app_cfg-cli.log` file. When a command returns a result different than zero and the standard output does not show a specific error, the exception is visible in this file.

Using the VMware Aria Automation Orchestrator API Services

In addition to configuring VMware Aria Automation Orchestrator by using Control Center, you can modify the VMware Aria Automation Orchestrator server configuration settings by using the VMware Aria Automation Orchestrator REST API, the Control Center REST API, or the command-line utility, stored in the appliance.

The Configuration plug-in is included in the VMware Aria Automation Orchestrator package, by default. You can access the Configuration plug-in workflows from either the VMware Aria Automation Orchestrator workflow library or the VMware Aria Automation Orchestrator REST API. With these workflows, you can change the trusted certificate and keystore settings of the VMware Aria Automation Orchestrator server. For information on all available VMware Aria Automation Orchestrator REST API service calls, see the *VMware Aria Automation Orchestrator Server API* documentation, located at https://your_orchestrator_FQDN/vco/api/docs.

Managing SSL Certificates Through the REST API

In addition to managing TLS certificates by using Control Center, you can also manage trusted certificates and keystores when you run workflows from the Configuration plug-in or by using the REST API.

The Configuration plug-in contains workflows for importing and deleting TLS certificates and keystores. You can access these workflows by navigating to **Library > Workflows > SSL Trust Manager** and **Library > Workflows > Keystores** in the Automation Orchestrator Client. You can also run these workflows by using the VMware Aria Automation Orchestrator REST API.

The Control Center REST API provides access to resources for configuring the VMware Aria Automation Orchestrator server. You can use the Control Center REST API with third-party systems to automate the VMware Aria Automation Orchestrator configuration. The root endpoint of the Control Center REST API is `https://your_orchestrator_FQDN/vco/api`. For information on all available service calls that you can make to the Control Center REST API, see the *VMware Aria Automation Orchestrator Control Center API* documentation, at https://your_orchestrator_FQDN/vco-controlcenter/docs.

Delete a TLS Certificate by Using the REST API

You can delete a TLS certificate by running the Delete trusted certificate workflow of the Configuration plug-in or by using the REST API.

1. Make a **GET** request at the URL of the Workflow service of the Delete trusted certificate workflow.

```
GET https://{{orchestrator_host}}:{{port}}/vco/api/workflows?conditions=name=Delete trusted certificate
```

2. Retrieve the definition of the Delete trusted certificate workflow by making a **GET** request at the URL of the definition.

```
GET https://{{orchestrator_host}}:{{port}}/vco/api/workflows/8a70a326-ffd7-4fef-97e0-2002ac49f5bd
```

3. Make a **POST** request at the URL that holds the execution objects of the Delete trusted certificate workflow.

```
POST https://{{orchestrator_host}}:{{port}}/vco/api/workflows/8a70a326-ffd7-4fef-97e0-2002ac49f5bd/executions/
```

4. Provide the name of the certificate you want to delete as an input parameter of the Delete trusted certificate workflow in an execution-context element in the request body.

Import TLS Certificates by Using the REST API

You can import TLS certificates by running a workflow from the Configuration plug-in or by using the REST API.

You can import a trusted certificate from a file or a URL. See [Import a Trusted Certificate with the Control Center](#)

1. Make a **GET** request at the URL of the Workflow service.

Option	Description
Import trusted certificate from a file	Imports a trusted certificate from a file.
Import trusted certificate from URL	Imports a trusted certificate from a URL address.
Import trusted certificate from URL using proxy server	Imports a trusted certificate from a URL address by using a proxy server.

Table continued on next page

Continued from previous page

Option	Description
Import trusted certificate from URL with certificate alias	Imports a trusted certificate with a certificate alias, from a URL address.

To import a trusted certificate from a file, make the following GET request:

```
GET https://{{orchestrator_host}}:{port}/vco/api/workflows?conditions=name=Import
trusted certificate from a file
```

2. Retrieve the definition of the workflow by making a GET request at the URL of the definition.

To retrieve the definition of the Import trusted certificate from a file workflow, make the following GET request:

```
GET https://{{orchestrator_host}}:{port}/vco/api/workflows/
93a7bb21-0255-4750-9293-2437abe9d2e5
```

3. Make a POST request at the URL that holds the execution objects of the workflow.

For the Import trusted certificate from a file workflow, make the following POST request:

```
POST https://{{orchestrator_host}}:{port}/vco/api/workflows/
93a7bb21-0255-4750-9293-2437abe9d2e5/executions
```

4. Provide values for the input parameters of the workflow in an execution-context element of the request body.

Parameter	Description
cer	The CER file from which you want to import the TLS certificate. This parameter is applicable for the Import trusted certificate from a file workflow.
url	The URL from which you want to import the TLS certificate. For non-HTTPS services, the supported format is <i>IP_address_or_DNS_name:port</i> . This parameter is applicable for the Import trusted certificate from URL workflow.

Create a Keystore by Using the REST API

You can create a keystore by running the Create a keystore workflow of the Configuration plug-in or by using the REST API.

1. Make a GET request at the URL of the Workflow service of the Create a keystore workflow.

```
GET https://{{orchestrator_host}}:{port}/vco/api/workflows?conditions=name/Create a
keystore
```

2. Retrieve the definition of the Create a keystore workflow by making a GET request at the URL of the definition.

```
GET https://{{orchestrator_host}}:{port}/vco/api/workflows/6c301bff-e8fe-4ae0-
ad08-5318178594b3/
```

3. Make a POST request at the URL that holds the execution objects of the Create a keystore workflow.

```
POST https://{{orchestrator_host}}:{port}/vco/api/workflows/6c301bff-e8fe-4ae0-ad08-5318178594b3/executions/
```

- Provide the name of the keystore you want to create as an input parameter of the Create a keystore workflow in an execution-context element in the request body.

Delete a Keystore by Using the REST API

You can delete a keystore by running the Delete a keystore workflow of the Configuration plug-in or by using the REST API.

- Make a GET request at the URL of the Workflow service of the Delete a keystore workflow.

```
GET https://{{orchestrator_host}}:{port}/vco/api/workflows?conditions=name=Delete a keystore
```

- Retrieve the definition of the Delete a keystore workflow by making a GET request at the URL of the definition.

```
GET https://{{orchestrator_host}}:{port}/vco/api/workflows/7a3389eb-1fab-4d77-860b-81b66bb45b86/
```

- Make a POST request at the URL that holds the execution objects of the Delete a keystore workflow.

```
POST https://{{orchestrator_host}}:{port}/vco/api/workflows/7a3389eb-1fab-4d77-860b-81b66bb45b86/executions/
```

- Provide the keystore you want to delete as an input parameter of the Delete a keystore workflow in an execution-context element in the request body.

Add a Key by Using the REST API

You can add a key by running the Add key workflow of the Configuration plug-in or by using the REST API.

- Make a GET request at the URL of the Workflow service of the Add key workflow.

```
GET https://{{orchestrator_host}}:{port}/vco/api/workflows?conditions=name=Add key
```

- Retrieve the definition of the Add key workflow by making a GET request at the URL of the definition.

```
GET https://{{orchestrator_host}}:{port}/vco/api/workflows/6c301bff-e8fe-4ae0-ad08-5318178594b3/
```

- Make a POST request at the URL that holds the execution objects of the Add key workflow.

```
POST https://{{orchestrator_host}}:{port}/vco/api/workflows/6c301bff-e8fe-4ae0-ad08-5318178594b3/executions/
```

- Provide the keystore, key alias, PEM-encoded key, certificate chain and key password as input parameters of the Add key workflow in an execution-context element in the request body.

Additional Configuration Options

You can use the Control Center to change the default VMware Aria Automation Orchestrator behavior. Starting with Automation Orchestrator 8.18, the Control Center service is deprecated and is removed in Automation Orchestrator 8.18.1 and later.

Reconfiguring Authentication

After you set up the authentication method during the initial configuration of Control Center, you can change the authentication provider or the configured parameters at any time.

Change the Authentication Provider

To change the authentication mode or the authentication provider connection settings, you must first unregister the existing authentication provider.

1. Log in to Control Center as `root`.
2. On the **Configure Authentication Provider** page, click the **UNREGISTER** button next to the host address text box to unregister the authentication provider that is in use.

You have successfully unregistered the authentication provider.

Reconfigure the authentication in Control Center. See [Configuring a Standalone Server](#).

Change the Authentication Parameters

When you use vSphere as an authentication provider in Control Center, you can change the default tenant of the VMware Aria Automation Orchestrator administrators group.

Configure vSphere as the authentication provider for your VMware Aria Automation Orchestrator deployment. See [Configure a standalone server with vSphere authentication](#).

NOTE

The VMware Aria Automation authentication does not include these parameters.

1. Log in to the Control Center as `root`.
2. Select **Configure Authentication Provider**.
3. Click the **CHANGE** button next to the **Default tenant** text box.
4. Replace the name of the tenant.
5. Click the **CHANGE** button next to the **Admin group** text box.

NOTE

If you do not reconfigure the administrators group, it remains empty and you are no longer able to access Control Center.

6. Enter the name of an administrator group and click **SEARCH**.
7. Select an administrator group.
8. Change the administrators group.
9. To finish editing the authentication parameters, click **SAVE CHANGES**.

Configuring the Workflow Run Properties

By default, you can run up to 300 workflows per node, and up to 10,000 workflows can be queued if the number of actively running workflows is reached.

When the VMware Aria Automation Orchestrator node has to run more than 300 concurrent workflows, the pending workflow runs are queued. When an active workflow run completes, the next workflow in the queue starts to run. If the

maximum number of queued workflows is reached, the next workflow runs fail until one of the pending workflows starts to run.

You can modify these workflow run characteristics by configuring the workflow run properties.

Option	Description
Enable safe mode	If safe mode is enabled, all running workflows are canceled and are not resumed on the next VMware Aria Automation Orchestrator node start.
Number of concurrent running workflows	The number of workflows that run simultaneously.
Number of concurrent running workflows	The number of workflow run requests that the VMware Aria Automation Orchestrator server accepts before becoming unavailable.
Maximum number of preserved runs per workflow	The maximum number of finished workflow runs that are kept as history per workflow. If the number is exceeded, the oldest workflow runs are deleted.
Log events expiration days	The number of days that log events are kept in the database before they are purged.

To configure a workflow run property, log in to the Control Center, navigate to the **System Properties** page, and add the corresponding property and value.

Option	System property	Default value
Enable safe mode	ch.dunes.safe-mode	false
Number of concurrent running workflows	com.vmware.vco.workflow-engine.executors-count	300
Maximum amount of running workflows in the queue	com.vmware.vco.workflow-engine.executors-max-queue-size	10000
Maximum number of preserved runs per workflow	ch.dunes.task.max-workflow-tokens	100
Log events expiration days	com.vmware.o11n.log-events-expiration-days	15

VMware Aria Automation Orchestrator Log Files

VMware Technical Support routinely requests diagnostic information when you submit a support request. This diagnostic information contains product-specific logs and configuration files from the host on which the product runs.

Automation Orchestrator Appliance logs are stored in the `/data/vco/usr/lib/vco/app-server/logs/` directory. You export the logs of your Automation Orchestrator Appliance deployment by logging in to the appliance command line and running the `vracli log-bundle` command. The generated log bundle is saved on the root folder of your Automation Orchestrator Appliance.

Logging Persistence

You can log information in any kind of VMware Aria Automation Orchestrator script, for example workflow, policy, or action. This information has types and levels. The type can be either persistent or non-persistent. The level can be DEBUG, INFO, WARN, ERROR, TRACE, and FATAL.

Table 103: Creating Persistent and Non-Persistent Logs

Log Level	Persistent Type	Non-Persistent Type
DEBUG	Server.debug("short text", "long text");	System.debug("text")
INFO	Server.log("short text", "long text");	System.log("text");
WARN	Server.warn("short text", "long text");	System.warn("text");
ERROR	Server.error("short text", "long text");	System.error("text");

Persistent Logs

Persistent logs (server logs) track past workflow run logs and are stored in the VMware Aria Automation Orchestrator database.

Non-Persistent Logs

When you use a non-persistent log (system log) to create scripts, the VMware Aria Automation Orchestrator server notifies all running VMware Aria Automation Orchestrator applications about this log, but this information is not stored in the database. When the application is restarted, the log information is lost. Non-persistent logs are used for debugging purposes and for live information. To view system logs, you must select a completed workflow run in the Automation Orchestrator Client and select the **Logs** tab.

VMware Aria Automation Orchestrator Logs Configuration

You can set the level of server log and the scripting log that you require. If either of the logs is generated multiple times a day, it becomes difficult to determine what causes problems.

To configure the Automation Orchestrator Appliance logs, log in to the Automation Orchestrator Client and navigate to **System Settings > Log Configuration**.

The default log level of the server log and the scripting log is `INFO`. Changing the log level affects all new messages that the server enters in the logs and the number of active connections to the database. The logging verbosity decreases in descending order.

CAUTION

Only set the log level to `DEBUG` or `ALL` to debug a problem. Do not use these settings in a production environment because it can seriously impair performance.

Generate VMware Aria Automation Orchestrator Logs

You can export the logs of your deployment by logging in to the Automation Orchestrator Appliance command line as `root` and running the `vracli log-bundle` command. The generated log bundle is stored in the root folder of the appliance.

NOTE

When you have more than one VMware Aria Automation Orchestrator instance in a cluster, the log-bundle includes the logs from all VMware Aria Automation Orchestrator instances in the cluster.

Configure Logging Integration with vRealize Log Insight

You can configure VMware Aria Automation Orchestrator to send your logging information to a vRealize Log Insight server.

- Configure your vRealize Log Insight server. See [vRealize Log Insight Documentation](#).

- Verify that your vRealize Log Insight version is 4.7.1 or later.

You can configure a logging integration to a vRealize Log Insight server through the Automation Orchestrator Appliance command line.

NOTE

For information on configuring a logging integration with a remote syslog server, see [Create or overwrite a syslog integration in](#).

- Log in to the Automation Orchestrator Appliance command line as **root**.
- To configure the logging integration with vRealize Log Insight, run the **vracli vrli set vRLI_FQDN** command.

NOTE

If your VMware Aria Automation Orchestrator instance uses a self-signed certificate, you can deactivate the SSL authentication by including the optional **-k** or **--insecure** argument.

For more information on vRealize Log Insight configuration options, run the **vracli vrli -h** command.

Create or overwrite a syslog integration in VMware Aria Automation Orchestrator

Create or overwrite a syslog integration

You can configure VMware Aria Automation Orchestrator to send your logging information to one remote syslog server.

Configure a remote syslog server.

The **vracli remote-syslog set** command is used to create a syslog integration or overwrite existing integrations. The VMware Aria Automation Orchestrator remote syslog integration supports three connection types:

- Over UDP.
- Over TCP without TLS.

NOTE

To create a syslog integration without using TLS, add the **--disable-ssl** flag to the **vracli remote-syslog set** command.

- Over TCP with TLS.

For information on configuring a logging integration with vRealize Log Insight, go to [Configure Logging Integration with](#).

- Log in to the Automation Orchestrator Appliance command line as **root**.
- To create an integration to a syslog server, run the **vracli remote-syslog set** command.

```
vracli remote-syslog set -id name_of_integration protocol_type://
syslog_URL_or_FQDN:syslog_port
```

NOTE

If you do not enter a port in the **vracli remote-syslog set** command, the port value defaults to 514.

NOTE

You can add a certificate to the syslog configuration. To add a certificate file, use the **--ca-file** flag. To add a certificate as plaintext, use the **--ca-cert** flag.

- To overwrite an existing syslog integration, run the **vracli remote-syslog set** and set the **-id** flag value to the name of the integration you want to overwrite.

NOTE

By default, the Automation Orchestrator Appliance requests that you confirm that you want to overwrite the syslog integration. To skip the confirmation request, add the **-f** or **--force** flag to the **vracli remote-syslog set** command.

To review the current syslog integrations in the appliance, run the **vracli remote-syslog** command.

Delete a Syslog Integration in VMware Aria Automation Orchestrator

You can delete syslog integrations from your Automation Orchestrator Appliance by running the **vracli remote-syslog unset** command.

Create one or more syslog integrations in the Automation Orchestrator Appliance. See [Create or overwrite a syslog integration in](#).

1. Log in to the Automation Orchestrator Appliance command line as **root**.
2. Delete syslog integrations from the Automation Orchestrator Appliance.
 - a) To delete a specific syslog integration, run the **vracli remote-syslog unset -id***Integration_name* command.
 - b) To delete all syslog integrations on the Automation Orchestrator Appliance, run the **vracli remote-syslog unset** command without the **-id** flag.

NOTE

By default, the Automation Orchestrator Appliance requests that you confirm that you want to delete all syslog integrations. To skip the confirmation request, add the **-f** or **--force** flag to the **vracli remote-syslog unset** command.

Enable Kerberos Debug Logging

You can troubleshoot VMware Aria Automation Orchestrator plug-in problems by modifying the Kerberos configuration file used by the plug-in.

The Kerberos configuration file is located in the `/data/vco/usr/lib/vco/app-server/conf/` directory of the Automation Orchestrator Appliance.

1. Log in to the Automation Orchestrator Appliance command line as **root**.
2. Run the **kubectl -n prelude edit deployment vco-app** command.
3. In the deployment file, locate and edit the `-Djava.security.krb5.conf=/usr/lib/vco/app-server/conf/krb5.conf` string.
`-Djava.security.krb5.conf=/usr/lib/vco/app-server/conf/krb5.conf`
`-Dsun.security.krb5.debug=true`
4. Save the changes and exit the file editor.
5. Run the **kubectl -n prelude get pods** command.
 Wait until all pods are running.
6. To monitor the Kerberos login, run the following command.
`tail -f /services-logs/prelude/vco-app/console-logs/vco-server-app.log`

7. Alternatively, you can enable debug logging in the VMware Aria Automation Orchestrator configurator by adding the `sun.security.krb5.debug = true` system property.

Enabling the OpenTracing extension

The OpenTracing extension for VMware Aria Automation Orchestrator provides tools for gathering data about your VMware Aria Automation Orchestrator environment. You can use this data for troubleshooting the VMware Aria Automation Orchestrator system and workflows.

- Verify that the Automation Orchestrator Appliance SSH service is enabled. See [Activate or Deactivate SSH Access to the](#).
- If you have enabled previous versions of the OpenTracing extension, you must remove it before enabling the current version. For example, if you have previously enabled version 8.1.0 of the OpenTracing extension, you must run the `rm /data/vco/usr/lib/vco/app-server/extensions/opentracing-8.1.0.jar` command.

Before you can configure VMware Aria Automation Orchestrator to use the OpenTracing extension, you must enable it in the Automation Orchestrator Appliance.

NOTE

Starting with VMware Aria Automation Orchestrator 8.8.2, the OpenTracing extension for VMware Aria Automation Orchestrator is deprecated and will be removed from the product in a future release.

1. Log in to the Automation Orchestrator Appliance over SSH as **root**.
2. To list all available extensions, run the `ls /data/vco/usr/lib/vco/app-server/extensions/` command.
3. Run the following command to enable the OpenTracing extension:

```
mv /data/vco/usr/lib/vco/app-server/extensions/opentracing-8.17.0.jar.inactive /data/vco/usr/lib/vco/app-server/extensions/opentracing-8.17.0.jar
```

4. Log in to the Control Center and confirm that the extension appears in the **Extension Properties** page.

Configure the OpenTracing integration with VMware Aria Automation Orchestrator in the **Extension Properties** page. See [Configure the OpenTracing Extension](#).

Configure the OpenTracing Extension

The OpenTracing extension sends data about workflow runs to a Jaeger server. Data includes the workflow status, input and output parameters, the user that initiated the workflow run, and the workflow ID data.

- Verify sure that OpenTracing is enabled in the Automation Orchestrator Appliance. See [Enabling the OpenTracing extension](#).
- Deploy a Jaeger server for use in the OpenTracing extension. For more information, see the [Getting Started with Jaeger documentation](#).

Starting with VMware Aria Automation Orchestrator 8.8.2, the OpenTracing extension for VMware Aria Automation Orchestrator is deprecated and will be removed from the product in a future release.

1. Log in to the Control Center as **root**.
2. Select the **Extension Properties** page.
3. Select the OpenTracing extension.
4. Enter the Jaeger server host address and port.

NOTE

Insert two forward slashes ("//") before entering the server address.

5. Click **Save**.

You have configured the Opentracing extension for VMware Aria Automation Orchestrator.

- To access the Jaeger UI containing the data collected by the Opentracing extension, visit the host address entered during configuration.
- Under the **Service** option, select **Workflows**.
- To specify what data to view, use the **Tags** option. For example, to view data about failed workflows, enter `status=failed`.

Configure the Wavefront Extension

Use the Wavefront extension to gather metric data about your VMware Aria Automation Orchestrator system and workflows.

1. Log in to the Automation Orchestrator Appliance command line as **root**.
2. To configure a direct connection to your Wavefront instance, run the `vracli waveform` command.

```
vracli waveform internal --url ${WAVEFRONT_URL} --token ${API_TOKEN}
```

Alternatively, you can configure a proxy connection by running the following command:

```
vracli waveform proxy --hostname ${PROXY_FQDN}
```

3. To finish configuring the Wavefront extension, run the `/opt/scripts/deploy.sh` command.

You have configured the Wavefront extension for VMware Aria Automation Orchestrator.

- To access the metrics collected by Wavefront, access the dashboard on the address entered during configuration.
- To get notifications about specific events in your VMware Aria Automation Orchestrator environment, you can use Wavefront Alerts. For more information, see the [Wavefront Alerts documentation](#).

Enable Time Synchronization for VMware Aria Automation Orchestrator

You can enable time synchronization on your VMware Aria Automation Orchestrator deployment with the Automation Orchestrator Appliance command line.

You can configure time synchronization for your standalone or clustered VMware Aria Automation Orchestrator deployment by using the Network Time Protocol (NTP) communication protocol. VMware Aria Automation Orchestrator supports two, mutually exclusive, NTP configurations:

NTP configuration	Description
ESXi	This configuration can be used when the ESXi server hosting the Automation Orchestrator Appliance is synchronized with an NTP server. If you are using a clustered deployment, all ESXi hosts must be synchronized with an NTP server. For more information on configuring NTP for ESXi, see Configuring Network Time Protocol (NTP) on an ESXi host using the vSphere Web Client .

Table continued on next page

Continued from previous page

NTP configuration	Description
	<p>NOTE If your VMware Aria Automation Orchestrator deployment is migrated to a ESXi host that is not synchronized to an NTP server, you can experience clock drift.</p>
systemd	<p>This configuration uses the systemd-timesyncd daemon to synchronize the clocks of your VMware Aria Automation Orchestrator deployment.</p> <p>NOTE By default, the systemd-timesyncd daemon is enabled, but configured with no NTP servers. If the Automation Orchestrator Appliance uses a dynamic IP configuration, the appliance can use any NTP servers received by the DHCP protocol.</p>

1. Log in to the Automation Orchestrator Appliance command line as **root**.
2. Enable NTP with ESXi.
 - a) Run the **vracli ntp esxi** command.
 - b) To confirm the status of the NTP configuration, run the **vracli ntp status** command.
3. Enable NTP with systemd.
 - a) Run the **vracli ntp systemd --setFQDN_or_IP_of_systemd_server** command.

NOTE

You can add multiple systemd NTP servers by separating their network addresses with a comma. Each network address must be placed inside single quotation marks. For example, **vracli ntp systemd --set 'ntp_address_1','ntp_address_2'**

- b) To confirm the status of the NTP configuration, run the **vracli ntp status** command.

You have enabled time synchronization for your VMware Aria Automation Orchestrator deployment.

The NTP configuration can fail if there is a time difference of above 10 minutes between the NTP server and the VMware Aria Automation Orchestrator deployment. To resolve this problem, reboot the Automation Orchestrator Appliance.

Deactivate Time Synchronization for VMware Aria Automation Orchestrator

You can deactivate the Network Time Protocol (NTP) time synchronization on your VMware Aria Automation Orchestrator deployment with the Automation Orchestrator Appliance command line.

Verify that you have configured time synchronization with ESXi or systemd. See [Enable Time Synchronization for](#).

You can also reset the NTP configuration of your Automation Orchestrator Appliance to the default state by running the **vracli ntp reset** command.

1. Log in to the Automation Orchestrator Appliance command line as **root**.

2. To deactivate time synchronization with ESXi or systemd, run the `vracli ntp disable` command.
3. To confirm the status of the NTP configuration, run the `vracli ntp status` command.

Configure VMware Aria Automation Orchestrator Kubernetes CIDR

You can change the Kubernetes Classless Inter-domain Routing (CIDR) subnet masks after deployment.

- Verify that the CIDR address values support at least 1024 hosts.
- The internal cluster CIDR and internal service CIDR must not share the same subnet value.
- The CIDR value for one of the subnets cannot include the value you want to add to the other subnet.

NOTE

For example, the `cluster-cidr` value cannot be `10.244.4.0/22 10.244.4.0/24`, because this would also include the subnet value for the `service-cidr` property. Each subnet value must be added separately.

The Automation Orchestrator Appliance configures and runs a Kubernetes cluster. The pods and services in this cluster are deployed in separate IPv4 subnets, represented by the internal cluster CIDR and internal service CIDR, respectively. The default values of the subnet masks set during OVF deployment are the following:

Kubernetes network property	Default value	Property description
<code>cluster-cidr</code>	<code>10.244.0.0/22</code>	The CIDR used for pods running inside the Kubernetes cluster.
<code>service-cidr</code>	<code>10.244.4.0/22</code>	The CIDR used for Kubernetes services inside the Kubernetes cluster.

The default CIDR network addresses can create a conflict with outside private networks that you might be using. In such scenarios, you can change the configuration of these CIDR values either during or after deploying your Automation Orchestrator Appliance.

NOTE

For information on changing the CIDR configuration during appliance deployment, see [Download and Deploy the](#).

1. Log in to the Automation Orchestrator Appliance as `root`.
2. Run the `vracli upgrade exec -y --prepare --profile k8s-subnets` command.
3. Back up your VMware Aria Automation Orchestrator deployment by taking a virtual machine (VM) snapshot. See [Take a Snapshot of a Virtual Machine](#).

CAUTION

VMware Aria Automation Orchestrator 8.x does not currently support memory snapshots. Before taking the snapshot of your VMware Aria Automation Orchestrator deployment, verify that the `Snapshot the virtual machine's memory` option is deactivated.

4. Change the values of the cluster CIDR and service CIDR subnets by running the `vracli network k8s-subnets` command.

```
vracli network k8s-subnets --cluster-cidr <CIDR_value> --service-cidr <CIDR_value>
```

5. To finish the CIDR configuration process, run the `vracli upgrade exec` command.

Update the DNS Settings for VMware Aria Automation Orchestrator

An administrator can update the DNS settings of the VMware Aria Automation Orchestrator deployment by using the `vracli network dns` command.

Verify that the Automation Orchestrator Appliance SSH service is enabled. See [Activate or Deactivate SSH Access to the .](#)

1. Log in to the Automation Orchestrator Appliance command-line over SSH as **root**.

NOTE

For clustered deployments, log in to appliance of any node in the cluster.

2. To set new DNS servers to your VMware Aria Automation Orchestrator deployment, run the **vracli network dns set** command.

```
vracli network dns set --servers DNS1,DNS2
```

3. Verify that the new DNS servers are properly applied to all VMware Aria Automation Orchestrator nodes by running the **vracli network dns status** command.

4. To stop the VMware Aria Automation Orchestrator services in your deployment, run the following set of commands:

```
/opt/scripts/svc-stop.sh
sleep 120
/opt/scripts/deploy.sh --onlyClean
```

5. Restart the VMware Aria Automation Orchestrator nodes and wait for them to start completely.
6. Log in to the command-line for each VMware Aria Automation Orchestrator node over SSH and verify that the new DNS servers are listed in the `/etc/resolve.conf` file.
7. To start the VMware Aria Automation Orchestrator services, run the `/opt/scripts/deploy.sh` script on one of the nodes in your deployment.

The VMware Aria Automation Orchestrator DNS settings are changed as specified.

Back Up and Restore VMware Aria Automation Orchestrator

You can back up and restore your VMware Aria Automation Orchestrator deployment by using vSphere virtual machine (VM) snapshots.

The following procedure is based around backing up and restoring a clustered VMware Aria Automation Orchestrator deployment. For standalone a VMware Aria Automation Orchestrator deployment, you take a vSphere snapshot and revert your deployment from it without the additional cluster specific steps outlined in this procedure.

NOTE

For more information on using vSphere virtual machine snapshots, see [Take a Snapshot of a Virtual Machine](#) and [Revert a Virtual Machine Snapshot](#).

1. Identify the primary node of your VMware Aria Automation Orchestrator cluster.
 - a) Log in to the Automation Orchestrator Appliance command line of one of your nodes over SSH as **root**.
 - b) Find the node with the `primary` role by running the **kubectl -n prelude exec postgres-0** command.

```
kubectl -n prelude exec postgres-0 --chpst -u postgres repmgr cluster show --terse --compact
```

- c) Find the FQDN address of the primary node by running the **kubectl -n prelude get pods** command.

```
kubectl -n prelude get pods -o wide
```

2. Back up your VMware Aria Automation Orchestrator deployment.

- Log in to the vSphere Web Client.
- Take snapshots of your VMware Aria Automation Orchestrator nodes.

When backing up your nodes, you must follow a specific order. First, back up your replica nodes and after that, back up the primary node.

NOTE

Do not take snapshots of your VMware Aria Automation Orchestrator nodes with the **Snapshot the virtual machine's memory** option enabled.

3. Restore your VMware Aria Automation Orchestrator deployment.

- Revert your VMware Aria Automation Orchestrator nodes from the snapshots you created in step 2.
- Power on the VMware Aria Automation Orchestrator nodes.

When powering on the nodes, you must follow a specific order. First, power on your primary node and after that, power on your replica nodes.

Configuration Use Cases and Troubleshooting

The configuration use cases provide task flows that you can perform to meet specific configuration requirements of your VMware Aria Automation Orchestrator server and troubleshooting topics to understand and solve a problem.

Verify the VMware Aria Automation Orchestrator server build number

In certain scenarios, you might be required to verify the server build number of your VMware Aria Automation Orchestrator deployment.

You can verify your VMware Aria Automation Orchestrator server build number by navigating to https://your_orchestrator_FQDN/vco/api/about. Your server build number is displayed in the <ns2:build-number> tags.

Verifying your server build number can be useful in use cases such as providing additional information to a support request (SR) that you have logged with VMware Support.

NOTE

The VMware Aria Automation Orchestrator server build number is different from the build number of your Automation Orchestrator Appliance. To verify the build number of your appliance, log in to the Automation Orchestrator Appliance command line and run the **vracli version** command. Verifying the appliance build number can help you confirm if your upgrade to the latest version of VMware Aria Automation Orchestrator is successful.

Configure the VMware Aria Automation Orchestrator Plug-in for the vSphere Web Client

To use the VMware Aria Automation Orchestrator plug-in for the vSphere Web Client, you must register VMware Aria Automation Orchestrator as an extension of vCenter.

- Verify that SSH access is enabled for the Automation Orchestrator Appliance. See [Activate or Deactivate SSH Access to the](#).
 - You must register VMware Aria Automation Orchestrator with vSphere authentication to the same Platform Services Controller that your managed vCenter instance authenticates with.
 - Copy the **vco-plugin.zip** to the Automation Orchestrator Appliance:
- Download the **vco-plugin.zip** file from the [VMware Technology Network](#).

2. Open an SSH client.

NOTE

For Linux or MacOS environments, you can use the Terminal command-line interface. For Windows environments, you can use the PuTTY client.

3. To copy the vco-plugin.zip file, run the secure copy command.

For Linux/MacOS: `scp ~/<zip_download_dir>/vco-plugin.zip root@<orchestrator_FQDN_or_IP>:/data/vco/usr/lib/vco/downloads/vco-plugin.zip`

For Windows: `pscp C:\<zip_download_dir>\vco-plugin.zip root@<orchestrator_FQDN_or_IP>:/data/vco/usr/lib/vco/downloads/vco-plugin.zip`

After you register your VMware Aria Automation Orchestrator server with vCenter Single Sign-On and configure it to work with vCenter, you must register VMware Aria Automation Orchestrator as an extension of vCenter.

1. Log in to the Automation Orchestrator Client.
2. Navigate to **Library > Workflows**.
3. Search for the **Register vCenter Orchestrator as a vCenter Server extension** workflow, and click **Run**.
4. Select the vCenter instance to register VMware Aria Automation Orchestrator with.
5. Enter `https://your_orchestrator_FQDN` or the service URL of the load balancer that redirects the requests to the VMware Aria Automation Orchestrator server nodes.
6. Click **Run**.

Cancel Running Workflows

You can use the VMware Aria Automation Orchestrator Control Center to cancel workflows that do not finish properly.

1. Log in to Control Center as `root`.
2. Click **Troubleshooting**.
3. Cancel running workflows.

Option	Description
Cancel all workflow runs	Enter a workflow ID, to cancel all tokens for that workflow.
Cancel workflow runs by ID	Enter all token IDs, you want to cancel. Separate IDs with a comma.
Cancel all running workflows	Cancel all running workflows on the server.

NOTE

Operations where you cancel workflows by ID might not be successful, as there is no reliable way to cancel the run thread immediately.

On the next server start, the workflows are set in a canceled state.

Enable VMware Aria Automation Orchestrator Server Debugging

You can start the VMware Aria Automation Orchestrator server in debug mode to debug issues when developing a plug-in.

Install and configure the Kubernetes command-line tool on your local machine. See [Install and Set Up kubectl](#).

1. Log in to the Automation Orchestrator Appliance command line as `root`.

2. Run the `kubectl -n prelude edit deployment vco-app` command.
3. Edit the deployment YAML file, by adding a debug environment variable to the `vco-server-app` container. The variable must be added under the `env` section of the `vco-server-app` container.

`containers:`

```
- command:
  ...
  env:
    - name: DEBUG_PORT
      value: "your_desired_debug_port"
  ...
name: vco-server-app
...
```

NOTE

When adding the debug environment variable to the `env` section, you must follow the YAML indentation formatting as presented in the preceding example.

4. Save the changes to the deployment file.
If the edit to the deployment file is successful, you receive the `deployment.extensions/vco-app edited` message.
5. Generate the Kubernetes configuration file, by running the `vracli dev kubeconfig` command.
As `kubeconfig` is a developer environment, you are prompted to confirm that you want to continue. Enter `yes` to continue or `no` to stop.
6. Copy the content of the generated configuration file from `apiVersion: v1` up to and including the `client-key-data` content.
7. Save the generated Kubernetes configuration file on your local machine.
8. Log out of the Automation Orchestrator Appliance.
9. Finish configuring the debug mode on your local machine.
 - a) Open a command-line shell.
 - b) Bind the `KUBECONFIG` environment variable to the saved configuration file.

NOTE

This example is based on a Linux environment.

```
export KUBECONFIG=/file/path/fileName
```

- c) To validate that the services are running, run the `kubectl cluster-info` command.
- d) To finish configuring the debug mode, perform the following Kubernetes API request.

NOTE

The value of the `localhost_debug_port` variable is the port set in your remote debugging configuration of your Integrated Development Environment (IDE). The value of the `vro_debug_port` variable is generated during step 3 of this procedure.

```
kubectl port-forward pod/vco_app_pod_ID localhost_debug_port:vro_debug_port
```

IMPORTANT

When configuring your debugging tool, provide the DNS and IP settings of the local machine where you performed the port forward command.

You have configured server debugging for your Automation Orchestrator Appliance.

Resize the Automation Orchestrator Appliance Disks

You can modify the disk size of the Automation Orchestrator Appliance by editing the disk size settings of the Automation Orchestrator Appliance virtual machine in vSphere.

Verify that the Automation Orchestrator Appliance SSH service is enabled. See [Activate or Deactivate SSH Access to the .](#)

1. Verify the currently available disk space in the Automation Orchestrator Appliance.

NOTE

The Automation Orchestrator Appliance disks need at least 20 percent free disk space.

- a) Log in to the Automation Orchestrator Appliance command line over SSH as **root**.
b) Run the **vracli disk-mgr** command.
2. Resize the disk of the Automation Orchestrator Appliance virtual machine in vSphere.
 - a) Log in to the vSphere Web Client as an **administrator**.
 - b) Right-click on the virtual machine and select **Edit Settings**.
 - c) On the **Virtual Hardware** tab, expand **Hard disk** to view and change the disk settings, and click **OK**.

For more information on changing the disk size of vSphere virtual machines, see [Change the Virtual Disk Configuration in vSphere Virtual Machine Administration](#).

3. Trigger the automatic resize in the Photon OS.

- a) Log in to the Automation Orchestrator Appliance command line over SSH as **root**.
b) Run the **vracli disk-mgr resize** command.

NOTE

You can track the progress of the disk resize procedure at `/var/log/vmware/prelude/disk_resize.log`.

You have resized the Automation Orchestrator Appliance disks.

4. Verify that the success of the disk resize procedure by running the **disk-mgr** command.

```
vracli disk-mgr
```

To troubleshoot problems with the disk resize procedure, see [KB 79925](#).

How to Scale the Heap Memory Size of the VMware Aria Automation Orchestrator Server

You can scale the heap memory size of the VMware Aria Automation Orchestrator server by creating a custom profile and modifying the resource metrics file.

- Scaling the heap memory of the Automation Orchestrator Appliance is only applicable for standalone VMware Aria Automation Orchestrator instances and is not supported for embedded VMware Aria Automation Orchestrator instances in VMware Aria Automation.

NOTE

To modify the heap memory of an embedded VMware Aria Automation Orchestrator instance, you must increase the VMware Aria Automation profile size through the VMware Aria Suite Lifecycle. For information on supported VMware Aria Automation profiles, see [System Requirements](#).

- Enable SSH access to the Automation Orchestrator Appliance. See [Activate or Deactivate SSH Access to the](#).
- Increase the RAM of the virtual machine on which VMware Aria Automation Orchestrator is deployed up to the next suitable increment. Because it is important that enough memory is left available for the rest of the services, the Automation Orchestrator Appliance resources must be scaled up first. For example, If the desired heap memory is 7G then the Automation Orchestrator Appliance RAM should be increased with 4G respectively because the subtraction between the default heap value of 3G and the desired heap memory is 4G. For information on increasing the RAM of a virtual machine in vSphere, see *Change the Memory Configuration in vSphere Virtual Machine Administration*.

You can adjust the heap memory size of the VMware Aria Automation Orchestrator server, so your orchestration environment can manage changing workloads. For example, you can increase the heap memory of your VMware Aria Automation Orchestrator deployment if you are planning to manage multiple vCenter instances.

- Log in the Automation Orchestrator Appliance command line over SSH as **root**.
- To create the custom profile directory and the required directory tree that is used when the profile is active, run the following script:

```
vracli cluster exec -- bash -c 'base64 -d <<<
IyBDcmVhdGUgY3VzdG9tIHByb2ZpbGUgZGlyZWN0b3J5Cm1rZGlyIC1wIC91dGMvdm13YXJ1LXByZWx1ZGUvcHJvZmlsZXMyY3VzdG9tLXByb2ZpbGUvCgojIENyZWF0ZSB0aGUgcmVxdWlyZWQgZGlyZWN0b3J5IHRyZWUgdGhhCB3aWxsIGJ1IHVzZWQgd2h1biB0aGUgcHJvZmlsZSBpcyBhY3RpdmUKbWtkaXIgLXAgL2V0Yy92bXdhcmUtcHJ1bHVkZS9wcm9maWx1cy9jdXN0b20tcHJvZmlsZS9oZWxtL3ByZWx1ZGVfdmNvLwoKIyBDcmVhdGUgImNoZWNrIiBmaWx1IHRoYXQgaXMgYW4gZXh1Y3V0YWJsZSBmaWx1IHJ1biBieSBkZXBs3kgc2NyaXB0LgpjYXQgPDXFT0YgPiAvZXRjL3Ztd2FyZS1wcmVsdWRlL3Byb2ZpbGVzL2N1c3RvbS1wcm9maWx1L2NoZWNrCiMhL2Jpbi9iYXNoCmV4aXQgMApFT0YKY2htb2QgNzU1IC91dGMvdm13YXJ1LXByZWx1ZGUvcHJvZmlsZXMvY3VzdG9tLXByb2ZpbGUvY2h1Y2sKCiMgQ29weSB2Uk8gcmVzb3VyY2UgbWV0cm1jcyBmaWx1IHRvIH1vdXIgY3VzdG9tIHByb2ZpbGUKY2F0IDw8RU9GID4gL2V0Yy92bXdhcmUtcHJ1bHVkZS9wcm9maWx1cy9jdXN0b20tcHJvZmlsZS9oZWxtL3ByZWx1ZGVfdmNvLzkWlxJ1c291cmN1cy55Yw1sCnBvbHlnbG90UnVubmVytWVtb3J5TG1taXQ6IDYwMDBNcnBvbHlnbG90UnVubmVytWVtb3J5UmVxdWVzdD0gMTAwME0KcG9seWdsb3RSdW5uZXJNZW1vcn1MaW1pdFZjbzogNTYwME0KcnN1cnZ1ck1lbW9yeUxpBw100iA2RwpzZXJ2ZXJNZW1vcn1sZXF1ZXN0Oia1RwpzZXJ2ZXJKdm1IZWFwTWF4Oia0RwoKY29udHJvbENlbnR1ck1lbW9yeUxpBw100iAxLjVHCmNvbnRyb2xDZw50ZXJNZW1vcn1sZXF1ZXN0Oia3MDBtCkVPRgpjaG1vZCA2NDQgL2V0Yy92bXdhcmUtcHJ1bHVkZS9wcm9maWx1cy9jdXN0b20tcHJvZmlsZS9oZWxtL3ByZWx1ZGVfdmNvLzkWlxJ1c291cmN1cy55Yw1sCg== | bash'
```

- Edit the resource metrics file in your custom profile with the desired memory values.

```
vi /etc/vmware-prelude/profiles/custom-profile/helm/prelude_vco/90-resources.yaml
```

- The 90-resources.yaml file should contain the following default properties:

```
polyglotRunnerMemoryRequest: 1000M
polyglotRunnerMemoryLimit: 6000M
polyglotRunnerMemoryLimitVco: 5600M

serverMemoryLimit: 7G
serverMemoryRequest: 5G
```

```

serverJvmHeapMax: 4G
serverJvmMetaspaceMax: 1G

controlCenterMemoryLimit: 1.5G
controlCenterMemoryRequest: 700m

```

Property Type	Description
Polyglot properties	<p>Memory properties associated with the Polyglot scripting feature. The value of these properties is set in megabytes (M). When editing these values, remember that on average a container needs 64M of memory. With the default memory limit of 6000M, you can run approximately 100 Polyglot scripts in parallel. If you want to increase the number of Polyglot scripts that can run in parallel, you need to increase the values of the <code>polyglotRunnerMemoryLimit</code> and <code>polyglotRunnerMemoryLimitVco</code> properties.</p> <p>First, edit the memory limit of the <code>polyglotRunnerMemoryLimit</code> property and then change the value of <code>polyglotRunnerMemoryLimitVco</code> to be 300M less than the value you set in the <code>polyglotRunnerMemoryLimit</code> property.</p> <p>The following is an example polyglot memory limit configuration:</p> <pre> polyglotRunnerMemoryRequest: 1000M polyglotRunnerMemoryLimit: 7000M polyglotRunnerMemoryLimitVco: 6700M </pre>
Server memory properties	<p>The memory properties of the VMware Aria Automation Orchestrator server. The value of these properties is set in gigabytes (G). First, edit the <code>serverJvmHeapMax</code> property with the desired memory value. The values of the <code>serverMemoryLimit</code> and <code>serverMemoryRequest</code> properties must be adjusted by adding 3G for <code>serverMemoryLimit</code> and 1G for <code>serverMemoryRequest</code> on top of the memory value selected for the <code>serverJvmHeapMax</code> property. The following is an example server memory configuration:</p>

Table continued on next page

Continued from previous page

Property Type	Description
	serverMemoryLimit: 10G serverMemoryRequest: 8G serverJvmHeapMax: 7G serverJvmMetaspaceMax: 1G
Control Center memory properties	The memory properties of the VMware Aria Automation Orchestrator Control Center. The values of these memory properties must not be updated.

- Save the changes to the resource metrics file and run the `deploy.sh` script.

```
/opt/scripts/deploy.sh
```

You have changed the heap memory size of your VMware Aria Automation Orchestrator server.

Disaster Recovery of VMware Aria Automation Orchestrator by Using Site Recovery Manager

You must configure Site Recovery Manager to protect your VMware Aria Automation Orchestrator. Secure this protection by completing the common configuration tasks for Site Recovery Manager.

Prepare the Environment

You must ensure that you meet the following prerequisites before you start configuring Site Recovery Manager.

- Verify that vSphere 6.0 or later is installed on the protected and recovery sites.
- Verify that you are using Site Recovery Manager 8.1 or later.
- Verify that VMware Aria Automation Orchestrator is configured.

Configure Virtual Machines for vSphere Replication

You must configure the virtual machines for vSphere Replication or array based replication in order to use Site Recovery Manager.

To enable vSphere Replication on the required virtual machines, perform the following steps.

- In the vSphere Web Client, select a virtual machine on which vSphere Replication should be enabled and click **Actions > All vSphere Replication Actions > Configure Replication**.
- In the **Replication type** window, select **Replicate to a vCenter Server** and click **Next**.
- In the **Target site** window, select the vCenter for the recovery site and click **Next**.
- In the **Replication server** window, select a vSphere Replication server and click **Next**.
- In the **Target location** window, click **Edit** and select the target datastore, where the replicated files will be stored and click **Next**.
- In the **Replication options** window, keep the default setting and click **Next**.
- In the **Recovery settings** window, enter time for **Recovery Point Objective (RPO)** and **Point in time instances**, and click **Next**.
- In the **Ready to complete** window, verify the settings and click **Finish**.
- Repeat these steps for all virtual machines on which vSphere Replication must be enabled.

Create Protection Groups

You create protection groups to enable Site Recovery Manager to protect your virtual machines.

Verify that you performed one of the following tasks:

- Included virtual machines in datastores for which you configured array-based replication.
- Satisfied the requirements in *Prerequisites for Storage Policy Protection Groups* and reviewed the *Limitations of Storage Policy Protection Groups in the Site Recovery Manager Administration guide*.
- Configured vSphere Replication on your virtual machines.
- Performed a combination of some or all the above.

You can organize protection groups in folders. The **Protection Groups** tab displays the names of the protection groups, but does not display in which folder they are placed. If you have two protection groups with the same name in different folders, it might be difficult to tell them apart. Therefore, ensure that protection group names are unique across all folders. In environments in which not all users have view privileges for all folders, to be sure of the uniqueness of protection group names, do not place protection groups in folders.

When you create protection groups, wait to ensure that the operations finish as expected. Make sure that Site Recovery Manager creates the protection group and that the protection of the virtual machines in the group is successful.

- In the vSphere Client or vSphere Web Client, click **Site Recovery > Open Site Recovery**.
- On the Site Recovery home tab, select a site pair and click **View Details**.
- Select the **Protection Groups** tab, and click **New** to create a protection group.
- On the Name and direction page, enter a name and description for the protection group, select a direction, and click **Next**.
- On the Protection group type page, select the protection group type, and click **Next**.

Option	Action
Create an array-based replication protection group	Select Datastore groups (array-based replication) and select an array pair.
Create vSphere Replication protection group	Select Individual VMs (vSphere Replication) .
Create a storage policy protection group	Select Storage Policies (array-based replication) .

- Select datastore groups, virtual machines, or storage policies to add to the protection group.

Option	Action
Array-based replication protection groups	Select datastore groups and click Next . When you select a datastore group, the virtual machines that the group contains appear in the Virtual machines table.
vSphere Replication protection groups	Select virtual machines from the list, and click Next . Only virtual machines that you configured for vSphere Replication and that are not already in a protection group appear in the list.
Storage policy protection groups	Select storage policies from the list, and click Next .

- On the Recovery plan page, you can optionally add the protection group to a recovery plan.

Option	Action
Add to existing recovery plan	Adds the protection group to an existing recovery plan.
Add to new recovery plan	Adds the protection group to a new recovery plan. If you select this option, you must enter a recovery plan name.

Table continued on next page

Continued from previous page

Option	Action
Do not add to recovery plan now.	Select this option if you do not want to add the protection group to a recovery plan.

8. Review your settings and click **Finish**.

You can monitor the progress of the creation of the protection group on the **Protection Group** tab.

- For array-based replication and vSphere Replication protection groups, if Site Recovery Manager successfully applied inventory mappings to the protected virtual machines, the protection status of the protection group is *OK*.
- For storage policy protection groups, if Site Recovery Manager successfully protected all the virtual machines associated with the storage policy, the protection status of the protection group is *OK*.
- For array-based replication and vSphere Replication protection groups, if you did not configure inventory mappings, or if the Site Recovery Manager was unable to apply them, the protection status of the protection group is *Not Configured*.
- For storage policy protection groups, if Site Recovery Manager cannot protect all the virtual machines associated with the storage policy, the protection status of the protection group is *Not Configured*.

For array-based replication and vSphere Replication protection groups, if the protection status of the protection groups is *Not Configured*, apply inventory mappings to the virtual machines:

- To apply site-wide inventory mappings, or to check that inventory mappings that you have already set are valid, see *Configure Inventory Mappings* in the *Site Recovery Manager Administration guide*. To apply these mappings to all the virtual machines, see *Apply Inventory Mappings to All Members of a Protection Group* in the *Site Recovery Manager Administration guide*.
- To apply inventory mappings to each virtual machine in the protection group individually, see *Configure Inventory Mappings for an Individual Virtual Machine in a Protection Group* in the *Site Recovery Manager Administration guide*.

For storage policy protection groups, if the protection status of the protection group is *Not Configured*, verify that you have satisfied the requirements in *Prerequisites for Storage Policy Protection Groups* and reviewed the *Limitations of Storage Policy Protection Groups* in the *Site Recovery Manager Administration guide*.

Create a Recovery Plan

You create a recovery plan to establish how Site Recovery Manager recovers virtual machines.

- In the vSphere Client or the vSphere Web Client, click **Site Recovery** > **Open Site Recovery**.
- On the Site Recovery home tab, select a site pair, and click **View Details**.
- Select the **Recovery Plans** tab, and click **New** to create a recovery plan.
- Enter a name, description, and direction for the plan, select a folder, and click **Next**.
- Select the group type from the menu.

Option	Description
Protection groups for individual VMs or datastore groups	Select this option to create a recovery plan that contains array-based replication and vSphere Replication protection groups.
Storage policy protection groups	Select this option to create a recovery plan that contains storage policy protection groups. If you are using stretched storage, select this option.

- Select one or more protection groups for the plan to recover, and click **Next**.

7. From the **Test Network** drop-down menu, select a network to use during test recovery, and click **Next**.
If there are no site-level mappings, the default option **Use site-level mapping** creates an isolated test network.
8. Review the summary information and click **Finish** to create the recovery plan.

Organize Recovery Plans in Folders

To control the access of different users or groups to recovery plans, you can organize your recovery plans in folders.

Organizing recovery plans into folders is useful if you have many recovery plans. You can limit the access to recovery plans by placing them in folders and assigning different permissions to the folders for different users or groups. For information about how to assign permissions to folders, see *Assign Site Recovery Manager Roles and Permissions* in the *Site Recovery Manager Administration* guide.

1. On the **Site Recovery** home tab, select a site pair, and click **View Details**.
2. Click the **Recovery Plans** tab, and in the left pane right-click **Recovery Plans** and click **New Folder**.
3. Enter a name for the folder to create, and click **Add**.
4. Add new or existing recovery plans to the folder.

Option	Description
Create a new recovery plan	Right-click the folder and select New Recovery Plan .
Add an existing recovery plan	Right-click a recovery plan from the inventory tree and click Move . Select a target folder and click Move .

Edit a Recovery Plan

You can edit a recovery plan to change the properties that you specified when you created it. You can edit recovery plans from the protected site or from the recovery site.

1. In the vSphere Client, click **Site Recovery** > **Open Site Recovery**.
2. On the **Site Recovery** home tab, select a site pair, and click **View Details**.
3. Click the **Recovery Plans** tab, right-click a recovery plan, and click **Edit**.
4. Change the name or description of the plan, and click **Next**.

You cannot change the direction and the location of the recovery plan.

5. Select or deselect one or more protection groups to add them to or remove them from the plan, and click **Next**.
6. From the drop-down menu select a different test network on the recovery site, and click **Next**.
7. Review the summary information and click **Finish** to make the specified changes to the recovery plan.

You can monitor the update of the plan in the **Recent Tasks** view.

Setting System Properties

You can set system properties to change the default Orchestrator behavior.

Setting Server File System Access for Workflows and Actions

In VMware Aria Automation Orchestrator, the workflows and actions have limited access to specific file system directories. You can extend access to other parts of the server file system by modifying the `js-io-rights.conf` configuration file.

Rules in the js-io-rights.conf File Permitting Write Access to the VMware Aria Automation Orchestrator System

The `js-io-rights.conf` file contains rules that permit write access to defined directories in the server file system.

Mandatory Content of the js-io-rights.conf File

Each line of the `js-io-rights.conf` file must contain the following information.

- A plus (+) or minus (-) sign to indicate whether rights are permitted or denied
- The read (r), write (w), and run (x) levels of rights
- The path on which to apply the rights.

NOTE

The `js-io-rights.conf` file is located in the `/data/vco/usr/lib/vco/app-server/conf/` folder.

All content with access to the VMware Aria Automation Orchestrator file system must be mapped under this root folder.

Default Content of the js-io-rights.conf File

The default content of the `js-io-rights.conf` configuration file in the Orchestrator Appliance is as follows:

```
-rwx /
+rwx /var/run/vco
+rx /etc/vco
-rwx /etc/vco/app-server/security/
+rx /var/log/vco/
```

The first two lines in the default `js-io-rights.conf` configuration file allow the following access rights:

```
-rwx /
All access to the file system is denied.

+rwx /var/run/vco
Read, write, and run access is permitted in the /var/run/vco directory.
```

Rules in the js-io-rights.conf File

VMware Aria Automation Orchestrator resolves access rights in the order they appear in the `js-io-rights.conf` file. Each line can override the previous lines.

IMPORTANT

You can permit access to all parts of the file system by setting `+rwx /` in the `js-io-rights.conf` file. However, doing so represents a high security risk.

Set Server File System Access for Workflows and Actions

To change which parts of the server file system that workflows and the VMware Aria Automation Orchestrator API can access, modify the `js-io-rights.conf` configuration file. The `js-io-rights.conf` file is created when a workflow attempts to access the VMware Aria Automation Orchestrator server file system.

1. Log in to the Automation Orchestrator Appliance command line as **root**.
2. Navigate to the `/data/vco/usr/lib/vco/app-server/conf` directory.

3. Open the `js-io-rights.conf` configuration file in a text editor.
4. Add the necessary lines to the `js-io-rights.conf` file to allow or deny access to areas of the file system.
For example, the following line denies the execution rights in the `/data/vco/var/run/vco/noexec` directory:
`-x /data/vco/var/run/vco/noexec`
`/data/vco/var/run/vco/noexec` retains execution rights, but `/data/vco/var/run/vco/noexec/bar` does not. Both directories remain readable and writable.

You modified the access rights to the file system for workflows and for the VMware Aria Automation Orchestrator API.

Set JavaScript Access to Java Classes

By default, VMware Aria Automation Orchestrator restricts JavaScript access to a limited set of Java classes. If you require JavaScript access to a wider range of Java classes, you must set an VMware Aria Automation Orchestrator system property.

Allowing the JavaScript engine full access to the Java virtual machine (JVM) presents potential security issues. Malformed or malicious scripts might have access to all the system components to which the user who runs the VMware Aria Automation Orchestrator server has access. Therefore, by default the VMware Aria Automation Orchestrator JavaScript engine can access only the classes in the `java.util.*` package.

If you require JavaScript access to classes outside of the `java.util.*` package, you can list in a configuration file the Java packages to which to allow JavaScript access. You then set the `com.vmware.scripting.rhino-class-shutter-file` system property to point to this file.

1. Create a text configuration file to store the list of Java packages to which to allow JavaScript access.
For example, to allow JavaScript access to all the classes in the `java.net` package and to the `java.lang.Object` class, you add the following content to the file.
`java.net.*`
`java.lang.Object`
2. Enter a name for the configuration file.
3. Save the configuration file in a subdirectory of `/data/vco/usr/lib/vco`.

NOTE

The configuration file cannot be saved under another directory.

4. Log in to Control Center as `root`.
5. Click **System Properties**.
6. Click **New**.
7. In the **Key** text box, enter `com.vmware.scripting.rhino-class-shutter-file`.
8. In the **Value** text box, enter `/usr/lib/vco/your_configuration_file_subdirectory`.
9. In the **Description** text box, enter a description for the system property.
10. Click **Add**.
11. Click **Save changes** from the pop-up menu.
A message indicates that you have saved successfully.
12. Wait for the VMware Aria Automation Orchestrator server to restart.

The JavaScript engine has access to the Java classes that you specified.

Set Custom Timeout Property

When vCenter is overloaded, it takes more time to return the response to the VMware Aria Automation Orchestrator server than the 20000 milliseconds set by default. To prevent this situation, you must modify the VMware Aria Automation Orchestrator configuration file to increase the default timeout period.

If the default timeout period expires before the completion of certain operations, the VMware Aria Automation Orchestrator server log contains errors.

```
Operation 'getPropertyContent' total time : '5742228' for 1823 calls, mean time : '3149.0', min time : '0', max time : '32313'Timeout, unable to get property 'info'  
com.vmware.vmo.plugin.vi4.model.TimeoutException
```

1. Log in to Control Center as **root**.
2. Click **System Properties**.
3. Click **New**.
4. In the **Key** text box enter `com.vmware.vmo.plugin.vi4.waitUpdatesTimeout`.
5. In the **Value** text box enter the new timeout period in milliseconds.
6. In the **Description** text box enter a description for the system property.
7. Click **Add** and wait for the VMware Aria Automation Orchestrator server to restart.

The value you set overrides the default timeout setting of 20000 milliseconds.

Adding a JDBC connector for the VMware Aria Automation Orchestrator SQL plug-in

This example demonstrates how you can add a MySQL connector for the VMware Aria Automation Orchestrator SQL plug-in.

The VMware Aria Automation Orchestrator SQL plug-in supports only certain database database types. Before adding a MySQL connector, verify that your are using one of the following database types:

- Oracle
- Microsoft SQL Server
- PostgreSQL
- MySQL

1. Add the MySQL connector.jar file to the VMware Aria Automation Orchestrator Appliance.

NOTE

For clustered VMware Aria Automation Orchestrator deployments, perform this operation on the appliances of all the nodes.

- a) Log in to the VMware Aria Automation Orchestrator Appliance command line over SSH as **root**.

- b) Navigate to the `/data/vco/var/run/vco` directory.

```
cd /data/vco/var/run/vco
```

- c) Create a `plugins/SQL/lib/` directory.

```
mkdir -p plugins/SQL/lib/
```

- d) Copy your MySQL connector.jar file from your local machine to the `/data/vco/var/run/vco/plugins/SQL/lib/` directory by running a secure copy (SCP) command.

```
scp ~/local_machine_dir/your_mysql_connector.jar root@orchestrator_FQDN_or_IP:/  
data/vco/var/run/vco/plugins/SQL/lib/
```

NOTE

You can also use alternative methods for copying your connector.jar file to the VMware Aria Automation Orchestrator Appliance, such as PSCP.

2. Add the new MySQL property to the Control Center.

- a) Log in to the Control Center as **root**.
- b) Select **System Properties**.
- c) Click **New**.
- d) Under **Key**, enter `o1ln.plugin.SQL.classpath`.
- e) Under **Value**, enter `/var/run/vco/plugins/SQL/lib/your_mysql_connector.jar`.

NOTE

The value text box can include multiple JDBC connectors. Each JDBC connector is separated by a semicolon (";"). For example:

```
/var/run/vco/plugins/SQL/lib/your_mysql_connector.jar;/var/run/vco/  
plugins/SQL/lib/your_mssql_connector.jar;/var/run/vco/plugins/SQL/lib/  
your_other_connector.jar
```

- f) Enter a description for the MySQL system property.
- g) Click **Add**, and wait for the VMware Aria Automation Orchestrator server to restart.

NOTE

Do not save your JDBC connector.jar file in another directory and do not set a different value to the `o1ln.plugin.SQL.classpath` property. Otherwise, the JDBC connector becomes unavailable to your VMware Aria Automation Orchestrator deployment.

Activating basic authentication

You can activate basic authentication for your VMware Aria Automation Orchestrator deployment by setting a system property.

The basic authentication of your VMware Aria Automation Orchestrator deployment is deactivated by default. In certain use cases you must activate this authentication by setting the `com.vmware.o1ln.sso.basic-authentication.enabled` system property. For example, you must activate this system property if you are planning on using the VMware Aria Automation Orchestrator Multi-Node plug-in for deployments which are authenticated with VMware Aria Automation.

1. Log in to the Control Center as **root**.
2. Select **System Properties**.
3. Click **New**.
4. Under **Key**, enter `com.vmware.o1ln.sso.basic-authentication.enabled`.
5. Under **Value**, enter `true`.
6. Enter a description for the new system property.
7. Click **Add**, and wait for the VMware Aria Automation Orchestrator server to restart.

Where to go from here

When you have installed and configured Automation Orchestrator, you can use Automation Orchestrator to automate frequently repeated processes related to the management of the virtual environment.

- Log in to the Automation Orchestrator Client, run, and schedule workflows on the vCenter inventory objects or other objects that Automation Orchestrator accesses through its plug-ins. See [Using Automation Orchestrator](#).
- Duplicate and modify the standard VMware Aria Automation Orchestrator workflows and write your own actions and workflows to automate operations in vCenter.
- To extend the functionality of the VMware Aria Automation Orchestrator platform, develop plug-ins.
- Manage your VMware Aria Automation Orchestrator inventory across multiple VMware Aria Automation Orchestrator instances with the integration of a remote Git repository. See [Using Automation Orchestrator](#).
- Run workflows on your vSphere inventory objects by using the vSphere Web Client.

VMware Aria Automation Transition Guide

You can use this transition guide to help you migrate your vRealize Automation 7 environment to VMware Aria Automation 8.

Currently, the VMware Aria Automation 8 Migration Assistant tool only supports migration from 7.6 source environments. However, you can run a migration assessment for these source environments:

- vRealize Automation 7.6
- vRealize Automation 7.5
- vRealize Automation 7.4
- vRealize Automation 7.3

Restrictions: The VMware Aria Automation 8 migration assistant does not support:

- Migration with an external Automation Orchestrator instance. The migration assistant only supports embedded Automation Orchestrator migrations.

For information about migrating vRealize Automation 7.x extensibility to VMware Aria Automation 8, see the [Aria Automation 8.x Extensibility Migration Guide](#).

- Migration of VMware Aria Operations integrations. You must manually migrate your VMware Aria Operations integrations to VMware Aria Automation 8.

How can I migrate to VMware Aria Automation 8.x

Depending on your circumstances, you can migrate to VMware Aria Automation 8 using the Migration Assistant or by using the onboarding feature.

Migrating to VMware Aria Automation 8 using the Migration Assistant

For most circumstances, the Migration Assistant provides ample support for migrating from vRealize Automation 7.x to VMware Aria Automation 8. However, for some customers migration using onboarding is recommended. For onboarding use cases see Migrating to VMware Aria Automation using the onboarding feature in the section below. Migrating using the Migration Assistant is recommended for:

- **Networking**
 - The migration assistant has advanced capabilities for identifying deployment constructs, specifically for networking. The migration assistant supports the migration of: all network objects in all clouds, IP management with native IPAM, load balancers, and security groups. Onboarding does not support this functionality.
- **VCT assignment to workloads**
 - The migration assistant can assign the blueprints to the workloads being migrated. The workloads are compatible with the VCT in VMware Aria Automation 8. Onboarding does not support this functionality.
- **Custom properties and property groups (limited) are automatically recognized**
 - The migration assistant automatically recognizes any custom properties or property groups used in blueprints and workloads and applies them to the workloads in VMware Aria Automation 8 to maintain the functionality and expected behavior of the custom properties.
- **Capabilities of migration assistant that are not present in onboarding**
 - The Migration Assistant includes many capabilities that onboarding does not. For example, support for migrating deployment history, retaining deployment metadata (such as names, descriptions, lease expirations, and ownership), migrating custom resources, migrating custom forms, lease policy compatibility, retaining the vRA 7.x consumption model, etc.
- **Cloudzone mapping and compatibility with limits**
 - When workloads are migrated using the Migration Assistant they are automatically placed in the right cloudzone. They are also compliant with the limits specified as the project-cloudzone assignment.
- **Scale out support**
 - In VMware Aria Automation 8, there are no day 2 actions for scale out of machines. To overcome this, VMware Aria Automation uses iterative deployments where the VCT parameters are changed and then re-applied to the provisioned deployment to scale it out. Onboarding does not support this functionality.

Migrating to VMware Aria Automation using the onboarding feature

As an alternative to using the Migration Assistant, you can use the onboarding feature to migrate certain vRealize Automation 7.x workloads to 8.x. Migration using Onboarding is limited to machine and connected objects (disks and networks) only. Onboarding also allows you onboard one or many machines to Automation Assembler using a single onboarding plan. Migrating using the onboarding feature is recommended for:

- **Side by side VCF migration**
 - Onboarding is recommended, if you want to migrate VCF 3.x to 4.x alongside migrating vRealize Automation 7.x to 8.x. To migrate, set up a separate VCF 4 stack and migrate workloads with HCX. After, you can onboard these workloads to the new VMware Aria Automation 8 instance that is deployed in the VCF 4 stack.
- **vRealize Automation changes in deployment structure**
 - Onboarding is recommended if you want to change how VMware Aria Automation is consumed in 8.x compared to 7.x. For example, if you want to consolidate business groups into fewer projects, reconstruct blueprints, ignore any non-relevant content present in 7.x, update existing processes to new methods, etc.
- **Make changes to deployments such as update name or add custom properties**

NOTE

Workload onboarding does not connect to vRealize Automation 7.x and does not have access to vRA 7 constructs and metadata such as blueprints and custom properties. It only operates on inventory discovered by VMware Aria Automation 8.

- Onboarding is recommended if you want to make changes to your deployment metadata such as renaming it or adding additional custom properties.
- **Require changes in production vRealize Automation 7.x**
 - Onboarding is recommended if you do not want to make any changes to your 7.x environment in production to address incompatibilities reported by the migration assistant. For example, if you are unable to unpublish content you no longer use, if you make changes in blueprints, update vRO workflows, update entitlements, update custom day 2 actions, etc.
- **Migrate from vRealize Automation 7.x to VMware Aria Automation Cloud**
 - Onboarding is recommended if you want to migrate your vRA 7.x on-prem environment to VMware Aria Automation Cloud. Currently, the Migration Assistant does not support this migration path use case.

For additional information on bulk VMware Aria Automation 8 onboarding, see [VMware Aria Automation 8 bulk onboarding](#).

For more information on onboarding, see [What are onboarding plans](#).

How do I upgrade to VMware Aria Automation 8.x

Using VMware Aria Suite Lifecycle, you can upgrade your VMware Aria Automation 8.x instance to the latest VMware Aria Automation 8.x version.

For information on upgrading VMware Aria Automation 8.x, see [Upgrading Aria Suite Lifecycle and Aria Suite Products](#).

Using the VMware Aria Automation 8 Migration Assistant to run a migration assessment

Before you can migrate to VMware Aria Automation 8, you need to perform a migration assessment.

You can perform a migration assessment against your source environment and any embedded VMware Aria Automation Orchestrator instances to determine the migration readiness of your vRealize Automation 7 source environment. The migration assessment alerts you to any system object and its dependencies that are not ready for migration and that will impact your migration process. See [Considerations about Aria Automation 8](#).

After performing a migration assessment you can then migrate to import content and configuration data from your current vRealize Automation 7 source environment to VMware Aria Automation 8.

Before you can run a migration assessment and migration, you must enable the migration assistant service.

To enable the migration assistant feature:

1. After upgrading and deploying a new VMware Aria Automation 8 instance, navigate to Identity and Access Management.
2. Select the user, edit the role to Cloud Administrator, and migration service administrator or viewer. Add the migration assessment service.
3. Log user out of VMware Aria Automation 8.
4. Log user in to VMware Aria Automation 8 to see the Migration Assessment tile.

Running a Migration Assessment on a source instance

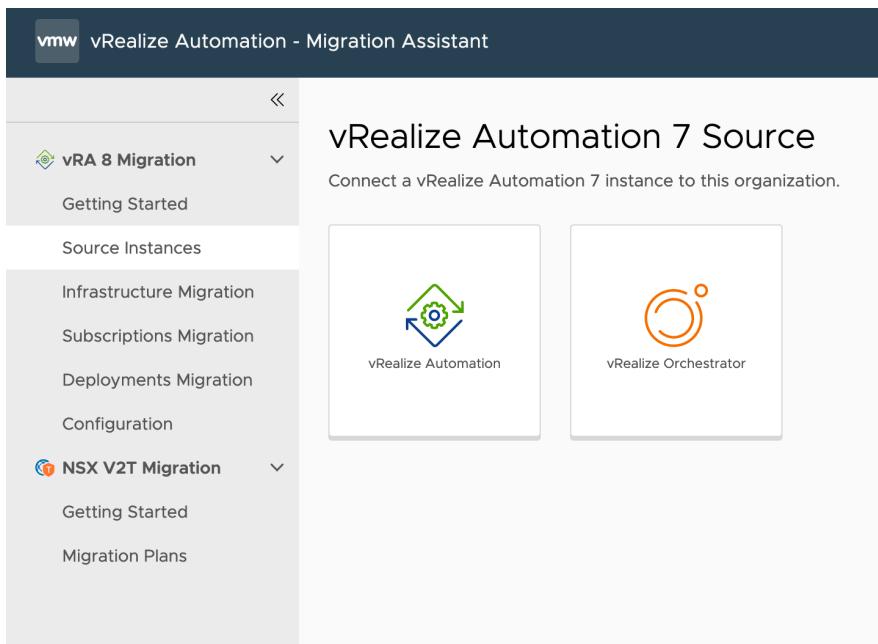

You can run a migration assessment against a single vRealize Automation 7, or vRealize Orchestrator source instance to determine migration readiness.

The screenshot shows the 'vRealize Automation - Migration Assistant' interface. On the left, there's a sidebar with sections like 'Getting Started', 'Source Instances', 'Infrastructure Migration', 'Subscriptions Migration', 'Deployments Migration', 'Configuration', and 'NSX V2T Migration'. The 'Source Instances' section is currently selected. The main content area displays the 'Getting Started with vRealize Automation 8 Migration Assistant' page. It includes three main steps: 1. Configure source instances, which describes connecting to vRealize Automation 7 and embedded vRealize Orchestrator instances; 2. Review Migration Assessment Results, which shows how to view results on Infrastructure, Subscriptions, and Deployments tabs; and 3. Migration, which details the process of incrementally migrating source environment to vRealize Automation 8. At the bottom, there's a 'NEXT: ADD A SOURCE INSTANCE' button.

The migration assessment process includes connecting to your vRealize Automation 7 source instances and assessing the vRealize Automation 7 and embedded vRealize Orchestrator instances.

The migration assessment identifies what objects to carry over and migrate. You can review the assessment results and correct items in your source environment that are not correctly set up or ready for migration.

1. From the Source Instance page, Click **Add a Source Account**.
2. Select a vRealize Automation or vRealize Orchestrator source type.

3. Enter the credentials of your vRealize Automation 7 or vRealize Orchestrator source environment.

NOTE

You must provide the vRealize Automation primary node's FQDN or an IP address for the source in the hostname text box. For example, test-n-88-087.test.vmware.com

4. Click **Validate and Save** to validate and identify all the tenants that are available for migration.

NOTE

You must provide the system administrator and password of your source environment to identify all available tenants.

5. In **Allow migrations from these tenants**, toggle and select which tenants you want to assess in VMware Aria Automation 8.

NOTE

To assess and migrate multi-tenant environments, you must manually create all tenants and run a migration from each tenant individually. All vRA 7 tenants are visible to VMware Aria Automation 8 tenants.

NOTE

When running a migration assessment on an embedded vRealize Orchestrator only, do not select any tenants.

6. (Optional) To run the migration on an embedded vRealize Orchestrator , select **Enabled Assessment for the embedded vRealize Orchestrator**.
7. Click **Save** to finish the migration assessment of the selected source tenants.

Your source environment is assessed for migration readiness. You can view the details of the source environment configuration on the source instances page. Additionally, you can export the assessment report to your local drive by clicking **Export** on the source instance's tile.

NOTE

Do not export reports containing more than 200 business groups. A report for an assessment larger than 200 business groups will be compiled from assessment service memory and will not contain business group details.

View Assessment Results

After running a migration assessment on your source instance, you can view the results.

The assessment results are itemized into tabs in the Migration pane:

- Infrastructure
- Subscriptions
- Deployments

The assessed items are listed with their status:

- Ready - Ready for migration. No action is needed for migration readiness.
- Ready with warnings - Ready but needs review. Remediate any issues that might impact migration. For example, some custom properties can be ready with warnings. The custom property: VMware.Network.Type is partially supported and is flagged as ready with warnings because it is unclear how this property behaves regarding extensibility in VMware Aria Automation 8.
- Not Ready - Not ready for migration. Review details of the item in your source environment and correct areas needing attention or deselect these items for migration. If you proceed with migration, items marked as Not Ready are excluded from migration.
- Assessing - Item is still being assessed for migration readiness.
- Assessment failed - The assessment failed, retry assessment.

If applicable, after modifying any items listed as not ready or ready with warnings, click **Update** to update its status in the assessment results table.

NOTE

If you make changes to your source environment, you must update and reassess the tenants in your source environment before migrating.

Considerations About VMware Aria Automation 8

VMware Aria Automation 8 introduces various functional changes.

Review the changes that VMware Aria Automation 8 introduces to get a better understanding of VMware Aria Automation 8.

Scalability Considerations

VMware Aria Automation 8 includes new scalability considerations.

Before proceeding with migration, review the [Scalability and Concurrency Maximums](#).

Using Legacy Extensibility

After migration, the extensibility functionality is hosted in the Automation Assembler service and managed by the Event Broker.

Depending on your source environment, you might need to modify existing workflows and action code to optimize extensibility in VMware Aria Automation 8. Modifications and new functionality include:

- Automation Orchestrator plugin support
- Postgres and Microsoft SQL server database access
- Rewriting workflow or action code for use with Automation Assembler
- Using subscriptions with Automation Assembler

For more information on extensibility changes between vRealize Automation 7.x and 8.x, refer to the [VMware Aria Automation 8.x Extensibility Migration Guide](#).

Automation Orchestrator Plugins

Several Automation Orchestrator plugins are not supported in VMware Aria Automation.

These plugins are no longer supported:

- VMware Aria Automation CAFE plugin
- VMware Aria Automation .NET plugin
- VMware Aria Automation REST Plugin

You must rewrite all custom content in Automation Orchestrator to use the new VMware Aria Automation 8 API interface. Implementations that rely on API calls to VMware Aria Automation using the REST plugin must be rewritten.

For information on writing workflows that require a reduced effort to refactor, see [Writing Workflow and Action Code for vRealize Automation](#).

Writing Workflows and Action Code for Automation Assembler

Using these best practices, you can write extensibility code and workflows to easily interact with Automation Assembler.

For more information on extensibility in Automation Assembler 8.x, see the [VMware Aria Automation 8.x Extensibility Migration Guide](#).

Use Payload from Event Broker

In Automation Assembler, when you subscribe to an event the event broker triggers a workflow and passes to it a payload. The payload should have all of the data that the workflow needs. If the workflow needs additional data, it is available by calling various VMware Aria Automation 8 service APIs.

Extensibility Actions

In Automation Assembler you can create customized actions, called Action-Based Extensibility (ABX), using Python, Node.js, and PowerShell scripts without dependency on Automation Orchestrator. For more information on ABX, see [Learn more about extensibility actions](#).

Using Subscriptions in Automation Assembler

After migration, use migrated VMware Aria Automation 7 extensibility in Automation Assembler with these subscriptions accordingly.

Not all subscriptions from vRealize Automation 7 can be migrated to VMware Aria Automation 8. To determine if a subscription can be migrated, review the assessment report.

Table 104: Subscriptions in vRealize Automation Cloud Assembly

vRealize Automation 7.x Subscription	VMware Aria Automation 8 Subscription
Blueprint component completed	Deployment resource completed
Blueprint component requested	Deployment resource requested
Blueprint configuration	Blueprint configuration
Blueprint request completed	Deployment completed
Blueprint requested	Deployment requested
Business group configuration	Not supported
Catalog request completed	Deployment completed
Catalog request received	Deployment requested
Component action completed	Deployment resource action completed
Component action requested	Deployment resource action requested
Deployment action completed	Deployment action completed (deployment.action.post)
Deployment action requested	Deployment action requested (deployment.action.pre)
Endpoint action	Not supported
EventLog default event	EventLog
Infrastructure endpoint test connection	Not supported
IPAM IP lifecycle event completion	Not supported
Machine lifecycle	Not supported
Machine provisioning	Conditional, dependent on state.
Orchestration server configuration	Not supported
Orchestration server configuration (XaaS)	Not supported
Post Approval	Not supported
Pre Approval	Not supported
Resource Reclamation completion event	Not supported

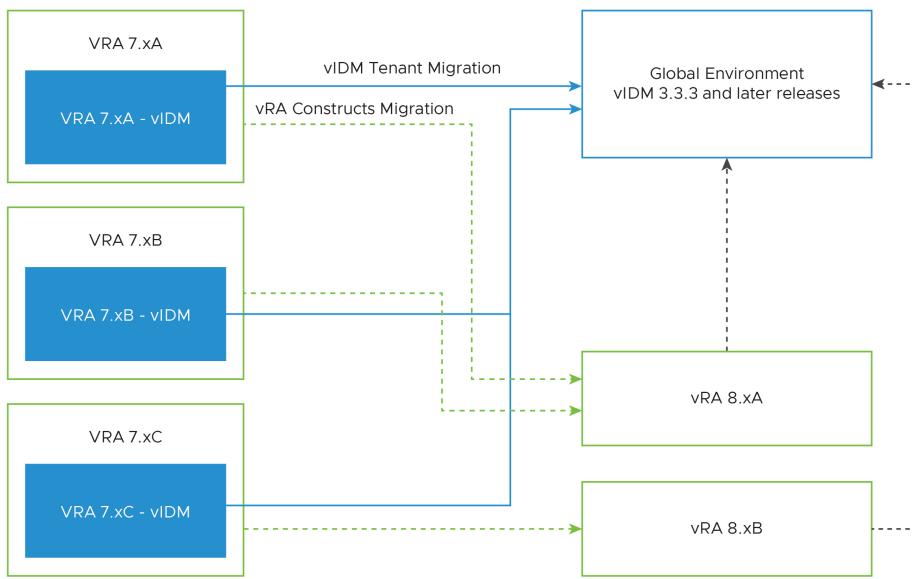

Migrating Tenants Using VMware Aria Suite Lifecycle

Depending on your system needs, you might need to migrate your source tenants using VMware Aria Suite Lifecycle before you can migrate to VMware Aria Automation 8.x.

Tenant Migration involves close coordination between Workspace ONE Access (formerly known as VMware Identity Manager), VMware Aria Suite Lifecycle, and VMware Aria Automation. When migrating tenants using VMware Aria Suite Lifecycle, embedded VMware Identity Manager data in vRealize Automation 7 is migrated to the Global Environment of VMware Identity Manager version 3.3.3 and later. After migrating tenants, you can perform the merge tenant operation in VMware Aria Automation, in which you migrate vRealize Automation 7 environment to VMware Aria Automation 8. For more information on adding, deleting, or managing your tenants, refer to the [Tenant Management](#) section of the VMware Aria Suite Lifecycle documentation. For a video walkthrough of migrating tenants using VMware Aria Suite Lifecycle, see [Aria 8.x -Tenant Migration](#).

NOTE

Tenant migration using VMware Aria Suite Lifecycle is not supported for vRealize Automation 7.4. Tenant migration is only supported for 7.5 and 7.6. To migrate tenants from vRealize Automation 7.4 to 8.x, you must migrate them manually. VMware Aria Automation 8.x does not support assessing and migrating a tenant from vRealize Automation 7.x to 2 or more organizations of the same VMware Aria Automation 8.x instance.

Prerequisites

Before you can migrate tenants, you must perform these prerequisites:

- Importing vRealize Automation 7.5 or 7.6
- Installing or upgrading to VMware Identity Manager 3.3.3
- Upgrading to Aria Automation
- Performing an inventory sync on vRealize Automation 7.x or VMware Aria Automation 8.x and Global Environment
- Enabling Multi-tenancy

Prerequisites for Tenant Migration

Before migrating tenants, review these prerequisites and important instructions for migrating and merging tenants.

- Import vRealize Automation 7.5/7.6
- Install or upgrade VMware Identity Manager
- Upgrade Aria Automation
- Perform an inventory sync on vRealize Automation 7 and 8 environments
- Enable Multi-Tenancy

Importing vRealize Automation 7.5/7.6

If you have an existing vRealize Automation 7.5 or 7.6 environment, you must import this environment to VMware Aria Suite Lifecycle, so that VMware Aria Suite Lifecycle can manage the VMware Aria Automation environment.

NOTE

For vRealize Automation 7.4 and earlier versions, upgrade to vRealize Automation 7.5 or 7.6, and then import this environment to VMware Aria Suite Lifecycle.

Installing or Upgrading to VMware Identity Manager 3.3.3

You can perform a new fresh installation of VMware Identity Manager or upgrade an existing instance, using VMware Aria Suite Lifecycle. You can also upgrade outside VMware Aria Suite Lifecycle, and then reimport by triggering the inventory sync in VMware Aria Suite Lifecycle.

For more information about the latest version of VMware Identity Manager and upgrade instructions, see the [VMware Identity Manager Release Notes](#), and then trigger an upgrade from VMware Aria Suite Lifecycle.

When upgrading VMware Identity Manager, using VMware Aria Suite Lifecycle:

- Verify that you have taken a snapshot of VMware Identity Manager nodes.
- Verify that you have your product binaries mapped.
- For a clustered VMware Identity Manager upgrade, ensure to disable all the stand-by nodes in the load-balancer so that the traffic is not routed to the stand-by nodes and enable them back once the upgrade is completed.

To complete the upgrade steps, refer to the [Upgrade VMware Identity Manager](#) section of the VMware Aria Suite Lifecycle documentation.

Upgrading to VMware Aria Automation 8

You can upgrade VMware Aria Automation in VMware Aria Suite Lifecycle, and then apply patch 1. When upgrading, follow these instructions.

- Ensure that you have upgraded VMware Aria Suite Lifecycle to the latest version.
- Ensure that you have upgraded VMware Identity Manager to 3.3.7.
- If you have installed vRealize Automation 8.0, 8.0.1, or 8.1, then upgrade it to the latest VMware Aria Automation 8.x version.
- Perform the binary mapping of the VMware Aria Automation patch file from Local, myvmware or NFS share. For more information on binary-mapping, see [Configure Product Binaries](#).
- Increase the CPU, memory, and storage as per the system requirements in [Hardware Requirements..](#)

For instructions on applying the VMware Aria Automation patch, see [Patching products by using VMware Aria Suite Lifecycle](#).

Performing an Inventory Sync on vRealize Automation 7 and 8 Environments, and Global Environment

If you configure your product outside of VMware Aria Suite Lifecycle, then the products managed from VMware Aria Suite Lifecycle are out of sync. To update the configuration, you have to trigger the inventory sync.

Performing an inventory sync is useful:

- If there is any failure, inventory sync updates the correct primary node in VMware Aria Suite Lifecycle.
- If any components of products are added or deleted outside of VMware Aria Suite Lifecycle, the inventory sync also updates them.
- If a product password is modified, even if you sync it with the inventory, the request eventually fails. In this scenario, retry with the correct password. To modify the password directly in the application, for example, in VMware Aria Automation, you must run the inventory sync of the product in VMware Aria Suite Lifecycle so that the modified passwords are synchronized. This action prompts you to provide the modified passwords during an inventory sync.

For all the products across all environments, follow these methods to sync your inventories.

- Click the horizontal ellipses on the product card and click **Trigger Inventory Sync**.
- If there are multiple environments and multiple products within an environment, click the **Trigger Inventory Sync** on the Environment page, which triggers the inventory sync on all the products across all environments.
- Click **View Details** of the product, and then click the **Trigger Inventory Sync**, which triggers the inventory sync for the required product.

Enabling Multi-Tenancy

For tenant migration, you can enable multi-tenancy.

When enabling multi-tenancy:

- Use VMware Identity Manager global environment versions 3.3.3 or later.

- Verify the inventories are synchronized for all the environments in VMware Aria Suite Lifecycle and all environments and products are up to date. This is to discover all the VMware Identity Manager-product integrations required for VMware Identity Manager re-register.
- Verify that the VMware Identity Manager global environment certificate is managed through the VMware Aria Suite Lifecycle Locker service.
- Take a snapshot of VMware Identity Manager. VMware Identity Manager must be accessed through tenant FQDNs and existing VMware Identity Manager URLs are not accessible.
- For a clustered VMware Identity Manager, verify VMware Identity Manager cluster health status is green by triggering cluster health. For more information, see the VMware Aria Suite Lifecycle documentation.
- Verify the VMware Identity Manager certificate is updated with the primary tenant alias FQDN. Also ensure that the A-type DNS record is added mapping the primary tenant alias FQDN.

How do I migrate tenants

VMware Aria Suite Lifecycle migrates VMware Identity Manager data for vRealize Automation 7.5, 7.6, 8.0 to Global Environment of VMware Identity Manager 3.3.3 and later.

- The SMTP information of the source tenant must be configured on the Global Environment of VMware Identity Manager. This information is required to receive email instructions to reset the password for all local users. All local users in the source tenant must have valid email IDs before migrating tenants.
- For migration, you must enable remote connection from the Global Environment of VMware Identity Manager to the vRealize Automation 7.x database. Refer to [KB 81219](#) for more information on enabling remote connection.
- Ensure that you have DNS configured in VMware Aria Automation and VMware Identity Manager. For more information on DNS and certificate requirements, refer to DNS and Certificate Requirement in the VMware Aria Suite Lifecycle documentation.
- Ensure that the source vRealize Automation 7.x environment is in a healthy state and directories are synced before tenant migration.

VMware Aria Suite Lifecycle migrates:

- Tenants
- Directories
- Custom groups
- Roles and rule set
- User attributes
- Access policies
- Network ranges
- Third-party IDP configurations

1. On the My Services dashboard of VMware Aria Suite Lifecycle, click **Identity and Tenant Management**.
2. Select **Tenant Management**, and then click **Tenant Migrations**.
3. Read the information on VMware Identity Manager Tenant Migration and VMware Aria Automation Tenant Mapping, and then click **Continue**.
4. On the Environment Selection tab, select the Source Environment and Target Environment. Based on your source and the target environment selection, you can view a tabular representation of the available tenants on the source vRealize Automation. You can also view the status of the migrated or merged tenants on VMware Aria Automation 8.x.
5. Click **Next**.
6. On the Tenant Migration Workflow page, you can view the workflow of Tenant Migration and Tenant Merge, and understand the correlation between the two operations.

In Tenant migration, the specific data of VMware Identity Manager is migrated to the destination tenant of Global Environment using VMware Aria Suite Lifecycle. VMware Aria Suite Lifecycle also creates 7.x endpoint when adding a new tenant on VMware Aria Automation 8.x. In Tenant Merge, the directories and tenants are already created on the source VMware Aria Automation 8.x. VMware Aria Suite Lifecycle creates the 7.x endpoint to the

existing tenants on VMware Aria Automation 8.x, so that you can migrate the business groups, infrastructure, and other specific tenants on VMware Aria Automation.

7. Click **SAVE AND NEXT** and read the list of manual steps which must be performed to proceed with the migration. Select the check box to confirm that you have read and verified the prerequisites and limitations.
8. To specify the Tenant Migration Workflow, enter these details on the **Tenant Details** tab.

1. Select the **Source Tenant**.

NOTE

The source tenants which are listed are not the migrated or merged tenants.

2. Enter the **Tenant Name**.
3. Under Target Tenant administrator details, enter the **Target Tenant Username, First Name, Last Name, valid Email ID, and Password**.
4. Click **SAVE AND NEXT**. To specify a directory that must be migrated from the source vRealize Automation 7.x to VMware Aria Automation 8.x tenant, select one of these directories on the Directory Migration tab.
 - System Directory: Connector selection and password creation are not required.
 - JIT directory: Connector selection and password creation are not required.
 - Active Directory over LDAP: Select a Windows or Linux target Connector and enter the BindPassword.
 - OpenLDAP: Select a Windows or Linux target Connector and enter the BindPassword.
 - Active Directory with IWA: You can only select a Windows target Connector for the VMware Identity Manager 3.3.3 version. Enter the Bind Password and Domain Admin Password that is required for migration.

NOTE

To migrate a directory is a one-time operation, select all the directories which must be migrated. If the required directories are not selected during migration, you have to perform this operation manually.

9. Click **Validate**. After a successful validation, click **SAVE AND NEXT**.
10. Click **Run Precheck** to validate the tenant details and certificate details. Click **SAVE AND NEXT**.
11. On the **Summary Step** tab, you can view the summary of your selections.
12. Click **SUBMIT** if your validations are successful.

If the validations are not successful and you want to make changes, and then resume the tenant migration operation, click **SAVE AND EXIT**. The same wizard can be opened anytime to rerun the precheck to complete and proceed.

You can view the tenant migration details under the Request Details page. Both VMware Identity Manager and VMware Aria Automation tenants can be accessed through its tenant FQDNs.

How do I merge tenants

Using VMware Aria Suite Lifecycle, you can merge tenants.

- VMware Aria Automation 8.1 does not require you to accept a source certificate during migration assessment. To merge or manage the tenant using VMware Aria Suite Lifecycle, you can delete the manually added source environment from VMware Aria Automation.
- Ensure that specific data of VMware Identity Manager is migrated to the target data in the Global Environment.

1. On the My Services dashboard of VMware Aria Suite Lifecycle, click **Identity and Tenant Management**.
2. Select **Tenant Management**, and then click **Tenant Migrations**.

3. Read the information on VMware Identity Manager Tenant Migration and VMware Aria Automation Tenant Mapping, and then click **Continue**.
4. On the Environment Selection tab, select the Source Environment and Target Environment.

Based on your source and the target environment selection, you can view a tabular representation of the available tenants on the source vRealize Automation. You can also view the status of the migrated or merged tenants on VMware Aria Automation 8.x.

5. Click **Next** on the Tenant Migration Workflow page. You can view the workflow of Tenant Migration and Tenant Merge.
 6. On the **Merge Details** tab, you can select one or multiple tenant mappings for vRealize Automation 7.x and merge it with the same or different destination tenants for VMware Aria Automation 8.x.
- If you cannot view the target tenant, perform an inventory sync, or perform a product association for the tenant.
7. Click **Next** and you can view the summary of your selections on the Summary Step tab.
 8. Click **SUBMIT** if your validations are successful.

If the validations are not successful and you want to make changes, and then resume the tenant merge operation, click **SAVE AND EXIT**. The same wizard can be opened anytime to rerun the precheck to complete and proceed.

Using the VMware Aria Automation 8 Migration Assistant to run a migration

After running a migration assessment, use the migration assistant tool to migrate your source environment to VMware Aria Automation 8.

The VMware Aria Automation 8 Migration Assistant allows you to incrementally migrate your source environment with zero downtime or a scheduled maintenance window. This provides more customization and control over which infrastructure, subscription, and deployment components are migrated to VMware Aria Automation 8. The VMware Aria Automation migration assistant only migrates used or published content. The migration assistant does not migrate disabled or draft content. Before you can migrate you have to perform a migration assessment on your source environment. This assessment determines the migration readiness of your source environment components. After running a migration assessment, the results are listed on the **Assessment > Infrastructure** page by tenant. All assessed items are listed with their status:

- Ready - Ready for migration. No action is needed for migration readiness.
- Ready with warnings - Ready but needs review. Remediate any issues that might impact migration.
- Not Ready - Not ready for migration. Review details of the item in your source environment and correct areas needing attention.
- Assessing - Still being assessed for migration readiness.
- Assessment failed - The assessment failed. Verify that Automation Orchestrator and VMware Aria Automation are accessible and retry assessment.

To migrate, select the items you want to migrate and click **Migrate**. The status updates to:

- Migrating - Item is being migrated.
- Migrated - Migration is complete and successful. You can view and use the migrated item in your VMware Aria Automation 8 environment.
- Failed - The migration failed. Review the item in your source environment, modify as needed, retry migration.
- Excluded - Business group, subscription, or deployment that was listed as Not ready was migrated but its not ready items were not migrated and are listed as excluded.

If the component you are migrating has dependencies that have not been migrated first the migration fails. For example, if you want to migrate a subscription that has infrastructure criteria you must first migrate the infrastructure component.

NOTE

Once you migrate a deployment, the migration of its associated business group is complete.

After migration, your vRealize Automation 7 source content remains unchanged.

Incremental Migration

The VMware Aria Automation 8 migration assistant allows you to incrementally migrate your source environment instead of performing a full migration all at once using the migrate with reassessment option. The migrate with reassessment option reassesses your source environment and migrates any changes to the target environment. For example, if you migrate a business group with 5 blueprints, then create or publish 5 more in your source environment, you can migrate the new 5 blueprints to the same business group. Only new source environment content is migrated. Changes to any migrated source content will not be migrated.

Migration Prerequisites

Before you can use the migration assistant tool to migrate your vRealize Automation 7 source environment to VMware Aria Automation 8, ensure that these prerequisites are met.

Migration Prerequisites

- Backup your vRealize Automation 7 source environment.
- If your source vRealize Automation 7 content has dependencies on an external vRealize Orchestrator, you must first migrate vRealize Orchestrator. See [Migrating](#).
- Create or [migrate tenants using Aria Suite Lifecycle](#).
- You must first import and install the IPAM plugin in Automation Assembler to migrate an IPAM endpoint. For more information, see [Download and deploy an external IPAM provider package for use in Aria Automation](#).
- After running a migration assessment, the Automation Orchestrator Azure endpoint configuration is populated on the Configuration tab. Before running a migration, you must manually enter the key by editing the configuration with the <https://FQDN/migration-ui/#/global-config> link. If you attempt to migrate without providing the endpoint key, the migration fails.
- For subscriptions, the input type 'payload' is not supported in VMware Aria Automation 8. Before migrating your vRealize Automation 7 subscriptions, you must update the input type to 'Properties'.
- VMware Aria Automation 8.1 did not require you to accept a source certificate during migration assessment. As a result, you must reassess your source environment. To reassess your source environment and accept the source certificate: delete the source environment, re-add it, accept the certificate, and reassess the source environment using the migration assistant service.
- Ensure your vRA license is up-to-date and active before proceeding with migration.

NOTE

The vRealize Automation 7.x advanced license supports public cloud, however the VMware Aria Automation 8 advanced license does not. During the migration assessment, any public cloud items are flagged.

- In preparation for migration, ensure you exclude virtual machine memory from snapshots on the target environment.

Migration Limitations

The VMware Aria Automation 8 migration assistant tool includes some migration limitations.

Blueprint Limitations

VMware Aria Automation 8 Migration Assistant tool includes these limitations.

- In VMware Aria Automation 8, Blueprints are called VMware Cloud Templates.
- Nested blueprints (Parent blueprint with children blueprints) are not supported in VMware Aria Automation 8. You can flatten nested blueprints, if desired. However, flattening blueprints will cause you to lose the abstraction layer.
- During migration, lease policies are migrated but the **Minimum lease days** field is not. VMware Aria Automation 8 migrates minimum lease days as **Maximum Lease Days** and maximum lease days as **Maximum Total Lease**.
- If your source Blueprint contained a reservation policy and that reservation policy is deleted before migration, the reservation policy is migrated and tagged on the VMware Cloud Template. However, when you attempt to provision a VMware Cloud Template (formerly Blueprint) in VMware Aria Automation 8, it fails because the reservation policy does not exist and issues this error message during provisioning:
"No placement exists that satisfies all of the request requirements. See if suitable placements and cloud zones exist for the current project and they have been properly tagged."

To remediate this, open the VMware Cloud Template in VMware Aria Automation 8 and remove the tag.

- When migrating blueprints, the Migration Assistant ignores NSX settings set at the blueprint level, such as Transport Zone and Networking Reservation Policy. When the migrated blueprint is deployed, the VM and Edge are placed in the same cluster.

XaaS Limitations

VMware Aria Automation 8 includes these XaaS Limitations.

If your source environment contains multiple XaaS Blueprints or Custom Resources, they are assessed and migrated these ways:

- If the XaaS Blueprints or Custom Resources belong to the same business group, they are detected during the migration assessment but are blocked for migration. You must unpublish all XaaS Blueprints or Custom Resources except for one. The remaining published XaaS Blueprint or Custom Resource can be migrated. You can then publish the remaining XaaS Blueprints or Custom Resources and remigrate. Remigration only migrates the new content while preserving the previously migrated content.
- You can't have two XaaS blueprints configured to the same workflow. When you have 2 or more XaaS Blueprints or Custom Resources that belong to different business groups but are configured to the same workflow, they are not detected during the migration assessment. When migrated, the first migrated XaaS Blueprint or Custom Resource creates the VMware Aria Automation 8 XaaS Cloud Template or Custom Resource and is linked to the workflow. As a result, the subsequent XaaS Blueprints or Custom Resources are not configured to the workflow during migration.
- If multiple XaaS Blueprints contain the same custom resource but use different create, update, and delete workflows, the migrated custom resource only uses the workflows associated with the first migrated XaaS Blueprint. When migrated, all other XaaS Blueprints containing the same custom resource issue an error regarding missing input/output parameters for the custom resource.

Network Limitations

The VMware Aria Automation 8 Migration Assistant tool includes these network limitations.

- You can only set one CIDR and only use the corresponding IP ranges.
- CIDR and Subnet size might be inaccurate. You can correct this by editing the sizes in the Network Profile post migration.
- VMware Aria Automation 8 only supports Infoblox. No other third-party IPAM is supported. All other third-party IPAMs must be ported to the VMware Aria Automation 8 IPAM SDK by the user.
- Before you can migrate to VMware Aria Automation 8.x, the source and target IPAM endpoint configurations must be the same.
- The VMware Aria Automation 8 Migration Assistant does not support blueprints with a private network component that do not contain a private network profile for migration.
- Virtual machine IP allocations for both VMs and onboarded VMs are checked during deployment migration and allocated against the onboarded resources in VMware Aria Automation 8. If you only migrate your source

infrastructure and not your deployments, provisioning virtual machines might fail because your source IP addresses are not migrated and allocated against VMware Aria Automation 8 onboarded resources.

- After migrating to VMware Aria Automation 8, all IPAM information is migrated. However, day2 operations, such as deleting deployments, release the IP addresses from an external IPAM for deployments containing external network profiles only. You must manually remove the IP address from IPAM for deployments containing on-demand networks. As a workaround, you can create a subscription to remove the IP from IPAM.
- If IP addresses are not allocated when migrating network profiles, they are allocated during deployment migration.

Deployment Limitations

The VMware Aria Automation 8 migration assistant has these deployment limitations.

- Migration of a deployment is final regardless of whether it succeeded or failed. You cannot retry a deployment migration. You can rerun the plan created by the migration service, under Onboarding service. When rerun using the Onboarding service the owner, lease, and history of the deployment are not migrated.
- Historical costing information is not migrated with deployments. For more information on pricing and costs, see [What are Pricing Cards](#).
- For deployments with on-demand networks, if you migrate a deployment that contains an IPAM-managed IP and then delete the migrated deployment from VMware Aria Automation 8, you must also manually delete the associated IP address from Infoblox.
- After migrating to VMware Aria Automation 8, all IPAM information is migrated. However, day2 operations, such as deleting deployments, release the IP addresses from an external IPAM for deployments containing external network profiles only. You must manually remove the IP address from IPAM for deployments containing on-demand networks. As a workaround, you can create a subscription to remove the IP from IPAM.
- If your source environment includes a load balancer configured to an existing network that is not connected to a machine, the external network is not migrated and the IP is not allocated during migration.
- The "Update Deployment" functionality only works for deployments containing vSphere machine components. Running an "Update Deployment" action on deployments that contain other component types (networks, AWS machines, Azure machines, and so on) attempts to recreate the deployment components.
- vRealize Automation 7 does not collect data from Azure endpoints nor can it identify if an Azure machine was deleted outside of vRealize Automation 7. During Migration Assessment in VMware Aria Automation 8, any deleted Azure deployments are listed as Ready but are excluded during migration because the migration assistant cannot find the VMs.
- You cannot migrate a source deployment if it has mixed network types, such as both NAT/route networks in the same deployment for NSX-T/NSX-V.
- Source deployments that contain more than one NSX Load Balancer component are not migrated.
- If your source environment contains multiple deployments of a one ARM existing load balancer (on-demand load balancer with existing network) created from the same blueprint on NSX-T, the migration assistant only creates one load balancer. Only one of the migrated deployments will have the load balancer component listed. All other existing one ARM load balancer deployments do not have the load balancer component.
- The IP address configured to the NAT network in your source deployments is not marked as allocated post migration. However, the IP addresses of migrated load balancers and VMs are marked as allocated under **Infrastructure > Networks > IP Address** post migration.
- If your source vRealize Automation 7 deployment contains an invalid resource, for example it does not have properties for a resource, then the resource is not migrated. If all the resources are invalid in the deployment, the entire deployment is not migrated.
- During brownfield migration, both onboarded and migrated machines are not linked to cloud zones. As a result, these machines are not calculated into storage maximum definitions.
- If you migrate a deployment with a single machine component and an existing network component, vRealize Automation attempts to recreate the existing machine and fails with a 'Subnet is required' error.
- If you migrate a vSphere deployment that is linked to a Cloud Template, and then update the Cloud Template post migration the deployment fails.
- If a deployment contains DNAT rules, reconfigure day 2 actions cannot be performed post migration.

- Migrated clustered machines do not support scale in / scale out when applying iterative Cloud Template updates to the parent deployment.
- You can only migrate clustered deployments from vRealize Automation 7.6 source environments. Migrating clustered deployments is not supported for vRealize Automation 7.5, 7.4, or 7.3 source environments.
- Migration fails if a deployment contains 2 VMs that are configured to the same single network profile but belong to different networks. Before you can migrate this deployment, you must update the networks manually in vCenter by changing the network adapter to be the same for both VMs. Ensure data collection is completed and the VMs are updated with the changed networks in the source deployments.

vIDM Limitations

The VMware Aria Automation 8 Migration Assistant includes these vIDM limitations.

- vIDM tenant migration is not supported. You must manually create tenants in VMware Aria Suite Lifecycle Manager.

Endpoint Limitations

The VMware Aria Automation 8 migration assistant tool includes these endpoint limitations.

- After running a migration assessment, the Automation Orchestrator Azure endpoint configuration is populated on the **Configuration** tab. Before running a migration, you must manually enter the key by editing the configuration. If you attempt to migrate without providing the endpoint key, the migration fails.

NOTE

If the Automation Orchestrator Azure endpoint was not captured during the migration assessment, re-run the assessment and ensure the endpoint is captured for the business group.

- For third-party IPAM endpoints, VMware Aria Automation 8 only supports Infoblox. All other third-party IPAMS must use the VMware Aria Automation 8 IPAM SDK.
- To be assessed and migrated, endpoints must contain at least one active reservation.
- In vRealize Automation 7, fabric groups were created to specify which regions/compute resources from a given endpoint were available to be managed by VMware Aria Automation (For example, the regions/compute resources that we can use when provisioning workloads). When an endpoint is migrated, the restrictions imposed by fabric groups are not preserved. Instead, all regions/compute resources belonging to the endpoint are available for management.
- VMware Aria Automation 8 only supports vSphere 6.x and later. Migration fails for vSphere 5.x or earlier.

Subscription Limitations

The VMware Aria Automation 8 Migration Assistant tool includes these subscription limitations.

NOTE

You must first migrate before you can migrate VMware Aria Automation subscriptions.

VMware Aria Automation 8 also no longer stops processing subscriptions in the event a workflow fails. If a workflow fails, the migration continues and issues an error saying it is not supported.

VMware Aria Automation 8 does not support these subscriptions:

- Business groups configuration
- Endpoint action
- Infrastructure endpoint test connection
- IPAM IP lifecycle event completion
- Machine lifecycle

- Orchestration server configuration
- Orchestration server configuration (XaaS)
- Post Approval
- Pre Approval
- Resource reclamation completion event

Custom Properties Limitations

The VMware Aria Automation 8 Migration Assistant tool includes these custom properties limitations.

VMware Aria Automation 8 only supports vSphere custom property components. It does not support migration for these custom properties:

- Custom properties specified in compute resources
- Custom properties specified in reservations
- Custom properties specified in endpoints
- Predefined custom properties:
 - _debug_deployment
 - _Notes
 - NSX.Edge.ApplianceSize
 - NSX.Edge.HighAvailability
 - NSX.Edge.HighAvailability.PortGroup
 - VirtualMachine.Rdp.SettingsN
 - VirtualMachine.Software%.ISO.Location
 - VirtualMachine.Software%.ISO.Name
 - VirtualMachine.Software%.Name
 - VirtualMachine.Software%.ScriptPath
- Property Groups. Custom properties in property groups are flatten out into blueprint migration.

NOTE

If a blueprint has a custom properties that use the '.' character it is replaced with '_' character. For example, VirtualMachine.Core.Count becomes VirtualMachine_Core_Count.

Cloud Zone Limitations

VMware Aria Automation 8 includes these cloud zone limitations.

- Network and storage allocation does not follow the normal compute selection hierarchy and can fail with errors when shared resources exist across business groups. In the case this type of blueprint, provisioning fails because VMware Aria Automation 8 cannot find a common resource placement. To prevent this, add a constraint tag to the network and then provision the machine.

Reservation Limitations

VMware Aria Automation 8 includes these reservation limitations.

- vRealize Automation 7.x supported the use of AWS IaaS endpoints to create a keypair on demand for each deployment. This is not supported in VMware Aria Automation 8.
- The Migration Assistant only supports vSphere clusters with DRS enabled. If you attempt to migrate a VC cluster with DRS disabled, the cluster is listed as a host in VMware Aria Automation 8 while the same cluster is shown as cluster in vRA7. This causes migration to fail as the Migration Assistant can not find the cluster.

Business Group Limitations

The VMware Aria Automation 8 migration assistant includes these user limitations.

User and Groups

- If your source 7.x environment contains business groups that include users or groups that use special characters (for example, #, !, spaces, &, etc), the migration assessment fails for all business groups for that tenant. You must remove the users or user groups from the business group in your source environment business groups, and rerun the migration assessment. After, you must manually add the user in VMware Aria Automation 8.
- If your source 7.x environment contains business groups that include "local users, custom groups, or All Users", they are skipped and not migrated. You must manually add these users and groups in VMware Aria Automation 8 after migrating business groups.
- Verify that the expected groups and users for the migrated project are present. If they are not present, you must add the users and groups before proceeding to deployment migration.

How do I perform a brownfield migration

Using the migration assistant tool, you can perform a brownfield migration of your vRealize Automation 7 source instance and VMware Aria Automation 8.

If you created infrastructure in VMware Aria Automation 8 and want to align it with your vRealize Automation 7 infrastructure, you must run a migration assessment and then migrate your source environment. The migration assistant tool compares your existing VMware Aria Automation 8 infrastructure to the infrastructure in your vRealize Automation 7 source environment. After this comparison, the migration tool only migrates the difference between the two environments. For example: if you created a project named vSphere Users with one cloud template in VMware Aria Automation 8 and your vRealize Automation 7 environment contains a business group named vSphere Users with four blueprints, the migration assistant tool only migrates the additional three blueprints (as VMware cloud templates) to the VMware Aria Automation 8 vSphere Users project.

If the migration is rolled back, the existing VMware Aria Automation 8 infrastructure is rolled back to its original state before the vRealize Automation 7 migration. Only the migrated source environment content is rolled back, leaving the pre-migration VMware Aria Automation 8 content intact.

NOTE

Post-migration cloud zone tags are not removed during rollback.

Before performing a brownfield migration, review these considerations:

Cloud Zones

For AWS and Azure, the reservations are merged into one when they use the same region criteria. Similarly, all vSphere reservations are merged into one cloud zone, if they contain the same computes. New tags are added to the cloud zone based on reservation name and reservation policy.

IP Ranges

If your source environment contains overlapping IP ranges, the migration to VMware Aria Automation 8 fails.

Network Profiles

A new network profile is always created for on-demand networks. During migration, the source environment network profiles are merged into one when they contain the same regionId, isolation type, networks, security groups, and load balancers.

Storage Profiles

For Azure and vSphere, storage profiles are merged into one when they contain the same region and storage description. vRealize Automation 7 does not support storage profiles for AWS.

Projects

New zones are added to existing projects. If the zone exists in the project, the memory limit, instances, and storage limits are set to the maximum of existing project and source projects. Priority is set to the lowest of the two (lower is higher). The user roles of existing projects are also updated if the user already exists.

Migrating vRealize Automation 7 Infrastructure

After running a migration assessment on your vRealize Automation 7 source environment, you can migrate individual business groups to VMware Aria Automation 8.

The infrastructure results of your migration assessment are listed on the **Migration > Infrastructure** tab. All assessed business groups are listed with their status:

- Ready - Business group is ready for migration. No action is needed for migration readiness.
- Ready with warnings - Business group is ready but needs review. Remediate any issues that might impact migration.
- Not ready - Business group is not ready for migration. Review details of the business group in your source environment and correct areas needing attention.
- Assessing - Business group is still being assessed for migration readiness.
- Assessment failed - The assessment failed, retry assessment.

If applicable, after modifying any business groups listed as not ready or ready with warnings, select the business group and click **Update** to update its status in the assessment results table.

	Name	Status
<input type="checkbox"/>	BusinessGroup	⚠ Not ready
<input checked="" type="checkbox"/>	Development	🕒 Migrating
<input type="checkbox"/>	Finance	⚠ Not ready
<input type="checkbox"/>	Quality Engineering	⚠ Not ready

Migrate

Are you sure you want to migrate the selected business groups?

All dependencies for the business groups will be migrated.

Migrating vRealize Automation 7 reservations might reuse and share existing vRealize Automation 8 cloud zones. Shared cloud zones can impact governance by exposing and granting user access to clusters that were previously restricted. It can also impact resource allocation when provisioning new workloads.

Business groups: 1

Migration is a multi-step operation that may take several minutes.

To migrate business groups, select one or more business groups with a ready or ready with warnings status and click migrate. You can roll back previously migrated business groups by selecting the migrated business group and clicking rollback.

NOTE

If time passed between assessing your business groups and migrating them, the migration assistant tool reassesses your business groups. Reassessing business groups is the most time-consuming part of the migration. Consider turning reassessment off if you have not made changes to the source system since the last assessment.

NOTE

If you modify any migrated items and then rollback, all edits post-migration are deleted.

After migrating, you can click the business group name to view its assessment and migration results and status:

- Migrating - Business groups is being migrated.
- Migrated - Migration is complete and successful. You can view and use the migrated business group in your VMware Aria Automation 8 environment.
- Failed - The migration failed. Review the business group in your source environment, modify as needed, retry migration.
- Excluded - Business group that was listed as Not ready was migrated but it is not ready items were not migrated and are listed as excluded. To migrate the not ready/excluded items, you must correct them, reassess, and then remigrate them.

Dependency Type	Status	Total Items
Blueprint	Migrated	8
Business Group	Migrated	1
Custom Resource	Migrated	3
Custom Resource Action	Migrated	3
Endpoint	Migrated	3
Network Profile	Excluded	1
Reservation	Migrated	3
XaaS Blueprint	Migrated	5

You can continue to explore the details of the migrated business group by clicking a dependency type and viewing the itemized statuses. Any unsupported infrastructure components that were not able to be migrated are listed as excluded.

NOTE

If you are upgrading to VMware Aria Automation 8.3 from VMware Aria Automation 8.0 or later, you must reassess all tenants of all sources to update your migration assessment report. For migrated business groups, you can remigrate with the reassessment option enabled to automatically update the assessment report.

In the event your business group migration fails, it might be due to a stale token. Restart all vRA services and retry migration. For more information on restarting your vRA services, see [Starting and Stopping vRealize Automation](#).

How are Business Groups mapped in VMware Aria Automation 8

Business groups and their components are mapped differently in VMware Aria Automation 8.

Table 105: Business Group VMware Aria Automation 8 Mapping

vRealize Automation 7 Item	VMware Aria Automation 8 Mapping
Business Group	Project
Machine prefix	Naming template
Custom properties	Custom properties NOTE The Encrypted and Show in request flags are not migrated to VMware Aria Automation 8.
Active Directory policy/Active Directory container	Active Directory integration account/project configuration NOTE VMware Aria Automation 8 does not support migration for Active directories. You must manually configure them post-migration.
Capacity alert email address	N/A NOTE VMware Aria Automation 8 does not support migration for capacity alert email addresses.
Business group managers	Project administrators
Business group users	Project members
Support users	Project members
Shared access users	Project members

Users

Users are migrated from vRealize Automation 7 to VMware Aria Automation 8 as strings.

VMware Aria Automation 8 does not perform user validation on migrated users. To make sure your users work, it is recommended to create users first in VMware Aria Automation 8 then migrate your source environment.

Rule-Based Object Entitlements

In vRealize Automation 7, users were granted object entitlements by user account. In VMware Aria Automation 8, object entitlements are rule-based by user role, meaning all users of the same role have the same object entitlements. For example, two users with the same user role assigned to the same business group have the same entitlements to all project items.

To govern object entitlements:

1. Create a separate project.
2. Assign the desired user to the project.
3. Assign associated entitled objects to the project.

NOTE

You cannot share deployments between projects.

Blueprint Considerations

In VMware Aria Automation 8, Blueprints are called VMware Cloud Templates. All migrated vRealize Automation 7 blueprints are migrated as VMware Cloud Templates.

Basic Blueprint Support

VMware Aria Automation 8 supports these component types and provisioning methods:

- Amazon EC2
- Azure
- vSphere
- Cloning
- Linked Clone

NOTE

VMware Aria Automation 8 does not support "Use current snapshot".

- OVF

NOTE

OVF server basic authentication and proxy servers are not supported.

- Reservation policies are migrated as constraint tags.

Component Profile Support

Image and Size component profile value sets are migrated as input properties in VMware Cloud Templates.

- Image value sets
 - For OVF image value sets: Proxy server configuration, and basic authentication username and password fields are not migrated to VMware Aria Automation 8. The VMware Aria Automation 8 migration assistant supports these provisioning methods used by image value sets:
 - Clone
 - Linked Clone
 - OVF
- Size value sets
 - The storage field is not migrated to VMware Aria Automation 8.

How do I migrate and share a cloud template between projects

VMware Aria Automation 8 supports sharing VMware Cloud Templates between projects.

During migration, you can migrate blueprints that are shared with existing projects. You can also maintain shared VMware Cloud Templates across projects even when the original project is rolled back. When the original project is rolled back, the cloud template ownership is transferred to another project.

To migrate shared blueprints:

1. Run a migration assessment on your VMware Aria Automation 7 source environment. For more information on how to run a migration assessment, see [Run a Migration Assessment on a vRealize Automation Instance](#).
2. Select the **Infrastructure** tab, select the first business group containing the blueprint, and click **Migrate**. The migrated blueprints and their associated projects are seen on the **Design** tab of Automation Assembler and as catalog items in Automation Service Broker.
3. Navigate back to the **Infrastructure** tab, select the additional business groups containing the blueprint, and click **Migrate**.

In Automation Assembler, the cloud template is shown as only belonging to the first migrated project, but in Automation Service Broker the cloud template lists all projects in which it belongs.

If you want to rollback the migration of the original business group and transfer blueprint ownership, navigate to the **Infrastructure** tab, select the original business group, and click **Rollback**. After rolling back the original business group, the cloud template ownership automatically transfers to the remaining migrated project associated with the cloud template. Any associated custom forms are also retained post rollback.

How do I use vRealize Automation 6.x blueprints

Before you can use blueprints from vRealize Automation 6.x in VMware Aria Automation 8, you must first migrate them to vRealize Automation 7.4, 7.5, or 7.6.

After the migrating the blueprints to vRealize Automation 7, they are marked as 'Not Ready - blueprint is using Create workflow' after running a migration assessment. If the blueprint does not use the create workflow, you must open the blueprint in your source environment and save it without making any changes and rerun the migration assessment. After rerunning the assessment, the blueprint is marked as Ready. If the blueprint does use the create workflow, it cannot be migrated to VMware Aria Automation 8.

VMware Cloud Templates

When comparing your vRealize Automation 7 source to your new VMware Aria Automation 8 environment, the blueprint object types are different and are called VMware Cloud Templates.

Table 106: vRealize Automation 7 Blueprint Types to VMware Cloud Templates in VMware Aria Automation 8

Type	vRealize Automation 7	VMware Aria Automation 8.0
vSphere (vCenter) machine	Infrastructure.CatalogItem.Machine.Virtual.vSphere	Cloud.vSphere.Machine
AWS	Infrastructure.CatalogItem.Machine.Cloud.AmazonEC2	Cloud.AWS.EC2.Instance
Azure Machine		Cloud.Azure.Machine
Generic Virtual Machine	Infrastructure.CatalogItem.Machine.Virtual.Generic	Cloud.Machine
On-Demand Load Balancer (NSX)	Infrastructure.Network.LoadBalancer.NSX.OnDemand	Cloud.NSX.LoadBalancer
On-Demand Routed Network (NSX)	Infrastructure.Network.Network.NSX.OnDemand.Routed	Cloud.NSX.Network
NSX-T On-Demand Routed Network	Infrastructure.Network.Network.NSXT.OnDemand.Routed	Cloud.NSX.Network
NSX-T On-Demand NAT Network	Infrastructure.Network.Network.NSXT.OnDemand.NAT	Cloud.NSX.Network
Existing Network	Infrastructure.Network.Network.Existing	Cloud.vSphere.Network
On-Demand Private Network (NSX)	Infrastructure.Network.Network.NSX.OnDemand.Private	Cloud.NSX.Network

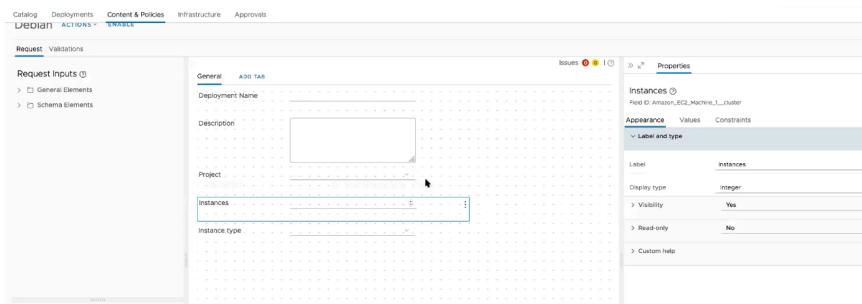

Custom Form Blueprints

Using the migration assistant tool, you can migrate Custom Form blueprints to VMware Aria Automation 8.

To migrate a custom form blueprint, first perform a migration assessment on your vRealize Automation 7 source instance, then on the **Infrastructure** tab select the business group that contains the custom form blueprint and click migrate.

After migrating, open Service Broker and click the **Content and Policies** tab. Click the three dot icon next to the migrated cloud template to view and customize the custom form related fields.

Also, validate that all external values from vRealize Orchestrator workflows are present along with any other expressions. If values or expressions are missing, rework the vRealize Orchestrator workflow.

Component Profile Blueprints

Using the migration assistant tool, you can migrate component profile blueprints to VMware Aria Automation 8.

To migrate a component profile blueprint, first perform a migration assessment on your vRealize Automation 7 source instance, then on the **Infrastructure** tab select the business group that contains the component profile blueprint and click migrate.

After migrating, open Service Broker and click the **Catalog** tab. Click **Request** to view the component profile fields. For example, this migrated blueprint contains size and image fields populated with their vRealize Automation 7 values.

After migrating, verify the migrated template with the added inputs for sizes.

NSX Support

These NSX components are supported in VMware Cloud Templates.

Supported NSX Components

- NSX (T/V) On-Demand Routed Network
- NSX (T/V) On-Demand Nat Network
- NSX (T/V) On-Demand Load Balancer
- NSX (T/V) Existing Security Group
- NSX V On-Demand Private Network
- NSX V On-Demand Security Group

Unsupported NSX Components

- NSX (T/V) App Isolation
- NSX V Existing Security Tag

XaaS Considerations

XaaS Blueprints

XaaS blueprints are migrated into two different types of VMware Cloud Templates depending on their details.

Before you can migrate a XaaS blueprint, the associated workflow must be migrated to 8 first. VMware Aria Automation 8 supports:

- Request Form (Catalog item details and submitted request details are not supported)
- Search field on Request form
- Tree field on Request form
- Conditional default values only support a single condition. If conditions are nested, the conditions are ignored during migration.
- The read only, minimum length, and maximum length constraints value only supports constant values.
- The field visibility can be set both conditionally and externally using the form designer.

VMware Aria Automation 8 no longer includes or supports the **Make Available as Component in Design Canvas** functionality.

Before migrating, if the associated workflow is not compatible with VMware Aria Automation 8, save the XaaS blueprint as a draft to continue the migration assessment and migration without it.

XaaS Blueprints Without a Defined Provision Resource

vRealize Automation 7 XaaS blueprints without a defined provision resource are migrated to VMware Aria Automation 8 as XaaS Cloud Templates with the associated workflow and original request form fields. You might need to reorder the fields, as the fields' order is not preserved post migration.

XaaS Blueprints with a Defined Provision Resource

vRealize Automation 7 XaaS blueprints with a defined provision resource are migrated to VMware Aria Automation 8 as VMware Cloud Templates along with the associated workflow and original request form. They are no longer listed as an XaaS blueprint. VMware Aria Automation 8 requires these XaaS blueprints to have an assigned update workflow and destroy workflow. If the XaaS blueprint does not contain one, VMware Aria Automation 8 assigns a dummy id to these workflow fields. You must replace the dummy id and assign an update and destroy workflow post migration.

NOTE

The component lifecycle scalable functionality is not supported in VMware Aria Automation 8 and is flagged during the migration assessment.

Custom Resources

VMware Aria Automation 8 includes these custom resource considerations.

When migrating XaaS Custom Resources, only the original fields are migrated. Any user added fields or tabs are not migrated and must be added post migration. Any vRealize Automation 7 plugins used in your custom resources must also exist in VMware Aria Automation 8. If the custom resource contains a plugin that is not supported in VMware Aria Automation 8, you must unpublish the associated XaaS blueprint to exclude it from migration.

These plugins, fields, and views are not supported in VMware Aria Automation 8:

- VCAC/VCACCAFE plugin
- Resource List view
- Submitted Action details

Resource Mapping and Resource Actions

Resource mapping and resource actions are not supported because VMware Aria Automation 8 does not support their underlying vRealize Automation 7 components.

VMware Aria Automation 8 only includes an out-the-box workflow to map virtual machine types to orchestrator type VC:VirtualMachine in catalog resources.

Entitlement Considerations

VMware Aria Automation 8 includes these entitlement considerations.

When migrating from vRealize Automation 7.x to 8.8 or later, entitlements are migrated to a content sharing policy type by adding all associated catalog items as individual items instead of as a content source.

If your source instance includes existing entitlements with items added as an entitled service, the migration assistant identifies all the catalog items that belong to the service and creates a content sharing policy for every entitlement by adding them as individual items.

How are Entitled Actions mapped in VMware Aria Automation 8

VMware Aria Automation 8 uses built-in resource mapping for Entitled to Day 2 Policy actions.

During Migration, these entitled actions are mapped to these Day 2 Policy actions. All other entitled actions not listed in the table are currently not mapped during migration.

Table 107: Entitled Actions Mapping

Type	vRealize Automation 7 Entitled Actions	VMware Aria Automation 8 Day 2 Policy Actions
Deployment	Change Lease	Deployment.ChangeLease
	Destroy	Deployment.Delete
	Change owner	Deployment.ChangeOwner
Machine	Connect to Remote Console	Cloud.vSphere.Machine.Remote.Console
	Power off	Cloud.vSphere.Machine.PowerOff Cloud.AWS.EC2.Instance.PowerOff Cloud.Azure.Machine.PowerOff
	Reboot	Cloud.vSphere.Machine.Reboot Cloud.AWS.EC2.Instance.Reboot
	Reconfigure	(Partially Supported) Cloud.vSphere.Machine.Add.Disk Cloud.vSphere.Machine.Remove.Disk Cloud.vSphere.Machine.Resize Cloud.vSphere.Machine.Compute.Disk.Resize Cloud.Azure.Machine.Add.Disk

Table continued on next page

Continued from previous page

Type	vRealize Automation 7 Entitled Actions	VMware Aria Automation 8 Day 2 Policy Actions
		Cloud.Azure.Machine.Remove.DiskCloud.Azure.Machine.Resize Cloud.AWS.EC2.Instance.Add.Disk Cloud.AWS.EC2.Instance.Remove.Disk Cloud.AWS.EC2.Instance.Resize Cloud.AWS.EC2.Instance.Compute.Disk.Resize
	Shutdown	Cloud.vSphere.Machine.Shutdown
	Suspend	Cloud.vSphere.Machine.Suspend Cloud.Azure.Machine.Suspend
Virtual Machine	Create Snapshot	Cloud.vSphere.Machine.Snapshot.Create
	Delete Snapshot	Cloud.vSphere.Machine.Snapshot.Delete
	Revert to Snapshot	Cloud.vSphere.Machine.Snapshot.Revert
Cloud Machine	Destroy	Cloud.Azure.Machine.Delete Cloud.AWS.EC2.Instance.Delete
Azure Virtual Machine	Delete	Cloud.Azure.Machine.Delete
	Restart	Cloud.Azure.Machine.Restart
	Start	Cloud.Azure.Machine.PowerOn
	Stop	Cloud.Azure.Machine.PowerOff
VMware NSX Security Group	Reconfigure	Cloud.NSX.LoadBalancer.LoadBalancer.Reconfigure Cloud.LoadBalancer.LoadBalancer.Reconfigure

Endpoint Considerations

VMware Aria Automation 8 includes these endpoint considerations.

The migration service only assesses endpoints if there are active reservations attached to it. If you want to exclude an endpoint from assessment/migration, you can disable or delete any reservations that are attached to it. Furthermore, any workloads (VMs) that are associated with an obsolete endpoint are flagged as 'not ready' during assessment and they are excluded from migration.

VMware Aria Automation 8 supports the following endpoints:

Table 108: VMware Aria Automation 8 Supported Endpoints

Endpoint	Added as ...
Microsoft Azure	Added as a cloud account.
Amazon AWS	Added as a cloud account.
Google Cloud Platform	Added as a cloud account.

Table continued on next page

Continued from previous page

Endpoint	Added as ...
vCenter	Added as a cloud account.
NSX-T	Added as a cloud account.
NSX-V	Added as a cloud account.
Puppet	<p>Added as an integration account.</p> <p>NOTE You cannot migrate Puppet endpoints to VMware Aria Automation 8. However, VMware Aria Automation 8 does support adding Puppet endpoints as integrations post-migration or installation.</p>
Ansible	<p>Added as an integration account.</p> <p>NOTE You cannot migrate Ansible endpoints to VMware Aria Automation 8. However, VMware Aria Automation 8 does support adding Ansible endpoints as integrations post-migration or installation.</p>
IPAM	Added as an integration account.
vRealize Orchestrator	Added as an integration account.

VMware Aria Automation 8 does not support the following endpoints:

- Hyper-V (standalone)
- Hyper-V (SCVMM)
- KVM (RHEV)
- NetApp ONTAP
- Openstack
- Proxy
- vCloud Air
- vROPs
- XenServer

Infoblox IPAM

Before migrating an Infoblox endpoint, you must first install the latest Infoblox plugin for VMware Aria Automation 8 from the [VMware Marketplace](#) in your target VMware Aria Automation 8 environment. VMware Aria Automation 8 also requires that you select an address space. If you attempt to migrate a network profile without a selected address space, the migration process fails.

VMware Aria Automation 8 does not support or migrate the following properties and property groups:

- Infoblox.IPAM.createFixedAddress
- Infoblox.IPAM.createAddressAndPtrRecords
- Infoblox.IPAM.Network0.enableDhcp
- Infoblox.IPAM.Network0.aliases
- Infoblox.IPAM.createReservation
- Infoblox.IPAM.Network0.msDhcpServer
- Infoblox.IPAM.Network0.comment

- Infoblox.IPAM.createAddressRecord
- Infoblox.IPAM.Network0.enableDns
- Infoblox.IPAM.CustomHostname.ConditionalMachineCustomProperty0.Value
- Infoblox.IPAM.enableCustomHostname
- Infoblox.IPAM.Network0.dnsView
- Infoblox.IPAM.CustomHostame.ConditionalMachineCustomProperty0.Name
- Infoblox.IPAM.restartIfNeeded
- Infoblox.IPAM.createHostRecord

Approval Policy Considerations

VMware Aria Automation 8 includes these approval policy considerations.

Approval policies in VMware Aria Automation 8 do not support:

- Post Levels
- Multi Levels
- Nested Criteria
- AP integration with Event Subscriptions
- Approver determination based on Requests
- Approver Groups
- Approvals by Email

You can only use cost, requestedBy, cpucount, and memory criteria fields in your VMware Aria Automation 8 approval policies.

When migrating your vRealize Automation 7 approval policies to VMware Aria Automation 8, they are migrated as either Catalog Requests or Day 2 Action Request types.

Table 109: Catalog Request

vRealize Automation 7 Catalog Request Type	VMware Aria Automation 8 Type
Service Catalog - Catalog Item Request	Deployment.Create
Service Catalog - Catalog Item Request - Virtual Machine	Deployment.Create (resourceType = Cloud.vSphere.Machine)
Service Catalog - Catalog Item Request - Cloud Machine	Deployment.Create (resourceType = Cloud.AWS.EC2.Instance)
Service Catalog - Catalog Item Request - Existing Network	Deployment.Create (resourceType = Cloud.vSphere.Network)
Service Catalog - Catalog Item Request - NSX-T On-Demand Load Balancer	Deployment.Create (resourceType = Cloud.NSX.LoadBalancer)
Service Catalog - Catalog Item Request - NSX-T Existing NS Group	Deployment.Create (resourceType = Cloud.SecurityGroup)

vRealize Automation 7 Action Type	VMware Aria Automation 8 Action Type
Resource Action Request - Expire - Machine Resource Action Request - Install Tools - Machine Resource Action Request - Manage Public IP Address - Azure Virtual Machine Resource Action Request - Power Cycle - Machine Resource Action Request - Reconfigure - Machine Resource Action Request - Register VDI - Virtual Machine Resource Action Request - Remove from Catalog - Azure Virtual Machine Resource Action Request - Resume - Deployment Resource Action Request - Scale In - Deployment Resource Action Request - Scale Out - Deployment Resource Action Request - Start - Container Resource Action Request - Stop - Container Resource Action Request - Unregister - Machine Resource Action Request - Unregister VDI - Virtual Machine Resource Action Request - Unregister - VMware NSX Network Resource Action Request - Unregister - VMware NSX-T Network	

Networking Considerations

VMware Aria Automation 8 includes these NSX, Load Balancer, and Security Group considerations.

NSX (T/V) Considerations

NOTE

These considerations only apply to vSphere Networking with NSX.

The VMware Aria Automation 8 Migration Assistant does not support blueprints with a private network component that do not contain a private network profile for migration.

In VMware Aria Automation 8, every on-demand NSX-T network creates a new Tier-1 logical router, and every on-demand NSX-V network creates a new Edge.

When migrating NSX components from VMware Aria Automation 7 to VMware Aria Automation 8, they are renamed.

Table 111: Blueprint Components

vRealize Automation 7 Component	VMware Aria Automation 8 Component
NSX-(V/T) On-Demand Nat Network	Cloud.NSX.Network (networkType: outbound) + Cloud.NSX.Gateway (Only if Nat rules specified in 7 BP)
NSX-(V/T) On-Demand Routed Network	Cloud.NSX.Network (networkType: routed)
NSX-(V/T) On-Demand LB	Cloud.NSX.LoadBalancer
NSX-V On-Demand Private Network	Cloud.NSX.Network (networkType: private)
NSX-(V/T) Existing Security Group	Cloud.SecurityGroup
Existing Network	Cloud.vSphere.Network
NSX-V On-Demand Security Group	Not Supported.
NSX-V Existing Security Tag	

Table 112: Deployment Components

vRealize Automation 7 Component	VMware Aria Automation 8 Component
NSX-(V/T) On-Demand Nat Network	Network Component (networkType: outbound)
NSX-(V/T) On-Demand Routed Network	Network Component (networkType: routed)
NSX-(V/T) On-Demand LB	Cloud.NSX.LoadBalancer
NSX-V On-Demand Private Network	Network Component (networkType: private)
NSX-(V/T) Security Group	SecurityGroup Component (type : Existing)
Existing Network	Network Component (networkType: existing)

Table 113: Endpoint Mapping

vRealize Automation 7 Endpoint	VMware Aria Automation 8 Endpoint
NSX-V	NSX-V NOTE The NSX-V endpoint is linked to vCenter.
NSX-T	NSX-T NOTE The NSX-T endpoint is linked to vCenter (1:N Mappings).
NSX-T and NSX-V	vCenter (Hybrid) NOTE All 3 endpoints are migrated but only the NSX-T endpoint is linked with VC. If needed, you must manually create additional links.

Network Profiles

If your vRealize Automation 7 source environment contains both reservations and a network profile, they are merged during migration into one Network Profile in VMware Aria Automation 8.

Table 114: Network Profile Conversion

Name	vRealize Automation 7	VMware Aria Automation 8
External Profile	Assigned to Network in the Reservation	Equivalent CIDR is set on the 8.x subnet. IP Ranges are set on the subnet.
Routed Profile	Linked to External Profile. External Profile is set on the DLR or Tier -0 Logical Router in Reservation.	A Separate Network Profile with Isolation Type as Subnet is created. The equivalent CIDR (of VMware Aria Automation 7 routed profile) and subnet is determined and set in the NP. Subnet size is determined by the VMware Aria Automation 7 subnet mask.
Nat Profile	Linked to External Profile. External Profile is set on the DLR or Tier -0 Logical Router in Reservation.	A Separate Network Profile with Isolation Type as Subnet is created. The equivalent CIDR (of 7 VMware Aria Automation nat profile) and subnet is determined and set in the NP. By default, the subnet size is 29. If VMware Aria Automation 7 has both DHCP enabled and static IP ranges, VMware Aria Automation 8 assigns DHCP and Static as the IP range.
Private Profile	Linked to External Profile. External Profile is set on the DLR or Tier -0 Logical Router in Reservation.	A Separate Network Profile with Isolation Type as Subnet is created. The equivalent CIDR (of 7 VMware Aria Automation private profile) and subnet is determined and set in the NP. By default, the subnet size is 29.

NOTE

External IPAM is supported for all network profiles. However, the CIDR is not set and the IP blocks of the IPAM are set as ranges.

When creating Network Profiles, you must select the address space and existing IP blocks.

NAT Network Profile with Third-Party IPAM

In vRealize Automation 7, you didn't need to select the address space. Only the IP ranges were specified in the Network Profile. During deployment, a new on-demand address space was created and IP range set.

In VMware Aria Automation 8, when creating a Network Profile you must select the address space and existing IP blocks.

Security Groups

In VMware Aria Automation 8, Security Groups are linked only if you have a Network component. During Blueprint/Deployment migration, a network component is created by default when a VM is not attached to a Network Component.

For vRealize Automation 7 blueprints, the static IP is assigned to the NIC without having to link a network component. During migration to VMware Aria Automation 8, a default network component is created for these blueprints.

Azure Networking

VMware Aria Automation 8 supports Azure blueprints with these components:

- With Security Groups.
- With vNET and Subnet

NOTE

VMware Aria Automation 8 does not support Azure blueprints with load balancers. You must create a new load balancer.

Reservation Considerations

VMware Aria Automation 8 includes these reservation considerations.

In VMware Aria Automation 8, reservations use cloud zones for compute policies, storage profiles to storage policies, and network profiles for network policies. These constructs are linked together using tags. In VMware Aria Automation 8, cloud zones are linked to one or more projects.

During reservation migration:

1. The compute components are migrated as a cloud zone and assigned a tag.
2. The storage components are migrated as one or more storage profiles and assigned the previously created tag.
3. The network components are migrated as a network profile and assigned the previously created tag.
4. The cloud zone is attached to the project.

NOTE

If the reservation contains a reservation policy, a capability tag is also assigned to the cloud zone to represent the policy post migration.

VMware Aria Automation 8 also introduces default storage profiles. When a migrated reservation contains multiple storage profiles, VMware Aria Automation 8 assigns one as a default storage profile. Before provisioning, ensure that the correct storage profile is selected as default. If it is not, select the check box next to the desired storage profile under the reservation.

NOTE

In vRealize Automation 7, Amazon reservations cannot configure storage placement policies. In VMware Aria Automation 8, the migration assistant tool does not create storage profiles during Amazon reservation migrations.

NOTE

Only enabled storage paths are migrated to VMware Aria Automation 8. Disabled storage paths are not migrated to VMware Aria Automation 8.

Optimized Reservations

During migration, reservations are consolidated into fewer cloud zones.

Reservations are consolidated into as few cloud zones, storage profiles, and network profiles as possible based on their computations to optimize them. For example, if you have five reservations using the same compute resource, they are migrated and consolidated into a single cloud zone in VMware Aria Automation 8.

- Multiple reservations that use the same compute resource are migrated as a single cloud zone.
- Multiple reservations that use the same storage paths are migrated as a single storage profile.
- Multiple reservations that use the same networks are migrated as a single network profile.

Custom Properties Considerations

VMware Aria Automation 8 includes these custom properties considerations.

During blueprint migration, these custom properties are migrated as Input property parameters and linked to the Cloud Template component field.

- VirtualMachine.CPU.Count
- VirtualMachine.Memory.Size
- VirtualMachine.NetworkN.PrimaryDNS
- VirtualMachine.NetworkN.SecondaryDNS
- VirtualMachine.NetworkN.Gateways
- VirtualMachine.NetworkN.DnsSuffix
- VirtualMachine.NetworkN.DnsSearchSuffixes
- VirtualMachine.NetworkN.Address
- VirtualMachine.NetworkN.AddressType
- VirtualMachine.NetworkN.NetworkProfileName
- VirtualMachine.NetworkN.ProfileName
- VirtualMachine.NetworkN.SubnetMask
- Custom properties attached to a deployment resource. These custom properties are migrated with their 7.x properties that might not work or be relevant in VMware Aria Automation 8.

All other custom properties are migrated as part of the Cloud Template schema.

Each property defined in VMware Cloud Templates supports string, boolean, decimal, object, array, and number types.

Property Group Considerations

VMware Aria Automation 8 includes these property group considerations.

A property group is a group of custom properties that you can use to customize your Cloud Template. When migrating property groups from vRealize Automation 7.x to VMware Aria Automation 8.x, review these considerations:

- In vRA 7.x, a property group could be linked to a single tenant or shared across tenants. In VMware Aria Automation 8.x, these property groups are migrated and linked to a single tenant and the name of the tenant is added to the property group name: <propertygroupname>_<tenantname>. If a group is shared across tenants, in VMware Aria Automation 8.x it is migrated as is and without any changes to its name.
- Property groups containing constant properties (show in request: false) are migrated as constant type property groups: <propertygroupname>_constants. Property groups containing editable properties (show in request: true) are migrated as input type property groups: <propertygroupname>_inputs. During migration, if a property group contains both constant and editable properties the property group is split into two property groups: <propertygroupA>_constants and <propertygroupA>_inputs. However, if a property group contains a property that is a dropdown based on a vRO action, then the property group is not split into two property groups.
- If your VMware Aria Automation 8.x environment contains a property group with the same name as one being migrated, the migrated property group name is amended with a random number: <propertygroupname>_3439553.
- VMware Aria Automation 8 does not support the use of "-" and "." characters in property names. During migration these characters are replaced with the "_" character.
- Custom properties directly on Cloud Templates or components take precedence over property groups.

- VMware Aria Automation 8.x supports all property data types. However, VMware Aria Automation 8 does not support all functionality within those data types. The unsupported functionality is flagged in the migration assessment report.
- VMware Aria Automation 8.x does not support migrating the display order for properties.

Table 115: Supported Property Group Attributes

Attribute in vRA 7.x	VMware Aria Automation 8.x Mapping	
Property Group Attributes		
Name	Display Name	
ID	Name	
Visibility: all tenants	N/A	
Visibility: this tenant	Visibility: this tenant	
Description	Description	
Property Group Property Attributes		
Name	Name	
Value	Default Value	
Encrypted	Encrypted	
Show in request: true	Created as part of an input type property group. If a property definition exists for this property, the definition is applied.	
Show in request: false	Created as part of a constant type property group. If a property definition exists for this property, the definition is ignored.	
Property Definition Attributes		
Name	Name	
Label	Display Name	
Visibility: all tenants	N/A

Multi-Tenancy Considerations

VMware Aria Automation 8 includes these multi-tenancy considerations.

When migrating multiple tenants to a single tenant in VMware Aria Automation 8, consider:

- Subscriptions - When a second subscription with the same name as an existing subscription is migrated, the conditions and workflows are updated according to the second subscription criteria.
- Blueprint - When migrating a second blueprint with the same name from another tenant, the blueprint is skipped and the first migrated blueprint is shared between the business groups of both tenants.
- CustomResource - When migrating the first custom resource, the migration assistant creates the create, update, destroy workflow, and Day 2 actions (if applicable) criteria. If you migrate a second custom resource with the same name, only the Day 2 actions are updated.

Migrating vRealize Automation 7 Subscriptions

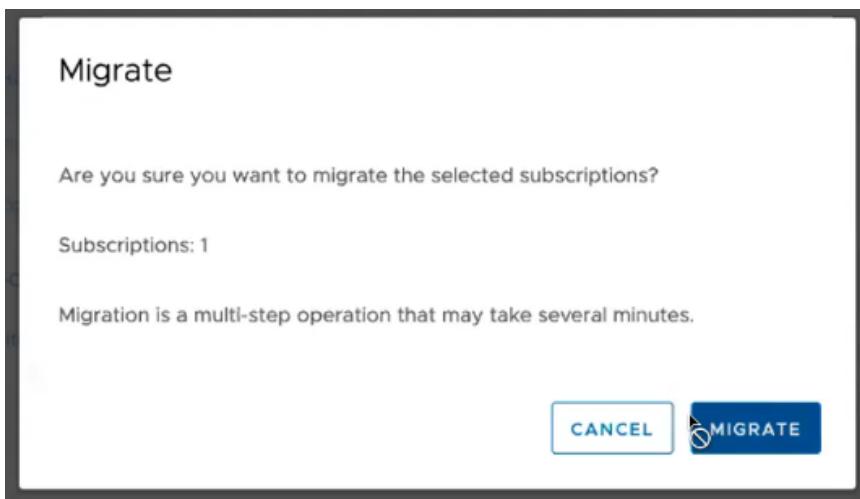

After running a migration assessment on your vRealize Automation 7 source environment, you can migrate individual subscriptions to VMware Aria Automation 8.

The subscriptions results of your migration assessment are listed on the **Migration > Subscriptions** tab. All assessed subscriptions are listed with their status:

- Ready - Subscription is ready for migration. No action is needed for migration readiness.
- Ready with warnings - Subscription is ready but needs review. Remediate any issues that might impact migration.
- Not ready - Subscription is not ready for migration. Review details of the subscription in your source environment and correct areas needing attention.
- Assessing - Subscription is still being assessed for migration readiness.
- Assessment failed - The assessment failed, retry assessment.

If applicable, after modifying any subscriptions listed as not ready or ready with warnings, select the subscription and click **Update** to update its status in the assessment results table. The assessment report also flags which subscription conditions are not supported. Before you can migrate these subscriptions, you must correct the unsupported conditions and reassess the subscription.

	Name	Status	Source Account
<input checked="" type="checkbox"/>	deployment.operation.completed	Ready	064
<input type="checkbox"/>	deployment.operation.requested	Ready	064

To migrate subscriptions, select one or more subscriptions with a ready or ready with warnings status and click migrate.

NOTE

Before you can migrate a subscription, you must have at least one migrated business group in VMware Aria Automation 8 first. If a subscription has dependencies on vRO workflows, it will fail to migrate until these dependencies are migrated first.

After migrating, you can click the subscription name to view its assessment and migration results and status:

- Migrating - Subscription is being migrated.
- Migrated - Migration is complete and successful. You can view and use the migrated subscription in your VMware Aria Automation 8 environment.
- Failed - The migration failed. Review the subscription in your source environment, modify as needed, retry migration.
- Excluded - Subscription that was listed as Not ready was migrated but its not ready items were not migrated and are listed as excluded.

Migrated subscriptions are listed in **Cloud Assembly > Extensibility**. On the Extensibility tab, when you open a migrated subscription, the associated conditions and IDs are listed.

NOTE

If a vRealize Automation 7 subscription contains an "or" condition, the subscription is migrated into two VMware Aria Automation 8 subscriptions in which both send the event to the same workflow.

You can roll back previously migrated subscriptions by selecting the migrated subscription and clicking rollback.

NOTE

If you modify any migrated items and then rollback, all edits post-migration are deleted.

Subscription Mapping and Considerations

When migrating from vRealize Automation 7 to VMware Aria Automation 8, subscriptions are mapped and supported differently.

To learn how to use your vRealize Automation 7 subscriptions with VMware Aria Automation 8, review the mapping table.

Table 116: VMware Aria Automation 8 Subscription Mapping

vRealize Automation 7 Subscription	In VMware Aria Automation 8, becomes ...	Considerations
Blueprint component completed	Deployment resource completed	Supported Conditions in VMware Aria Automation 8: <ul style="list-style-type: none">• componentId• blueprintId• deploymentId
Blueprint component requested	Deployment resource requested	Supported Conditions in VMware Aria Automation 8: <ul style="list-style-type: none">• componentId• blueprintId• deploymentId
Blueprint configuration	Blueprint configuration	Supported Condition in VMware Aria Automation 8: <ul style="list-style-type: none">• blueprintId Supported Schema: <ul style="list-style-type: none">• name• eventType• status• id• description
Blueprint request completed	Deployment completed	Supported Conditions in VMware Aria Automation 8: <ul style="list-style-type: none">• blueprintId• deploymentId
Blueprint requested	Deployment requested	Supported Conditions in VMware Aria Automation 8: <ul style="list-style-type: none">• blueprintId• deploymentId
Catalog request completed	Deployment completed	Supported Conditions in VMware Aria Automation 8: <ul style="list-style-type: none">• blueprintId• deploymentId
Catalog request received	Deployment requested	N/A
Component action completed	Deployment resource action completed	Supported Conditions in VMware Aria Automation 8: <ul style="list-style-type: none">• componentId• blueprintId• deploymentId
Component action requested	Deployment resource action requested	Supported Conditions in VMware Aria Automation 8: <ul style="list-style-type: none">• componentId• blueprintId• deploymentId

Table continued on next page

Continued from previous page

vRealize Automation 7 Subscription	In VMware Aria Automation 8, becomes ...	Considerations
Deployment action completed	Deployment action completed (deployment.action.post)	Supported Conditions in VMware Aria Automation 8: • blueprintId • deploymentId Supported Schema: • actionPerformed • deploymentId • statusId • failureMessage
Deployment action requested	Deployment action requested (deployment.action.pre)	Supported Conditions in VMware Aria Automation 8: • blueprintId • deploymentId Supported Schema: • actionPerformed • deploymentId • id
EventLog default event	EventLog (broker.event.log)	N/A
Machine Provisioning	Lifecycle state events For more information on specific lifecycle states and event topics, refer to the lifecycle state events table below.	Supported Conditions in VMware Aria Automation 8: • lifecycleState • componentId • blueprintName • componentTypeId • endpointId

Lifecycle state events

Machine Provisioning vRealize Automation 7 subscriptions are converted to lifecycle state events subscriptions in VMware Aria Automation 8 that support various states, events, and event topics.

State	Events	Event Topic
VMPSMasterWorkflow32		
Building Machine		Compute provision
DeactivateMachine		Compute removal
Disposing	• OnDisposeComplete (Provision) • OnDisposeTimeout (Provision) • OnUnregisterMachine (Provision)	Compute removal
MachineActivated	OnCatalogRegistrationComplete (Provision)	Compute Post Provision
MachineProvisioned		Compute Post Provision
Requested	OnProvisionMachine (Provision)	Compute provision

Table continued on next page

CustomizeOS	<ul style="list-style-type: none"> • OnCustomizeOS • OnCustomizeOSComplete • OnCustomizeOSTimeout 	Compute Provision

Migrating vRealize Automation 7 Deployments

After running a migration assessment on your vRealize Automation 7 source environment, you can migrate deployments to VMware Aria Automation 8.

The results of your business groups' deployments migration assessment are listed on the **Migration > Deployments** tab. All assessed deployments are listed with their status:

- Ready - Deployment is ready for migration. No action is needed for migration readiness.
- Ready with warnings - Deployment is ready but needs review. Remediate any issues that might impact migration.
- Not ready - Deployment is not ready for migration. Review details of the deployment in your source environment and correct areas needing attention.
- Assessing - Deployment is still being assessed for migration readiness.
- Assessment failed - The assessment failed, retry assessment.

If applicable, after modifying any deployments, to re-assess your deployments select the business group and click **Update** to update its status in the assessment results table.

NOTE

You can only migrate deployments after successfully migrating the associated business group to VMware Aria Automation 8, regardless of deployment assessment status.

Required: Before migrating your deployments, you must take a snapshot of your VMware Aria Automation 8 environment.

To migrate deployments, select one or more business groups under the **Deployments** tab with any status and click **migrate**. Deployments that are Not ready are excluded from migration.

NOTE

Migration of a deployment is final regardless of whether it succeeded or failed. You cannot retry a deployment migration.

After migrating, you can click the business group's name to view its deployments assessment and migration results and status:

- Migrating - Deployment is being migrated.
- Migrated - Deployment was migrated successfully. You can view and use the migrated deployment in your VMware Aria Automation 8 environment.
- Failed - Deployment failed to migrate.
- Excluded - Deployment was excluded from migration because it was Not ready.

Before you can migrate a deployment of a specific business group, the business group infrastructure must be migrated first. The status of the infrastructure migration is also shown on the **Migration > Deployments** tab.

Deployment Considerations

Deployment migration is a three-step process that involves migrating infrastructure deployment components, migrating XaaS deployment components, and customizing migrated deployments.

Migrate Infrastructure Deployment Components

VMware Aria Automation provisions Infrastructure components on Cloud providers. Migrating infrastructure components uses the VMware Aria Automation 8 Onboarding feature and consists of two parts:

- Resource Tagging
 - Migrating vRealize Automation 7 endpoints creates VMware Aria Automation 8 Cloud Accounts and triggers data collection against the Cloud providers the legacy endpoints represent. Migration uses the source deployments to locate and tag matching resources in VMware Aria Automation 8 with the necessary data to onboard them for VMware Aria Automation 8 management.
- Resource Onboarding
 - Migration creates an onboarding plan (one per business group) and a specific onboarding rule to link the relevant tagged resources to the plan and reconstruct the deployment/component hierarchy as it exists vRealize Automation 7. Once the plan is complete, the Migration Assistant uses it to migrate source deployments.

Migrate XaaS Deployment Components

The Migration Assistant manages XaaS components separately from Infrastructure:

- If your deployments only contain XaaS components, the Migration Assistant migrates the deployment and all its XaaS components.
- If your deployment contains both Infrastructure and XaaS components, the Migration Assistant identifies the target deployment that was created during onboarding and moves all the XaaS components to it.

NOTE

If attempted, rerunning the onboarding plan created by the Migration Assistant retries onboarding for the infrastructure components only. It does not re-trigger migration for XaaS deployment components or deployment customizations.

Customize Migrated Deployments

This last step fine tunes the migrated deployments by applying these customizations in this order:

1. Set the deployment name and description. Unlike vRealize Automation 7, VMware Aria Automation 8 does not allow deployments with identical names. During migration, the Migration Assistant enforces unique names when migrating deployment containers.
2. Set the deployment lease.
3. Replicate deployment request history in Cloud Assembly.
4. Set deployment owner.

Deployment Considerations

VMware Aria Automation 8 Migration Assistant includes these additional deployment considerations.

- During deployment migration, the compute processing consumes project placement quota. Ensure you have enough placement quota before migrating your deployments by navigating to **Cloud Assembly > Infrastructure > Project > Provisioning**. Each cloud zone is shown with its limits.

- After migrating deployments, the deployments are active in both your source environment and VMware Aria Automation 8 environment. To prevent the machine from accidentally being deleted or destroyed, remove the user from your vRealize Automation 7 business group and modify the deployment's lease to never expire in your source environment.
- If you migrate your source infrastructure and attempt to migrate your deployments, the deployment migration might fail. If your deployment migration fails, rerun the onboarding plan. [Learn more about Onboarding Plans](#).

NSX Deployment On-Boarding Support

These NSX components are supported during Deployment On-Boarding.

Supported NSX Components

- NSX (T/V) On-Demand Routed Network
- NSX (T/V) On-Demand Nat Network
- NSX (T/V) External Network
- NSX (T/V) Existing Security Group
- NSX V On-Demand Private Network
- NSX (T/V) App Isolation. This becomes an existing security group.
- NSX V On-Demand Security Group. This becomes an existing security group.
- NSX (T/V) On-Demand Load Balancer

NOTE

If any NAT rules are specified on the network, they are not set on the onboarded network component. Also, if your external network is not attached to a VM in your source deployment it is not onboarded.

Migrating VMware Aria Automation Orchestrator

You can migrate your existing vRealize Orchestrator that is embedded in a vRealize Automation 7.x environment to an embedded VMware Aria Automation Orchestrator 8.x.

For information about migrating standalone vRealize Orchestrator environments, see the [Migrating a Standalone vRealize Orchestrator](#).

Migration is supported for vRealize Orchestrator 7.3 or later.

The VMware Aria Automation Orchestrator migration transfers an embedded source vRealize Orchestrator configuration to your current VMware Aria Automation Orchestrator 8.x environment, overwriting all existing elements such as workflows, actions, configuration and resource elements, including secure strings in workflows and configuration elements, packages, tasks, policies, certificates and trusted certificates, plug-ins and plug-in configurations, custom records in the `js-io-rights.conf` file, Control Center system properties. The migration includes both built-in and custom VMware Aria Automation Orchestrator content.

The migrated VMware Aria Automation Orchestrator configuration does not include the following data that might affect the target VMware Aria Automation Orchestrator performance and use.

- The VCAC, VCACCAFE, GEF, Data Management, and Workflow Documentation plug-ins of the source vRealize Orchestrator. Aside from workflow runs, all vRealize Orchestrator content associated with these plug-ins is not migrated to the target environment.
- Syslog server configuration in the **Logging Integration** page in Control Center.
- Workflow execution logs.
- Dynamic Types plug-in configurations.

NOTE

Before migrating, if your vRealize Orchestrator endpoints are not assessed, you must reassess your vRealize Orchestrator instance.

Migrate an Embedded vRealize Orchestrator 7.x Instance

You can migrate a single node vRealize Orchestrator instance that is embedded in vRealize Automation 7.x to an embedded VMware Aria Automation Orchestrator 8.x deployment.

- Migration is supported for embedded vRealize Orchestrator 7.3 or later.
- Back up the target VMware Aria Automation environment.
- Verify that SSH access is enabled on the source vRealize Automation 7 instance and target VMware Aria Automation environment by logging into VMware Aria Automation 8 via SSH using root, then running the `curl -v telnet://<FQDNofvRO7>:22` command.
- Verify that the source vRealize Automation database is accessible from the target VMware Aria Automation environment by running the `curl -v telnet://<FQDNofvRO7>:5432` command.

The migration transfers an embedded vRealize Orchestrator 7.x configuration to your VMware Aria Automation Orchestrator 8.x environment. The migration involves overwriting all existing elements in your VMware Aria Automation Orchestrator 8.x environment.

You perform the migration by using the `vro-migrate` script bundled with the VMware Aria Automation Orchestrator appliance.

NOTE

The migration script stops the VMware Aria Automation Orchestrator services automatically. You might have to schedule a maintenance window for your source VMware Aria Automation environment.

1. Log in to the VMware Aria Automation Orchestrator appliance command line of your target environment over SSH as **root**.
2. To start the migration, run the `vro-migrate` script.
3. Follow the command prompts to provide the fully qualified domain name (FQDN) and credentials of the source vRealize Orchestrator instance.
4. To follow the migration progress, access the migration log:
 - a) Log in to your target VMware Aria Automation Orchestrator appliance command line over a separate SSH session as **root**.
 - b) Run the `tail -f /var/log/vro-migration.log` command.
- The migration process begins. You receive a notification on the target VMware Aria Automation Orchestrator appliance when the migration finishes.
5. After the migration process finishes, log in to the source vRealize Orchestrator appliance and restart the `vco-server` and `vco-configuration` services.

NOTE

Restarting the vRealize Orchestrator services ensures that your 7.x deployment is accessible after migration. After the restart, navigate to the **Services** tab in the source vRealize Automation, and verify that the vRealize Orchestrator services are registered.

6. Log in to the target VMware Aria Automation appliance over SSH, run `kubectl get pods -n prelude`, and verify that the VMware Aria Automation Orchestrator appliance reports 3 / 3.

NOTE

You might have to wait for up to 20 minutes before you run the `kubectl get pods -n prelude` command.

- Verify that VMware Aria Automation Orchestrator is accessible in the target VMware Aria Automation environment.

Migrate an Embedded vRealize Orchestrator 7.x Cluster

You can migrate a clustered vRealize Orchestrator deployment that is embedded in a vRealize Automation 7.x environment to an embedded Automation Orchestrator 8.x environment.

- Migration is supported for embedded vRealize Orchestrator 7.3 or later.
- Configure a Automation Orchestrator cluster in your target VMware Aria Automation 8.x environment. See *Configure a vRealize Orchestrator Cluster* in *Installing and Configuring VMware vRealize Orchestrator*.
- Back up the target VMware Aria Automation environment.
- Verify that SSH access is enabled on the source vRealize Automation instance and target VMware Aria Automation environment.
- Verify that the source vRealize Automation database is accessible from the target VMware Aria Automation environment.

The migration transfers a clustered vRealize Orchestrator 7.x configuration to your Automation Orchestrator 8.x environment. The migration involves overwriting all existing elements in your Automation Orchestrator 8.x environment. You perform the migration by using the `vro-migrate` script bundled with the vRealize Orchestrator appliance.

NOTE

The migration script stops the vRealize Orchestrator services of the primary node automatically. Before you run the migration script, stop the services of the replica nodes of your clustered 7.x deployment.

```
service vco-server stop  
service vco-configuration stop
```

- Log in to the vRealize Orchestrator appliance command line of your target environment over SSH as **root**.
- To start the migration, run the `vro-migrate` script.
- Follow the command prompts to provide the fully qualified domain name (FQDN) and credentials of the source vRealize Orchestrator instance.
- To follow the migration progress, access the migration log:
 - Log in to your target Automation Orchestrator appliance command line over a separate SSH session as **root**.
 - Run the `tail -f /var/log/vro-migration.log` command.
- If the migration process begins. You receive a notification on the target Automation Orchestrator appliance when the migration finishes.
- If you want to access your vRealize Orchestrator 7.x environment after migration, log in to the source vRealize Orchestrator appliance and restart the `vco-server` and `vco-configuration` services.

You have migrated your clustered vRealize Orchestrator deployment.

Additional Migration Requirements for Content Accessing the File System

Content migrated to the VMware Aria Automation Orchestrator file system must follow the requirements of the new container-based appliance.

Because the VMware Aria Automation Orchestrator Appliance is running in a container, it has limitations regarding access to the file system. The `js-io-rights.conf` file still determines if a file is accessible from the VMware Aria Automation Orchestrator scripting API, but you cannot use arbitrary folders in the file system. The main folder accessible to the VMware Aria Automation Orchestrator service is `/var/run/vco`. Under the VMware Aria Automation Orchestrator

Appliance file system, this folder is mapped under `/data/vco/var/run/vco`. All local files that access the VMware Aria Automation Orchestrator scripting API must be moved to the specified main directory. Under the main directory, you can create subdirectories for your content.

For example, if you want to mount an external NFS volume to your VMware Aria Automation Orchestrator appliance, you must mount it in `/data/vco/var/run/vco/mount_directory_path`. Afterwards, the VMware Aria Automation Orchestrator scripting API can access the mounted NFS volume at `/var/run/vco/mount_directory_path`.

Kerberos Configuration

To use a Kerberos configuration, you can only use the `/data/vco/usr/lib/vco/app-server/conf/krb5.conf` file. For information on Kerberos debug logging, see *Enable Kerberos Debug Logging* in *Installing and Configuring VMware Aria Automation Orchestrator*.

How do I view my migration results

After migrating your vRealize Automation 7 source environment components, you can view the migration results.

To view your migration results, click the Migration Results tab on the Infrastructure, Subscriptions, and Deployments tabs. The migrated components are listed with their status:

- Migrating - Item is being migrated.
- Migrated - Migration is complete and successful. You can view and use the migrated item in your VMware Aria Automation 8 environment.
- Failed - The migration failed. Review the item in your source environment, modify as needed, retry migration.
- Excluded - Not Ready business group, subscription, or deployment was migrated but any of its not ready items were not migrated and are listed as excluded.
- Rollback - Migrated item was rolled back and is no longer available for use in VMware Aria Automation 8.

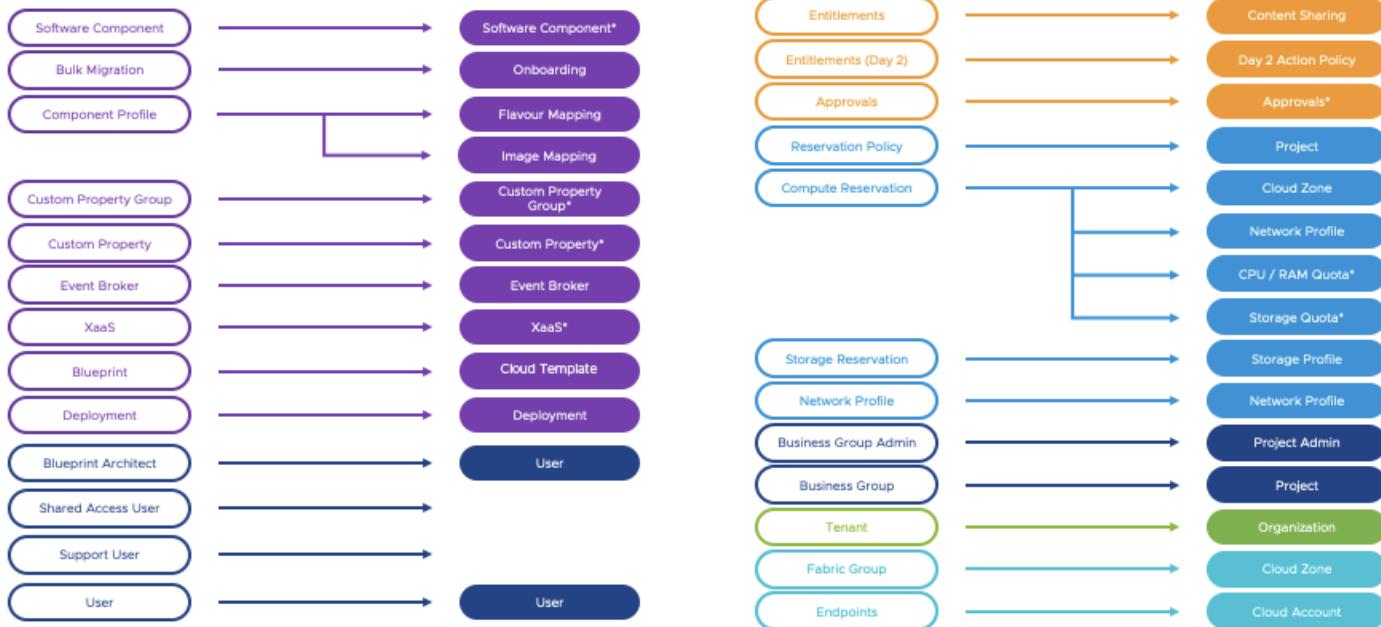

You can also export your migration results by clicking export. The migration results report includes live links that when clicked open the migrated content in VMware Aria Automation 8.

How do I view constructs mapping between vRealize Automation 7 and VMware Aria Automation 8

Using the migration assistant tool, you can view mapping between your vRealize Automation 7 source instance and VMware Aria Automation 8.

After migration, components might be mapped differently in VMware Aria Automation 8 than they were in vRealize Automation 7. When viewing your migration results, refer to the mapping constructs table to identify how your source components were migrated and stored.

Concept Comparisons

Common Reservations

Common reservations are identified by matching cloud zones, compute, and region parameters. When migrated, the migration assistant tool assigns a tag based on the reservation policy to common reservations and merges them into one under the same cloud zone. This merging process also applies to Network Profiles and Storage Profile migrations.

NOTE

If you do not previously define a network profile before migrating, the migration assistant tool creates a new one based on the reservation name and reuse it for each subsequent reservation.

You can view the migration results and reservation mapping by clicking the migrated business group and selecting the **Migration Results** tab.

What happens during a migration rollback

If necessary, you can rollback migrated items using the migration assistant.

The migration assistant has a rollback feature that allows you to remove migrated items from your VMware Aria Automation 8 environment. If the migrated item was modified post-migration in VMware Aria Automation 8 and then rolled back, all post-migration edits are deleted. If you rollback a business group that contains a shared cloud template, the cloud template ownership is transferred to the remaining migrated project associated with the cloud template.

NOTE

Cloud zone tags and custom forms are retained after performing a rollback. Business groups cannot be rolled back if there are active deployments associated with a project.

To rollback migrated items:

1. Navigate to the Migration Assistant Service.
2. Select the migrated item from the Infrastructure or Subscription page.

NOTE

You can only rollback migrated business groups and subscriptions.

3. Click **Rollback**.

How do I migrate updates to my source environment made after migration

After performing an initial migration to VMware Aria Automation 8, you might make changes to your source 7.x environment that you also want to migrate.

Depending on the type updates, new content versus updates to existing content, you might have to remigrate or rollback.

New content added to 7.x source environment

If you created new content in your 7.x source environment, you do not have to rollback your VMware Aria Automation 8 migration. To migrate your new content, remigrate your 7.x source environment. The migration assistant identifies and migrates the new content.

Updated existing 7.x source environment

If you updated existing content in your 7.x source environment you must rollback your VMware Aria Automation 8 migration. After rolling back, remigrate your source environment.

Manual Post Migration Steps

After migrating to VMware Aria Automation 8, you might have to perform some manual post migration steps.

Catalog Icons and Branding

To use catalog icons and any branding items, you have to manually add them to VMware Aria Automation 8 as they are not carried over during migration.

Post Migration Validation Steps

After migrating to VMware Aria Automation 8, review these post migration steps to validate your migration.

Review Migrated Infrastructure

Step	Details
Review Cloud Accounts to ensure endpoints were migrated correctly.	
Review projects to ensure the correct zones are enabled.	Each business group should be a project.
Reservations might be consolidated. Review your cloud zones, network profiles, storage profiles, image mapping, and flavor mappings.	Verify that network profiles have the correct CIDR for IP management. Copy the tag from your network and storage profiles and enter it in Tag Usage to view all associated artifacts.
Review Cloud Templates.	Blueprints are now Cloud Templates. The Cloud Templates should be associated with their correct project. Run a test Cloud Template to verify that tags for placement between the networks and zones are correct.

Table continued on next page

Continued from previous page

Step	Details
	(Optional) Add a "preventDelete:true" flag to your properties in Cloud Templates to prevent a migrated machine from being destroyed or deleting during an update.
Review XaaS items.	Verify XaaS blueprints are migrated to the Cloud Templates with custom resources or Service Broker workflow services.
Review users and approval policies.	Perform a user sync and verify approval policies and users.

Review Migrated Subscriptions

After migrating your subscriptions, review and verify these items:

- Verify the event topics are correct.
- Verify that the conditional logic is correct.
- A single subscription might be migrated into multiple subscriptions. Verify all expected subscriptions were migrated.
- Verify that the workflows associated with the subscriptions are correct and that payload variables and custom properties were manually updated. See the [Extensibility Migration Guide](#) for more information.
- Any subscription that was not migrated might need rework. Check the migration assessment report for the subscriptions that did not migrate and rework migrated subscriptions in your target environment.

Review Migrated Data

After migrating to VMware Aria Automation 8, review your migrated data:

- Verify that machines are connected to the correct networks and storage locations.
- Verify the account that ran the migration owns the migrated deployments.
- Verify that migrated deployments are not associated with a Cloud Template.

Troubleshooting your migration

If you encounter problems during migration, perform these migration troubleshooting steps.

The cause of any issues and troubleshooting steps depend on what stage of migration you are currently performing. For information on troubleshooting your migration:

- [Troubleshooting: Migration Assessment](#)
- [Troubleshooting: Migration Failed](#)
- [Troubleshooting: Migration Rollback Failed](#)

Troubleshooting: Migration Assessment

If your migration assessment fails or encounters problems, perform these troubleshooting steps.

Table 117: Troubleshooting Migration Assessment

Problem	Reason	Solution
Business group assessment failed	Your migration assessment might fail after connecting a source account.	Retry the migration assessment.

Table continued on next page

Continued from previous page

Problem	Reason	Solution
Assessment Report only shows information for one tenant when I assessed multiple.	Assessment reports only shows the tenant information of the last assessed tenant and not all assessed tenants.	Re-add the missing tenant and rerun assessment. Repeat for each missing tenant.
After adding a multi-org source environment, the source instance page shows a 404 Bad Request error.	One or more tenants are opened as tabs in the same browser window.	Use a different browser for each tenant.
Cannot add vRA 7.x source environment for migration assessment, issuing the error message "Http failure response for https://<vRA8 FQDN>/migration/api/tenants/GUID/include: 500 OK".	The SSL certificate has the wrong hostname and a vRA 7 source system with the same hostname found in the SSL certificate was already added.	Contact support.

Troubleshooting: Migration Failed

For various reasons, your migration to VMware Aria Automation 8 might fail. If your migration fails, perform these troubleshooting steps.

Table 118: Troubleshooting Failed Migration

Type of Migration	Reason	Solution
Cloud Account Migration	Your cloud account migration might fail due to a migration timeout.	Retry cloud account migration.
Blueprint Migration failure for blueprints that contain NSX components.	During bulk migration, if any of the endpoints fail to migrate for the business group and the same business group contains NSX components, the NSX association might fail. For example, blueprints containing security groups fail to migrate because the migration assistant service does not find the associated NSX cloud account.	Manually add the NSX association to vCenters in VMware Aria Automation 8 and retry migration.
Subscription migration failed	Some subscriptions depend on fields such as deploymentId and blueprintId. If infrastructure components have not been migrated first, subscription migration fails.	Migrate infrastructure components and then retry subscription migration.
XaaS Blueprint or Custom Resource migration failed	If the underlying workflows have not been migrated or are not supported in VMware Aria Automation 8, XaaS blueprint/Custom Resource migration fails.	Migrate underlying workflows and then retry XaaS Blueprint/Custom Resource migration. If the workflow is not supported the blueprint/resource can't be migrated.

Troubleshooting: Migration Rollback Failed

For various reasons, your migration rollback might fail. If it fails, perform these troubleshooting steps.

Table 119: Troubleshooting Failed Rollbacks

Reason for Failure	Solution
If your VMware Aria Automation 8 environment contains active deployments, the bulk rollback of business groups and projects fails.	<p>Delete active deployments from your VMware Aria Automation 8 environment and retry rollback.</p> <p>WARNING Use caution. Deleting deployments is destructive to the workloads.</p>

Use Case: How do I identify and plan for changes to my production environment without changing my live production environment?

In some circumstances, you might want to identify and plan for production changes before committing to changing your live production environment.

You might want to identify and plan for production changes without immediately applying them or scheduling downtime. By creating a duplicate environment you can review changes before applying them and modifying your live production environment. The duplicate environment is also useful for troubleshooting any issues outside of your live environment.

1. Create a duplicate environment by migrating your existing vRA 7.6 production environment to a new vRA 7.6 dev environment.
2. Disable the agents on the dev environment.
3. Perform a VMware Aria Automation 8 migration assessment on the 7.6 dev environment using the Migration Assistant.
4. Review the assessment results to identify what changes are needed on your 7.6 production environment.
5. Apply the changes to your vRA 7.6 production environment.
6. Migrate your production environment to VMware Aria Automation 8.

Upgrading and Migrating Automation Orchestrator

Upgrading Automation Orchestrator provides information and instructions about upgrading and migrating VMware Aria Automation Orchestrator standalone or clustered deployments, and migrating to the latest version of VMware Aria Automation Orchestrator.

Intended Audience

This information is intended for advanced VMware Aria Automation Orchestrator or vSphere administrators.

Upgrading VMware Aria Automation Orchestrator

Upgrade VMware Aria Automation Orchestrator 8.x to the latest product version.

Upgrade a Standalone or Clustered VMware Aria Automation Orchestrator 8.x Deployment

You can upgrade your VMware Aria Automation Orchestrator 8.x or later deployment to the latest product version by using a mounted ISO image. Upgrading VMware Aria Automation Orchestrator 7.x or earlier to VMware Aria Automation Orchestrator 8.x is not supported.

- Verify that your VMware Aria Automation Orchestrator upgrade path is supported. See the [VMware Product Interoperability Matrix](#).
- Download and mount the ISO image:
 1. Download the ISO image from the official VMware download site.
 2. Connect the CD-ROM drive of the VMware Aria Automation Orchestrator Appliance virtual machine in vSphere. See the [vSphere Virtual Machine Administration](#) documentation.

NOTE

After connecting the CD-ROM drive, navigate to your VMware Aria Automation Orchestrator Appliance VM settings page and verify that **Connect At Power On** is enabled.

3. Mount the ISO image to the CD-ROM drive of the VMware Aria Automation Orchestrator Appliance virtual machine in vSphere. See the [vSphere Virtual Machine Administration](#) documentation.
- Before upgrading VMware Aria Automation Orchestrator deployments authenticated with VMware Aria Automation, verify that the VMware Aria Automation product version matches the version of VMware Aria Automation Orchestrator you are upgrading to. For example, if you are upgrading to VMware Aria Automation Orchestrator 8.9, you must verify you are using VMware Aria Automation 8.9 as a authentication provider.
 - If you are upgrading VMware Aria Automation Orchestrator from a version older than 8.8, you might have to activate basic authentication. For more information, go to [Activate Basic Authentication](#).
1. Log in to the VMware Aria Automation Orchestrator Appliance command line as **root**.
 2. Run the **blkid** command, and note the device name for the VMware Aria Automation Orchestrator Appliance CD-ROM drive.
 3. Mount the CD-ROM drive.

```
mount /dev/xxx /mnt/cdrom
```

IMPORTANT

For clustered VMware Aria Automation Orchestrator deployments, you must perform steps 2 and 3 on all nodes in the cluster.

4. Back up your VMware Aria Automation Orchestrator deployment by taking a virtual machine (VM) snapshot. See [Take a Snapshot of a Virtual Machine](#).

CAUTION

VMware Aria Automation Orchestrator 8.x does not currently support memory snapshots. Before taking the snapshot of your VMware Aria Automation Orchestrator deployment, verify that the **Snapshot the virtual machine's memory** option is deactivated.

- To initiate the upgrade, run the `vracli upgrade exec -y --repo cdrom://` command on one of the nodes in your deployment.

NOTE

For VMware Aria Automation Orchestrator deployments authenticated with vSphere, enter the credentials of the user who registered your deployment with the vCenter Single Sign-On (SSO) service. Alternatively you can also, export the your password as a environmental variable. This can be useful for scenarios where you are using an automated script to upgrade multiple VMware Aria Automation Orchestrator deployments. To export the SSO password, run the `export VRO_SSO_PASSWORD=your_sso_password` command.

During the upgrade, you are automatically logged out of your terminal, because the VMware Aria Automation Orchestrator Appliance reboots.

- Log in to the VMware Aria Automation Orchestrator Appliance command line as **root** and follow the upgrade progress by running the `vracli upgrade status --follow` command.

CAUTION

The `vracli upgrade status --follow` command can occasionally display a false error message that indicates that the upgrade has failed. To troubleshoot this problem, see step 7.

- If you receive an error message while running the `vracli upgrade status --follow` command, follow these steps:

- Verify that you receive the following error message:

```
Running health check after upgrade for nodes and pods.
```

```
Health check after upgrade for nodes and pods failed.
```

```
... Upgrade terminated due to critical error. Follow the upgrade guide to
recover the system. ...
```

- Navigate to the `/var/log/vmware/prelude/upgrade-report-latest` and confirm that you receive the following error:

```
Pod: vco-app-xxxx is not in Ready or Completed state. All pods must be in
either of these states
```

- Run the `kubectl get pods -n prelude -w | grep -E 'vco|orchestration-ui'` command and verify that the status of all 3 vco-app pods and the orchestration-up-app pod is **RUNNING**.

NOTE

It can take up to 5-10 minutes after receiving the error message for all pods to enter the **RUNNING** state.

orchestration-ui-app-xxxx	1/1	Running	0	5h42m
vco-app-xxxx	3/3	Running	0	5h47m

- d) Run the `curl -k https://<your_orchestrator_FQDN>/vco/api/healthstatus` command and verify that the health check is returning a RUNNING status.

```
{"state": "RUNNING", "health-status":  
{"state": "OK", "time": 1615296823325}, "instance-id": "your_orchestrator_FQDN"}
```

IMPORTANT

The preceding command must run in an environment different from the VMware Aria Automation Orchestrator command line. You can run the command from the command line of a different virtual machine. You can also view the health status information in a browser by navigating directly to `https://<your_orchestrator_FQDN>/vco/api/healthstatus`.

You have upgraded your VMware Aria Automation Orchestrator deployment. To troubleshoot possible problems with the upgrade, see [Troubleshooting Upgrades](#).

Validate that the VMware Aria Automation Orchestrator Appliance upgrade was successful by running the `vracli version` command in the command line of the appliance. By running this command, you can validate the product version and build number of the VMware Aria Automation Orchestrator Appliance.

Troubleshooting VMware Aria Automation Orchestrator Upgrades

Your VMware Aria Automation Orchestrator deployment can encounter issues during and after attempting to upgrade the deployment to the latest product version.

False Upgrade Failure Notification

The upgrade log indicates that the upgrade process has failed, but the individual nodes of the deployment are upgraded.

After the upgrade script finishes running, you receive the following message in your VMware Aria Automation Orchestrator Appliance indicating that the upgrade has failed:

```
Upgrade failed and left the system in non-working state. Check the error report below to  
correct the problem. Once addressed, you can continue the upgrade by running 'vracli  
upgrade exec --resume'
```

However, the upgrade log lists that the nodes of your VMware Aria Automation Orchestrator deployment are upgraded.

Hostname: <your_vRO_node_FQDN>

Status: Upgraded

Cluster Member: Yes

Version Before: <build_before_upgrade>

Version After: <build_after_upgrade>

Description: The node is upgraded successfully.

To resolve this problem, verify that the nodes are running, and resume the upgrade.

1. Verify that your VMware Aria Automation Orchestrator nodes are running.

```
kubectl get all pods
```

2. If your VMware Aria Automation Orchestrator nodes are running, resume the upgrade process.

```
vracli upgrade exec --resume
```

Migrating VMware Aria Automation Orchestrator

You can migrate your existing VMware Aria Automation Orchestrator 7.x deployment to a VMware Aria Automation Orchestrator 8.x environment. Migration is supported for VMware Aria Automation Orchestrator 7.3 or later authenticated with vSphere or with VMware Aria Automation 7.x.

What does the migration include?

The VMware Aria Automation Orchestrator migration transfers an external source VMware Aria Automation Orchestrator configuration to your current VMware Aria Automation Orchestrator environment, overwriting all existing elements such as workflows, actions, configuration and resource elements, including secure strings in workflows and configuration elements, packages, tasks, policies, certificates and trusted certificates, plug-ins and plug-in configurations, custom records in the `js-io-rights.conf` file, Control Center system properties. The migration includes both built-in and custom VMware Aria Automation Orchestrator content.

- The migration of VMware Aria Automation Orchestrator instances authenticated with vSphere also includes the state of currently running entities, such as workflow execution tokens, scheduled tasks, policy runs.
- For VMware Aria Automation Orchestrator instances authenticated with VMware Aria Automation Orchestrator, the currently running entities appear in a failed state in the target VMware Aria Automation Orchestrator environment.

What is not migrated?

The migrated VMware Aria Automation Orchestrator configuration does not include the following data that might affect the target VMware Aria Automation Orchestrator performance and use.

- The VCAC, VCACCAFE, GEF, Data Management, and Workflow Documentation plug-ins of the source VMware Aria Automation Orchestrator. Aside from workflow runs, all VMware Aria Automation Orchestrator content associated with these plug-ins is not migrated to the VMware Aria Automation Orchestrator target environment.
- Syslog server configuration in the **Logging Integration** page in Control Center.
- Workflow execution logs.
- Dynamic Types plug-in configurations.

Migrating embedded VMware Aria Automation Orchestrator environments

You can migrate your external VMware Aria Automation Orchestrator 7.x environment to both external and embedded VMware Aria Automation Orchestrator environments. However, migration of embedded VMware Aria Automation Orchestrator environments to external environments is not supported.

For information about migrating embedded VMware Aria Automation Orchestrator environments, see the VMware Aria Automation Transition Guide.

FIPS compliance considerations

Migrating or upgrading existing non-FIPS deployments to FIPS-compliant VMware Aria Automation Orchestrator 8.x environments is not supported.

By default, FIPS mode can be enabled only during installation. For more information, see [Download and Deploy the Automation Orchestrator Appliance](#).

To learn more about support for FIPS 140-2 in VMware products, see [this page](#).

Migrate a Standalone VMware Aria Automation Orchestrator 7.x to VMware Aria Automation Orchestrator 8.x

You can migrate an external standalone VMware Aria Automation Orchestrator 7.x instance to a VMware Aria Automation Orchestrator 8.x environment. Migration is supported for VMware Aria Automation Orchestrator 7.x instances authenticated with vSphere or with VMware Aria Automation 7.x.

- Migration is supported for VMware Aria Automation Orchestrator 7.3 or later.
- Download and deploy a VMware Aria Automation Orchestrator 8.x environment. See *Download and Deploy the VMware Aria Automation Orchestrator Appliance* in *Installing and Configuring VMware Aria Automation Orchestrator*.
- Configure the authentication provider of your target VMware Aria Automation Orchestrator environment. The authentication provider of the source VMware Aria Automation Orchestrator instance is not migrated. See *Configuring a Standalone VMware Aria Automation Orchestrator Server* in *Installing and Configuring VMware Aria Automation Orchestrator*.
- Back up the target VMware Aria Automation Orchestrator environment.
- Verify that SSH access is enabled on the source VMware Aria Automation Orchestrator instance and target VMware Aria Automation Orchestrator environment. See *Activate or Deactivate SSH Access to the VMware Aria Automation Orchestrator Appliance* in *Installing and Configuring VMware Aria Automation Orchestrator*.
- Verify that the source VMware Aria Automation Orchestrator database is accessible from the target VMware Aria Automation Orchestrator environment.

IMPORTANT

Upgrading VMware Aria Automation Orchestrator 7.x or earlier to VMware Aria Automation Orchestrator 8.x is not supported.

The migration transfers an external standalone VMware Aria Automation Orchestrator 7.x configuration to your VMware Aria Automation Orchestrator 8.x environment. The migration involves overwriting all existing elements in your VMware Aria Automation Orchestrator 8.x environment, such as workflows, actions, configuration and resource elements, including secure strings in workflows and configuration elements, packages, tasks, policies, certificates and trusted certificates, plug-ins and plug-in configurations, custom records in the `js-io-rights.conf` file, Control Center system properties. The migration of VMware Aria Automation Orchestrator instances authenticated with vSphere also includes the state of currently running entities, such as workflow execution tokens, scheduled tasks, policy runs. For VMware Aria Automation Orchestrator instances authenticated with VMware Aria Automation, the currently running entities appear in a failed state in the target VMware Aria Automation Orchestrator environment. The migration includes both built-in and custom VMware Aria Automation Orchestrator content.

NOTE

Migration of clustered VMware Aria Automation Orchestrator 7.x deployments to VMware Aria Automation Orchestrator 8.x is not supported. You can migrate the primary node of your clustered deployment by stopping the services of the replica nodes before you run the migration script.

```
service vco-server stop  
service vco-configurator stop
```

You perform the migration by using the `vro-migrate` command on the VMware Aria Automation Orchestrator appliance.

NOTE

The migration script stops the VMware Aria Automation Orchestrator services automatically.

1. Log in to the VMware Aria Automation Orchestrator appliance command line of your target environment over SSH as **root**.
2. To start the migration, run the `vro-migrate` command.

3. Follow the command prompts to provide the fully qualified domain name (FQDN) and credentials of the source VMware Aria Automation Orchestrator instance.
4. To follow the migration progress, access the migration log:
 - a) Log in to your target VMware Aria Automation Orchestrator appliance command line over a separate SSH session as **root**.
 - b) Run the `tail -f /var/log/vmware/prelude/vro-migration.log` command.

NOTE

The name of the migration log file includes the date and time of when the migration log is generated.

`vro-migration-YYYY-MM-DD-HH-MM-SS.log`

5. If you want to access your source VMware Aria Automation Orchestrator 7.x environment after migration, restart the `vco-server` and `vco-configuration` services on the source system.

The migration process begins. You receive a notification on the target VMware Aria Automation Orchestrator appliance when the migration finishes.

Additional Migration Requirements for Content Accessing the File System

Content migrated to the VMware Aria Automation Orchestrator file system must follow the requirements of the new container-based appliance.

Because the VMware Aria Automation Orchestrator Appliance is running in a container, it has limitations regarding access to the file system. The `js-io-rights.conf` file still determines if a file is accessible from the VMware Aria Automation Orchestrator scripting API, but you cannot use arbitrary folders in the file system. The main folder accessible to the VMware Aria Automation Orchestrator service is `/var/run/vco`. Under the VMware Aria Automation Orchestrator Appliance file system, this folder is mapped under `/data/vco/var/run/vco`. All local files that access the VMware Aria Automation Orchestrator scripting API must be moved to the specified main directory. Under the main directory, you can create subdirectories for your content.

For example, if you want to mount an external NFS volume to your VMware Aria Automation Orchestrator appliance, you must mount it in `/data/vco/var/run/vco/mount_directory_path`. Afterwards, the VMware Aria Automation Orchestrator scripting API can access the mounted NFS volume at `/var/run/vco/mount_directory_path`.

Kerberos Configuration

To use a Kerberos configuration, you can only use the `/data/vco/usr/lib/vco/app-server/conf/krb5.conf` file. For information on Kerberos debug logging, see *Enable Kerberos Debug Logging in Installing and Configuring VMware Aria Automation Orchestrator*.

VMware Aria Automation NSX-V to NSX-T (NSX V2T) Migration

VMware Aria AutomationNSX-V to NSX-T migration enables you to take advantage of the NSX Data Center Migration Coordinator (was NSX-T Data Center Migration Coordinator) from within the constructs of VMware Aria Automation. While the migration process is primarily run in the VMware Aria Automation environment, there are several interconnected actions within the process that involve both the VMware Aria Automation administrator and the NSX administrator working together to share information.

You can migrate your NSX-V Manager (NSX-V) to NSX Manager (NSX-T) by using the prescriptive VMware Aria AutomationNSX-V to NSX-T migration assistant in VMware Aria Automation. The migration assistant consists of a getting started page and sequential migration plan pages.

NOTE

Starting with VMware Aria Automation 8.18.1, the migration assistant is no longer supported and you cannot perform the NSX V2T migration. The migration assistant is still supported for earlier versions of VMware Aria Automation.

Each source NSX-V cloud account requires a separate migration plan in the VMware Aria AutomationNSX-V to NSX-T migration assistant.

By migrating your NSX-V cloud accounts and their related objects to NSX-T, you can take advantage of the many enhanced features and functions of NSX-T itself and as integrated within VMware Aria Automation.

While you work with the migration plan in VMware Aria Automation, there is a point in the process where the VMware Aria Automation administrator and the NSX administrator must share files with one another as input to, and output from, the NSX Data Center Migration Coordinator (was NSX-T Data Center Migration Coordinator) utility. The migration plan on-screen help informs you when you and the NSX administrator need to communicate with one another to share the needed files.

The VMware Aria AutomationNSX-V to NSX-T migration assistant is available for migrating NSX-V cloud accounts and their related objects to NSX-T within your current VMware Aria Automation release. It is not available for migrating NSX cloud accounts from one VMware Aria Automation release to another.

This guide is meant for use with the VMware Aria AutomationNSX-V to NSX-T migration assistant and its prescriptive migration plans. Use this guide to supplement the on-screen instructions provided in the VMware Aria AutomationNSX-V to NSX-T migration plan on-screen guidance.

For information about the related NSX Data Center Migration Coordinator (was NSX-T Data Center Migration Coordinator) utility, see [NSX-T Data Center Migration Coordinator Guide](#) in the VMware NSX product documentation.

For more information about the benefits of migrating to NSX-T, see the [Migrate to VMware NSX-T](#) product page.

Supported topologies

VMware Aria Automation supports migration of NSX-V objects to NSX-T release 3.1.1 or later objects, including NSX-T release 3.1.3. It does not support migration of NSX-V objects to NSX-T release 3.1.0 or earlier objects.

NOTE

The VMware Aria AutomationNSX-V to NSX-T migration process is currently designed to work with the Migration Coordinator in NSX-T 3.1.x and later. The expectation is that the process will also work, in future VMware Aria Automation releases, with NSX Fixed Mode. VMware Aria Automation does not currently support either NSX Fixed Mode or NSX User-Defined Mode.

The NSX-V to NSX-T migration process migrates to NSX-T Policy API. It does not migrate to NSX-T Manager API.

vCenter 6.7 associations are migrated to vCenter 6.7. vCenter 7.0 or greater associations are migrated to vCenter 7.0 or greater.

The NSX-V to NSX-T migration process supports NSX-V to NSX-T migration for deployments that were migrated from VMware vRealize Automation 7.x to VMware vRealize Automation 8.x or VMware Aria Automation and for deployments that originated in VMware vRealize Automation 8.x or VMware Aria Automation.

In the following scenario, workloads are migrated from VMware vRealize Automation 7.x to VMware Aria Automation and then NSX objects are migrated from NSX-V to NSX-T in VMware Aria Automation.

1. Deploy your current VMware Aria Automation release.
2. Migrate your workloads to your current VMware Aria Automation release by using the migration wizard. Reference the [VMware Aria](#)

Automation Transition

Guide for your release.

3. Deploy the NSX-T application.
4. Add an NSX-T cloud account to your current VMware Aria Automation environment and map it to an NSX-T endpoint.
5. Create and run an NSX-V to NSX-T migration to move your workloads from NSX-V to NSX-T, as described in this documentation and in the on-screen migration assistant.
6. When a new VMware Aria Automation release is made available, you can upgrade to it normally by using the [VMware Aria Suite Lifecycle](#) application.

The following topologies are supported and available for migration:

- Existing networks (Static and DHCP)
- Routed networks (Static and DHCP)
- Private networks (Static and DHCP)
- Existing security groups
- On-demand security groups
- On-demand one armed load balancers on existing networks
- Outbound networks (Static and DHCP) with or without shared gateway
 - User-defined DNAT rules are not supported
 - Load balancers with outbound networks are not supported
- Machine (DHCP IP) connected to an outbound network
- Multiple outbound networks connected through a gateway
- Deployments that contain outbound or private networks that use isolation policy as an on-demand security group
- Private networks that are isolated by a security group
- Outbound networks that are isolated by a security group
- On-demand routed networks with DHCP and one-armed load balancer
- On-demand and existing security groups and load balancer
- On-demand outbound networks with DHCP and load balancer

The following topologies are also supported:

- NSX-V networks associated with vCenter 6.7 and CVDS 6.7. Migration is to NSX-T 3.1.1 or greater with vCenter 6.7 and NVDS or vCenter 7.0 and NVDS.
- NSX-V networks associated with vCenter 7.0 and CVDS. Migration is to NSX-T with vCenter 7.0 and NVDS.

For related information about supported topologies, see [Topologies Supported for Integration with VMware Aria Automation](#) in the VMware NSX product documentation.

Unsupported topologies

The following topologies are not supported for migration:

- Deployments that contain NAT or DNAT rules configured on the NAT or gateway component
- Routed networks with shared T1

- One-arm load balancer or inline load balancer on any on-demand network
- On-demand inline load balancers on existing networks
- Deployments that use the public network type
- Deployments that reference vSphere network types.

Manager API to Policy API migration is not supported.

If the assessment step in the migration plan encounters an unsupported topology, it generates a validation error.

Running data collection if NSX-V and vCenter objects were migrated from vRealize Automation 7.x

If any deployments in your VMware Aria Automation environment were migrated from vRealize Automation 7.x, you must run data collection on their NSX-V and vCenter cloud accounts before you create your VMware Aria AutomationNSX-V to NSX-T migration plan. This step is needed to collect information about migrated resources such as load balancers and security groups.

Accessing the VMware Aria AutomationNSX-V to NSX-T Migration Assistant

This section provides an overview of the migration process.

Open the VMware Aria AutomationNSX-V to NSX-T migration assistant from the cloud services console.

1. Using your VMware Aria Automation administrator credentials and migration role privileges, log in to your VMware Aria Automation console and click the VMware Aria Automation **Migration Assistant** service tile.
2. Click **Getting Started** from the **NSX V2T Migration** menu. To gain an overview of the process, review the information on the **Getting Started** page. For more information, see [Getting started with VMware Aria AutomationNSX-V to NSX-T migration](#).
3. When you are ready to start the migration, click **Migration Plan** from the **NSX V2T Migration** menu and then click **New Plan**.
4. The migration plan wizard provides the sequential instruction you need to advance through each step in the process. For more information, see [Creating and running the VMware Aria AutomationNSX-V to NSX-T migration plan](#).

Getting started with VMware Aria AutomationNSX-V to NSX-T migration

Getting started with NSX V2T migration

The NSX-V to NSX-T migration process operates primarily within the context of a VMware Aria Automation migration plan wizard, which uses a series of on-screen instructions and prompts. The VMware Aria Automation administrator and the NSX administrator must communicate with one another prior to migration and during one of the migration plan steps in the process.

To gain an overall understanding of the migration process and its supported topologies before you begin the tasks described on the **Getting Started** screen, review the following migration overview. For reference, links to specific documentation topics that apply to each migration plan screen are provided.

The VMware Aria AutomationNSX-V to NSX-T Migration **Getting Started** screen shows the step sequence.

1. Prepare for migration

To prepare for migration, work with your NSX administrator. Each migration plan requires input to and output from the NSX Data Center Migration Coordinator (was NSX-T Data Center Migration Coordinator) utility in NSX. During migration, the migration plan on-screen help informs you when to share data files with the NSX administrator.

Coordination between you, as the VMware Aria Automation administrator, and the NSX administrator is helpful for successful migration. Inform them of your plans so that they can make time in their schedule to help you by importing and exporting files in the NSX Data Center Migration Coordinator (was NSX-T Data Center Migration Coordinator) utility, which is the utility that performs the underlying NSX migration. During step 4 in the migration plan, you and the NSX

administrator must share NSX Data Center Migration Coordinator (was NSX-T Data Center Migration Coordinator) files with one another, as described in [Creating and running the VMware Aria AutomationNSX-V to NSX-T migration plan](#). For more information about the NSX Data Center Migration Coordinator (was NSX-T Data Center Migration Coordinator), see [Migrating NSX Data Center for vSphere \(NSX-V\) with vRealize Automation](#) in the VMware NSX product documentation.

2. Configure cloud accounts

Before you can migrate your NSX-V cloud accounts to NSX-T using the VMware Aria AutomationNSX-V to NSX-T migration assistant, you must create a new and unassociated NSX-T target cloud account in VMware Aria Automation for each source NSX-V cloud account.

Add a new target NSX-T cloud account to VMware Aria Automation for each source NSX-V cloud account in your VMware Aria Automation projects.

You must create one target NSX-T cloud account for each source NSX-V cloud account to be migrated. You specify the 1:1 mapping from a source NSX-V cloud account to a target NSX-T cloud account when you create the migration plan. Each 1:1 cloud account mapping requires its own separate migration plan. The plan step is described in [Creating and running the VMware Aria AutomationNSX-V to NSX-T migration plan](#).

- The target NSX-T cloud account must be at NSX Data Center version 3.1.1 or higher.
- You must specify the **Policy API method** option when you create the target NSX-T cloud account. The **Manager API method** is not supported by the migration utility for a target NSX-T cloud account.
- The target NSX-T cloud account *must not* be associated to a vCenter cloud account. You create that association later in the process.
- The NSX-T cloud account specified must not be in use by a VMware Aria Automation deployment.

For information about how to create an NSX-T cloud account, see [Using Automation Assembler](#).

3. Create an NSX-V to NSX-T migration plan

By starting the VMware Aria AutomationNSX-V to NSX-T migration utility, you begin to populate the NSX migration plan by following the perspective on-screen instructions and prompts.

The NSX migration plan guides you through the following required steps:

1. Configure source and target cloud accounts.
2. Run an assessment to determine readiness for migration.
3. Enter maintenance mode for the cloud accounts.
4. Transfer configuration and mapping files to and from your NSX administrator.
5. Run migration to map source NSX-V objects to new target NSX-T objects.
6. Test your system.
7. Exit maintenance mode for the cloud accounts.

See [Creating and running the VMware Aria AutomationNSX-V to NSX-T migration plan](#).

Creating and running the VMware Aria AutomationNSX-V to NSX-T migration plan

[Creating and running the NSX-V to NSX-T migration plan](#)

To migrate your NSX-V cloud accounts to NSX-T cloud accounts, and map existing NSX-V objects in VMware Aria Automation to new NSX-T objects, use on-screen migration plan instructions and supporting documentation.

Before you can create your migration plan, you must perform the tasks described on the **Getting Started** screen. See [Getting started with VMware Aria AutomationNSX-V to NSX-T migration](#).

The **Migration Plan** screens contain sequential steps that you need to perform to successfully migrate a source NSX-V cloud account and its associated objects to NSX-T within VMware Aria Automation.

Each step in the numbered sequence of migration plan screens requires successful completion of the previous plan screen. The migration plan advances in a linear sequence. Each numbered screen represents a stage in the process.

Prerequisites

To create and run a migration plan, you require the following service roles:

- Automation Assembler Administrator
- VMware Aria Automation Migration Assistant Administrator

Create a new plan

From the VMware Aria Automation Migration Assistant service screen, click **NSX V2T Migration** > **Migration Plans** > **New plan** to start your new migration plan.

The 7 step migration plan screen appears. Proceed sequentially through each step of the plan.

1. NSX accounts - Add source and target NSX accounts

Enter your new VMware Aria AutomationNSX-V to NSX-T migration plan name and enter the 1:1 mapping for your source NSX-V cloud account and its target NSX-T cloud account.

1. Enter a migration plan name. You can optionally enter a plan description.
2. Enter the existing VMware Aria Automation source NSX-V Manager cloud account name.
Each source NSX-V cloud account requires a separate migration plan in the VMware Aria AutomationNSX-V to NSX-T migration assistant.

The source NSX-V cloud account must be associated with a vCenter 7.0 or later cloud account.

3. Enter the VMware Aria Automation target NSX Manager cloud account name.

This is the target NSX-T cloud account that you created during the prerequisite phase of migration using instructions on the **Getting Started** screen.

The target NSX-T cloud account must meet the following conditions:

- The target NSX-T cloud account must be at NSX Data Center version 3.1.1 or higher.
 - You must specify the **Policy API method** option when you create the target NSX-T cloud account. The **Manager API method** is not supported by the migration utility for a target NSX-T cloud account.
 - The target NSX-T cloud account *must not* be associated to a vCenter cloud account. You create that association later in the process.
 - The NSX-T cloud account specified must not be in use by a VMware Aria Automation deployment.
4. Click **Next: Assessment** to move to the next screen in the plan and continue with the migration process.

2. Assessment - Run an assessment of your current VMware Aria Automation integration with NSX-V

Determine the migration readiness of the source NSX-V cloud account and its related objects to NSX-T. Also determine the readiness of the target NSX-T cloud account to receive the migrated objects.

1. Click **Run assessment** to run the initial assessment.
2. If the assessment displays an error, examine the output messages.
3. Based on the messages that you receive, open the **Summary** tab and each relevant tab to check for readiness.

Assessment evaluates NSX-V objects to determine if they can be migrated.

RUN ASSESSMENT **EXPORT**

Summary Deployments Network Profiles Networks Load Balancers Security Groups

Name: mp-new-plan

Assessment status: (1) Not ready

Last run: Nov 22, 2020, 2:59:29 PM

Name	Assessment Status	Description
mp-nsxv	Ready	NSXV cloud account : 'mp-nsxv' supported.
mp-nsxt	Not Ready	NSXT cloud account : 'mp-nsxt' supported.

NEXT

Make any needed corrections and then click **Run assessment** again.

4. Open each tab to examine the objects that are ready for migration.
For example, open the **Networks** tab and examine the network objects that are ready for migration.
5. When you are satisfied with the assessment and are ready to continue, click **Export**.
You can use the exported file to help you with post-migration testing prior to taking the cloud accounts out of maintenance mode.
6. Click **Next** to move to the next screen in the plan and continue with the migration process.

3. Maintenance Mode - Enter maintenance mode for the cloud accounts

Put the cloud accounts that you are about to migrate into maintenance mode. When a cloud account is in maintenance mode, all allocation, provisioning, Day 2 actions, and scheduled enumeration is stopped for that cloud account. This ensures that no impacted VMware Aria Automation deployments can be initiated, edited, or in operation while its affiliated NSX-V cloud account is in the process of being migrated to NSX-T.

NOTE

Do not create, update, or delete any deployments after their cloud accounts have been put into maintenance mode. Although the migration administrator has such privileges (for testing purposes post-migration), deployments that are deleted by a migration administrator after the cloud accounts are put into maintenance mode cause serious errors later in the migration process.

While maintenance mode prevents the use of the cloud account, and any objects that are related to the cloud account, during the migration process, VMware Aria Automation administrators who have the *Migration Administrator Service* role are provided with testing access.

1. Click **Enter maintenance mode**.
2. As prompted, create a backup of your VMware Aria Automation environment.
3. After you have created the needed backup, click **Backups are created and I am ready to continue** and then click **Next** to move to the next screen in the plan and continue with the migration process.

The screenshot shows a maintenance mode configuration screen. At the top, there's a dropdown menu with 'Maintenance Mode' selected and a note: 'Enter maintenance mode for cloud accounts'. Below this, a message states: 'These cloud accounts must be in maintenance mode during migration. While in maintenance mode data collection is paused and provisioning is disabled for users that do not have the Migration Administrator role.' A table lists three cloud accounts: v2t-nsxv, v2t-nsxt, and v2t-vcenter, all marked as 'In maintenance'. Below the table, a note says: '⚠️ Now that the accounts have been placed into maintenance mode, [save a backup](#) to ensure that a stable system can be restored in case of error.' There's also a 'Documentation' link and a checked checkbox for 'Backups are created and I am ready to continue.' A 'NEXT' button is at the bottom.

4. NSX Migration - Transfer files to and from the NSX Data Center Migration Coordinator (was NSX-T Data Center Migration Coordinator)

Generate a deployment configuration file for input to the NSX Data Center Migration Coordinator service. You give that configuration file to the NSX administrator for their input to the NSX Data Center. You then receive and import a mapping output file, which is generated by the NSX Data Center coordinator service and which you obtain from the NSX administrator.

This procedure describes tasks that are performed by the VMware Aria Automation administrator in VMware Aria Automation and tasks that are performed by the NSX administrator in NSX. The VMware Aria Automation administrator and the NSX administrator can be different people or they may be the same person.

- As prompted, create the deployment configuration file by clicking **Create File**.

The screenshot shows a step titled 'Create Deployment Configuration File'. It includes a note: 'Reassess to ensure all information is up to date then create and download the Deployment Configuration File. This file is required as input for NSX-T Data Center Migration Coordinator.' Below this are 'REASSESS' and 'CREATE FILE' buttons. A note below the buttons says: ' ⓘ Send the Deployment Configuration File to your NSX administrator. NSX-T Data Center Migration Coordinator can take over 2 hours to complete. You can close this plan and return when you receive the Output Mapping File.' A close button 'X' is at the top right of the note area.

NOTE

If you receive errors or warnings about objects that are not ready for migration, address the issues as suggested and then click **Reassess**. The **Create File** option is not re-enabled until you click **Reassess** and receive no further errors or warnings.

- Respond to prompts to save the .json file and review the instructions about where to send the file.
- After the deployment configuration file is generated, and as prompted, send it to the NSX administrator and ask them to import it into the NSX Data Center Migration Coordinator (was NSX-T Data Center Migration Coordinator) service.

The NSX administrator imports the file into the NSX Data Center Migration Coordinator (was NSX-T Data Center Migration Coordinator) service, which subsequently generates the output mapping file that you need to complete the next step on this migration plan screen. For information about the process by which the NSX administrator imports the file into the NSX Data Center Migration Coordinator (was NSX-T Data Center Migration Coordinator) service, see [Import the NSX Data Center for vSphere Configuration](#) in the NSX-T Data Center Migration Coordinator Guide.

It can take some time between this step and the next. During this wait period, your cloud accounts remain in maintenance mode.

- Obtain the output mapping file, which is generated by the NSX Data Center Migration Coordinator (was NSX-T Data Center Migration Coordinator), from the NSX administrator.

The NSX Data Center Migration Coordinator (was NSX-T Data Center Migration Coordinator) can generate a partial or a complete output mapping file. The migration plan requires a complete output mapping file. To save time and avoid confusion, confirm with the NSX administrator that they are giving you the complete, not partial, output mapping file.

5. Click **Import File** and import the NSX Data Center Migration Coordinator (was NSX-T Data Center Migration Coordinator) output mapping file supplied to you by the NSX administrator.

Import the Output Mapping File

After NSX-T Data Center Migration Coordinator is completed an output Mapping File is created. This file is required to continue.

IMPORT FILE

When you import the completed output mapping file from NSX Data Center Migration Coordinator (was NSX-T Data Center Migration Coordinator), the migration plan uses it to migrate cloud accounts and their related objects in VMware Aria Automation.

If you import a partial output mapping file, the import task eventually fails with the following error message: The output mapping file was downloaded before the NSX migration completed. Use the output mapping file downloaded after the migration process completed.

For information about the contents of an output mapping file, see [Overview of Output Mapping File](#) in the VMware NSX product documentation.

6. When the import task is finished successfully, click **Next** to move to the next screen in the plan and continue with the migration process.

5. VMware Aria Automation Migration - Migrate from source to target cloud accounts

Run migration to map the source NSX-V cloud account and its related objects in VMware Aria Automation to the target NSX-T cloud account.

This stage of the migration uses data from the NSX Data Center Migration Coordinator (was NSX-T Data Center Migration Coordinator) output mapping file (which you imported on the previous screen in the migration plan) to migrate your NSX-V cloud account to NSX-T in VMware Aria Automation.

1. Click **Run migration** to migrate the NSX-V cloud accounts and their associated objects in VMware Aria Automation to NSX-T cloud accounts and objects.
2. When the **Run migration** is complete, a summary message appears.

Migration updates the objects in vRealize Automation to use the NSX-T objects created by NSX-T Data Center Migration Coordinator

Name	Migration Status	Details
aa_v2t_network	SUCCESS	

1 - 1 of 1 items

If the **Run migration** action is not successful, examine the output messages on the **Summary** screen and open each relevant tab to discover where problems were found.

Depending on what problems may have occurred during migration, you might decide to continue or to use the snapshot backups that you created earlier to discard the migration and restore your cloud accounts and objects to their pre-migration status. If the objects have been migrated in the NSX Data Center Migration Coordinator (was NSX-T Data Center Migration Coordinator), you would also need to roll back the actual NSX migration.

3. Click **Export** to generate a history file of the migration for your future reference.
4. Click **Next** to move to the next screen in the plan and continue with the migration process.

6. Test Phase - Test your system

After migration is complete, leave your cloud accounts in maintenance mode and run tests to verify the migration results.

The cloud accounts and their related objects are still in maintenance mode and no work can be done on them. However, VMware Aria Automation administrators who have the *Migration Assistant Administrator* role can access the cloud account objects for post-migration testing. VMware Aria Automation administrators who have the *Migration Assistant Administrator* role can perform limited testing on cloud accounts that are in maintenance mode.

Ideally you will have created a test plan for your organization, but general suggestions for testing are provided on-screen and include the following basics. Reference the assessment files that you exported on screens 2 and 5 of the migration plan as part of your post-migration testing.

- Review any warnings that were generated during migration.
- Test the 1:1 cloud account mapping that you specified in plan step 1.
- Test a sample or all of the impacted cloud templates and deployments.
- Examine mapped NSX load balancers, networks, and security groups to verify that they are configured as expected.
- Provision and destroy applications by deploying cloud templates and confirming that the applications land on the correct endpoint and that they are functional.
- Monitor previously deployed applications to verify that they are functioning as intended.

After you complete post-migration testing, click **Next** to move to the next screen in the plan and complete the migration process.

7. Finish - Exit maintenance mode and finish

After you have completed your post-migration testing, remove the cloud accounts from maintenance mode and exit the VMware Aria AutomationNSX-V to NSX-T migration plan.

1. Select the VMware Aria Automation resources that are currently in maintenance mode and remove their maintenance mode marker. Respond to any prompts.
2. To complete the cloud account migration process and exit the plan, click **Finish**.

Perform post-migration cleanup tasks in vCenter

After you exit the migration plan, you must perform some post-migration cleanup tasks in the associated vCenter environments. See [Performing post-migration tasks and working with migrated resources in VMware Aria Automation](#).

Performing post-migration tasks and working with migrated resources in VMware Aria Automation

Perform post-migration tasks and work with migrated resources

Congratulations on your successful NSX-V to NSX-T migration. Your NSX-T objects are now available for use in the VMware Aria Automation projects that you manage. However, there are some final cleanup steps needed in vCenter.

To complete the overall migration process, you'll need to perform some final post-migration tasks, particularly around NSX-V object clean-up in your vCenter environment. After you have completed these final post-migration tasks, you can share information with your users about moving forward with the migrated resources.

Perform post-migration cleanup tasks

After you have verified your successful migration, you need to do some post-migration cleanup of any remaining NSX-V items. For example, you should delete expired controllers, edges, vCenter plug-ins, configuration files, and so on. This is a manual step and is described in the [Uninstalling NSX for vSphere After Migration](#) in the VMware NSX product documentation.

Work with migrated NSX resources

For information about using NSX-T objects in VMware Aria Automation, see the *Using Automation Assembler* guide.

For information about working with NSX-T itself, see the VMware NSX product documentation.

VMware Aria Automation Extensibility Migration Guide (8.18)

The *VMware Aria Automation Extensibility Migration* guide provides information about functionality changes between vRealize Automation 7.x extensibility and VMware Aria Automation 8.x extensibility.

The *VMware Aria Automation 8.x Extensibility Migration Guide* includes use cases that demonstrate the extensibility functionality in VMware Aria Automation 8.x.

For information on migrating VMware Aria Automation to 8.x, see the *VMware Aria Automation 8 Transition Guide*.

Sample Package and Dynamic Types Plug-in Generator

To develop the use cases documented in this guide, you must download the required sample package. You can also download an updated Dynamic Types plug-in generator that can be used for third-party API integrations.

Sample Package

The use cases in this guide reference resources included in the sample package hosted on VMware {code}. To download the package, see [vRealize Automation Extensibility Migration Guide Samples](#).

Dynamic Types plug-in generator version 3

When developing integrations with third-party APIs for your VMware Aria Automation 8.x environment, the Dynamic Types plug-in generator version 3 can be used to replace version 2 of the generator that was designed for vRealize Orchestrator 7.x. To download the version 3 of the plug-in generator, see [Dynamic Types plug-in generator version 3](#).

Accessing VMware Aria Automation Objects and Properties

Most of the scenarios in this guide require access to the objects of the VMware Aria Automation services. This process is required so you can access and configure object properties or run operations on the objects.

You can access the VMware Aria Automation 8.x services through the REST API by using a REST Client, or through the VMware Aria Automation plug-in for VMware Aria Automation Orchestrator.

The VMware Aria Automation REST APIs are documented in:

- The built-in Swagger/OpenAPI documentation hosted on your VMware Aria Automation server. This documentation can be found at https://your_vRA_FQDN/automation-ui/api-docs/
- [The VMware Aria Automation API Programming Guide](#).

The VMware Aria Automation plug-in for VMware Aria Automation Orchestrator 8.x is documented in *Using VMware Aria Automation Orchestrator 8.x Plug-ins* and the API Explorer built into the VMware Aria Automation Orchestrator Client.

Different services can have different API behavior such as:

- The Infrastructure as a Service (IaaS) service has a different query service syntax and paging syntax from the other services.
- The IaaS service returns a payload of the object created on POST. Other services returns the object ID in the location header.

You can enable the developer view to capture calls to the VMware Aria Automation services to receive more information about:

- Operations (GET, PUT, POST, PATCH, DELETE)
- Base URL (/service/api/resource)
- Parameters (paging, sorting, queries)
- Request payload (The JSON information passed to create / update objects)

- Response payload (The JSON information returned to describe the object and their properties)

However, there are some considerations and differences regarding the VMware Aria Automation API services:

- The user interface uses some proprietary service endpoints. These are not documented or supported and might be changed or become inaccessible outside the user interface in following product releases without notice.
- The enabled operations are different. For example, it is not possible to update machine custom properties in VMware Aria Automation 8.1. However, the functionality is available in VMware Aria Automation 8.2. In the user interface, it was always available in VMware Aria Automation 8.1.
- The response payload might be different as some properties might be missing.

The VMware Aria Automation user interface uses the public API fully and has more options to access service APIs, including software development kits (SDKs) for different languages. In VMware Aria Automation, all extensibility functions include Event Broker subscriptions, Anything as a Service (XaaS) cloud templates, custom resources, and resource actions. XaaS cloud template components, such as custom resources, leverage VMware Aria Automation Orchestrator workflows. Custom forms leverage VMware Aria Automation Orchestrator actions.

For many use cases in VMware Aria Automation, this VMware Aria Automation Orchestrator based extensibility requires access to VMware Aria Automation to get further information from the payload passed from VMware Aria Automation to VMware Aria Automation Orchestrator. The services also list VMware Aria Automation objects, so these objects can be used in extensibility. The most common approach to accessing VMware Aria Automation objects is from the VMware Aria Automation plug-in for VMware Aria Automation Orchestrator. This plug-in can be accessed either from the built-in REST client or through plug-in objects.

The VMware Aria Automation plug-in provides:

1. A way to persist and manage VMware Aria Automation orchestrated hosts with their credentials.
2. The ability to pass host and credentials from a VMware Aria Automation user to the VMware Aria Automation plug-in to make API queries as this user.
3. An inventory of 92 objects allowing users to select objects by their name or properties in drop-down menus or tree-view.
4. Over 800 JavaScript scripting objects and their documentation (API explorer).
5. Hundreds of library actions and workflows supporting common operations.

The updated VMware Aria Automation plug-in for VMware Aria Automation Orchestrator (available in the marketplace for VMware Aria Automation 8.4 and built-in from VMware Aria Automation 8.5 and later) provides:

1. A way to persist and manage VMware Aria Automation orchestrated hosts with their credentials.
2. The ability to pass host and credentials from a VMware Aria Automation user to VMware Aria Automation plug-in to make API queries as this user.
3. An inventory of 11 objects allowing users to select objects by their name or properties in drop-down menus or tree-view. These objects automatically manage VMware Aria Automation API paging capabilities.
4. Over 40 JavaScript scripting objects and their documentation available in the API Explorer.
5. Close to a hundred library actions and workflows supporting common operations.

This section of the guide discusses the implementation of the above use cases in VMware Aria Automation 8.x.

Many of the workflows triggered by VMware Aria Automation leverage the VMware Aria Automation plug-in to access VMware Aria Automation services. The workflow elements making use of these plug-ins and those using the VMware Aria Automation REST API must be rewritten.

To identify the workflow elements that require a rewrite after migrating to VMware Aria Automation 8.x, please use the VMware Aria Automation Migration Assistant. The migration assistant is available from https://your_vRA_FQDN/migration-ui. For more information on migrating to VMware Aria Automation 8.x, see the *VMware Aria Automation 8 Transition Guide*.

Another way to identify workflow elements that require a rewrite is to import the extensibility workflows in VMware Aria Automation 8.x and use the workflow validation tool which identifies errors in each workflow item. Additionally, when importing content from a vRealize Orchestrator 7.6 environment to a VMware Aria Automation Orchestrator 8.x environment, you might want to avoid importing the VMware Aria Automation plug-in library workflows. These workflows are in a read-only state and after importing them, you will be unable to delete them from the VMware Aria Automation Orchestrator 8.x server.

Persist and Manage VMware Aria Automation Orchestrated Hosts with Their Credentials

Learn how to persist and manage VMware Aria Automation orchestrated hosts.

VMware Aria Automation hosts can be persisted and managed with the VMware Aria Automation 8.x plug-in for Automation Orchestrator. See *Add a VMware Aria Automation Host* in *Using VMware Automation Orchestrator plug-ins*.

The examples provided in the sample section of this guide include a default VMware Aria Automation host created by using a shared session. The host is stored as `VRA:Host` and is saved in the "vRA plug-in" configuration element.

Pass Credentials from a VMware Aria Automation User to the VMware Aria Automation Plug-in for Automation Orchestrator

This use case presents alternatives that you can use to pass user credentials without using the VMware Aria Automation plug-in "per user" session capability.

In some use cases, it is required that the roles and permissions for the workflow accessing back to VMware Aria Automation are the same as the user who initiated the workflow from VMware Aria Automation. Some of the use cases that require this are:

- For auditing purposes - when it is necessary to track which user made a change, even if this is through a workflow the user triggered in VMware Aria Automation.
- For presenting information that the user can access, such as the content of a drop-down menu run by XaaS operations or a query run within a workflow.
- For taking actions, modifying properties with the role and permissions of the user. For all operations, the user can trigger that through extensibility.

As of VMware Aria Automation 8.4, there is no solution to pass the VMware Aria Automation authentication from VMware Aria Automation to Automation Orchestrator so it can be used to authenticate back in VMware Aria Automation. The VMware Aria Automation plug-in supports per user sessions, but the plug-in uses a service user role with limited rights.

The workaround for this limitation is to query the end user to reenter their credentials when they run the workflow. However, doing so exposes their credentials to the Automation Orchestrator developer.

Another solution that prevents users from accessing unauthorized data is to use a service account and create action-based filters by project based on user permissions.

The sample workflows provided in the sample package use the default host provided when running the `Set vRA Host` workflow.

VMware Aria Automation 8.x Finder Objects

The vRealize Automation 7.x inventory includes 92 finder objects that can be used to select other inventory objects by name or properties.

The finder objects can be applied through either drop-down menus or a tree view.

You can implement drop-down menus or tree views for the plug-in objects that are documented in API Explorer under `vRA / Types` by adding them as workflow inputs. With the latest version of the plug-in for added in product version 8.4, these objects types are :

- VRA:CloudAccount
- VRA:CloudAccountNsxt
- VRA:CloudAccountNsxv
- VRA:CloudAccountVsphere
- VRA:DataCollector
- VRA:Host
- VRA:Infrastructure
- VRA:Project
- VRA:Region
- VRA:Tag (supports only drop-down menus)
- VRA:Zone

For the other object types you can implement a drop-down menu either with string-based inputs displaying object names bound to an action, or by using one of the following methods:

- Authenticating in VMware Aria Automation by passing the VRA:Host including the specific credentials. The object is included with the sample package.
- Creating a REST query to list the objects by applying filters if necessary.
- Return the object names from the JSON payload.

The string-based input drop-down menu can be populated with actions that return properties that include the ID of the object as a key and the name of the object as a value. By using these properties, you can access the object ID without needing to create actions that query the object by name. An example of such an action is the `getDeploymentsIdsAndNames` action included in the sample package.

To perform efficient queries to find objects, it is necessary to use the query service. Retrieving all objects and iterating through them in a loop is not a best practice, particularly for objects that can have hundreds or thousands of iterations.

Use filtering as much as possible to avoid using CPU, IO, memory, input/output (I/O), or network resources on both the VMware Aria Automation and the Automation Orchestrator deployment.

The following example includes a query used to find an IaaS (Infrastructure as a Service) machine by name. The sample code snippet is taken from the sample action `getMachineByNameQS`.

```
var url = "/iaas/api/machines";
// Query service parameter
var nameFilter = "name eq '" + machineName + "'";
var parameters = "$filter=" + encodeURIComponent(nameFilter).replace("'", "%27");
var machines =
System.getModule("com.vmware.vra.extensibility.plugin.rest").getObjects(vraHost,url,parameters);
if (machines.length == 1) return machines[0];
if (machines.length == 0) return null;
// More Machines returned than expected !
System.warn("getProjectByNameQS returned " + projects.length + " projects");
```

```
return null;
```

You must encode any variable that can contain spaces or other special characters that are not accepted in the URL or from the server. For example, an apostrophe (') must be replaced with %27.

Paging must also be handled. The default number of object returned in a single query is limited. To get all objects, it is possible to:

- Change the default number of objects per page.

NOTE

There can be a maximum limit.

- Make different queries for different page numbers until all objects are received.

The samples actions `getIaaSObjects` and `getDeploymentObjects` provide samples on how to use the paging parameters with the IaaS and deployment services. Depending on the service in use, this is done either with the `skip` parameter or the `page` parameter.

The following sample includes the `getIaaSObjects` sample code:

```
if (vraHost == null || url == null) return null;

var iaasObject =
System.getModule("com.vmware.vra.extensibility.plugin.rest").getObjectFromUrl(vraHost,url,
parameters);
var content = iaasObject.content;

var skip = 0;
var elementsLeft = iaasObject.totalElements - iaasObject.numberOfElements;
var allContent = content;
var numberOfElements = iaasObject.numberOfElements

while (elementsLeft >0) {
    var skip = skip + numberOfElements;
    if (parameters == null) parameters = "$skip=" + skip;
    else parameters = parameters + "&$skip=" + skip;
    iaasObject =
System.getModule("com.vmware.vra.extensibility.plugin.rest").getObjectFromUrl(vraHost,url,
parameters);
    content = iaasObject.content;
    elementsLeft = elementsLeft - iaasObject.numberOfElements;
```

```

    allContent = allContent.concat(content);
}

return allContent;

```

The following sample includes the `getDeploymentObjects` sample code:

```

if (vraHost == null || url == null) return null;

var object =
System.getModule("com.vmware.vra.extensibility.plugin.rest").getObjectFromUrl(vraHost,
url,
parameters);
var content = object.content;

var page = 1;
var allContent = content;

while (object.last == false) {
    if (parameters == null || parameters == "") newParameters = "page=" + page;
    else newParameters = parameters + "&page=" + page;
    object =
System.getModule("com.vmware.vra.extensibility.plugin.rest").getObjectFromUrl(vraHost,
url,
newParameters);
    content = object.content;
    allContent = allContent.concat(content);
    page++;
}

return allContent;

```

To avoid searching for which service is using which query service syntax for paging, the `getObjects()` action checks which query service format to use based on the properties of the JSON file and returns all objects.

As an example of providing an alternative to having inventory objects, the sample package includes the `Drop` down folder. The folder contains workflow examples with forms that use actions to populate the drop-down menus, including deployments, deployment resources, and deployment resource tags.

Another alternative to plug-in inventory objects is to create Automation Orchestrator dynamic types for the required VMware Aria Automation objects. In this way, you can use an object as input supporting different properties or a tree view.

In some use cases, a single tree view is more convenient than multiple drop-down menus because you can filter for the object you want to select based on its parents.

VMware Aria Automation 8.x Scripting Objects

The Automation Orchestrator plug-in for VMware Aria Automation includes several scripting objects with different functionalities.

The latest release of the Automation Orchestrator plug-in for VMware Aria Automation include some scripting objects. The list of the managed object types is located in the API explorer under vRA / Objects. These object types can be used to:

- Define objects specification to create them by using "VraProjectSpecification".
- Get objects details by using "VraProject".
- Run methods on these objects by using VraProject.putCustomPropertiesItem.

Using these object types simplifies workflow development. Objects are documented in API explorer and provide intelliSense capabilities displaying object properties and methods. When these are also used as inventory objects, troubleshooting is also simplified as their properties can be inspected in a workflow run.

VMware Aria Automation Scripting Objects and REST Queries

In VMware Aria Automation 8.x , you can use REST queries to substitute the scripting objects included in the vRealize Automation 7.x plug-in, which can be used to construct, access, and document all program-based objects.

The equivalent of these objects at the REST level is documented in the Models section in Swagger. The Swagger models include JSON examples for object properties that can be included in a Automation Orchestrator action. The Swagger documentation is essential for understanding the properties of the objects returned by REST queries and constructing objects to pass as the body of PUT, POST, PATCH requests.

The following example, createZone, is used to create a zone:

```
if (vraHost == null || regionId == null || name == null) return null;

var customPropertiesObject =
System.getModule("com.vmware.vra.extensibility.plugin.rest.iaas").propertiesToCustomPrope
rtiesObject(customProperties);
var tagsObject =
System.getModule("com.vmware.vra.extensibility.plugin.rest.iaas").propertiesToTagsObject(ta
gs);
var tagsToMatchObject =
System.getModule("com.vmware.vra.extensibility.plugin.rest.iaas").propertiesToTagsObject(ta
gsToMatch);

var url = "/iaas/api/zones"
```

```

var zone =
{
  "customProperties": customPropertiesObject,
  "folder": folder,
  "regionId": regionId,
  "tagsToMatch": tagsToMatchObject,
  "name": name,
  "description": description,
  "placementPolicy": placementPolicy,
  "tags": tagsObject
}

var content = JSON.stringify(zone);
var operation = "POST";

try {

  var contentAsString =
System.getModule("com.vmware.vra.extensibility.plugin.rest").invokeRestOperation(vraHost,
operation, url, content);

  var object = JSON.parse(contentAsString);

  return object.id;

} catch (e) {
  throw "POST " + url + "Failed" +
\n Error : " + e;
}

```

The VMware Aria Automation plug-in included in 7.x also includes "singleton" objects that provide a global access point to properties (Enumerations : constants) and methods. The methods provide special functionalities. For example, methods to find objects by their properties. The latest version of the Automation Orchestrator plug-in for VMware Aria Automation includes a special singleton object called `VraEntitiesFinder` including methods to get plug-in objects for a specific VMware Aria Automation host by type or by ID. These methods also support providing a string-based filter similar to the filters used by the VMware Aria Automation UI and documented in vRA API documentations.

For cases where `vRAEntitiesFinder` does not support the search you are looking for, it is possible to provide equivalent functionality through actions using REST queries. The following example includes code from the sample action `getNetworksByTagsQS` that can be used to find networks.

```

if (vraHost == null) return null;

var tagsFilters = new Array();
for each (var tag in tags) {
  tagsFilters.push(getTagFilter(tag));
}

// Query service parameter
var tagsFilter = tagsFilters.join(" and ");
if (tags.length == 0) var parameters = "expand";
else var parameters = "expand&$filter=" + encodeURIComponent(tagsFilter).replace("'", "%27");

var url = "/iaas/api/fabric-networks";
return
System.getModule("com.vmware.vra.extensibility.plugin.rest").getObjectsProperty(vraHost,
url, parameters, "name");

function getTagFilter(tag) {
  tag = tag.replace(":", "*");
  return "(expandedTags.item.tag eq '*' + tag + '*'))"
}

```

Actions and Workflows Supporting Common Operations

Actions and workflows can be written by using the Automation Orchestrator plug-in for VMware Aria Automation scripting objects and/or the REST client of the VMware Aria Automation plug-in.

When writing actions and workflows by using the REST API, you must follow these guidelines:

- Create action and Create workflows must return the object ID received in the payload or in the "location" response header after invoking a POST operation.
- Delete and Update actions and workflows must have an ID input to pass to the REST query.
- Workflows run by the end user must have an input form that retrieves object names and IDs that return an array of properties.

To test REST API calls, you can use two sample workflows.

- The Invoke VRA 8 REST Operation from URL sample workflow allows you to enter free form URLs.
- The Invoke VRA 8 REST Operation from swagger and display result sample workflow provides a drop-down menu of services, operations, and URLs based on the VMware Aria Automation server Swagger.

Invoke VRA 8 REST Operation from swagger and display result

vRA REST Host *	vRA 8.2	<input type="button" value="X"/>
Service *	Infrastructure as a Service	<input type="button" value="▼"/>
Operation *	GET	<input type="button" value="▼"/>
URL *	/iaas/api/networks	<input type="button" value="▼"/>

Customizing Machine Provisioning

In VMware Aria Automation 8.x, you can customize machine properties or deployments in two ways. You can use event topics that are already available in Automation Assembler to modify custom properties during provisioning, or you can use the VMware Aria Automation API to trigger Day 2 operations on deployments that are already completed.

Customize Machine Properties or Deployments with Extensibility Topics

You can update machine properties or deployments by using the available extensibility topics during the deployment life cycle.

Verify that you have access to the extensibility code samples package.

To update the deployment payload, you can create new subscriptions using available extensibility topics such as **Provisioning Request** and **Disk Allocation** that call VMware Aria Automation Orchestrator workflows or extensibility actions.

1. To customize machine CPU or memory properties, create a new extensibility subscription.
 - a) Enter a subscription name. For example, `Customize CPU/Memory`.
 - b) In **Event Topic**, select **Provisioning request**.
 - c) Next to **Action/workflow**, set an output of type String called `flavor`.

NOTE

You cannot change the machine CPU and memory properties directly if you do not set a new flavor mapping. The output property must be called `flavor`, and the value must be an existing flavor mapping profile.

The following code snippet is taken from a sample extensibility action.

```
def handler(context, inputs):
    outputs = {
        "flavor": "large"
    }
    return outputs
```

2. To customize disk allocation, create another extensibility subscription.

- a) Enter a subscription name. For example, you can name it `Disk size`.
- b) In **Event Topic**, select **Disk allocation**.
- c) Next to **Action/workflow**, set an output of type Array called `diskSizesInGb`.

The following code snippet is taken from a sample VMware Aria Automation Orchestrator workflow.

```
// Customize the size of the first VM disk
var vm_disks = inputProperties.get("diskSizesInGb");
if (isParameterReadOnly("diskSizesInGb") == false) {
    vm_disks[0]=30;
}
```

```
diskSizesInGb = vm_disks;
```

3. Request a new virtual machine from the VMware Aria Automation Catalog Item.

Once the deployment is ready, navigate to the virtual machine settings. Verify that the CPU, memory, or disk size are set to the values configured in the extensibility action or VMware Aria Automation Orchestrator workflow that are used in the subscriptions you created.

Customize Machine Properties or Deployments using the VMware Aria Automation API

To customize machine properties on already completed deployments in VMware Aria Automation 8.x, you can use third party tools or VMware Aria Automation Orchestrator workflows to trigger day 2 operations with API calls.

The following examples use Swagger. You can access the VMware Service Broker API at https://your_VRA_FQDN/deployment/api/deployments/{depId}/resources/{resourceId}/requests

1. Update the CPU/memory values for a machine resource.

Submit a resource action request.

```
POST /deployment/api/deployments/{depId}/resources/{resourceId}/requests
```

The following code snippet is a sample body:

```
{
  "actionId": "Cloud.vSphere.Machine.Resize",
  "targetId": "e9d88d23-2edb-4dcb-812b-b3593368b164",
  "inputs": {"cpuCount": 4, "totalMemoryMB": 4096}
}
```

NOTE

The `actionId` depends on the Machine object type. For vSphere machines, the object is `Cloud.vSphere.Machine`. The `targetId` is the machine resource object ID. You can access both from the machine resource object custom properties in the VMware Aria Automation Client.

2. Update the disk size value for a Disk resource.

Submit a resource action request.

```
POST /deployment/api/deployments/{depId}/resources/{resourceId}/requests
```

The following code snippet is a sample body:

```
{
  "actionId": "Cloud.vSphere.Disk.Disk.Resize",
  "targetId": "710f6d3b-4fdc-4883-8acf-08129c2ad07a",
```

```

  "inputs": {"capacityGb":30}

}

```

NOTE

The `actionId` depends on the Disk resource object type. For a vSphere disk the object is `Cloud.vSphere.Disk`. The `targetId` is the Disk resource object ID. You can access these from the disk resource object custom properties in the VMware Aria Automation Client.

3. Update the Deployment Lease.

Submit a resource action request.

```
POST /deployment/api/deployments/{depId}/resources/{resourceId}/requests
```

The following code snippet is a sample body:

```

{
  "actionId": "Deployment.ChangeLease",
  "targetId": "2da7675d-a791-4a4a-bc4f-5817b5c5e9d2",
  "inputs": {"Lease Expiration Date":"2020-09-20T13:07:00.000Z"}
}

```

NOTE

The `targetId` is the deployment ID. You can access it from the deployment URL in the VMware Aria Automation Client.

Verify that the POST request is successful in the VMware Aria Automation Client.

Day 2 Operations on IaaS Entities

This section discusses changes between vRealize Automation 7.x and VMware Aria Automation 8.x actions.

VMware Aria Automation actions can be separated in three different categories. The examples presented here use the Postman API platform.

Out of the box actions

Out of the box actions can be categorized as follows:

- There are equivalent actions in VMware Aria Automation 8.x, such as **Create Snapshot**. For this category of actions, no changes are required.
- There is no replacement, such as **Get Expiration Reminder**. You must either remove these missing actions from your development lifecycle, or create custom actions to perform the required function.
- There are new actions in VMware Aria Automation 8.x, such as **Revert To Snapshot**. Since these actions are new to VMware Aria Automation, no changes are required.

Custom actions

Custom actions are user written workflows. You export these workflows to Automation Orchestrator 8.x as part of a package and, if applicable, replace the vRealize Automation 7.x API calls. For example, to add a vCPU to a virtual machine, you look up the cloud zone quota before adding the new resource. The following sample includes the output of a GET call to /iaas/api/projects/{id}. The zone `cpuLimit` has a value of zero which means that there is no limit to this parameter.

```

25             "_links": {
```

In Automation Assembler, you create a resource action and add a binding between the Automation Orchestrator `VC:VirtualMachine` input type used in the workflow and the VMware Aria Automation Automation Assembler `Cloud.vSphere.Machine` resource type. To account for the other input parameters in the workflow, you can customize the request form that users see when they request the action. For an example of implementing custom actions, see [How to create a VMware Aria Automation Automation Assembler custom action to vMotion a virtual machine](#) in [Using and Managing VMware Aria Automation Automation Assembler](#).

vRealize Automation 7.x specific actions

Some vRealize Automation 7.x concepts are not valid in VMware Aria Automation 8.x, such as ownership per virtual machine. Instead, VMware Aria Automation 8.x has ownership per deployment. Deployments can be shared among project members.

As a vRealize Automation 7.x user, you can write a day 2 action that changes virtual machine ownership from a provisioning user to an end user. To do the same in VMware Aria Automation 8.x, you must:

1. Enable deployment sharing for your project.
2. Add all users to the project.

Alternatively, you can write a workflow that adds a user to the project by using the following project API call:

```
PATCH /iaas/api/projects/{id}
```

This workflow must have two input parameters, one for project name and one for user name. You create a catalog item for this workflow, and you apply a request form to the catalog item. This request uses another workflow to retrieve project

names. For example, this API call adds testUser2 to a project:

The screenshot shows a POST request in Postman. The URL is `https://sm-vra81.sqa.local/iaas/api/projects/1f3d6aaaf-3a90-4acc-991d-51ddbb28b689?apiVersion=2019-01-15`. The 'Body' tab is selected, showing a JSON payload with the following structure:

```

1  {
2    "administrators": [],
3    "members": [
4      {
5        "email": "testUser2"
6      }
7    ],
8    "viewers": [],
9    "zones": [],
10   "constraints": {},
11   "operationTimeout": 0,
12   "sharedResources": true,
13   "name": "test2",
14   "description": "",
15   "id": "1f3d6aaaf-3a90-4acc-991d-51ddbb28b689",
16   "organizationId": "289b71ef-c7c5-47dc-b17c-d1e30be6723d",
17   "orgId": "289b71ef-c7c5-47dc-b17c-d1e30be6723d",
18   "_links": {
19     "self": {
20       "href": "/iaas/api/projects/1f3d6aaaf-3a90-4acc-991d-51ddbb28b689"
21     }
22   }
23 }
```

The 'Body' tab also shows the raw JSON response, which is identical to the request body.

At the bottom right, the status bar indicates: Status: 200 OK Time: 954 ms Size: 797 B.

Custom Form API Call Examples

You can request a VMware Aria Automation 8.x catalog item with custom forms that use API calls. All examples in this scenario use the Postman API platform.

Obtain a bearer token and refresh token

The screenshot shows the Postman interface with the following details:

Run a script action in a custom form to retrieve data

The screenshot shows a Postman interface with the following details:

- Method:** POST
- URL:** <https://sm-vra81.sqa.local/form-service/api/forms/renderer/external-value?projectId=0b504179-9a70-4532-b43c-d96048683351>
- Body (JSON):**

```

1
2   "contextParameters": {},
3   "dataSource": "scriptAction",
4   "parameters": [],
5   "requestId": 0,
6   "uri": "com.vmware.constants/list_environments"
7 }
```
- Response Headers:**
 - Status: 200 OK
 - Time: 2.30 s
 - Size: 420 B
- Body (Pretty):**

```

1 {
2   "data": "DEV",
3   "requestId": 0
4 }
```

Submit a cloud template request

The forms service API in VMware Aria Automation 8.1 does not support form execution. You cannot request a catalog item that uses a custom form to capture user inputs. As a workaround, you can use two API calls:

- Form service API to retrieve input data.
- Cloud template API to submit the request.

NOTE

Cloud templates were previously known as blueprints.

The screenshot shows a Postman request to `https://sm-vra81.sqa.local/blueprint/api/blueprint-requests`. The request method is POST. The Body tab is selected, showing a JSON payload:

```

1  {
2      "blueprintId": "40c00419-aba8-4090-85bb-2f886a42e1c3",
3      "deploymentName": "maks122",
4      "description": "test iaas deployment",
5      "inputs": {
6          "cpuCount": "2",
7          "totalMemoryMB": "2048"
8      },
9      "projectId": "0b504179-9a70-4532-b43c-d96048683351",
10     "reason": "test again",
11     "simulate": false
12 }

```

The response status is 202 Accepted, with a response body containing the created blueprint request details:

```

1  {
2      "id": "7b7f03ce-fd87-488d-97e0-476c384fbade",

```

Using Dynamic Types with Custom Resources in VMware Aria Automation Automation Assembler

You can expand the functionality of your VMware Aria Automation cloud templates by using dynamic types-based custom resources.

When you create cloud templates in VMware Aria Automation Automation Assembler, you can use different resource types. Examples of resource types include Amazon S3 Buckets, Cloud Agnostics Machines, NSX networks, vSphere Virtual Machines, Microsoft Azure Resource Groups, and others.

You can use VMware Aria Automation Automation Assembler to create custom resources for use cases that are not covered by the preconfigured resource types.

Each custom resource is based on a Automation Orchestrator SDK inventory type and is created by a Automation Orchestrator workflow that has an output which is an instance of your desired SDK type. Primitive types, such as Properties, Date, string, and number are not supported for the creation of custom resources. You can add custom resources to your cloud template design canvas for use during you lifecycle extensibility deployments.

NOTE

SDK object types can be differentiated from other property types by the colon ":" used to separate the plug-in name and the type name. For example, AD:UserGroup is a SDK object type used to manage Active Directory user groups.

For more information on VMware Aria Automation Automation Assembler custom resources, see *How to create custom resource types to use in VMware Aria Automation Automation Assembler cloud templates* in *Using and Managing VMware Aria Automation Automation Assembler*.

The sample workflows included with the sample package in this guide, contain a generic implementation for basic dynamic types objects. The dynamic types sample code creates the object definition, including the dynamic types namespace, if required. All instance of the defined objects are stored in a custom resource as a JSON string. This approach can help speed up VMware Aria Automation custom resource prototyping with dynamic types.

The current guide includes a use case that demonstrates this functionality with a example based on storing additional metadata related to web servers that are deployed by VMware Aria Automation 8.x. In this use case, you use a dynamic types based custom resource to store information about the website that the deployed web server hosts.

In addition to the example provided below, that demonstrates how you can create dynamic types from scratch, you can also leverage the Dynamic Types plug-in generator version 3 to automatically create a plug-in from a OpenAPI/Swagger definition or from individual HTTP REST GET URLs. To download the plug-in generator, see [Dynamic Types plug-in generator version 3](#).

Creating the Dynamic Types Configuration

Before you can begin creating your custom resource, you must first create the necessary dynamic types configuration.

The presented configuration is created through the dynamic types plug-in. To create the configuration, run the `Configure Dynamic Types` workflow included in the sample package. The dynamic type configuration has the following parameters:

Parameter Type	Value
Namespaces	Websites
Object Type	Site
Properties for Site object	<p>domain, host, euro, lease</p> <p>NOTE The dynamic types plug-in only supports strings as property values.</p>
Object Type	SiteFolder

Table continued on next page

Continued from previous page

	<p>NOTE All dynamic types objects are required to have a parent folder, so you are required to create a SiteFolder object.</p>
Relationship	SiteFolder-Site

The above parameters represent the inputs of the working example. You have the `Websites` namespace and an object type called `Site`. In addition to these input parameters, you are also specifying four additional properties, `host`, `euro`, `domain`, and `lease`, that are configured with the default name and ID properties. In the Automation Orchestrator inventory the objects that are created are listed with the name property displayed.

When this workflow finishes running, you can navigate to the inventory section of the Automation Orchestrator Client and review the dynamic types inventory. In the inventory, you should see the `Websites` namespace and the `SiteFolder` parent folder.

Dynamic Types Object and Custom Resource Requirements

After configuring the dynamic types plug-in, you can create some dynamic types object to test the new dynamic types configuration.

You can create an instance of your new dynamic types object by running the `Create Website Object` workflow that is included in the sample package. This workflow creates a dynamic types object called `Websites Site`, which includes the input parameters required for your custom resource.

NOTE

The `Create Website Object` workflow generates an ID for the newly created object if no ID is supplied when first calling the action. Depending on your use case, you might want to supply the ID for these objects by specifying the `ID` property when creating the object.

NOTE

The object types follows the `namespace.object` format. For this use case, the object type would be `Websites.Site`.

When the workflow finishes running, you should see the new object in the dynamic types plug-in inventory under the `Sites` folder.

The data backing the object displayed in the dynamic types inventory is saved as a custom resource under the `VMware/PVE/dynamictypes/dataPersistance` folder.

Regarding the custom resource itself, there are key requirements for Create and Delete workflows:

- The Create workflow must have string type inputs for each required object property.
- The Create workflow must have a dynamic types object as the only output for the workflow.
- The Delete workflow must have single dynamic types object input.

The sample package has workflows for both create and delete website objects.

Create the Dynamic Types Custom Resource

After configuring the dynamic types plug-in and creating some test objects, you must create the custom resource definition in Automation Assembler.

1. In Automation Assembler, select **Design > Custom Resource**, and click **New Custom Resource**.
2. Provide the following values:

Setting	Sample Value
Name	<p>Website</p> <p>This is the name that appears in the cloud template resource type palette. You can use another name if desired.</p>
Resource Type	<p>Custom.website</p> <p>The resource type must begin with Custom. and each resource type must be unique.</p> <p>Although the inclusion of Custom. is not validated in the text box, the string is automatically added if you remove it.</p> <p>This resource type is added to the resource type palette so that you can use it in the cloud template.</p>
Activate	<p>To enable this resource type in the cloud template resource type list, verify that Activate option is toggled on.</p>
Scope	<p>Define if you want this custom resource to be shared across projects or specific to a single project.</p>
Lifecycle Actions - Create	<p>Select the Create Website Object workflow.</p> <p>If you have multiple VMware Aria Automation Orchestrator integrations, select the workflow on the integration instance you use to run these custom resources.</p> <p>After selecting the workflow, the external type drop-down menu becomes available.</p> <p>NOTE An external source type can be used only once if shared and once per project. In this use case, you are providing the same custom resource for all the projects. It does mean that you cannot use the same external type for any other resource types for all projects. If you have other workflows that require the selected type, you must create individual custom resources for each project.</p>
Lifecycle Actions - Destroy	<p>Select the Delete Website Object workflow.</p>

3. To finish creating the custom resource, click **Create**.

You have created a sample custom resource definition that uses the dynamic types plug-in.

When you create a cloud template, the website object should now be available from the left resource pane and can be dragged into the cloud template canvas. After deploying the cloud template, a instance of the site object is displayed in the

dynamic types plug-in inventory. Similarly, if the deployment is destroyed, the instance of the site object is removed from the dynamic types plug-in inventory.

Lifecycle Extensibility

VMware Aria Automation provides pre-defined application and services life cycles operations with some level of applicable configurations. However each user has specific processes and integrations that require customizing this life cycle via extensibility.

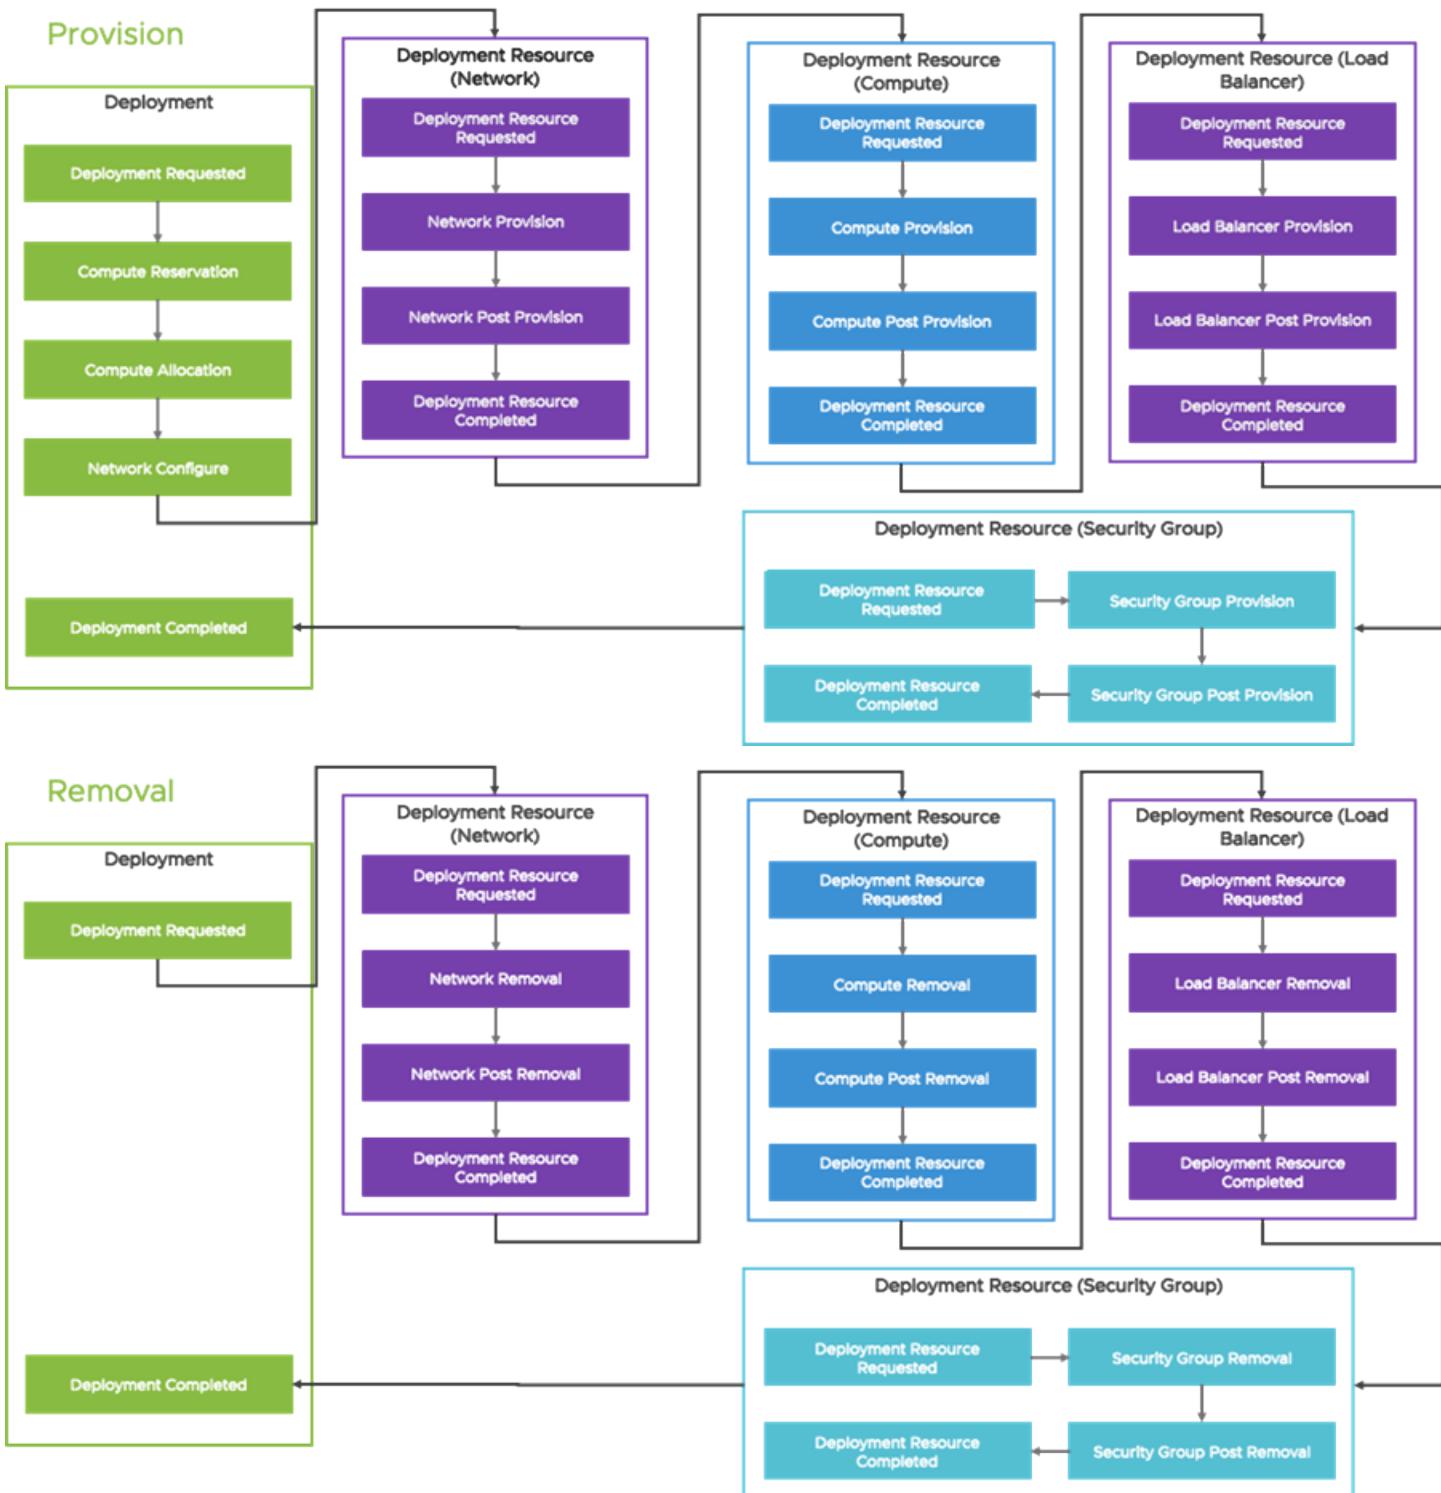

In vRealize Automation 7.x and VMware Aria Automation 8.x lifecycle extensibility is applied through the Event Broker service. The most common use case are related to the machine provisioning that supports different subscriptions including for example:

- Pre-provisioning to take action on third party systems or to modify the provisioning configuration.
- Post-provisioning to run an operation on the provisioned resources.
- Notify or record request provisioning data in external systems.

Event Broker subscriptions exist in VMware Aria Automation 8.x, but they:

- Use different event topics. VMware Aria Automation 8.x event topics are similar to vRealize Automation 7.x event topics, but are not identical.
- VMware Aria Automation 8.x subscriptions use different a payload to pass parameters.
- VMware Aria Automation 8.x subscriptions use different metadata.
- VMware Aria Automation 8.x subscriptions use a different approach to create criteria to filter the cases where the subscription start a workflow.
- Action-based extensibility can be used to provide function as a service (FaaS) operations for on-premises and cloud deployments.

VMware Aria Automation 8.x provisioning event topics are redesigned with a set of high level topics calling deployment resources topics:

Migrating Subscriptions from vRealize Automation 7.x to VMware Aria Automation 8.x

You can migrate Event Broker subscriptions from vRealize Automation 7.x to VMware Aria Automation 8.x.

For vRealize Automation 7.x event topics that have equivalent topics in VMware Aria Automation 8.x, you can use the VMware Aria Automation Migration Assistant.

You can also migrate event topics manually by using the following mapping as reference:

vRealize Automation 7.x Workflow State	VMware Aria Automation 8.x Event Topic	Notes
Catalog request received	Deployment requested	None
N/A	Compute.Reservation.Pre	Changes Placement
N/A	Compute.Allocation.Pre	Overrides Allocations
N/A	Network.Configure	Issued for network selection. The event overrides the IPAM Integration.
Blueprint component requested	Deployment resource requested	None
Requested WaitingToBuild BuildingMachine PRE	Compute.Provision.Pre	Deployed before the instance was deployed.
InitialPowerOn PRE InitialPowerOn EVENT	compute.initial.power.on	Issued before initial power on. Used for additional VM customization.
BuildingMachine POST MachineProvisioned MachineActivated	Compute.Provision.Post	Posts the machine online.
Blueprint component completed	Deployment resource completed	None
Catalog Item Requested completed	Deployment completed	None
N/A	Deployment requested "eventType": "DESTROY_DEPLOYMENT"	None
N/A	Deployment resource requested "eventType": "DELETE_RESOURCE"	
Deactivate Unprovision Disposing Pre	Compute.Removal.Pre	Issued before a machine is destroyed.
Disposing Event Disposing Post	Compute.Removal.Post	Used after a machine is destroyed.
N/A	Deployment resource completed	None

TurningOn – POST On – PRE	Deployment resource action completed "actionName": "PowerOn" "status": "FINISHED"	None

Creating a Subscription

You can use event topics as part of Event Broker subscriptions to define lifecycle extensibility.

To select the most appropriate event topic, it is important to evaluate if the event is triggered at the right step of the process and if it carries the payload necessary to perform the extensibility operation.

The payload can be identified with selecting the different event topics.

The **Read Only - No** tag is used for properties that support both read and write operations. With read and write operations, it is possible to use a workflow output to set the property back in VMware Aria Automation. To do this, it is mandatory to set the subscription to be blockable. For more information on blockable extensibility subscriptions, see *Blocking event topics* in *Using and Managing VMware Aria Automation Automation Assembler*.

The following are some of the event topics support setting properties:

- **Compute reservation** is used to change the placement.
- **Compute allocation** is used to change resource names or hosts
- **Compute post provision** is used after deployment resources are provisioned.
- **Network configure** is used to configure the network profile and individual network settings.

For more information on event topics included in VMware Aria Automation 8.x, see *Event topics provided with Automation Assembler* in *Using and Managing VMware Aria Automation Automation Assembler*.

Extensibility subscriptions in VMware Aria Automation 8.x work similarly to the subscriptions included in vRealize Automation 7.x. However, there are some key differences:

- You cannot bind a workflow for all events anymore.
- The conditions for running the subscription are now based on JavaScript.
- Subscriptions can be scoped to individual projects or configured to be shared across all projects in a given organization.
- You can set a recover workflow in case the subscription workflow fails.
- Timeout behavior is similar with some differences:

- VMware Aria Automation uses a timeout for the workflows being started by Event Broker blocking subscriptions. If a workflow run lasts more than the set timeout period, then it is considered failed by VMware Aria Automation.
- In vRealize Automation 7.x, the default timeout value for all states and events is 30 minutes and is configured in the VMware Aria Automation global settings.
- In both vRealize Automation 7.x and VMware Aria Automation 8.x a timeout value can be set at the subscription level.

NOTE

The default timeout period in VMware Aria Automation 8.x is 10 minutes and that you should change the project request timeout if it is lower than the subscription timeout.

- In vRealize Automation 7.x, it is also possible to configure individual state and event timeout values by changing configuration files in the IaaS server.
- Priority defines the order of running blocking subscription where 0 means highest priority and 10 means lowest priority. The default value is 10.

Create a Wrapper Workflow

Some VMware Aria Automation operations require you to create a wrapper workflow in Automation Orchestrator.

You can design a wrapper workflow from scratch or duplicate the sample `Event Broker template workflow` included in the sample package and modify it as required.

We call it the "wrapper" workflow because it is often a workflow that connects VMware Aria Automation to Automation Orchestrator workflows. For example, extracting data from the payload, finding a VM object in the Automation Orchestrator inventory by ID, and starting another workflow by taking the action on this VM.

The first requirement for creating a wrapper workflow is that it must have the single payload input of the Properties type named `inputProperties`. This is different from vRealize Automation 7.x where the input can be named anything as long as it was of the Properties type.

In this wrapper workflow, you might need to retrieve specific information from the `inputProperties` input or system context metadata. Similarly to vRealize Automation 7.x, this is done with the `inputProperties.get(parameterName)`; and `System.getContext().getParameter("metadataName")`; methods, except the parameter and metadata names are changed and can be identified in the **Event Topic** and **Workflow Run** tabs in Automation Assembler.

A good practice for wrapper workflows is to have a first "Get payload and execution context" element, as either a scriptable task or action element, that retrieves the required information. You can bind these elements as a output to the workflow variables and use them as input parameters in subsequent elements, such as scriptable tasks, actions, and workflows.

Retrieving the individual properties from the Properties type `InputProperties` is done through the GET method.

The returned properties value can be of the type string, number, boolean, or an array of any of these or complex properties which maps to the Properties type in Automation Orchestrator.

Many of these properties are object IDs that need further processing to retrieve useful information.

For example, retrieving some information from the catalog is done as follows (code snippet from the `Create an Event Broker subscription workflow` sample):

```
var catalogItemId = inputProperties.get("catalogItemId");
if (catalogItemId != null && catalogItemId != "") {
```

```

var catalogItemObject = getObjectFromUrl("/catalog/api/items/" + catalogItemId);

if (catalogItemObject != null) {
    System.debug(getPropertiesText(object2Properties(catalogItemObject), "Catalog
Item\n", 1));
    System.log("CatalogItem ID : " + catalogItemObject.id);
    System.log("CatalogItem name : " + catalogItemObject.name);
    System.log("CatalogItem description : " + catalogItemObject.description);
    System.log("CatalogItem type name : " + catalogItemObject.type.name);
    System.log("CatalogItem created By : " + catalogItemObject.createdBy);
}
}

```

This example can be used to retrieve a vCenter VM (code snippet from the Create an Event Broker subscription workflow sample):

```

try {
    if (inputProperties.get("componentTypeId") == "Cloud.vSphere.Machine") {
        var vcUUID = inputProperties.get("customProperties").get("vcUuid");
        var vmUUIDs = inputProperties.get("externalIds");
        for each(var vmUUID in vmUUIDs) {
            vCenterVM =
System.getModule("com.vmware.vra.extensibility").getVCenterVMByUUID(vcUUID, vmUUID);
            if (vCenterVM != null) {
                System.log("Got vCenter VM " + vCenterVM.name + " with ID " +
vCenterVM.id);
            }
        }
    }
} catch (e) {
    System.warn(e);
}

```

This example can be used to retrieve metadata properties below (code snippet from the Create an Event Broker subscription workflow sample):

```

// The execution context is where the vRA extensibility metadatas are passed
var executionContext = System.getContext();

```

```
// Getting specific execution context parameters
var eventTopicId = executionContext.getParameter("__metadata_eventTopicId");
var eventId = executionContext.getParameter("__metadata_id");
var isEventBlocking = executionContext.getParameter("__metadata_hdr_blocking");
var orgId = executionContext.getParameter("__metadata_orgId");
Read and write parameters can be configured by creating workflow outputs matching their name and types.
```

Another important element of working with wrapper workflows is using tags. The following example shows you how you can add a tag:

```
// Adding TAG
tags = inputProperties.get("tags");
if (tags == null) tags = new Properties();
tags.put("serviceLevel", "Gold");
```

The payload and metadata parameters values and the output values set by your workflow can be monitored by navigating to **Extensibility > Activity > Workflow Runs**.

The sample workflows include a `Create an Event Broker subscription` workflow, which can be used to automate the creation of subscriptions, and a `Create sample "Event Broker Template" subscriptions` workflow, that creates a subscription for each event topic starting the `Event Broker Template` workflow. This workflow provides the following capabilities:

- Displaying the content of the payload.
- Displaying the content of metadata.
- Provides an example on reaching back to VMware Aria Automation to retrieve the properties of the objects provided as IDs in the payload.
- Provide an example on converting payload IDs to Automation Orchestrator objects to bind the operation workflow on the object. You can use this to convert to `VC:VirtualMachine` to create a snapshot.
- Display the parameters that support being changed with workflow outputs.
- Update custom properties.
- Update tags.
- Update VM names.
- Get host selections.

There is a different Event Broker template workflow under the `inventory objects` folder that retrieves the plug-in inventory objects available from the payload. This allows you to set workflow variables to objects such as projects to bind them as input parameters of other workflows.

Onboarding a Customer Organization

There are several key concepts and requirements, you must be aware of before onboarding a customer organization.

There is a significant amount of configuration involved in setting up IaaS infrastructure, so it can make resources available to end users. In vRealize Automation 7.x, configuration is done with business groups, reservations, and so on.

Many VMware Aria Automation users have automated onboarding for customers. Automated onboarding includes importing data from other systems and using specific naming conventions.

In VMware Aria Automation 8.x, the concepts for assigning resources and providing entitlements to content have changed. Now this is done with projects, zones, and flavors. All of these components are listed under the **Infrastructure** tab of Automation Assembler.

VMware Aria Automation 8.x includes a guided setup wizard that guides you through the steps needed to create a cloud account, project, zone, and images by assigning a default configuration. To access this wizard, click **Guided Setup** on the top-right of the user interface.

While this wizard is useful for getting started, it does not address the organization onboarding scenario as some steps require end user inputs, external integrations and further granularity for some settings.

Configuring the onboarding organization infrastructure is done by automating the creation of the required objects, such as cloud accounts, projects, zones and others. This process can include the entire configuration or only the setting up the components where automation and integration provides more value.

This must be done by creating individual workflows or actions that create each object as needed. Afterwards, these objects are incorporated on a master workflow, that automates the whole process.

This process must follow as specific order, because some objects are dependant on other objects existing first. The order is as follows:

1. Cloud account
2. Zone
3. Project
4. Flavor mapping
5. Image mapping
6. Network profile
7. Storage profile

Deleting objects must also follow a specific order, because you cannot delete an object that is being used or referenced by another object. This process also has more steps than the deployment workflow as it requires deleting all the objects that can possibly be created by end users, such as deployments, Code Stream pipelines and others. The following is a non-exhaustive list of objects based on deletion order.

1. Integrations
2. User operations
3. Pipelines
4. Endpoints
5. Variables
6. Action runs
7. Workflow runs
8. Subscriptions
9. Extensibility actions
10. Storage profiles
11. Drafted cloud templates
12. Deployed cloud templates
13. Deployments and resources
14. Projects
15. Zones
16. Cloud accounts

NOTE

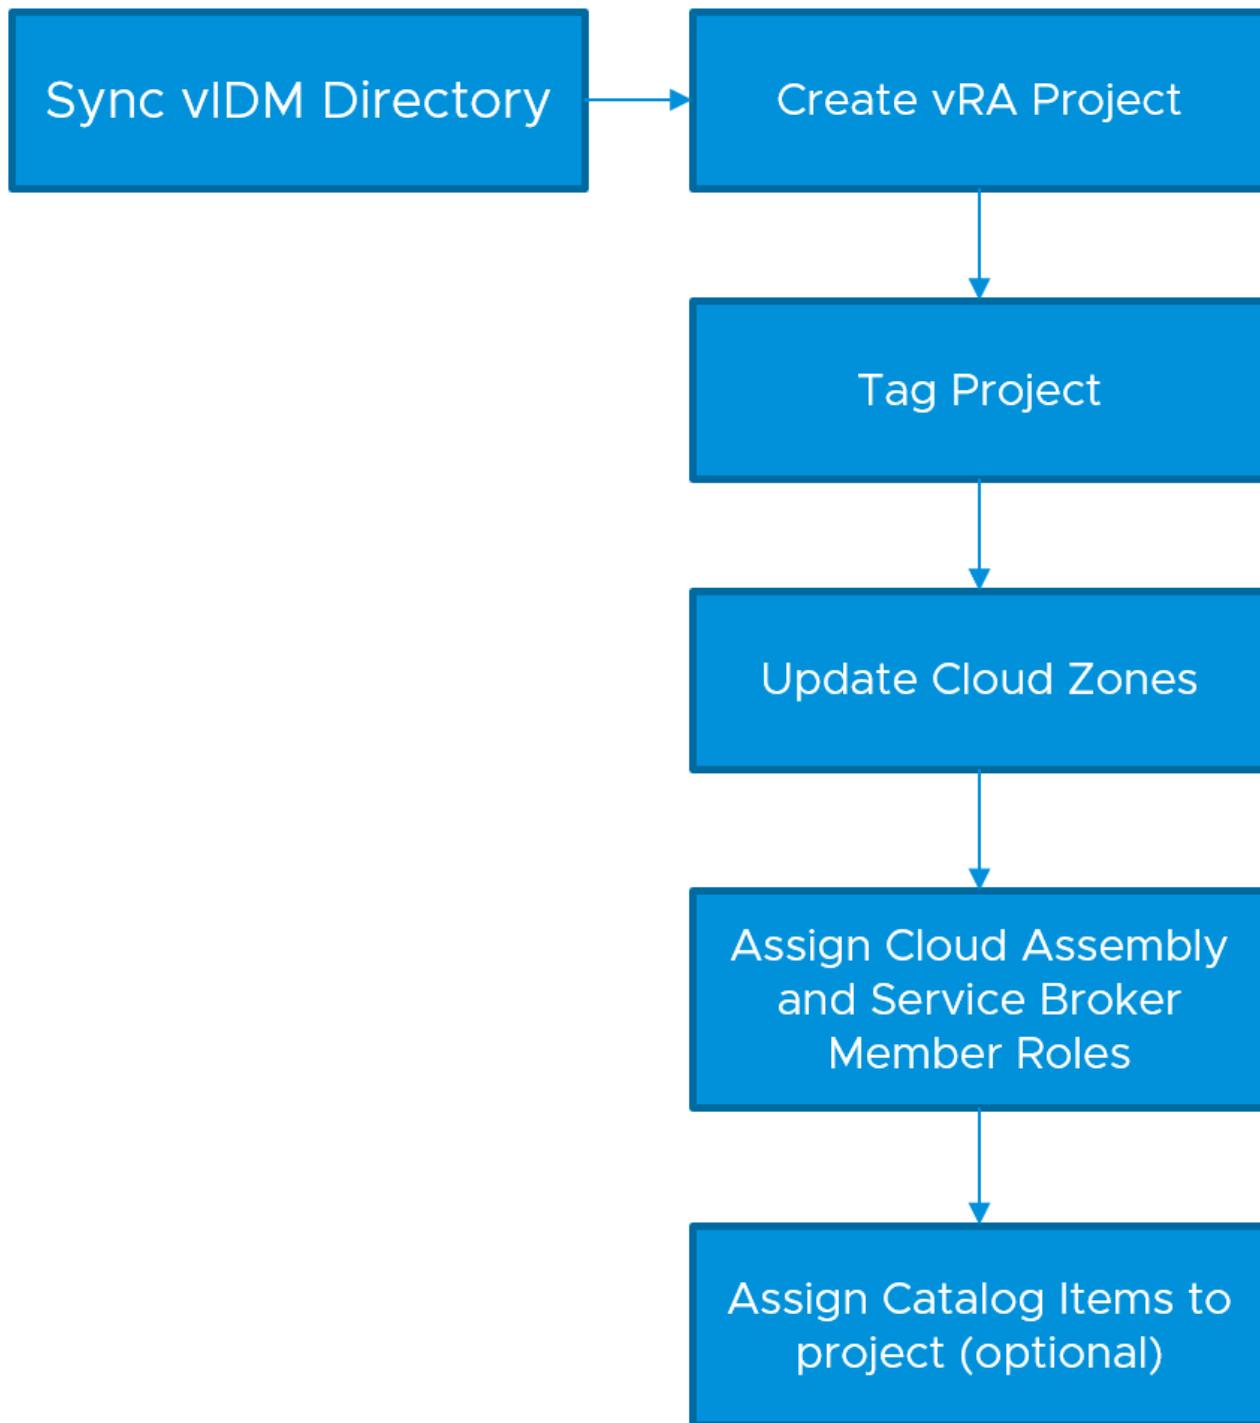

The delete operation might not always finish before the deletion of the resources. It might be necessary, in case of deletion failure because of a dependent resource is not yet deleted, to wait further in the workflow before retrying deletion. Also, to delete a project, you must first patch it to remove the dependencies on all its zones.

Onboarding a Project

This topic includes a scenario that demonstrates how you can onboard a project.

This scenario goes through the steps needed to automate the repeatable components of onboarding a project in VMware Aria Automation to enable self-service consumption.

The following diagram presents the main flow of this scenario:

Synchronizing the Workspace ONE Access Directory

Synchronize with the Workspace ONE Access directory by using a POST API call.

This scenario is optional depending of your end to end process, but if you are also automating the creation of Active Directory (AD) groups for your project, these groups must be synchronized in the Workspace ONE Access service (previously known as VMware Identity Management) before they can be associated to a project for user access. In this use case, you are using the Lifecycle Manager (LCM) API to perform the synchronization operation. LCM performs the downstream synchronization call to Workspace ONE Access .

The call is perform by using the POST method with the following URL:

/lcm/authzn/api/idp/dirConfigs/syncprofile-sync

The request itself has the following content:

```
{
  "directoryConfigId": directoryId,
  "directoryType": "ActiveDirectory",
  "isGetBeforeUpdate": true,
  "isTenantConfiguredByPath": true,
  "vidmAdminPassword": password,
  "vidmAdminUser": username,
  "vidmHost": hostname
}
```

Creating a VMware Aria Automation Project

While creating a project, you can also specify the users and administrators that are part of the project.

You can create a project by using a POST API call that uses the /project-service/api/projects URL to create a project.

```
{
  "administrators": [
    {
      "email": "${ADMINISTRATOR_VIDM_GROUP}",
      "type": "group"
    }
  ],
  "members": [
    {
      "email": "${USER_VIDM_GROUP}",
      "type": "group"
    }
  ],
}
```

```

"viewers": [],
"zones": [],
"constraints": {},
"operationTimeout": 0,
"sharedResources": true,
"name": "${PROJECT_NAME}",
"description": "",
"orgId": "${ORGANISATION_ID}",
"properties": {}
}

```

To run this command, the following information is required. AD groups should be synced by using a directory configuration in LCM.

- The group name to be assigned the project administrators role.
- The group name to be assigned the project member role.
- A name for the new project.
- The VMware Aria Automation organization ID. This ID can be retrieved through the VMware Aria Automation API.

Associating a Tag with the Project

In this example, you are associating a tag with the newly created project. The tag is inherited onto the workloads provisioned from this project.

To associate a tag with a object, you can use a PATCH API call that uses the `/iaas/api/projects/${projectId}/resource-metadata` URL.

```

{
  "tags": [
    {
      "key": "costCode",
      "value": "${costCode}"
    }
  ]
}

```

Add Cloud Zones to the Project

The next step in the onboarding scenario is to add one or more cloud zones to the project. With the API, you can add cloud zones.

You can add cloud zones by using a PATCH API call that uses the `/iaas/api/projects/${NEW_PROJECT_ID}` URL.

```
{
  "zoneAssignmentConfigurations": [
    {
      "storageLimitGB": 0,
      "cpuLimit": 0,
      "memoryLimitMB": 0,
      "zoneId": "${CLOUDZONE_ID1}",
      "maxNumberInstances": 0,
      "priority": 0
    },
    {
      "storageLimitGB": 100,
      "cpuLimit": 100,
      "memoryLimitMB": 100,
      "zoneId": "${CLOUDZONE_ID2}",
      "maxNumberInstances": 20,
      "priority": 0
    }
  ]
}
```

Assign Automation Assembler and Service Broker User Roles

Aside from assigning users at the project level, you must also assign the organisation role to users within VMware Aria Automation Identity and Access Management service. You assign roles so users have access to their required VMware Aria Automation services. In this use case, the services are Automation Assembler and Service Broker.

You can assign roles in VMware Aria Automation when you first log in as an administrator by navigating to **Identity and Access Management** and assigning the required service roles to the user. For more information on editing user roles from the VMware Aria Automation user interface, see *How do I edit user roles in VMware Aria Automation in Administering VMware Aria Automation*.

You can also assign roles by using a POST API call that uses the `/csp/gateway/portal/api/orgs/${ORGANISATION_ID}/groups` URL.

```
{
  "ids": [
    "${GROUP_ID}"
  ],
}
```

```

"organizationRoleNames": [
  "org_member"
],
"serviceRoles": [
{
  "serviceDefinitionId": "${CLOUD_ASSEMBLY_SERVICE_ID}",
  "serviceRoleNames": [
    "automationservice:user"
  ]
},
{
  "serviceDefinitionId": "${SERVICE_BROKER_SERVICE_ID}",
  "serviceRoleNames": [
    "catalog:user"
  ]
}
]
}

```

Assign Catalog Items to a Project

You can assign catalog items to a VMware Aria Automation 8.x project by using a API call.

To run the following API call, you must have the following information:

- The project ID. This is returned by the API call when the project is created.
- The cloud template ID. This ID can be attained by listing the cloud templates with GET commands. If the values of these cloud templates are consistent, then this value can be stored in Automation Orchestrator or in a extensibility action.

You can assign catalog items to a project by using a POST API call that uses the `/catalog/api/admin/entitlements` URL.

```
{
  "projectId": "${projectId}",
  "definition": {
    "type": "CatalogItemIdentifier",
    "id": "${BLUEPRINT_ID}",
    "name": ""
}
```

```
"description": "",  
"numItems": 0,  
"sourceType": ""  
}  
}
```

Automation Orchestrator Implementation for Project Onboarding

Use a Automation Orchestrator workflow to implement project onboarding.

The previous scenario for assigning a catalog item is implemented as a Automation Orchestrator workflow provided in the sample section under **vRA plug-in > REST > Organization infrastructure onboarding > Project Onboarding**. It covers all aspects of onboarding, excluding the optional Workspace ONE Access synchronization.

The following workflow creates IaaS project with:

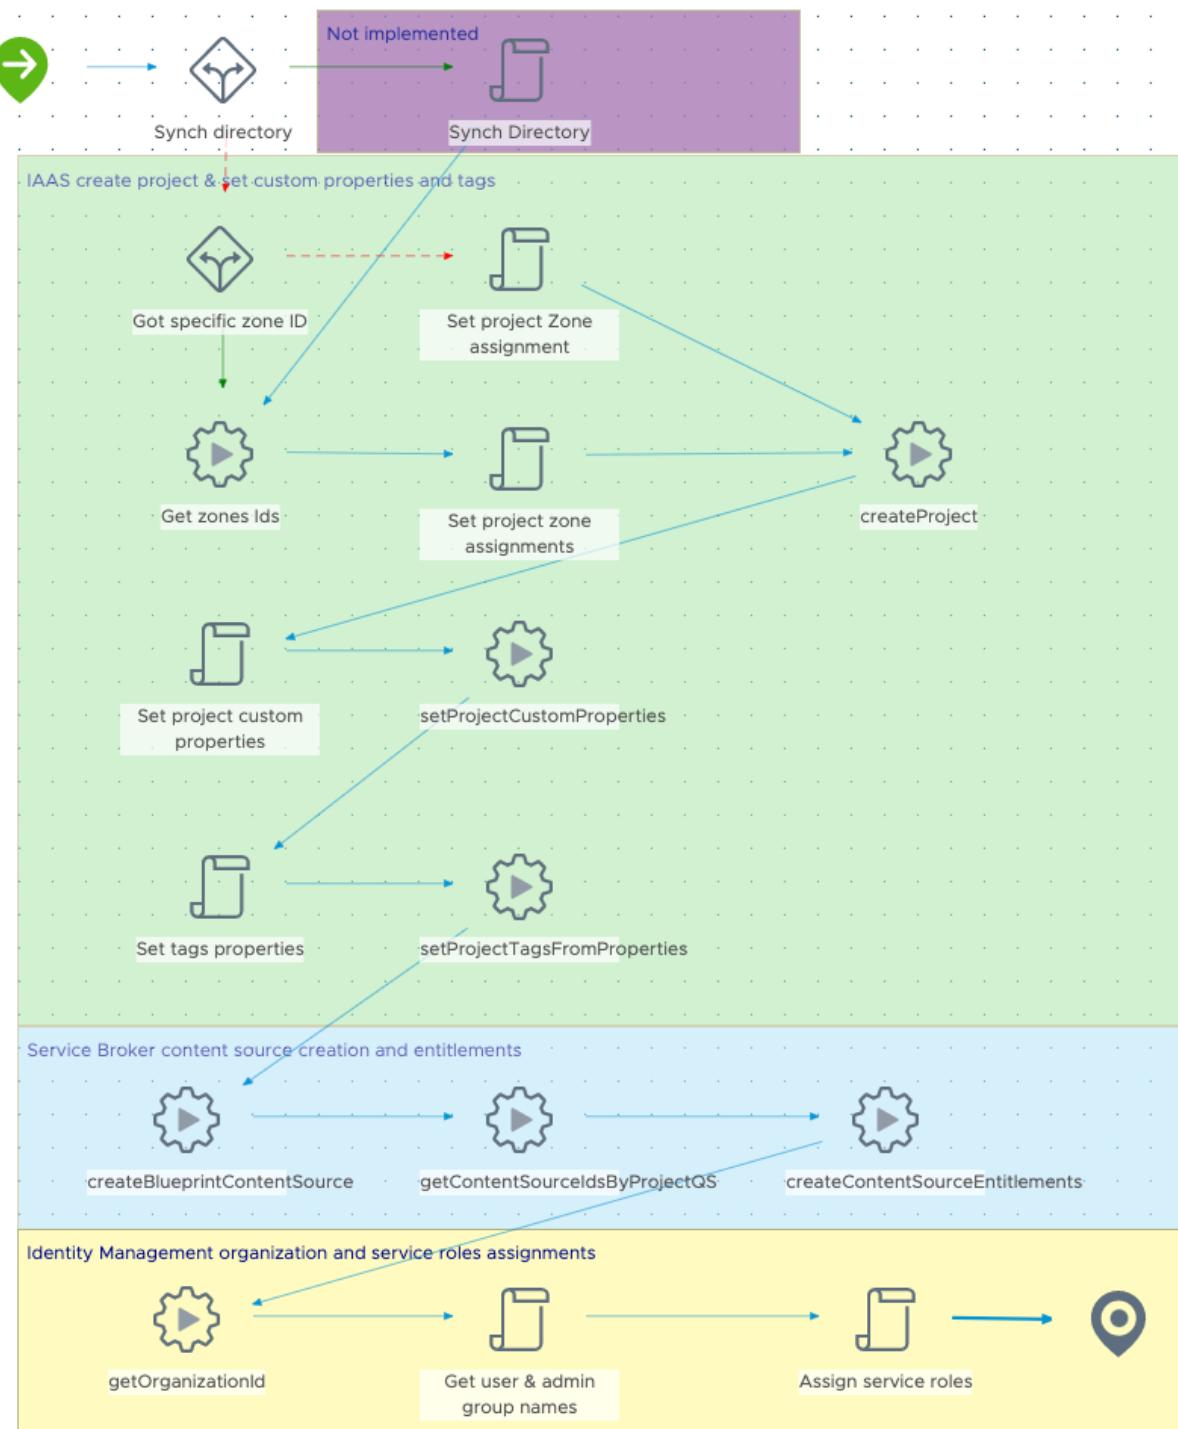

- Setting a single zone if this was provided as input. If no specific zone is provided as an input, the workflow configures all available zones.
- Set the network constraint passed as a input parameter.
- Set tags and custom properties for cost code and project name provided as input.
- Set specific folders for the project and for the environment.
- Set a specific naming template.
- Set administrator and user groups.

The workflow also performs the following Service Broker updates:

- Create a specific content source for the project.
- Share this content source and other sharable content in this project.

Finally, the workflow performs the following Identity Management configurations:

- Assign admin group Automation Assembler, Service Broker, and Orchestrator administrator roles.
- Assign user group Automation Assembler and Service Broker user roles.

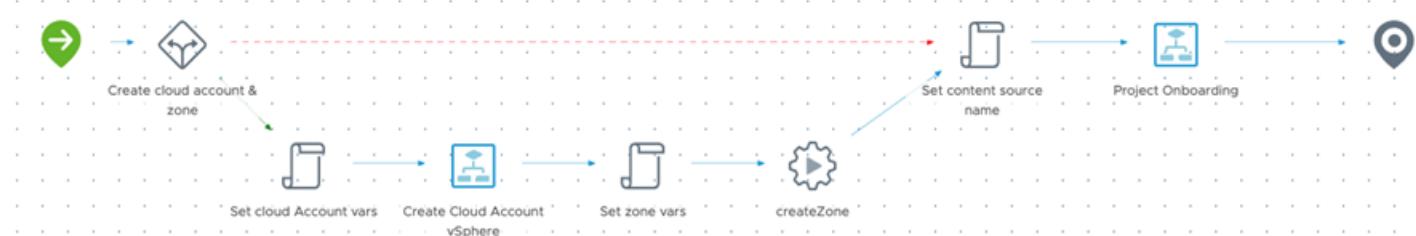

There is another project onboarding workflow under **vRA plug-in > inventory objects > Organization infrastructure onboarding > Project Onboarding** where the custom create project action delivered as part of the samples is replaced by the **Create Project** workflow that is part of the Automation Orchestrator plug-in for VMware Aria Automation.

Adding Resource Provisioning to a Project

You can use a Automation Orchestrator workflow to add resource provisioning to your project.

The sample workflow Organization infrastructure onboarding / Organization Onboarding is a front end for the project onboarding workflow that enables you to:

- Create a vSphere Cloud account.
- Create a zone for this cloud account.

The workflow inputs are separated in different tabs and include group search with filters.

If a cloud account and a zone are created they are assigned to the project, otherwise the available zones from existing cloud accounts are assigned to the project.

Organization onboarding

Cloud account and zone	Project	Constraints	Custom properties and tags
	Project		
Project name *	pj45556		
Project administrators group filter	vra		
Project administrators group *	vra-ea-team		
Project users group filter	ME		
Project users group *	groupME		

Requesting Catalog Items

A key functionality of VMware Aria Automation is requesting catalog items.

A common scenario seen in vRealize Automation 7.x includes an XaaS catalog item requesting a composite blueprint. While it is still possible to request a catalog item with the API service, this scenario focuses on achieving the same result through customizing the request at runtime using custom forms with dynamic selection of tags.

In VMware Aria Automation 8.x, form constructs are standardized around the VMware Aria Automation custom forms designer. Given the change in VMware Aria Automation APIs with 8.x, this is a good opportunity to remove previous technical debt as you transition and also standardize cloud template deployment by using custom forms.

The below table summarizes some of the common patterns used for placement selection to contrast the options and changes now available in VMware Aria Automation 8.x.

vRA 7.x - placement (custom logic)	vRA 8.x – placement (standardized on tags)
<ul style="list-style-type: none"> • XaaS, custom forms, or IaaS forms <ul style="list-style-type: none"> – API - Compute population of reservation policy name and ID selection in code. – API - Network – Based on naming conventions and reservations population of applicable network profiles. – API - Storage – Storage reservation population through code. 	<ul style="list-style-type: none"> • Custom forms with tag based inputs <ul style="list-style-type: none"> – API - Dynamic Tag selection based on keys and filters – Alternatively, using Event Broker read or write properties.

In VMware Aria Automation 8.x, placement logic is standardized by using tags, resources are tagged with capabilities and constraints are applied to a cloud template for the placement engine to select the relevant downstream resources.

API Tag Filtering Examples

As a prerequisite to dynamically populating tag data through the API, this section provides some examples of using the VMware Aria Automation IaaS API return tags and filters to return suitable tags based on known keys.

Get All Tags

Return a list of all available tags, keys and values.

```
GET /iaas/api/tags
```

Filter Tags by Key

Return all available tags with a key of location. For example the tag can return the location:newyork and location:sydney values. The core element in this example is that you can return all relevant tags based on your defined key.

```
GET /iaas/api/tags?$filter=key eq 'location'
```

Filter Networks by Tag Key and Value

Filter networks based on the key and value to then find suitable subsequent tags for further filtering.

```
GET /iaas/api/fabric-networks?$filter=tags.item.key eq 'environment' and tags.item.value eq 'dev'
```

Filter Networks by Cloud Account ID and Environment

Filter networks based on cloud account ID and tag key and value, this can be used when you have different placement logic between public cloud and on-premises deployments to display the relevant tags for the target cloud.

```
GET /iaas/api/fabric-networks?$filter=cloudAccountIds.item eq 'ec4822a755a755906c6b3822b2' and tags.item.key eq 'environment' and tags.item.value eq 'dev'
```

Automation Orchestrator Action Example

You can create a generic Automation Orchestrator action to be used in custom forms to populate external values.

In this scenario, you want the ability to return a list of suitable tags for placement based on an input of tag key.

Having the tag key as an action makes this action reusable regardless of the tag you must return. In this case, you authenticate with VMware Aria Automation by using a REST host stored in a configuration element. You then make a call to find all suitable tags matching the supplied tag key.

These tag keys and values are pushed into an array to return the values for our drop-down menu. This action returns an array of strings containing the filtered tags.

The `getTagByKey` action below is included in the samples.

```
var url = "/iaas/api/tags"
var parameters = encodeURI("$filter=key eq " + tagKey);

var tags =
System.getModule("com.vmware.vra.extensibility.plugin.rest").getObjects(vraHost,
url, parameters);

var tagArray = new Array();
for each (var tag in tags) {
    tagArray.push(tag.key + ":" + tag.value);
}

return tagArray;
```

Basic Sample Cloud Template

You can bind two constraints as inputs in your cloud template.

To demonstrate a simple version of this scenario, you can bind two constraints as inputs in the cloud template yaml, platform, and environment. These constraints enable your cloud account and compute placement.

```
formatVersion: 1
inputs:
  platform:
    type: string
    title: cloud platform
  environment:
    type: string
    title: environment
resources:
  Cloud_vSphere_Machine_1:
    type: Cloud.Machine
    properties:
      image: centos
```

```

flavor: small
customizationSpec: Linux
constraints:
  - tag: '${input.platform}'
  - tag: '${input.environment}'
networks:
  - network: '${resource.Cloud_vSphere_Network_1.id}'
Cloud_vSphere_Network_1:
  type: Cloud.Network
  properties:
    networkType: existing

```

Associating an External Value with the getTagByKey Action

When you have versioned and released your cloud template, you must then import the content into Service Broker to allow you to customize the custom forms.

In custom forms, you associate the generic `getTagByKey` action as an external value for your drop-down menu fields. You supply the input tag key as a constant in the following example as a "platform":

cloud platform

Field ID: platform

Appearance	Values	Constraints
> Default value	platform:vsphere	
▽ Value options	External source	
Value source	External source	▼
Select action	com.vmware.vra.extensibility.plugin.rest.iaas/getTagByKey	✖
Action inputs		
vraHost	Constant	https://cava-6-240-022.eng.vmware.co... ✖
tagKey	Constant	platform

The same action is reused for the environment field.

environment

Field ID: environment

Appearance	Values	Constraints
> Default value	environment:development	
▽ Value options	External source	
Value source	External source 	
Select action	com.vmware.vra.extensibility.plugin.rest.iaas/getTagByKey 	
Action inputs		
vraHost	Constant 	https://cava-6-240-022.eng.vmware.co... 
tagKey	Constant 	environment

Example Service Broker Catalog Request

After requesting your catalog item, you can now see your constraint tags to enable placement are now dynamically loaded.

The following screenshot shows an example Service Catalog request:

New Request

centos Version 2 ▾

Project * ▾

Deployment Name *

Description

cloud platform platform:vsphere ▾

environment * environment:development
environment:production

SUBMIT **CANCEL**

Requesting Catalog Items Programmatically

While custom forms allow you to customize the requests, there are scenarios requiring you to use a programmatic approach when handling requests. For example, when Automation Orchestrator is used for external integrations requiring triggering requests or when automating requests.

In vRealize Automation 7.x, you can manage requests with the VMware Aria Automation plug-in or matching REST API:

- From a catalog item get the provisioning request data by using `getProvisioningRequestForCatalogItem()` and `getProvisioningrequestData()`. The provisioning request data is a type of template similar to the VMware Aria Automation 8.x cloud template YAML, but here formatted in JSON.
- Update the provisioning request data.
- Use `requestCatalogItemWithProvisioningRequest(catalogItem, provisioningRequest)`.

This provisioning request data is a complex object including many fields that are not necessarily matching what the end user would see at request time. For example to change the number of CPUs it is necessary to change `provisioningrequestData.ComponentName.data.cpu = cpuNb`. It is also mandatory to set some fields like the business group ID, which is the equivalent of a VMware Aria Automation 8.x project.

In VMware Aria Automation 8.x, requesting a catalog item programmatically is simpler. The request is done by using the Service Broker API `/catalog/api/items/{id}/request`. The body of the request includes:

- deploymentName
- projectId
- requestCount
- The request inputs defined in the YAML.

The requests returns an array of deployment IDs since some cloud templates support more than 1 request.

The following is an example of a request body:

```
{
  "deploymentName": "TestRequest",
  "projectId": "1628469a-3f98-44f1-ba80-e9ee610686a3",
  "bulkRequestCount": 1,
  "inputs": {
    "platform": "platform:vSphere",
    "environment": "environment:production"
  }
}
```

The input keys can be obtained with a GET /catalog/api/items/" + catalogItemId call. The sample action getCatalogItemInputProperties does that and outputs the list of inputs in a data grid.

The following example includes sample code from the createCatalogItemRequest action:

```
var url = "/catalog/api/items/" + catalogItemId + "/request";
var requestBody =
{
  "deploymentName": deploymentName,
  "projectId": projectId,
  "bulkRequestCount": bulkRequestCount,
  "inputs": inputProperties
}

var content = JSON.stringify(requestBody);
var operation = "POST";

try {
  var contentAsString =
System.getModule("com.vmware.vra.extensibility.plugin.rest").invokeRestOperation(vraHost,
operation, url, content);
```

```
    } catch (e) {
        throw "POST " + url + "Failed" +
    "\n Error : " + e;
}

var deployments = JSON.parse(contentAsString);
var deploymentIds = new Array();

for each (var deployment in deployments) {
    deploymentIds.push(deployment.deploymentId);
}

return deploymentIds;
```

The sample workflow [Request Catalog Item \(Service Broker Only\)](#) lists the catalog items in a drop-down menu. The list of inputs is preconfigured so the value can be edited and when submitted, run the `createCatalogItemRequest` action.

Tags and Custom Properties

You can use tags and custom properties to further configure your VMware Aria Automation components and deployments.

In vRealize Automation 7.x, custom properties are responsible for:

- Providing information about the deployment.
- Modifying deployment configuration elements, such as VM hardware and OS configurations.

- Modifying configuration elements for VMware Aria Automation integrations.
- Attaching information to deployments for use in reporting and for additional payload properties to use in extensibility.
- Modifying the deployment placement.

Custom properties function as both custom key and value pairs, and also as reserved properties. For more information on reserved properties, see the [Custom Properties Reference](#) guide.

These custom properties can be set at different levels including endpoint, reservation, compute resource, business group, cloud template, and property group.

They can also be set at request time in the input forms, changed with Event Broker using the `virtualMachineAddOrUpdateCustomProperties` workflow output or using the `addUpdatePropertyFromVirtualMachineEntity` parameter.

VMware Aria Automation 8.x offers similar functionality with some changes:

- The properties are now part of the Automation Assembler cloud template designer schema. They can also be set at deployment time through input form inputs.
- The names and meanings have changed and are documented in the [VMware Aria Automation Resource Type Schema](#). The properties that impact the deployment on change are documented as `recreateOnUpdate: true`.
- Some extensibility features can also use predefined custom properties, such as the AD integration.

As an example of this custom properties functionality, you can use the scenario for setting the folder name in vCenter that machine will deploy to. In vRealize Automation 7.x, this can be done with the `VMware.VirtualCenter.Folder` property. This property specifies the name of the inventory folder in the data center in which to put the virtual machine. The default folder is VRM, which is also the vSphere folder in which VMware Aria Automation places provisioned machines if the property is not used. This value can be a path with multiple folders, for example production or email servers. A proxy agent creates the specified folder in vSphere if the folder does not exist. Folder names are case-sensitive. This property is available for virtual provisioning

The equivalent property in VMware Aria Automation 8.x is `folderName`.

```
folderName      string
minLength: 1
recreateOnUpdate: true
title: VM folder for provisioning

The path to the folder where the virtual machine is provisioned, relative to the datacenter that the resource pool is in.
```

In VMware Aria Automation 8.x, Event Broker can modify properties with the `customProperties` workflow output on many events and dedicated outputs as described in the Event Broker section.

In vRealize Automation 7.x, tags have a minor function. There are custom use cases where a Automation Orchestrator workflow or a PowerShell cmdlet can update a vCenter VM tag that can be used during or after the deployment.

In VMware Aria Automation 8.x, tags have a larger function.

- Capability tags define the placement logic during provisioning. They can be set on compute resources, cloud zones, images and image maps, networks, and network profiles.
- Constraint tags are set on cloud templates and projects so they can match the resources set with capability tags.
- Standard tags are used to filter, analyze, monitor, and group deployed resources.

Tags are included in different endpoints such as vSphere, Amazon Web Services (AWS), and Microsoft Azure, or created in VMware Aria Automation. Tags can be set at deployment time by Event Broker by using the `tags` workflow output parameter. VMware Aria Automation 8.x also allows you to update tags as day 2 operations on projects, deployment resources, and machines.

The following example can be used to update tags provided as a properties input on a deployment by using the deployment resource action `EditTags`. The sample is included in the

`setDeploymentResourceTagsFromProperties` Automation Orchestrator action that can be run as part of the `Edit deployment tags` workflow.

```

if (vraHost == null || deploymentId == null || resourceName == null) return null;

var operation = "POST";
var url = "/deployment/api/deployments/" + deploymentId + "/requests";

var object = {
  "actionId": "Deployment.EditTags",
  "targetId": deploymentId,
  "inputs": {}
}

object.inputs[resourceName] = new Array();
for each (var key in tags.keys) {
  var tag = {"key": key, "value": tags.get(key)};
  object.inputs[resourceName].push(tag);
}

var content = JSON.stringify(object);

try {
  var contentAsString =
System.getModule("com.vmware.vra.extensibility.plugin.rest").invokeRestOperation(vraHost,
operation, url, content);

  var object = JSON.parse(contentAsString);
} catch (e) {
  throw("Unable to POST object url : " + url + "\n" + e + "\nWith Content : " +
content);
}

```

The following example can be used to update tags on a project by using the PATCH operation. The sample is included the `setProjectTagsFromProperties` Automation Orchestrator action that can be run as part of the `Edit project tags` workflow.

```

if (vraHost == null || projectId == null) return null;

var operation = "PATCH";
var url = "/iaas/api/projects/" + projectId + "/resource-metadata";

var object = {"tags":[]};
for each (var key in tags.keys) {
    var tag = {"key": key,"value": tags.get(key)};
    object.tags.push(tag);
}

var content = JSON.stringify(object);

try {
    var contentAsString =
System.getModule("com.vmware.vra.extensibility.plugin.rest").invokeRestOperation(vraHost,
operation, url, content);
    var object = JSON.parse(contentAsString);
} catch (e) {
    throw("Unable to Patch object url : " + url + "\n" + e + "\nWith Content : " +
content);
}

```

The following example can be used to update custom properties on a machine by using the PATCH operation. The sample is included in the `setMachineCustomPropertiesFromProperties` Automation Orchestrator action that can be run as part of the Edit machine custom properties workflow.

```

if (vraHost == null || machineId == null) return null;

var url = "/iaas/api/machines/" + machineId;
var object = new Object();

var customPropertiesObject = {"customProperties" : customProperties};
var content = JSON.stringify(customPropertiesObject);
System.debug("Updated Custom properties : " + content);

```

```

var operation = "PATCH";

try {
    var contentAsString =
        System.getModule("com.vmware.vra.extensibility.plugin.rest").invokeRestOperation(vraHost,
        operation, url, content);
    var object = JSON.parse(contentAsString);
} catch (e) {
    throw("Unable to Patch object url : " + url + "\n" + e + "\nWith Content : " +
content);
}

```

Using VMware Aria Automation XaaS Services

VMware Aria Automation includes a XaaS capability that can be used to further automate your environment.

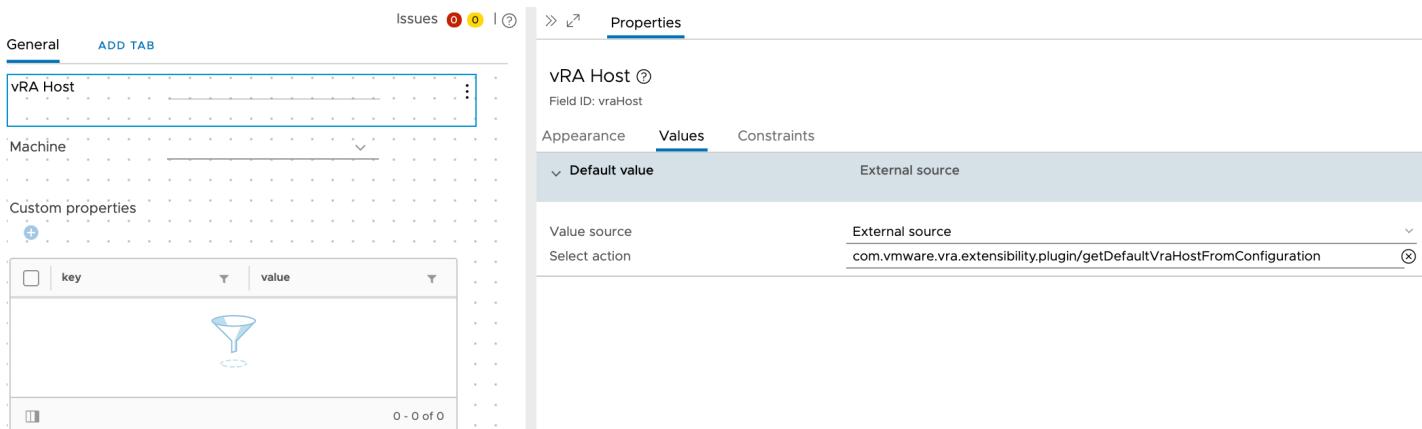

With Event Broker and other automation and integration scenarios, the Automation Orchestrator workflows run in the back-end. There are also use cases that require the end users to trigger the workflows from the VMware Aria Automation user interface. This capability is called Anything as a Service (XaaS).

Workflow Sample

The following workflow sample demonstrates how you can edit the custom properties of a virtual machine.

This workflow sample works in both Automation Orchestrator and VMware Aria Automation Service Broker. The following form implementation created in the Automation Orchestrator input form designer is mandatory.

For the default value to work in Service Broker, the `vRA Host` value is set by an action returning the content of the variables of the configuration element.

If the default value was set in Automation Orchestrator with a field variable binding, you would have to enable custom forms and set the constants after importing the workflow.

The `machineName` input labeled as `Machine` is defined as a drop-down menu that uses `getMachineIdsAndNames` as value options. This action returns an array of properties with the machine ID as a label and the machine name as a value.

customProperties ?

Field ID: `customProperties`

The `customProperties` data grid uses a `getMachineCustomProperties` action that returns a `Properties` type that can be bound directly to the `machineid` input.

Using Custom Resources

One of the primary features of using XaaS in VMware Aria Automation is using custom resources.

In vRealize Automation 7.x, it is possible to create an XaaS service blueprint. The service blueprint can be used to define and use a Automation Orchestrator workflow from VMware Aria Automation. The service blueprint can be published in the catalog service and entitled, and it can be used in the blueprint design canvas. In both cases, it can provision a custom resource as an option. This resource can:

- Appear in the **Items** tab (for versions earlier than vRealize Automation 7.6) or **Deployments** tab (for vRealize Automation 7.6) when request from the catalog.
- Appear as one of the components of the deployment when requested as part of a composite blueprint.

Provisioning a custom resource allows you to track the custom resource and its realtime properties from the user interface. It also enables you to perform day 2 operations known as resource actions.

In vRealize Automation 7.x resource actions can run a workflow in context of a custom resource for:

- Delete operations (Using a disposal option)
- Update operations (No option)
- Copy operations (Using a provisioning option)
- Move or stage operations (Using a provisioning & disposal option)

In VMware Aria Automation 8.x, custom resources offer similar capabilities in comparison to vRealize Automation 7.x. A custom resource in VMware Aria Automation 8.x has the following mandatory requirements:

- You must have a provisioning workflow that must output an Automation Orchestrator plug-in type that matches the type defined in the custom resource
- You must have a decommission workflow.

VMware Aria Automation 8.x custom resources allow you to use a specific Automation Orchestrator type once per project or having it shared with all projects once. It is not possible, for example, to use different provisioning workflows outputting the same custom resource type.

VMware Aria Automation 8.x resource actions have the following differences with vRealize Automation 7.x:

- Provisioning and decommissioning options.
- No capability to bind custom resources to Automation Orchestrator action parameters in the request form.

A core difference is that the availability of the resource action in VMware Aria Automation 8.x can be defined programmatically based on the resource properties. For example some actions might not be available if the state of the element is "OFF". The equivalent feature in vRealize Automation 7.x has less options because it is user interface based.

Resource Mappings

A resource mapping defines how a native VMware Aria Automation resource is converted to a Automation Orchestrator type.

In VMware Aria Automation 8.x, there are more resource types being supported than in comparison to vRealize Automation 7.x. Each of these resources has a schema defining the resource properties. You can define a Automation Orchestrator action that binds its inputs to these properties and return the equivalent Automation Orchestrator object. For example, the vSphere components have a `vCenterUuid` and `uuid` property that can be used to return a Automation Orchestrator type, such as `VC:VirtualMachine`. Another good example of this functionality is the built-in `findVcVMBByVcAndVMUuid` action introduced in VMware Aria Automation 8.x.

When the resource mapping is created, it is possible to add new day 2 operations on these resources that are workflows that use the matching Automation Orchestrator type as inputs.

The main difference in comparison to vRealize Automation 7.x, is that it uses a workflow for resource mapping. It might be necessary to migrate the workflows to actions to reuse their functionality in VMware Aria Automation 8.x.

Another difference is that VMware Aria Automation 8.x is that the resource mapping can be defined on a resource action basis. For each input of the resource action, it is possible to either expose the input at request time, map it to one of the schema resource properties, or associate a mapping action that uses one or more schema resource properties and returns the same type as the workflow input it binds to. This is useful to pass information from the schema directly without having to change the workflow or create a wrapper workflow that must be used to add the scripting logic to these required to query the VMware Aria Automation resource from Automation Orchestrator.

Custom Cloud Template Component

The application of custom components is a key element of cloud template development.

An important limitation of the XaaS components used in the cloud template designer is that, being custom resources-based, it must provision a custom component. This is different from vRealize Automation 7.x where the service can start any workflow, even if it was not outputting a custom resource.

If your environment includes vRealize Automation 7.x blueprints components that are, for example, implementing some configuration changes, it will be necessary to use other means to trigger this workflow. The alternative is to use Event Broker to do so.

Another area that is very different in VMware Aria Automation 8.x is the way that these components inputs and outputs can be bound to other components on the schema. In vRealize Automation 7.x, these bindings only supported simple types and were controlled through the user interface without any program based approach. In VMware Aria Automation 8.x, the Create workflow inputs define the properties in the YAML schema and these can be scripted. These inputs can be mapped to the cloud template input properties even if these are of complex types. With this you can, for example, use an input of a given resource type that can be searched.

VMware Aria Automation API Programming Guide

As a VMware Aria®Automation™ user or customer, you can perform VMware Aria Automation Assembler, VMware Aria Automation Service Broker, and VMware Aria Automation Pipelines functions programmatically by using REST API service calls.

API Services

VMware Aria Automation includes the following APIs. API documentation is available with the product. To access all Swagger specifications from a single landing page, go to https://<your_FQDN>/automation/api-docs where *your_FQDN* is the FQDN of your VMware Aria Automation appliance.

Table 120: VMware Aria Automation

Main Service	Service Name and Description
ABX	ABX Create or manage actions and their versions. Execute actions and flows.
Automation Service Broker	Approvals Enforce policies that control required approvals for a deployment or Day 2 action before the request is provisioned.
Automation Assembler	Blueprint Create, validate, and provision blueprints. NOTE Blueprints in the API are Automation Assembler Templates in the product.
Automation Service Broker	Catalog Access Automation Service Broker catalog items and catalog sources, including content sharing and the request of catalog items.
CMX	CMX When using Kubernetes with VMware Aria Automation , deploy and manage Kubernetes clusters and namespaces.
Automation Assembler	Content Gateway

Table continued on next page

Continued from previous page

Main Service	Service Name and Description
	Connect to your infrastructure as code content in external content sources, such as Source Code Management providers.
Automation Service Broker and Automation Assembler	Custom Forms Define dynamic form rendering and customization behavior in Automation Service Broker and Automation Assembler.
User Profile	Customization Configure branding information.
Automation Service Broker	Deployment Access deployment objects and platforms or blueprints that have been deployed into the system. NOTE Blueprints in the API are Automation Assembler Templates in the product.
Automation Service Broker	Deployment Metric Aggregated metric values for the deployment objects.
Identity	Identity Authenticate and manage the authorization of VMware Aria Automation users.
Automation Assembler	Infrastructure as a Service (IaaS) Perform infrastructure setup tasks, including validation, and provisioning of resources in an iterative manner.
Migration	Migration Assistant Run assessments and access migration services. Supports migration for vRealize Automation 7.6 content, and for NSX-V to NSX-T migration.

Table continued on next page

Continued from previous page

Main Service	Service Name and Description	
Relocation	Onboarding Define policies and plans to bring existing VMs from any cloud under management.	
Automation	Orchestrator	Orchestrator Design, manage, and run workflows, actions, and policies to automate complex IT tasks.
Automation	Orchestrator	Orchestrator Gateway Run workflows and actions to automate complex IT tasks.
Automation Pipelines	Pipelines Create and run pipelines for continuous delivery of your applications to production.	
Automation Service Broker	Policies Interact with policies created in Automation Service Broker.	
Project	Projects Provide visibility and isolation of provisioned resources for users with a project role. NOTE Swagger docs for the Platform and RBAC services are with the Projects Service.	

NOTE

VMware provides customers with a 12 month End-of-Life notice for any breaking changes to public APIs. Any breaking changes are announced in the release notes included with the [VMware Aria Automation Documentation](#).

API versioning

It is highly recommended but not necessary to use API versioning. API versioning allows you to lock the API to a value and control when you upgrade to a new API version. If you do not use API versioning, the default behavior varies depending upon the API.

- For the IaaS APIs, the latest version is 2021-07-15. If you consume the IaaS APIs without versioning or if you assign a value other than 2021-07-15, requests use the version 2019-01-15.

As a best practice, lock your IaaS API requests with the `apiVersion` query parameter assigned to 2021-07-15 so that you ensure a smooth transition to the latest version before the version 2019-01-15 reaches its end of life. See [Using APIs to Build your Resource Infrastructure](#).

- For other APIs, you can specify any date you choose for the `apiVersion` query parameter. If you leave the value unspecified, requests use the latest API version by default. However backward compatibility is not preserved and if the API changes, you might encounter an unexpected change in the API response.

As a best practice, use the `apiVersion` query parameter in your API requests and lock your API to the latest version listed in the Swagger specification. Then if a new API version is announced, you control when to opt-in to that version by changing the `apiVersion` query parameter to the new version value.

The following example shows how to use the `apiVersion` query parameter for the catalog API. The catalog API versions are: 2020-08-25, 2020-01-30, and 2019-01-15. Including the additional `apiVersion` query parameter locks the call to the API version that was in effect as of January 30, 2020 and through August 24, 2020.

```
GET https://appliance.domain.com/catalog/api/sources?apiVersion=2020-01-30
```

When you are ready to opt-in to the features released with the version dated 2020-08-25, change the value of the `apiVersion` query parameter.

```
GET https://appliance.domain.com/catalog/api/sources?apiVersion=2020-08-25
```

Setting the `apiVersion` query parameter to the latest version ensures that you will also get updates to the catalog API that occur after 2020-08-25. However, no breaking changes will occur until a new version is announced and you will only experience those changes if you change the value of the `apiVersion` query parameter to a date that is equivalent to the new version or later.

NOTE

API versions do not change for every VMware Aria Automation release and are not the same for all services. To check API versions for the services you use, go to <https://<FQDN>/automation-ui/api-docs> and click the cards to open the Swagger specifications.

How Developers Use the VMware Aria Automation APIs

To make API service calls, you use a browser application or an HTTP client application to send requests and review responses. The following open-source applications are commonly used:

- cURL. <http://curl.haxx.se>
- j_q parser. <https://stedolan.github.io/jq/>
- Postman application. <https://www.getpostman.com/>

To learn how to use the API, you start by getting an authentication token. Then you can perform steps outlined in the use cases in this guide. The use cases include `curl` commands in request examples. To use the commands, ensure that the `jq` command-line JSON processor is installed with `curl`. The `jq` parser ensures that responses are formatted for optimum readability. For information about `jq` installation, see <https://stedolan.github.io/jq/>.

Getting Your Authentication Token

In the REST API, VMware Aria Automation requires an HTTP authentication token in the request header. Getting your authentication token is a prerequisite for any use case.

The access token is the token you use to authenticate all API calls. To acquire an access token, you use the Identity Service and Infrastructure as a Service (IaaS) APIs. After you get the access token, use it to verify user roles.

Get Your Access Token for the VMware Aria Automation API

Get Your Access Token

To get the token used to authenticate your session, you use the Identity Service API to get an API token. Then you use the API token as input to the IaaS API to get an access token.

- Secure a channel between the web browser and the VMware Aria Automation server. Open a browser and enter the URL such as: <https://appliance.domain.com>.

The access token is valid for eight hours. If the token times out, request it again. The following procedure shows how to obtain the access token using both the Identity Service API and the IaaS API.

1. Assign values to the variables for the hostname of your VMware Aria Automation appliance, your user name, and your password.

```
url='https://<your_FQDN>'  
  
username='<your_username>'  
  
password='<your_password>'
```

2. Use the Identity Service API to obtain the API token.

The API token is also known as the refresh token. It is valid for 90 days and can be used to generate a new access token when the access token expires.

NOTE

You cannot revoke the refresh token.

```
api_token=`curl -X POST \  
"$url/csp/gateway/am/api/login?access_token" \  
-H 'Content-Type: application/json' \  
-H 'Accept: application/json' \  
-d '{  
  "username": "'$username'",  
  "password": "'$password'"  
}' | jq -r .refresh_token`
```

3. Verify the API token variable is assigned.

The token is a compact string of characters as in the following example.

```
# echo $api_token
```

```
ABCutJJ7oEq7sWYD9qkpnlrzYqlFlSzmrWXYZrkpGswN8nzjmkWeNqn8QA1RfhQg
```

4. With the API token assigned, use the IaaS API to request the access token.

```
access_token=`curl -X POST \  
"$url/iaas/api/login" \  
-H 'Content-Type: application/json' \  
-H 'Accept: application/json' \  
-d '{  
  "refreshToken": "'$api_token'"  
}' | jq -r .token`
```

5. Verify the access token variable is assigned.

The access token is a long JSON Web Token as in the following example.

```
# echo $access_token
eyJhbGciOiJSUzI1NiIsInR5cCI6IkpXVCIsImtpZCI6InNpZ25pbmdfMiJ9.eyJzdWIiOiJ2bXdhcmUuY29t
Oj...
...
tSQ74_XhszGifZe_gFdxw
```

After 25 minutes of inactivity, the access token times out and you must request it again. You can revoke an access token at any time.

You have obtained the access token required to authenticate your API calls. This access token is valid for VMware Aria Automation users and is necessary when using tools that are integrated with VMware Aria Automation.

Use the access token to verify user roles. See [Verify User Roles](#).

Verify User Roles

To use the API, a VMware Aria Automation user must be an organization member with at least a user service role. You use the access token to verify user roles.

Verify that you have an access token. See [Get Your Access Token for the API](#).

1. Assign values to the variables for the hostname of your VMware Aria Automation instance, your user name, and your password.

```
url='http://<FQDN>'

username='<your_username>'

password='<your_password>'
```

2. Get your organization ID.

```
curl -X GET \
"$url/csp/gateway/am/api/loggedin/user/orgs" \
-H "csp-auth-token: $access_token"
```

3. Examine the response and assign the organization ID variable.

```
org_id='<your_org_id>'
```

4. Get your organization role.

```
curl -X GET \
$url/csp/gateway/am/api/loggedin/user/orgs/$org_id/roles \
-H "csp-auth-token: $access_token" | jq "."
```

The name field displays the organization role and must be either `org_owner` or `org_member`.

5. Get your service role.

```
curl -X GET \
$url/csp/gateway/am/api/loggedin/user/orgs/$org_id/service-roles \
```

```
-H "csp-auth-token: $access_token" | jq "."
```

The serviceRolesNames field displays the service role for each service and must be at least user.

Verify User Roles

Using the access token previously obtained and assigned, verify user roles. See [Get Your Access Token for the API](#).

Assign variables.

```
# url='https://appliance.company.com'
# username='user@example.local'
# password='example_password'
```

Get your organization ID.

```
# curl -X GET \
"$url/csp/gateway/am/api/loggedin/user/orgs" \
-H "csp-auth-token: $access_token"
```

The response shows the organization ID.

```
{
  "refLinks": [
    "/csp/gateway/am/api/orgs/7f8c518a-65f5-494b-b714-f7e349957a30"
  ],
  "items": [
    {
      "name": "DEFAULT-ORG",
      "displayName": "DEFAULT-ORG",
      "refLink": "/csp/gateway/am/api/orgs/7f8c518a-65f5-494b-b714-f7e349957a30",
      "id": "7f8c518a-65f5-494b-b714-f7e349957a30",
      "metadata": null,
      "parentRefLink": null
    }
  ]
}
```

Assign the organization ID variable.

```
# org_id='7f8c518a-65f5-494b-b714-f7e349957a30'
```

Verify the organization role.

```
# curl -X GET \
$url/csp/gateway/am/api/loggedin/user/orgs/$org_id/roles \
-H "csp-auth-token: $access_token" | jq "."
```

The response shows that the organization role is `org_owner`.

```
{  
  "refLink": "/csp/gateway/am/api/orgs/7f8c518a-65f5-494b-b714-f7e349957a30/roles/  
52a6a411-2339-4bc3-91bc-62418977df11",  
  "name": "org_owner",  
  "displayName": "Organization Owner",  
  "organizationLink": "/csp/gateway/am/api/orgs/7f8c518a-65f5-494b-b714-f7e349957a30"  
}
```

Verify the service role.

```
# curl -X GET \
$url/csp/gateway/am/api/loggedin/user/orgs/$org_id/service-roles \
-H "csp-auth-token: $access_token" | jq "."
```

A snippet of the response shows the Service Role Names for the Automation Assembler service. `cloud_admin` satisfies the minimum service role.

```
...  
  
{  
  "serviceDefinitionLink": "/csp/gateway/slc/api/definitions/external/<service_id>",  
  "serviceRoleNames": [  
    "automationservice:cloud_admin"  
  ]  
}  
  
...
```

Prerequisites for API Use Case Examples

Before performing any task using API services, you must review the prerequisites. General prerequisites apply to all services. Prerequisites that are service-specific are common to all endpoints for the service, but may vary depending upon the service role for example, administrator or user.

See [Organization and service user roles in VMware Aria Automation](#).

General prerequisites for all services

Before performing any task for any service, the following prerequisites must be satisfied:

- Verify that you have an active access token. See [Getting Your Authentication Token](#).
- Verify that the URL variable is assigned.

```
url='https://appliance.domain.com'
```

Prerequisites specific to API services

The following table lists prerequisites that are specific to the services with use cases in this guide.

NOTE

Every service includes an API version variable. If you choose not to assign a value to the `apiVersion` or to assign it to a different value, review the information in <https://techdocs.broadcom.com/us/en/vmware-cis/aria/aria-automation/8-18/aria-automation-api-programming-guide-on-prem-8-18.html>.

Table 121: Prerequisites for VMware Aria Automation Service Use Cases

Product: Service	Service prerequisites	Role-specific prerequisites
Automation Assembler: Blueprint service To access the Swagger documentation for the Blueprint API, see <a href="https://<your_FQDN>/blueprint/api/swagger/ui/">https://<your_FQDN>/blueprint/api/swagger/ui/ .	Verify that the Blueprint API version variable is assigned as in the following example. <code>api_version='2019-09-12'</code>	Verify that you are at least an organization member in VMware Aria Automation with a Automation Assembler administrator service role.
Automation Service Broker: Catalog service To access the Swagger documentation for the Catalog API, see <a href="https://<your_FQDN>/deployment/api/swagger/swagger-ui.html?urls.primaryName=catalog">https://<your_FQDN>/deployment/api/swagger/swagger-ui.html?urls.primaryName=catalog .	Verify that the Catalog API version variable is assigned as in the following example. <code>api_version='2020-08-25'</code>	Verify that you are at least an organization member in VMware Aria Automation with a Automation Service Broker administrator service role.
Automation Service Broker: Deployment service To access the Swagger documentation for the Deployment API, see <a href="https://<your_FQDN>/deployment/api/swagger/swagger-ui.html?urls.primaryName=deployments">https://<your_FQDN>/deployment/api/swagger/swagger-ui.html?urls.primaryName=deployments .	Verify that the Deployment API version variable is assigned as in the following example. <code>api_version='2020-08-25'</code>	Verify that you are at least an organization member in VMware Aria Automation with a Automation Service Broker administrator service role.
NOTE For the Automation Assembler: Deployment service, use the prerequisites for the Automation Assembler: Infrastructure as a Service (IaaS) service.		
Automation Assembler: Infrastructure as a Service (IaaS) service To access the Swagger documentation for the IaaS API, see <a href="https://<your_FQDN>/iaas/api/swagger/ui/">https://<your_FQDN>/iaas/api/swagger/ui/ .	Verify that the IaaS API version variable is assigned as in the following example. <code>api_version='2021-07-15'</code>	<ul style="list-style-type: none"> • Verify that you are an organization owner in VMware Aria Automation with a Automation Assembler administrator service role.

Table continued on next page

Continued from previous page

Product: Service	Service prerequisites	Role-specific prerequisites
	If you do not assign a value to the <code>apiVersion</code> variable or you assign it to a value other than <code>2021-07-15</code> , the IaaS API behavior will default to value of the previous version or <code>2019-01-15</code> .	<ul style="list-style-type: none"> If working with cloud accounts, verify that you have cloud administrator credentials. See Credentials required for working with cloud accounts in VMware Aria Automation.
All products: Onboarding service To access the Swagger documentation for the Onboarding API, see <a href="https://<your_FQDN>/relocation/api/swagger/swagger-ui.html">https://<your_FQDN>/relocation/api/swagger/swagger-ui.html	No version variable needed	Verify that you are at least an organization member in VMware Aria Automation with an Automation Assembler administrator service role.
Automation Pipelines: Pipelines service To access the Swagger documentation for the Pipelines API, see <a href="https://<your_FQDN>/pipeline/api/swagger/swagger-ui.html">https://<your_FQDN>/pipeline/api/swagger/swagger-ui.html .	Verify that the Pipelines API version variable is assigned as in the following example. <code>api_version='2019-10-17'</code>	Verify that you are at least an organization member in VMware Aria Automation with an Automation Pipelines administrator service role.
Automation Service Broker: Policies service To access the Swagger documentation for the Policies API, see <a href="https://<your_FQDN>/deployment/api/swagger/swagger-ui.html?url.primaryName=policies">https://<your_FQDN>/deployment/api/swagger/swagger-ui.html?url.primaryName=policies .	Verify that the Policies API version is assigned as in the following example. <code>api_version='2020-08-25'</code>	Verify that you are at least an organization member in VMware Aria Automation with a Automation Service Broker administrator service role.
All products: Project service To access the Swagger documentation for the Projects API, see <a href="https://<your_FQDN>/project/api/swagger/swagger-ui.html">https://<your_FQDN>/project/api/swagger/swagger-ui.html .	Verify that the Projects API version variable is assigned as in the following example. <code>api_version='2019-01-15'</code>	Verify that you are at least an organization member in VMware Aria Automation with an administrator service role.

Automation Assembler Tutorials

As a Automation Assembler administrator, you can use these tutorials to learn how to perform tasks programmatically using the IaaS APIs.

In addition to the steps in the tutorials, there is additional information in the guide. Links are provided to relevant topics.

Working with tags

As an Organization administrator with the Assembler admin service role, you can use the Tags endpoints to create, manage, or delete tags in Automation Assembler.

For information about working with tags using the UI, see [..../using-automation-assembler/topics/maphead-how-to-use-tags.dita](#).

NOTE

- Tag filters are case-insensitive.
- There is no way to query for unused tags using the IaaS API. However, you can submit a request to check for tag usage of specific tag IDs.

Prerequisites for working with tags

- Verify that all general prerequisites and prerequisites for the Automation Assembler Infrastructure as a Service (IaaS) service have been satisfied. See [Prerequisites for API Use Case Examples](#).

Filtering for tags

You can filter for tags based on a key, value, or origin and the tag filters are case-insensitive.

The following example shows how to filter for a tag with `location` in the key name.

```
curl -X GET \
```

```
"$url/iaas/api/tags?$filter=key%20eq%20'location'&apiVersion=$api_version" \
```

```
-H 'Content-Type: application/json' \
```

```
-H "Authorization: Bearer $access_token" | jq "."
```

A sample response shows "key": "location".

```
{
```

```
  "content": [
```

```
    {
```

```
      "key": "location",
```

```
      "value": "MUM",
```

```
      "id": "9aabbe23-d4bf-3d55-89f7-dc7e67317442"
```

```
    }
```

```
  ],
```

```
  "totalElements": 1,
```

```
  "numberOfElements": 1
```

```
}
```

To filter for the origin of a tag, you specify `USER_DEFINED` or `DISCOVERED` for the origin value. The following example filters for tags with the `DISCOVERED` origin.

```
curl -X GET \
```

```
"$url/iaas/api/tags?$filter=origins.item%20eq%20%27DISCOVERED%27&apiVersion=$api_version" \
```

```
-H 'Content-Type: application/json' \
```

```
-H "Authorization: Bearer $access_token" | jq "."
```

Tag origins can also be both `USER_DEFINED` and `DISCOVERED` as in the following cases:

- If a tag's origin is `USER_DEFINED` and another tag with the same case-sensitive key/value pair is assigned to an endpoint resource from which Automation Assembler collects data, Automation Assembler adds the `DISCOVERED` origin.
- If a user assigns a tag with the `DISCOVERED` origin to any Automation Assembler resource such as a network profile, Automation Assembler also assigns the `USER_DEFINED` origin to the tag.

Creating tags

You create a tag with a name and an optional value. The following example shows how to create a tag named `environment` with the value `prod` that you could add to resources in your production environment.

```
curl -X POST \
"$url/iaas/api/tags?apiVersion=$api_version"
-H 'Content-Type: application/json'
-H "Authorization: Bearer $access_token"
-d '{
  "key" : "environment",
  "value" : "prod"
}' | jq ".."
```

The response provides the tag ID.

```
{ 
  "key": "environment",
  "value": "prod",
  "id": "ca0ed5ef-72b5-3d9f-bc6d-0707defff540"
}
```

Listing and deleting tags

To delete a tag, you specify the tag ID. To get the tag ID, you list all tags in your infrastructure.

```
curl -X GET \
```

```
"$url/iaas/api/tags?apiVersion=$api_version"
-H 'Content-Type: application/json'
-H "Authorization: Bearer $access_token"
}' | jq ".."
```

The response lists all the tag names, values, and IDs as in the following example.

```
{
  "content": [
    {
      "key": "location",
      "value": "MUM",
```

```

        "id": "9aabbe23-d4bf-3d55-89f7-dc7e67317442"
    }
    {
        "key": "Application",
        "value": "testing",
        "id": "57ead12-523a-3cd2-9447-06e757dcf382"
    }
],
"totalElements": 2,
"numberOfElements": 2
}

```

Before deleting a tag, a best practice is to check the tag usage of the ID that you plan to delete. The following example checks for usage of the tag with ID 9aabbe23-d4bf-3d55-89f7-dc7e67317442.

```

curl -X POST \
"$url/iaas/api/tags/tags-usage?apiVersion=$api_version" \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
  "tagIds" : ["9aabbe23-d4bf-3d55-89f7-dc7e67317442"]
}' | jq "."

- If the tag is being used, the response shows where it is being used. This sample response shows that the tag is being used in a network profile.

{
  "documentLinks": [
    "/provisioning/resources/network-profiles/8615bbfe-ea90-420a-a1cf-8048ba4271d4"
  ],
  "documents": {
    "/provisioning/resources/network-profiles/8615bbfe-ea90-420a-a1cf-8048ba4271d4": {
      "id": "a30929ec-3b06-484e-8785-cc43619b5b01",
      "name": "23360",
      "customProperties": {
        "edgeClusterRouterStateLink": "/resources/routers/2d57f1c4-fbe0-46ce-a061-3a5f1396f37b",
        "tier0LogicalRouterStateLink": "/resources/routers/9c965abe-9d69-40c0-99e0-be5aa7e52097",
      }
    }
  }
}
```

```

        "onDemandNetworkIPAssignmentType": "mixed"
    },
    "tagLinks": [
        "/resources/tags/ef254637-594d-3960-a642-f157f859a830",
        "/resources/tags/9aabbe23-d4bf-3d55-89f7-dc7e67317442"
    ],
    "expandedTags": [
        {
            "tag": "23360\n"
        },
        {
            "tag": "location\nMUM"
        }
    ],
    "documentVersion": 11,
    "documentKind": "com:vmware:admiral:compute:profile:NetworkProfileService:NetworkProfile",
    "documentSelfLink": "/provisioning/resources/network-profiles/8615bbfe-ea90-420a-a1cf-8048ba4271d4",
    "documentUpdateTimeMicros": 1696947968305000,
    "documentExpirationTimeMicros": 0
},
"documentCount": 1,
"documentVersion": 0,
"documentUpdateTimeMicros": 0,
"documentExpirationTimeMicros": 0}
• If the tag is not being used, the response shows no resource links.
{
    "documentLinks": [],
    "documents": {},
    "documentCount": 0,
    "documentVersion": 0,
    "documentUpdateTimeMicros": 0,

```

```
"documentExpirationTimeMicros": 0
}
```

To delete the unused tag, specify the tag ID. The delete action first checks to ensure that the tag is not associated with a resource before deleting it. The following example deletes the tag with ID 9aabbe23-d4bf-3d55-89f7-dc7e67317442.

```
curl -X DELETE \
"$url/iaas/api/tags/9aabbe23-d4bf-3d55-89f7-dc7e67317442?apiVersion=$api_version" \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
}' | jq ".."
```

NOTE

To delete a tag that is associated with a resource, you can use the `ignoreUsage` query parameter as in the following example that forces the deletion of a tag with ID 9aabbe23-d4bf-3d55-89f7-dc7e67317442. However, this removes all tag assignments from all the resources associated with the tag.

```
curl -X DELETE \
"$url/iaas/api/tags/9aabbe23-d4bf-3d55-89f7-dc7e67317442?
ignoreUsage=true&apiVersion=$api_version" \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" | jq ".."
```

Updating tags

You can use the IaaS API to add, remove, or update the tags associated with a resource. Using the ID of the resource, you submit a request get the details about the resource including the tag definitions. Then you submit a request to update the resource with new tag key/value pairs.

The following example shows how to update tags for a vSphere datastore

List all vSphere datastores.

```
curl -X GET \
"$url/iaas/api/fabric-vsphere-datastores?apiVersion=$api_version" \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" | jq ".."
```

Examine the response to find the ID of the datastore that you want to use and use the ID to get details about the datastore. The following request uses the datastore ID 002e0a62-846d-4fb2-a153-3dcd80e57ba9.

```
curl -X GET \
"$url/iaas/api/fabric-vsphere-datastores/002e0a62-846d-4fb2-a153-3dcd80e57ba9/?
apiVersion=$api_version" \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" | jq ".."
```

A snippet of the response lists the tags on the datastore.

```
...
"tags": [
  {
    "key": "Team",
    "value": "E2E"
  },
  {
    "key": "Owner/Requestor",
    "value": "User1"
  },
  {
    "key": "Product",
    "value": "vRA"
  }
],
...

```

Update the tags for the datastore. The following example payload:

- Removes the Team and Owner/Requestor keys.
- Adds the environment key.
- Updates the Product key.

```
curl -X PATCH \
"$url/iaas/api/fabric-vsphere-datastore/002e0a62-846d-4fb2-a153-3cd80e57ba9?
apiVersion=$api_version" \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d {
  "tags": [
    {
      "key": "environment",
      "value": "dev"
    },
    {
      "key": "Product",
      ...
    }
  ]
}
```

```

    "value": "saltstack"
}
],
}' | jq "."

```

Create a Kubernetes Zone with a Tag

As a Automation Assembler admin, you can use APIs to create a new tag and add it to a Kubernetes zone.

- Verify that all general prerequisites and prerequisites for the Automation Assembler Infrastructure as a Service (IaaS) service have been satisfied. See [Prerequisites for API Use Case Examples](#).
- Verify that you have the cloud account ID for a vSphere cloud account. See [Add a Cloud Account](#).

In the following procedure, you use the IaaS API to create a new tag. Then using the CMX API, you create a Kubernetes zone with a supervisor namespace on vSphere and assign the tag to the zone.

NOTE

To create a Kubernetes zone with a vSphere cloud account, the account must be Tanzu-enabled. When you open a Tanzu-enabled vSphere cloud account in the UI, the cloud account appears with the label **Available for Kubernetes deployment**.

For information on Tanzu-enabled vSphere integration, see [Use Tanzu supervisor clusters and namespaces in Automation Assembler](#)

1. Create a new tag with a key/value pair.

```

curl -X POST \
$url/iaas/api/tags?apiVersion=$api_version \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
  "key": "'<your_tag_key>'",
  "value": "'<your_tag_value>'"
}' | jq "."

```

The response includes a tag ID.

2. Assign the tag ID variable.

```
tag_id='<example-tagID-alphanumeric-string>'
```

3. Assign your vSphere cloud account ID to the cloud account ID variable.

```
cloud_account_id='<vsphere_cloud_account_ID>'
```

4. Use the cloud account ID to create the Kubernetes zone with the tag.

To associate the Kubernetes zone with a vSphere cloud account you specify "providerType": "VSPHERE_NAMESPACES".

```
curl -X POST \
```

```
"$url/cmx/api/resources/k8s-zones" \
```

```

-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
  "name": "<your_k8s_zone_name>",
  "providerId": "'$cloud_account_id'",
  "providerType": "VSPHERE_NAMESPACES",
  "tagIds": [
    "'$tag_id'"
  ]
}' | jq "."

```

Create a Kubernetes Zone with a Tag

Create a new tag with key `example_tag_key` and value `example_tag_value`. Create a Kubernetes zone named `K8s-test-zone` with the tag. To create a Kubernetes zone, you must associate it with a cloud account configured for Automation Assembler such as a vSphere cloud account with ID `8d4646bd-d629-4526-9009-10e3d4b66e44`.

Assign variables.

```

$url='https://appliance.domain.com'
$api_version='2021-07-15'

```

Create a new tag with the key/value.

```

$ curl -X POST \
"$url/iaas/api/tags?apiVersion=$api_version" \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
  "key": "example_tag_key",
  "value": "example_tag_value"
}' | jq "."

```

Examine the response for the tag ID.

```
{
  "key": "example_tag_key",
  "value": "example_tag_value",
  "id": "a6f324e4-101c-33f6-ac51-d9aaaa020123"
}
```

Assign a value to the tag ID variable.

```
$ tag_id1= 'a6f324e4-101c-33f6-ac51-d9aaaa020123'
```

Assign your vSphere cloud account ID to the cloud account ID variable.

```
$ cloud_account_id='8d4646bd-d629-4526-9009-10e3d4b66e44'
```

Create the Kubernetes zone with the tag and the cloud account ID.

```
$ curl -X POST \
"$url/cmx/api/resources/k8s-zones" \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
  "name": "k8s-test-zone",
  "providerId": "'$cloud_account_id'",
  "providerType": "VSPHERE_NAMESPACES",
  "tagIds": [
    "'$tag_id1'"
  ]
}' | jq ."
```

The response shows the Kubernetes zone.

```
{
  "id": "220a81ba-c8ca-4f01-97bc-6f497576d564",
  "createdMillis": 1674847375758,
  "updatedMillis": 1674847375758,
  "orgId": "20451685-2bf6-4ba4-9ea4-87ee61bd32f8",
  "name": "k8s-test-zone",
  "providerId": "8d4646bd-d629-4526-9009-10e3d4b66e44",
  "providerType": "VSPHERE_NAMESPACES",
  "tagIds": [
    "a6f324e4-101c-33f6-ac51-d9aaaa020123"
  ]
}
```

If you want to update the Kubernetes zone, assign the Kubernetes zone ID variable.

```
$ k8s_zone_id='220a81ba-c8ca-4f01-97bc-6f497576d564'
```

If you want to add another tag, assign another tag ID variable.

```
$ tag_id2='21ccbdd6-c849-37f3-a784-1f2452cf802d'
```

Update the Kubernetes zone to add the tag.

NOTE

When updating the zone, the update deletes any tags that are not included in the request payload. So when making the request, you must include all the tags that will remain assigned to the zone after the update.

```
$ curl -X PUT \
"$url/cmx/api/resources/k8s-zones/$k8s_zone_id" \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
  "id": "220a81ba-c8ca-4f01-97bc-6f497576d564",
  "createdMillis": 1674847375758,
  "updatedMillis": 1674847375758,
  "orgId": "20451685-2bf6-4ba4-9ea4-87ee61bd32f8",
  "name": "k8s-test-zone",
  "providerId": "'$cloud_account_id'",
  "providerType": "VSPHERE_NAMESPACES",
  "tagIds": [
    "'$tag_id1'",
    "'$tag_id2'"
  ]
}' | jq "."
```

How do I retrieve provisioning request details

How do I retrieve provisioning request details

To validate placement scenarios before deploying a cloud template, you use the IaaS API to retrieve the request graph for a simulated provisioning request.

Prerequisites for retrieving provisioning request details

- Verify that all general prerequisites and prerequisites for the Automation Assembler Infrastructure as a Service (IaaS) service have been satisfied. See [Prerequisites for API Use Case Examples](#).
- Assign an API version variable for the Blueprint API.
`api_version_blueprint='2019-09-12'`

NOTE

The Automation Assembler Infrastructure as a Service (IaaS) service and the Automation Assembler Blueprint service have different API version values. You set the API version value for the Automation Assembler Infrastructure as a Service (IaaS) service when you satisfied the general prerequisites.

- Verify that you have the ID for the cloud template that you plan to deploy. See [Create and Update a Cloud Template](#). You can also get the cloud template ID from the UI, by opening the cloud template listed on **Design > Templates** and inspecting the ID at the end of the URL.

Retrieving provisioning request details

This example shows how to get request details for a cloud template with the ID c8197446-d636-4ed9-aa2b-796da98ad10c. In the following procedure, you use the blueprint API to get the deployment ID and flow ID and provide those values as input for the IaaS API request graph endpoint.

Use the template ID to get the deployment ID and flow ID.

```
curl -X POST \
$uri/blueprint/api/blueprint-requests?apiVersion=$api_version_blueprint \
-H 'Accept: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
  "deploymentId": null,
  "deploymentName": null,
  "description": null,
  "plan": false,
  "blueprintId": "c8197446-d636-4ed9-aa2b-796da98ad10c",
  "content": null,
  "simulate": true
}' | jq "."
```

Examine the response to get the deployment ID and the flow ID.

```
{
  "id": "8b918325-21a7-4902-b464-f39f5fb1bb64",
  "createdAt": "2023-11-22T07:12:54.585430Z",
  "createdBy": "user@mycompany.com",
  "updatedAt": "2023-11-22T07:12:54.585430Z",
  "updatedBy": "user@mycompany.com",
  "orgId": "434f6917-4e34-4537-b6c0-3bf3638a71bc",
  "projectId": "267f8448-d26f-4b65-b310-9212adb3c455",
  " projectName": "testing",
  "deploymentId": "924fcbe3-2076-48c9-a5f5-64de7f1cbe3a",
  "requestTrackerId": "8b918325-21a7-4902-b464-f39f5fb1bb64",
  "deploymentName": "deployment_924fcbe3-2076-48c9-a5f5-64de7f1cbe3a",
```

```

"reason": "Simulate",
"plan": false,
"destroy": false,
"ignoreDeleteFailures": false,
"simulate": true,
"blueprintId": "c8197446-d636-4ed9-aa2b-796da98ad10c",
"inputs": {},
"status": "STARTED",
"flowId": "8b918325-21a7-4902-b464-f39f5fb1bb64"
}

```

Use the deployment ID and flow ID to get the provisioning request details.

```

curl -X GET \
$url/iaas/api/request-graph?apiVersion=$api_version \
-H 'Accept: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
  "deploymentId": "924fcbe3-2076-48c9-a5f5-64de7f1cbe3a",
  "flowId": "8b918325-21a7-4902-b464-f39f5fb1bb64",
}' | jq "."

```

Using the response to validate placement scenarios

The response provides task and project information for the simulated provisioning request.

The tasks section of the response lists the task ID and stages. To validate a placement scenario, the request must successfully transition through all stages and substages. Any stage that shows an error includes a failure message that you can use to troubleshoot the problem with the placement scenario.

In the following sample response, a snippet shows an error during the reserving stage. To validate the provisioning request, correct errors and rerun the API until all tasks finish successfully.

```

"tasks": [
  {
    "id": "46414006-8f71-46f8-b965-eea0bacbba7e",
    "stages": [
      {
        "transitionSource": {
          "timestampMicros": 0

```

```
        } ,  
        "taskSubStage": "CREATED",  
        "taskInfo": {  
            "stage": "STARTED",  
            "isDirect": false  
        } ,  
        "resourceLinks": [  
            "/iaas/api/machines/4323fd90-ad4e-4342-b9ca-62a9bb7193c9"  
        ] ,  
        "timestampMicros": 1702877437358001  
    } ,  
    ...  
} ,  
"taskSubStage": "ENHANCED",  
"taskInfo": {  
    "stage": "STARTED",  
    "isDirect": false  
} ,  
...  
} ,  
"taskSubStage": "RESOURCE_COUNTED",  
"taskInfo": {  
    "stage": "STARTED",  
    "isDirect": false  
} ,  
...  
} ,  
"taskSubStage": "RESERVING",  
"taskInfo": {  
    "stage": "STARTED",  
    "isDirect": false  
} ,  
...  
}
```

```

    ...
        "taskSubStage": "ERROR",
        "taskInfo": {
            "stage": "STARTED",
            "isDirect": false,
            "failure": {
                "message": "Cannot find matching image mappings for image: im1",
                "statusCode": 0,
                "errorCode": 0,
                "serverErrorId": "ad4d91ea-4319-4f11-abcf-3601c08f3ecd",
                "documentKind": "com:vmware:xenon:common:ServiceErrorResponse"
            }
        },
        ...
    }
]

```

The project section of the response provides reference information for the project associated with the template.

```

"project": {
    "administrators": [],
    "members": [],
    "viewers": [],
    "supervisors": [],
    "zones": [
        {

    }
  }
}

```

How do I list and edit zones associated with a project

How do I extract and edit zones associated with a project

To query and edit zones associated with a project, you use Project endpoints in the IaaS API.

Prerequisites for extracting zones associated with a project

- Verify that all general prerequisites and prerequisites for the Automation Assembler Infrastructure as a Service (IaaS) service have been satisfied. See [Prerequisites for API Use Case Examples](#).
- Verify that you have your project ID. If you do not have the ID, list all projects to find the name and ID of the project with the associated zones that you want to query or edit.

```
curl -X GET -H 'Accept: application/json' -H "Authorization: Bearer $access_token"
"$url/iaas/api/projects?apiVersion=$api_version" | jq "."
```

Examine the response to find your project name and ID as in the following example snippet.

...

```
[  
  "name": "project1",  
  "description": "",  
  "id": "6c2f2d0d-ecee-42e3-90be-7bb66d6da2f9",  
  "orgId": "f098d692-e980-41a5-b349-83084fce1ea0",  
  ...  
]
```

Querying zones associated with a project

You can retrieve the first 100 cloud zones associated with a project without including a query option. To retrieve information about cloud zones that are not among the first 100 listed, you add query options to your request.

For a complete list of query options, see [Querying with the APIs](#).

This example assumes that you have more than 100 zones associated with the project ID 6c2f2d0d-ecee-42e3-90be-7bb66d6da2f9. The following procedure shows how to use paging to get the second page of zones associated with the project.

For more information about pagination parameters, see [Using Pagination and Count](#).

Assign the project ID variable.

```
project_id='6c2f2d0d-ecee-42e3-90be-7bb66d6da2f9'
```

Append query options `top=100` and `skip=100` to the request to retrieve cloud zones.

```
curl -X GET \  
"$url/iaas/api/projects/$project_id/zones?apiVersion=$api_version&$top=100&skip=100" \  
-H 'Accept: application/json' \  
-H "Authorization: Bearer $access_token" \  
| jq ".">
```

The following response lists the second page of zones. Since there are 102 zones associated with the project, the second page lists two zones.

```
"content": [  
  {  
    "zoneId": "3cf514d6-0dfc-4941-95de-40b01d60e8d3",  
    "priority": 0,  
    "maxNumberInstances": 0,  
    "allocatedInstancesCount": 2,  
    "memoryLimitMB": 0,  
    "allocatedMemoryMB": 1254,  
    "cpuLimit": 0,
```

```
"allocatedCpu": 2,
"gpuLimit": 0,
"allocatedGpu": 0,
"storageLimitGB": 0,
"allocatedStorageGB": 0.0,
"id": "0966203d-63f5-41c7-8dcd-7c1833932ec4-3cf514d6-0dfc-4941-95de-40b01d60e8d3",
"updatedAt": "2021-10-28",
"orgId": "ce811934-eala-4f53-b6ec-465e6ca7d126",
"_links": {
    "project": { "href": "/iaas/api/projects/6c2f2d0d-ecee-42e3-90be-7bb66d6da2f9" }
}
,
{
    "zoneId": "e4c56d64-a5bc-4656-bfc6-9f8009af66d3",
    "priority": 0,
    "maxNumberInstances": 0,
    "allocatedInstancesCount": 0,
    "memoryLimitMB": 0,
    "allocatedMemoryMB": 0,
    "cpuLimit": 0,
    "allocatedCpu": 0,
    "gpuLimit": 0,
    "allocatedGpu": 0,
    "storageLimitGB": 0,
    "allocatedStorageGB": 0.0,
    "id": "0966203d-63f5-41c7-8dcd-7c1833932ec4-e4c56d64-a5bc-4656-bfc6-9f8009af66d3",
    "updatedAt": "2022-01-07",
    "orgId": "ce811934-eala-4f53-b6ec-465e6ca7d126",
    "_links": {
        "project": { "href": "/iaas/api/projects/6c2f2d0d-ecee-42e3-90be-7bb66d6da2f9" }
    }
}
```

```
[,
"totalElements": 2,
"numberOfElements": 2
```

Editing cloud zone assignments

You can edit the following cloud zone assignments in your project:

- Storage limit (GB)
- CPU limit
- Memory limit (MB)
- Maximum number of instances
- Provisioning priority

This example assumes that you have two zones associated with the project ID

094a2fab-7715-4844-94f9-71b45452da27, one with provisioning priority 0 and one with provisioning priority 1. The following procedure shows how to edit the zone assignments to add a new zone with priority 1 and change an existing zone to priority 2.

Assign the project ID variable.

```
project_id='094a2fab-7715-4844-94f9-71b45452da27'
```

List the zones provisioned in your project.

```
curl -X GET \
"$url/iaas/api/projects/$project_id/zones?apiVersion=$api_version&$top=100&$skip=100" \
-H 'Accept: application/json' \
-H "Authorization: Bearer $access_token" \
| jq "."
```

A snippet of the response shows two zone IDs:

- 3c2bbe36-bf8e-4484-9c31-ce552422aaf1
- 8992bdf0-136f-401c-822a-e22dae67259b

...

```
}
```

```
"zoneId": "3c2bbe36-bf8e-4484-9c31-ce552422aaf1",
"priority": 0
"maxNumberInstances": 0,
"allocatedInstancesCount":0,
...
},
{
"zoneId": "8992bdf0-136f-401c-822a-e22dae67259b",
```

```

    "priority": 1
    "maxNumberInstances": 0,
    "allocatedInstancesCount": 0,
    ...
}

}
...

```

NOTE

When updating project zone assignments, the update deletes any cloud zones that are not included in the request payload. So when making the request, you must include zone IDs for all cloud zones that will remain in the project after the update, even if there is no change to the zone assignment specification.

The zone assignment update includes information for three zones in the project:

- For zone ID 3c2bbe36-bf8e-4484-9c31-ce552422aaf1, maintain the zone with "priority": 0.
- For zone ID 8992bdf0-136f-401c-822a-e22dae67259b, maintain the zone but change to "priority": 2.
- For zone ID 66067958-7e43-47f8-9bc9-0d32594c47e9, add a new zone with "priority": 1.

```

curl -X PUT \
"$url/iaas/api/projects/$project_id/zones?apiVersion=$api_version"
-H 'Content-Type: application/json'
-H "Authorization: Bearer $access_token"
-d '{
  "zoneAssignmentSpecifications": [
    {
      "zoneId": "3c2bbe36-bf8e-4484-9c31-ce552422aaf1",
      "priority": 0
    },
    {
      "zoneId": "8992bdf0-136f-401c-822a-e22dae67259b",
      "priority": 2
    },
    {
      "zoneId": "66067958-7e43-47f8-9bc9-0d32594c47e9",
      "priority": 1
    }
  ]
}'

```

```
 }' | jq ".."
```

Examine the response.

```
{
  "progress": 0,
  "status": "INPROGRESS",
  "name": "Project Zones Assignment Task",
  "id": "a6241aeb-909e-4689-af5a-940b52d216ff",
  "selfLink": "/iaas/api/request-tracker/a6241aeb-909e-4689-af5a-940b52d216ff"
}
```

Assign the selflink variable.

```
selfLink_id='a6241aeb-909e-4689-af5a-940b52d216ff'
```

Use the selfLink for tracking.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token"
"$url/iaas/api/request-tracker/$selfLink_id?apiVersion=$api_version" | jq ".."
```

The zone assignments are complete when the response includes "status": "FINISHED".

```
{
  "progress": 100,
  "status": "FINISHED",
  "name": "Project Zones Assignment Task",
  "id": "a6241aeb-909e-4689-af5a-940b52d216ff",
  "selfLink": "/iaas/api/request-tracker/a6241aeb-909e-4689-af5a-940b52d216ff"
}
```

If you list the zones provisioned in your project again, a snippet of the response shows the newly added cloud zone and updated provisioning priorities.

```
...
}

"zoneId": "3c2bbe36-bf8e-4484-9c31-ce552422aaf1",
"priority": 0
"maxNumberInstances": 0,
"allocatedInstancesCount": 0,
...
},
{
```

```

"zoneId": "8992bdf0-136f-401c-822a-e22dae67259b",
"priority": 2
"maxNumberInstances": 0,
"allocatedInstancesCount":0,
...
}

{
"zoneId": "66067958-7e43-47f8-9bc9-0d32594c47e9",
"priority": 1
"maxNumberInstances": 0,
"allocatedInstancesCount":0,
...
}
...

```

Deploying and Managing Resources

As a Automation Assembler administrator, you can use the IaaS APIs to deploy and manage cloud resources.

Create and Deploy a Machine Resource

To create a new resource such as a VM, you can use the resources API to make a POST request with a project ID. The deployment creates a new resource without using a cloud template.

- Verify that all general prerequisites and prerequisites for the Automation Assembler Infrastructure as a Service (IaaS) service have been satisfied. See [Prerequisites for API Use Case Examples](#).
- Assign an API version variable for the Deployment API.

```
api_version_deployment='2020-08-25'
```

NOTE

The Automation Assembler Infrastructure as a Service (IaaS) service and the Automation Service Broker Deployment service have different API version values. You set the API version value for the Automation Assembler Infrastructure as a Service (IaaS) service when you satisfied the general prerequisites.

- Verify that you have the ID of the cloud account where you want to deploy the VM. See [Adding Cloud Accounts](#).
- Verify that you know the cloud zone in your cloud account where you want the new VM to be deployed. See [Create a Cloud Zone](#).
- Verify that you have the ID for a project that includes the cloud zone in your cloud account. See [Add a Cloud Zone to Your Project](#).
- Verify that the flavor and image for the new VM exist in your cloud account.
- Verify that you know the resource type for the AWS machine, GCP machine, vSphere machine, or Azure machine that you plan to create. For a list of all resource types and request schema, see the link to the schema that's available from [VMware Aria Automation Resource Schema Documentation](#).

This procedure shows how to provision a VM with a project and a cloud zone assigned to the project. The flavor and image for the VM must exist in your cloud account.

1. Assign the cloud account ID variable.

```
cloud_account_id='<your_cloud_account_id>'
```

2. Assign the project ID variable.

```
project_id='<your_project_id>'
```

3. List all cloud zones.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/zones?apiVersion=$api_version" | jq ".."
```

4. Examine the response for the zone where you want to place your VM.

You use the `externalRegionId` to filter for fabric flavor and fabric image. You use the cloud zone ID for VM placement.

5. Assign the external region ID variable.

```
external_region_id='<your_external_region_id>'
```

6. Assign the cloud zone placement variable.

```
placement_name='/iaas/api/zone/<your_cloud_zone_id>'
```

7. To list the fabric images in your cloud account and zone, specify the cloud account ID and external region ID in the request.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" \
      "$url/iaas/api/fabric-images/?apiVersion=$api_version" \
      '$filter'="((externalRegionId eq '') or (externalRegionId eq '$external_region_id'))" \
      and ((cloudAccountId ne '*') or cloudAccountId eq '$cloud_account_id'))" | jq ".."
```

8. Examine the response to select a fabric image.

9. Assign the fabric image variable.

```
image_name='<your_image_name>'
```

10. To list the fabric flavors in your cloud account and zone, specify the cloud account ID and external region ID in the request.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" \
      "$url/iaas/api/fabric-flavors/?apiVersion=$api_version" \
      '$filter'="((externalRegionId eq '') or (externalRegionId eq '$external_region_id'))" \
      and ((cloudAccountId ne '*') or cloudAccountId eq '$cloud_account_id'))" | jq ".."
```

11. Examine the response to select a fabric flavor.
12. Assign the fabric flavor variable.

```
flavor_name='<your_flavor_name>'
```

13. Assign the resource type variable.

```
resource_type='<your_resource_type>'
```

14. Create and deploy the VM.

```
curl -X POST \
$url/deployment/api/resources?apiVersion=$api_version_deployment \
-H "Authorization: Bearer $access_token" \
-H "Content-Type: application/json" \
-d '{
  "name": "<your_resource_name>",
  "projectId": "'$project_id'",
  "type": "'$resource_type'",
  "properties": {
    "imageRef": "'$image_name'",
    "flavor": "'$flavor_name'",
    "placement": "'$placement_name'"
  },
}' | jq ."
```

15. Examine the response for the deployment ID.
16. Assign the deployment ID.
17. Get the status of the deployment.

```
curl -X GET \
$url/deployment/api/deployments/$deployment_id?apiVersion=$api_version_deployment \
-H "Authorization: Bearer $access_token" | jq ."
```

When the status shows CREATE_SUCCESSFUL the VM is deployed.

Create and deploy a VM

With a cloud account ID and cloud zone in the cloud account, create and deploy an AWS machine named `cloud_machine_1` using the `Cloud.AWS.Instance` resource type.

Assign variables.

```
$ url='https://appliance.domain.com'
```

```
$ api_version=' 2021-07-15'
$ api_version_deployment=' 2020-08-25'
$ cloud_account_id='14e6b70c-0e76-4c5e-bb61-e6d70a5b43ef'
$ project_id='394a4ccb-22c6-4ef0-8c75-8b77efbefb51'
```

List all cloud zones.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token"
"$url/iaas/api/zones?apiVersion=$api_version" | jq "."
```

A snippet of the response shows the cloud account ID with the external region ID and cloud zone ID.

```
...
    "externalRegionId": "eu-west-1",
    "cloudAccountId": "14e6b70c-0e76-4c5e-bb61-e6d70a5b43ef",
    "name": "AWS / eu-west-1-changed",
    "description": "test description",
    "id": "f32a30fd-67ac-43e3-9512-60cf6ef7bee8"
...
```

Assign the external region ID variable.

```
$ external_region_id='eu-west-1'
```

Assign the cloud zone placement variable.

```
$ placement_name='/iaas/api/zone/f32a30fd-67ac-43e3-9512-60cf6ef7bee8'
```

To list the fabric images in your cloud account and zone, specify the cloud account ID and external region ID in the request.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" \
"$url/iaas/api/fabric-images/?apiVersion=$api_version&" \
'$filter'="((externalRegionId eq '') or (externalRegionId eq '$external_region_id')) \
\ and ((cloudAccountId ne '') or cloudAccountId eq '$cloud_account_id'))" | jq "."
```

Examine the response to find the image ID that you want.

```
...
    "externalRegionId": "eu-west-1",
    "isPrivate": false,
    "externalId": "ami-9a9012e9",
...
```

To list the fabric flavors in your cloud account and zone, specify the cloud account ID and external region ID in the request.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" \
"$url/iaas/api/fabric-flavors/?apiVersion=$api_version&" \
'$filter'="((externalRegionId eq '') or (externalRegionId eq '$external_region_id')) \
\ and ((cloudAccountId ne '*') or cloudAccountId eq '$cloud_account_id')))" | jq "."
Examine the response to find the flavor ID that you want.
```

```
...
{
  "id": "xle.xlarge",
  "name": "xle.xlarge",
  "cpuCount": 4,
  "memoryInMB": 124928,
  "storageType": "ssd",
  "dataDiskSizeInMB": 122880,
  "dataDiskMaxCount": 1,
  "networkType": "Up to 10 Gigabit"
},
...
```

Assign the resource type for the VM.

```
$ resource_type = 'Cloud.AWS.EC2.Instance'
```

To deploy the VM, assign variables for image and flavor.

```
$ image_name='ami-9a9012e9'
$ flavor_name='xle.xlarge'
```

Create and deploy the VM.

```
curl -X POST \
$url/deployment/api/resources?apiVersion=$api_version_deployment \
-H "Authorization: Bearer $access_token" \
-H "Content-Type: application/json" \
-d '{
  "name": "cloud_machine_1",
  "projectId": "'$project_id'",
  "type": "'$resource_type'",
  "properties": {
    "imageRef": "'$image_name',
```

```

"flavor": "'$flavor_name',
"placement": "'$placement_name'"
},
}' | jq "."

```

The response shows the deployment ID.

```
{
  "deploymentId": "fccd2081-fd44-44c8-878c-f962ef71969a",
  "projectId": "394a4ccb-22c6-4ef0-8c75-8b77efbefb51",
  "requestId": "1f8f2e4f-0b2e-448d-8439-f1a05b1e90c1",
  "resourceId": "9a510ccb-0543-47e8-a2f2-f1f65fc0b0a"
}
```

Assign the deployment ID variable.

```
$ deployment_id='fccd2081-fd44-44c8-878c-f962ef71969a'
```

Get the status of the deployment.

```
$ curl -X GET \
$url/deployment/api/deployments/$deployment_id?apiVersion=$api_version"
-H "Authorization: Bearer $access_token" | jq "."

```

A snippet of the response shows the deployment status.

```
...
],
"status": "CREATE_SUCCESSFUL"
}
```

Managing IP Addresses

As an Automation Assembler administrator, you can reserve IP addresses so that VMware Aria Automation does not use them for deployment. If you no longer need them, you can release them.

Before reserving IP addresses, you must verify that available IP addresses exist within a network IP range.

Query for IP Addresses

When you use Automation Assembler to create a deployment, VMware Aria Automation allocates IP addresses to manage resources. To identify the IP addresses that have been allocated, you query the network IP range. You can only reserve IP addresses that have not been allocated.

- Verify that all general prerequisites and prerequisites for the Automation Assembler Infrastructure as a Service (IaaS) service have been satisfied. See [Prerequisites for API Use Case Examples](#).

You create network IP ranges with a range of IP addresses. The following procedure shows how to determine the IP addresses in a range that are available.

- To get the ID of the network range that you want to use, list the internal network IP ranges in your deployment.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/network-ip-ranges?apiVersion=$api_version" | jq "."
```

Examine the response to find the ID of the network IP range that you want to use.

- Assign a variable for the network IP range ID.

```
ip_range_id='<your_network_ip_range_id>'
```

- To query IP ranges associated with a particular network and get information such as IP availability, you can use one of the following commands:

- If you have the network IP range ID, use:

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/network-ip-ranges/$ip_range_id?apiVersion=$api_version" | jq "."
```

- If you have the network ID, use:

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/networks/<your_network_id>/network-ip-ranges?apiVersion=$api_version" | jq "."
```

- If you have the networking fabric ID, use:

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/fabric-networks/<your_fabric_network_id>/network-ip-ranges?apiVersion=$api_version" | jq "."
```

- If you have the networking fabric for vSphere ID, use:

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/fabric-networks-vsphere/<your_fabric_network_vsphere_id>/network-ip-ranges?apiVersion=$api_version" | jq "."
```

Examine the response to see the number of allocated and available IP addresses. If the number of available IP addresses is too low, check another network IP range until you find one with enough IP addresses to fit your needs.

- Use the network IP range ID to query the status of IP addresses within the range.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/network-ip-ranges/$ip_range_id/ip-addresses?apiVersion=$api_version" | jq "."
```

Examine the result. All IP addresses appear with "ipAddressStatus": "ALLOCATED" or "ipAddressStatus": "RELEASED" and are not available.

Query for IP addresses within an IP range

The example query requests and responses show how to find allocated IP addresses.

Assign variables.

```
$ url='https://appliance.domain.com'
$ api_version='2021-07-15'
```

List the internal network IP ranges in your deployment.

```
$ curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/network-ip-ranges?apiVersion=$api_version" | jq "."
```

A snippet of the response shows the network IP ranges with their IDs.

```
...
  "startIPAddress": "fe45::2",
  "orgId": "8040fbde-5ff0-41f3-a8a1-9e25a3311be2",
  "endIPAddress": "fe45::ffff",
  "createdAt": "2023-02-28",
  "ipVersion": "IPv6",
  "name": "rangeIPv6",
  "id": "703a02df-3b6d-4ad7-b146-582b398055f2",
...

```

Assign the variable for the network IP range ID.

```
$ ip_range_id='703a02df-3b6d-4ad7-b146-582b398055f2'
```

Query the IP range associated with the network IP range ID.

```
$ curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/network-ip-ranges/$ip_range_id?apiVersion=$api_version" | jq "."
```

A snippet of the response shows the number of available and allocated IPv6 addresses. It also shows the IP version and the start and end of the IP address sequence.

```
{
  "numberOfAllocatedIPs": 2,
  "numberOfAvailableIPs": 65531,
  "numberOfReleasedIPs": 0,
  "totalNumberOfIPs": 65533,
  "numberOfUserAllocatedIPs": 0,
  "numberOfSystemAllocatedIPs": 2,
  "startIPAddress": "fe45::2",
  "endIPAddress": "fe45::ffff",
  "ipVersion": "IPv6",
  "name": "rangeIPv6",
  "id": "703a02df-3b6d-4ad7-b146-582b398055f2",
  "createdAt": "2023-02-28",
  "updatedAt": "2023-02-28",
  "organizationId": "8040fbde-5ff0-41f3-a8a1-9e25a3311be2",
  "orgId": "8040fbde-5ff0-41f3-a8a1-9e25a3311be2",
```

```

"_links": {
  "self": {
    "href": "/iaas/api/network-ip-ranges/703a02df-3b6d-4ad7-b146-582b398055f2"
  }
}

```

The following example shows how to query of IP ranges associated with fabric network ID 33c2bbb5-5b26-4a5a-87c6-9e96db72451d.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/fabric-networks/33c2bbb5-5b26-4a5a-87c6-9e96db72451d/network-ip-ranges?apiVersion=$api_version" | jq "."

```

The response shows two IP ranges with details about associated IPv4 addresses.

```

    }
}
}
],
"totalElements": 2,
"numberOfElements": 2
}

```

If the IP range has a sufficient number of available IP addresses, get more information about the IP addresses in that range.

```
$ curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer
$access_token" "$url/iaas/api/network-ip-ranges/$ip_range_id/ip_addresses?
apiVersion=$api_version" | jq "."
```

The response provides details about the unavailable IP addresses including their IP version and how they were allocated.

- "ipAllocationType": "SYSTEM" indicates that an IP address was automatically allocated for use in a deployment.
- "ipAllocationType": "USER" indicates that an IP address was manually allocated for use by a user.

```

You can allocate any of the IP addresses in the network range except fe4500:10:118:136:fcd8:d68d:9701:4440 and fe45:10:118:136:fcd8:d68d:9701:4450.

IP addresses with the status "ipAddressStatus": "ALLOCATED" or "ipAddressStatus": "RELEASED" are not available for allocation. You can allocate any of the remaining the IP addresses in the range. See [Allocate IP Addresses](#).

Allocate IP Addresses

As a cloud administrator, you can use the network IP range API to allocate the IP addresses that you want to reserve and make them unavailable for deployment by VMware Aria Automation.

- Verify that all general prerequisites and prerequisites for the Automation Assembler Infrastructure as a Service (IaaS) service have been satisfied. See [Prerequisites for API Use Case Examples](#).
- Verify that you have the ID of the network IP range that includes the IP addresses that you want to reserve. See [Query for IP Addresses](#).
- If you plan to specify the IP addresses from the network IP range, verify that you know the IPv4 or IPv6 addresses. See [Query for IP Addresses](#).
- If you are a cloud administrator and you plan to specify the number of IP addresses from the network IP range, verify that the number is less than or equal to the number of available IP addresses in the range.

To allocate IP addresses, you submit a request with either:

- A list of specific IP addresses.
- The number of IP addresses.

You can also provide an optional description.

NOTE

The following restrictions apply to the request:

- No more than 100 IP addresses can be allocated in a single call.
- If listing specific IP addresses, the addresses must all be of the same type. Mixing IPv4 and IPv6 addresses is not supported.

1. Assign the variable for the network IP range ID.

```
ip_range_id='<your_network_ip_range_id>'
```

2. Allocate the IP addresses by providing a list of addresses.

The following request example allocates two IP addresses.

- Specify either IPv4 or IPv6 addresses.
- To release additional IP addresses, provide additional addresses in the payload.

```
curl --location --request POST \
```

```
$url/iaas/api/network-ip-ranges/$ip_range_id/ip-addresses/allocate?
apiVersion=$api_version \
```

```
-H "Authorization: Bearer $access_token" \
-H 'Content-Type: application/json' \
```

```

-d '{
  "description": "<your_optional_description>",
  "ipAddresses": ["<ipv_address_1>", "<ipv_address_2>"]
}'

```

Examine the response for the self link to track the request.

3. If you do not list IP addresses, provide the number of IP addresses to allocate.

```

curl --location --request POST \
$url/iaas/api/network-ip-ranges/$ip_range_id/ip-addresses/allocate?
apiVersion=$api_version \
-H "Authorization: Bearer $access_token" \
-H 'Content-Type: application/json' \
-d '{
  "description": "<your_optional_description>",
  "numberOfIps": "<number_of_IPs>"
}'

```

Examine the response for the self link to track the request.

4. Assign the selfLink variable.

```
selfLink_id='example-selfLink-alphanumeric-string'
```

5. Use the selfLink variable to track the request.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer
$access_token" "$url/iaas/api/request-tracker/$selfLink_id?apiVersion=$api_version" |
jq "."
```

The IPs are allocated when the response includes "status": "FINISHED" and provides a list of allocated resources.

NOTE

If you specified the number of IP addresses to allocate, you query for the details of each resource in the response to get the allocated IP address associated with the resource.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer
$access_token" "$url/iaas/api/network-ip-ranges/$ip_range_id/ip-addresses/
<ip_address_id>?apiVersion=$api_version" | jq "."
```

Allocate IP addresses within an IP range

Using the network IP range with the IP addresses that you want to reserve, specify the IP addresses to allocate.

- Two IPv4 IP addresses used in this example are: ["196.192.2.19", "196.192.2.20"]
- Two IPv6 IP addresses used in this example are:
["fe45:10:118:136:fcd8:d68d:9701:8975", "fe45:10:118:136:fcd8:d68d:9701:8985"]

Assign variables.

```
$ url='https://appliance.domain.com'
$ api_version=' 2021-07-15'
$ ip_range_id='703a02df-3b6d-4ad7-b146-582b398055f2'

Allocate IPv4 addresses by providing a list.

curl --location --request POST \
    $url/iaas/api/network-ip-ranges/$ip_range_id/ip-addresses/allocate?
apiVersion=$api_version \
-H "Authorization: Bearer $access_token" \
-H 'Content-Type: application/json' \
-d '{
    "description": "Allocate ipv4 addresses for QA test machines",
    "ipAddresses": ["196.192.2.19", "196.192.2.20"]
}'
```

Or allocate IPv6 addresses by providing a list.

```
curl --location --request POST \
    $url/iaas/api/network-ip-ranges/$ip_range_id/ip-addresses/allocate?
apiVersion=$api_version \
-H "Authorization: Bearer $access_token" \
-H 'Content-Type: application/json' \
-d '{
    "description": "Allocate ipv6 addresses for QA test machines",
    "ipAddresses":
    ["fe45:10:118:136:fcd8:d68d:9701:8975", "fe45:10:118:136:fcd8:d68d:9701:8985"]
}'
```

Or specify the number of IP addresses to allocate, such as four.

```
curl --location --request POST \
    $url/iaas/api/network-ip-ranges/$ip_range_id/ip-addresses/allocate?
apiVersion=$api_version \
-H "Authorization: Bearer $access_token" \
-H 'Content-Type: application/json' \
-d '{
    "description": "Allocate four IP addresses for QA test machines",
    "numberOfIps": "4"
}'
```

The response provides the selfLink variable for tracking.

```
{  
  "progress": 1,  
  "status": "INPROGRESS",  
  "name": "IP Address Allocation Task",  
  "id": "ab726e31-ed8bfdfb-83d9-4964-b719-8b395c87d2c9",  
  "selfLink": "/iaas/api/request-tracker/ab726e31-ed8bfdfb-83d9-4964-b719-8b395c87d2c9"  
}
```

Assign the selfLink variable.

```
selfLink_id= 'ab726e31-e909-4bcc-87ef-5139294eb26a'
```

Track the request

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token"  
"$url/iaas/api/request-tracker/$selfLink_id?apiVersion=$api_version" | jq "."
```

When the request is complete, the response includes "status": "FINISHED".

- This is an example of the response when two IPv4 or IPv6 addresses are specified and allocated. You know the IP addresses because you provided them in the request.

```
{
  "progress": 100,
  "status": "FINISHED",
  "resources": [
    "/iaas/api/network-ip-ranges/703a02df-3b6d-4ad7-b146-582b398055f2/ip-
addresses/6212ac8b-a885-4416-bf0d-ebb88628bef1",
    "/iaas/api/network-ip-ranges/703a02df-3b6d-4ad7-b146-582b398055f2/ip-
addresses/9b65104d-debd-4830-8296-3cb87509d293"
  ],
  "name": "IP Address Allocation Task",
  "id": "ab726e31-e909-4bcc-87ef-5139294eb26a",
  "selfLink": "/iaas/api/request-tracker/ab726e31-e909-4bcc-87ef-5139294eb26a"
}
```

- This is an example of the response when four IP addresses are requested and allocated.

```
{
  "progress": 100,
  "status": "FINISHED",
  "resources": [
    "/iaas/api/network-ip-ranges/703a02df-3b6d-4ad7-b146-582b398055f2/ip-
addresses/a4cceea7-3a94-439b-99fa-420774e61eba",
    "/iaas/api/network-ip-ranges/703a02df-3b6d-4ad7-b146-582b398055f2/ip-
addresses/4c492669-5ec2-4465-992b-c9c252edf052",
    "/iaas/api/network-ip-ranges/703a02df-3b6d-4ad7-b146-582b398055f2/ip-
addresses/0ce9ee20-1a40-460d-80df-fb1791fb42a",
    "/iaas/api/network-ip-ranges/703a02df-3b6d-4ad7-b146-582b398055f2/ip-
addresses/d7d876b6-92b1-4530-a305-d586c8474f11"
  ],
  "name": "IP Address Allocation Task",
  "id": "ab726e31-e909-4bcc-87ef-5139294eb26a",
  "selfLink": "/iaas/api/request-tracker/ab726e31-e909-4bcc-87ef-5139294eb26a"
}
```

To get an IP address, query for the details of an allocated resource. The following example queries for the details of the resource with IP address ID a4cceea7-3a94-439b-99fa-420774e61eba.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/network-ip-ranges/$ip_range_id/ip-addresses/
a4cceea7-3a94-439b-99fa-420774e61eba?apiVersion=$api_version" | jq "."
```

The response provides details about the resource including the allocated IP address and IP version. "ipAllocationType": "USER" indicates that an Automation Assembler administrator manually reserved the IP address.

```
{
    "ipAddress": "196.192.2.20",
    "ipAddressDecimalValue": 168561941,
    "ipVersion": "IPv4",
    "ipAddressStatus": "ALLOCATED",
    "ipAllocationType": "USER",
    "id": "439f9c9b-2b2f-484d-8867-2d7b541ddeec",
    "createdAt": "2023-02-22",
    "updatedAt": "2023-02-22",
    "orgId": "8040fbde-5ff0-41f3-a8a1-9e25a3311be2",
    "_links": {
        "network-ip-range": {
            "href": "/iaas/api/network-ip-ranges/703a02df-3b6d-4ad7-b146-582b398055f2"
        },
        "self": {
            "href": "/iaas/api/network-ip-ranges/703a02df-3b6d-4ad7-b146-582b398055f2/ip-addresses/439f9c9b-2b2f-484d-8867-2d7b541ddeec"
        },
        "connected-resource": {
            "href": "/iaas/api/machines/81633fba-e86b-4bfa-a06f-3c4f7a754568/network-interfaces/1c26b194-2862-4d7e-be9c-9881d6cdb871"
        }
    }
}
```

If you no longer need allocated IP addresses, you can release them. See [Release IP Addresses](#).

Release IP Addresses

If you no longer need reserved IP addresses, you can release them so that VMware Aria Automation can use them for deployment.

- Verify that all general prerequisites and prerequisites for the Automation Assembler Infrastructure as a Service (IaaS) service have been satisfied. See [Prerequisites for API Use Case Examples](#).
- Verify that you have the ID of the network IP range that includes the IP addresses that you want to release. See [Query for IP Addresses](#).
- Verify that you know the IPv4 or IPv6 addresses that you want to release. The IP addresses must all be the same type. Releasing a mix of IPv4 and IPv6 addresses in the same request is not supported. See [Allocate IP Addresses](#).

This procedure shows how to request specific IP addresses to release.

- Assign the variable for the network IP range ID.

```
ip_range_id='<your_network_ip_range_id>'
```

- Release the IP addresses.

The following request releases two IP addresses.

- Specify either IPv4 or IPv6 addresses.
- To release more IP addresses, provide the IP addresses in the payload.

NOTE

No more than 100 IP addresses can be released in a single API call.

```
curl --location --request POST \
$url/iaas/api/network-ip-ranges/$ip_range_id/ip-addresses/release?
apiVersion=$api_version \
-H "Authorization: Bearer $access_token" \
-H 'Content-Type: application/json' \
-d '{
    "ipAddresses": ["<ipv_address_1>", "<ipv_address_2>"]
}'
```

Examine the response for the self link to track the request.

- Assign the self link variable.

```
selfLink_id='example-selfLink-alphanumeric-string'
```

- Use the selfLink variable to track the request.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer
$access_token" "$url/iaas/api/request-tracker/$selfLink_id?apiVersion=$api_version" |
jq ."
```

The IP addresses are released, when the response includes "status": "FINISHED".

Release IP addresses within an IP range

To release IP addresses, make a request with the network IP range and specify the IP addresses to release.

Assign variables.

```
$ url='https://appliance.domain.com'
$ api_version=' 2021-07-15'
```

```
$ ip_range_id='4e6b700c-5d07-4247-b0c7-ae13d1d7188a'
```

Release two IPv4 addresses.

```
curl --location --request POST \
$url/iaas/api/network-ip-ranges/$ip_range_id/ip-addresses/release?
apiVersion=$api_version \
-H "Authorization: Bearer $access_token" \
-H 'Content-Type: application/json' \
-d '{
    "ipAddresses": ["196.192.2.19", "196.192.2.20"]
}'
```

The response provides a **selfLink** for tracking.

```
{
    "progress": 1,
    "status": "INPROGRESS",
    "name": "IP Address Release Task",
    "id": "452bb595-ca0f-4685-8fcc-8bd6321bf7c6",
    "selfLink": "/iaas/api/request-tracker/452bb595-ca0f-4685-8fcc-8bd6321bf7c6"
}
```

Assign the **selfLink** variable.

```
selfLink_id= '452bb595-ca0f-4685-8fcc-8bd6321bf7c6'
```

Track the request.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token"
$url/iaas/api/request-tracker/$selfLink_id?apiVersion=$api_version | jq "."
```

The IP addresses are released, when the response includes "status": "FINISHED".

```
{
    "progress": 100,
    "status": "FINISHED",
    "resources": [
        "/iaas/api/network-ip-ranges/4e6b700c-5d07-4247-b0c7-ae13d1d7188a/ip-addresses/
3f08cabefedf-4e9b-96f6-d3bf69016cc4",
        "/iaas/api/network-ip-ranges/4e6b700c-5d07-4247-b0c7-ae13d1d7188a/ip-addresses/
ca287794-c06b-401c-9626-0b8f5f75d1c2"
    ],
    "name": "IP Address Release Task",
```

```

    "id": "452bb595-ca0f-4685-8fcc-8bd6321bf7c6",
    "selfLink": "/iaas/api/request-tracker/452bb595-ca0f-4685-8fcc-8bd6321bf7c6"
}

```

Creating and Using a First Class Disk

Using a vSphere Storage Profile that supports First Class Disk (FCD) storage, you can create block device-based storage that is independent of a VM.

First Class Disks offer many advantages. For example, you can attach an FCD to a VM and take multiple snapshots of the disk over time. If you find that you do not need certain snapshots, you can delete them. You can also revert an FCD to an earlier snapshot.

NOTE

If you attach an FCD to a VM and then delete the VM, both the FCD and its snapshots are deleted. And if the FCD is detached from a VM, you cannot delete the FCD without deleting its snapshots first.

Create a First Class Disk

To create a First Class Disk (FCD), you make a POST request using the block device specification. The request body includes a project ID, disk capacity, persistence setting, and constraints from the vSphere Storage Profile for an FCD creation.

- Verify that all general prerequisites and prerequisites for the Automation Assembler Infrastructure as a Service (IaaS) service have been satisfied. See [Prerequisites for API Use Case Examples](#).
- Verify that you have added a project and you have the project ID. See [Create a Project to use in](#).
- Know the capacity of the disk and the persistence of the disk that you are creating.
- Verify that you have created a storage profile for an FCD and that you have the `defaultItem` and the tags from the response. See [Create a Storage Profile for a First Class Disk](#).

1. Assign the project ID variable.

```
project_id='<your_project_id>'
```

2. Set the capacity and persistence for the disk.

```
capacity_in_gb=<integer>
```

```
persistence=<true|false>
```

3. Deploy the FCD.

- With `mandatory` set to true, all tags in the `expression` must match a storage profile, otherwise provisioning fails.
- The `expression` is the key:value tag pair used to create the storage profile. See [Create a Storage Profile for a First Class Disk](#).

```
curl -X POST \
```

```
$url/iaas/api/block-devices?apiVersion=$api_version \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
```

```
-d '{
  "projectId": "'$project_id'",
  "name": "FCD-example",
  "capacityInGB": "'$capacity_in_gb'",
  "persistent" : "'$persistent'",
  "constraints": [
    {
      "mandatory": "true",
      "expression": "type:fcd"
    }
  ]
}' | jq ".."
```

The response includes a selfLink value.

```
{
  "progress": 0,
  "status": "INPROGRESS",
  "name": "Provisioning",
  "id": "example-selfLink-alphanumeric-string",
  "selfLink": "/iaas/api/request-tracker/example-selfLink-alphanumeric-string"
}
```

4. Assign the selfLink variable.

```
selfLink_id='example-selfLink-alphanumeric-string'
```

5. Use the selfLink variable to track the progress of the FCD creation.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" $url/iaas/api/request-tracker/$selfLink_id?apiVersion=$api_version | jq .."
```

In the list of resources, the response includes block devices with the block device ID in the path.

```
{
  "progress": 100,
  "message": "success",
  "status": "FINISHED",
  "resources": [
    "/iaas/api/block-devices/example-blockdevice-alphanumeric-string"
  ]
}
```

```
],  
...  
}
```

6. Assign the block device ID variable.

```
block_device_id='example-blockdevice-alphanumeric-string'
```

7. Retrieve the created block device object.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer  
$access_token" $url/iaas/api/block-devices/$block_device_id?apiVersion=$api_version |  
jq ".."
```

8. Retrieve all the FCD block device types.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer  
$access_token" "$url/iaas/api/block-devices?  
%24filter=customProperties.diskType%20eq%20firstClass&apiVersion=$api_version" | jq  
.."
```

9. Delete the FCD block device.

```
curl -X DELETE -H 'Content-Type: application/json' -H "Authorization: Bearer  
$access_token" $url/iaas/api/block-devices/$block_device_id?apiVersion=$api_version |  
jq ".."
```

Create a First Class Disk

With constraints from a vSphere Storage Profile for FCD storage, use the block device specification to deploy a First Class Disk for a project ID with a two GB capacity and persistence set to false.

```
$ url='https://appliance.domain.com'  
$ api_version='2021-07-15'  
$ project_id='f5357a28-df59-47e0-b983-8a562910d0be'  
$ capacity_in_gb=2  
$ persistent=false  
Deploy the FCD.
```

```
$ curl -X POST \  
$url/iaas/api/block-devices?apiVersion=$api_version \  
-H 'Content-Type: application/json' \  
-H "Authorization: Bearer $access_token" \  
-d '{  
"projectId": "'$project_id'",
```

```

"name": "FCD-example",
"capacityInGB": "'$capacity_in_gb'",
"persistent" : "'$persistent'",
"constraints": [
{
    "mandatory": "true",
    "expression": "type:fcd"
}
]
}' | jq "."

```

The response provides a selfLink to the request.

```
{
    "progress": 0,
    "status": "INPROGRESS",
    "name": "Provisioning",
    "id": "86707da6-d5d6-4ebc-94a2-0a22f3fcb794",
    "selfLink": "/iaas/api/request-tracker/86707da6-d5d6-4ebc-94a2-0a22f3fcb794"
}
```

Assign the selfLink ID variable.

```
$ selfLink_id='86707da6-d5d6-4ebc-94a2-0a22f3fcb794'
```

Track the progress of the request.

```
$ curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token"
$url/iaas/api/request-tracker/$selfLink_id?apiVersion=$api_version | jq "."
```

After the request completes successfully, the response provides the block device ID.

```
{
    "progress": 100,
    "message": "success",
    "status": "FINISHED",
    "resources": [
        "/iaas/api/block-devices/e1cbc8e1-76bb-4bef-8e51-a582437266c2"
    ]
}
```

```
],
  "name": "Provisioning",
  "id": "86707da6-d5d6-4ebc-94a2-0a22f3fcb794",
  "selfLink": "/iaas/api/request-tracker/86707da6-d5d6-4ebc-94a2-0a22f3fcb794"
}
```

Assign the block device ID variable.

```
$ block_device_id='e1cbc8e1-76bb-4bef-8e51-a582437266c2'
```

Use the block device ID to attach your FCD to a VM and manage your FCD snapshots. See [Attach a First Class Disk](#) and [Manage First Class Disk Snapshots](#).

Attach a First Class Disk

To attach a First Class Disk (FCD) to a VM, you make a POST request with the machine ID of the VM. The request body includes the block device ID that you obtained from creating the FCD.

- Verify that all general prerequisites and prerequisites for the Automation Assembler Infrastructure as a Service (IaaS) service have been satisfied. See [Prerequisites for API Use Case Examples](#).
- Verify that you have created an FCD and you have a block device ID. See [Create a First Class Disk](#).
- Verify that the hardware version of the machine to which you plan to attach the FCD is vmx-13 or later.

1. Assign the block device ID variable.

```
block_device_id='<your_block_device_id>'
```

2. Get a list of machines.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" $url/iaas/api/machines?apiVersion=$api_version | jq "."
```

3. Examine the response to find the machine that you want to attach the FCD to.

4. Assign a machine ID.

```
machine_id='<your_machine_id>'
```

5. Attach the FCD to the machine.

```
curl -X POST \
$url/iaas/api/machines/$machine_id/disks?apiVersion=$api_version \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
  "blockDeviceId": "'$block_device_id'"
}' | jq "."
```

The response includes a selfLink value.

```
{
  "progress": 0,
  "status": "INPROGRESS",
  "name": "Provisioning",
  "id": "example-selfLink-alphanumeric-string",
  "selfLink": "/iaas/api/request-tracker/example-selfLink-alphanumeric-string"
}
```

6. Assign the selfLink variable.

```
selfLink_id='example-selfLink-alphanumeric-string'
```

7. Use the selfLink to track the progress of the FCD attachment.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" $url/iaas/api/request-tracker/$selfLink_id?apiVersion=$api_version | jq "."
```

Once complete, the response includes a list of resources with a machine that has your machine ID in the path.

```
{
  "progress": 100,
  "message": "success",
  "status": "FINISHED",
  "resources": [
    "/iaas/api/machines/your-machine-id"
  ],
  ...
}
```

8. Detach the FCD.

```
curl -X DELETE -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" $url/iaas/api/machines/$machine_id/disks/$block_device_id?apiVersion=$api_version | jq "."
```

Attach a First Class Disk

With the block device ID from the FCD, attach the FCD to a VM.

```
$ url='https://appliance.domain.com'
$ api_version='2021-07-15'
```

```
$ block_device_id='e1cbc8e1-76bb-4bef-8e51-a582437266c2'
```

Get a list of machines.

```
$ curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token"
$url/iaas/api/machines?apiVersion=$api_version | jq "."
```

Examine the response. Identify the machine that you want to attach the FCD to.

...

  "updatedAt": "2022-04-02T02:02:02-04:00",
  ...
}
```

Assign the machine ID variable.

```
$ machine_id='fcaad107-48c3-320f-989f-31b0c8d4a6a0'
```

Attach the FCD to the machine.

```
$ curl -X POST \
$url/iaas/api/machines/$machine_id/disks?apiVersion=$api_version \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
  "blockDeviceId": "'$block_device_id'"
}' | jq ."
```

The response provides a selfLink to the request.

```
{
  "progress": 0,
  "status": "INPROGRESS",
  "name": "Provisioning",
  "id": "18050d7d-e3b2-4dd0-b0a0-5883ec766999",
  "selfLink": "/iaas/api/request-tracker/18050d7d-e3b2-4dd0-b0a0-5883ec766999"
}
```

Assign the selfLink ID variable.

```
$ selfLink_id='18050d7d-e3b2-4dd0-b0a0-5883ec766999'
```

Track the progress of the request.

```
$ curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" \
$url/iaas/api/request-tracker/$selfLink_id?apiVersion=$api_version | jq ."
```

After the request completes successfully, the response includes your machine ID.

```
{
  "progress": 100,
  "message": "success",
  "status": "FINISHED",
  "resources": [
    "/iaas/api/machines/fcaad107-48c3-320f-989f-31b0c8d4a6a0"
  ],
  ...
}
```

Manage First Class Disk Snapshots

To create a snapshot of a First Class Disk (FCD), you make a POST request with the block device ID of the FCD. Using the snapshot ID created, you can revert an FCD to a snapshot or delete a snapshot of an FCD.

- Verify that all general prerequisites and prerequisites for the Automation Assembler Infrastructure as a Service (IaaS) service have been satisfied. See [Prerequisites for API Use Case Examples](#).
- Verify that you have created an FCD and you have a block device ID. See [Create a First Class Disk](#).

1. Assign the block device ID variable.

```
block_device_id='<your_block_device_id>'
```

2. Create a snapshot of the FCD.

```
curl -X POST \
      $url/iaas/api/block-devices/$block_device_id/operations/snapshots?
      apiVersion=$api_version \
      -H 'Content-Type: application/json' \
      -H "Authorization: Bearer $access_token" \
      -d '{
            "description": "example description"
          }' | jq "."
```

The response includes a selfLink value.

```
{
  "progress": 0,
  "status": "INPROGRESS",
  "name": "Provisioning",
  "id": "example-selfLink-alphanumeric-string",
  "selfLink": "/iaas/api/request-tracker/example-selfLink-alphanumeric-string"
}
```

3. Assign the selfLink variable.

```
selfLink_id='example-selfLink-alphanumeric-string'
```

4. Use the selfLink to track the progress of the FCD snapshot creation.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer
$access_token" $url/iaas/api/request-tracker/$selfLink_id?apiVersion=$api_version |
jq "."
```

The response indicates if the snapshot is successful.

```
{
  "progress": 100,
```

```

"message": "success",
"status": "FINISHED",
"resources": [
    "/iaas/api/block-devices/your-block-device-id"
],
...
}

```

5. To create additional FCD snapshots, repeat [manage-fcd-snapshots.dita#STEP_722CF989-37EC-4969-B983-DD1C27E56201-en](#) to [manage-fcd-snapshots.dita#STEP_2CDEF3CD-C103-4D45-8C84-F00F01E5089F-en](#).
6. To get a snapshot ID, list all FCD snapshots.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" $url/iaas/api/block-devices/$block_device_id/snapshots?apiVersion=$api_version | jq "."
```

If you created multiple snapshots, the response lists multiple snapshot IDs.

7. Examine the response and select a snapshot ID to assign as a variable.

```
snapshot_id=<your_snapshot_id>
```

8. You can list an individual snapshot.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" $url/iaas/api/block-devices/$block_device_id/snapshots/$snapshot_id?apiVersion=$api_version | jq "."
```

9. You can revert an FCD to a snapshot.

```
curl -X POST \
    $url/iaas/api/block-devices/$block_device_id/operations/revert?
id=$snapshot_id&apiVersion=$api_version \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '' | jq "."
```

To track the progress of the reversion, perform [manage-fcd-snapshots.dita#STEP_533302B9-3B9A-4770-8D97-2C0E3968F5AE-en](#) and [manage-fcd-snapshots.dita#STEP_2CDEF3CD-C103-4D45-8C84-F00F01E5089F-en](#).

10. You can delete a snapshot.

```
curl -X DELETE -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" $url/iaas/api/block-devices/$block_device_id/snapshots/$snapshot_id?apiVersion=$api_version | jq "."
```

Create snapshots of a First Class Disk and revert an FCD to a snapshot

With the block device ID from the created FCD, create multiple snapshots of an FCD.

```
$ url='https://appliance.domain.com'
$ api_version='2021-07-15'
$ block_device_id='e1cbc8e1-76bb-4bef-8e51-a582437266c2'

Create a snapshot of the FCD.

$ curl -X POST \
    $url/iaas/api/block-devices/$block_device_id/operations/snapshots?
apiVersion=$api_version \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
    "description": "Example description 1"
}' | jq .
```

The response provides a selfLink to the request.

```
{
  "progress": 0,
  "status": "INPROGRESS",
  "name": "Provisioning",
  "id": "d08bb46c-cf7e-40b6-bdf8-893390ba4d51",
  "selfLink": "/iaas/api/request-tracker/d08bb46c-cf7e-40b6-bdf8-893390ba4d51"
}
```

Assign the selfLink ID variable.

```
$ selfLink_id='d08bb46c-cf7e-40b6-bdf8-893390ba4d51'
```

Track the progress of the request.

```
$ curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token"
$url/iaas/api/request-tracker/$selfLink_id?apiVersion=$api_version | jq ."
```

Create a second snapshot of the FCD.

```
$ curl -X POST \
    $url/iaas/api/block-devices/$block_device_id/operations/snapshots?
apiVersion=$api_version \
-H 'Content-Type: application/json' \

```

```
-H "Authorization: Bearer $access_token" \
-d '{
  "description": "Example description 2"
}' | jq "."

```

List all the snapshots of the FCD.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" \
$url/iaas/api/block-devices/$block_device_id/snapshots?apiVersion=$api_version | jq "."

```

Examine the response to see all snapshot IDs.

```

    "self": {
      "href": "/iaas/api/block-devices/e1cbc8e1-76bb-4bef-8e51-a582437266c2/snapshots/
16cfdbb8-559c-49ff-8162-0a4c57079c81"
    }
  }
}
```

Revert the FCD to the snapshot.

```
$ curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token"
$url/iaas/api/block-devices/$block_device_id/snapshots/$snapshot_id?
apiVersion=$api_version | jq "."
```

To validate the reversion, list information about the snapshot again.

```
$ curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token"
$url/iaas/api/block-devices/$block_device_id/snapshots/$snapshot_id?
apiVersion=$api_version | jq "."
```

In the response, "isCurrent":true shows that the FCD has reverted to the snapshot.

```
{
  "name": "357ed3e5-8b2e-4533-b6fe-3ea6e15b8de5",
  "desc": "Example description 1",
  "isCurrent": true,
  "id": "16cfdbb8-559c-49ff-8162-0a4c57079c81",
  "createdAt": "2022-04-02",
  "updatedAt": "2022-04-02",
  "owner": "user@mycompany.com",

    "self": {
      "href": "/iaas/api/block-devices/e1cbc8e1-76bb-4bef-8e51-a582437266c2/snapshots/
16cfdbb8-559c-49ff-8162-0a4c57079c81"
    }
  }
}
```

Working with Azure Disk Snapshots

You can use the Automation Assembler IaaS API to create or delete snapshots of Azure managed disks. The snapshot provides a backup of your block device.

NOTE

If you create a snapshot of an independent disk and then delete the disk, the snapshot is left behind. So before deleting a disk from the Azure cloud account, check for snapshots. If snapshots exist, delete them first before deleting the disk.

Create a Block Device

If you do not already have an Azure managed disk, create a block device to use for your snapshot. To create a block device, you make a POST request using the block device specification. The request body includes a project ID, disk capacity, persistence setting, and constraints from the Azure Storage Profile for a managed disk.

- Verify that all general prerequisites and prerequisites for the Automation Assembler Infrastructure as a Service (IaaS) service have been satisfied. See [Prerequisites for API Use Case Examples](#).
- Verify that you have added a project and you have the project ID. See [Create a Project to use in](#).
- Know the capacity of the disk and the persistence of the disk that you are creating.
- Verify that you have created a storage profile for a managed disk and that you have the `defaultItem` and the tags from the response. See [Create a Storage Profile for a Managed Disk](#).

1. Assign the project ID variable.

```
project_id='<your_project_id>'
```

2. Set the capacity and persistence for the disk.

```
capacity_in_gb=<integer>
persistence=<true|false>
```

3. Deploy the block device.

- With `mandatory` set to false, tags in the `expression` are not required to match tags in an existing storage profile for the deployment to succeed. However if tags are provided, Automation will try to match them when deploying the block device.
- The `expression` is the key:value tag pair used to create the storage profile. See [Create a Storage Profile for a First Class Disk](#).

```
curl -X POST \
$url/iaas/api/block-devices?apiVersion=$api_version \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
  "projectId": "'$project_id'",
  "name": "block-device-example",
  "capacityInGB": "'$capacity_in_gb'",
  "persistent" : "'$persistent'",
  "constraints": [
    {
      "mandatory": "false",
      "expression": "type:managed"
    }
  ]
}' | jq "."
```

The response includes a `selfLink` value.

```
{
  "progress": 0,
  "status": "INPROGRESS",
  "name": "Provisioning",
  "id": "example-selfLink-alphanumeric-string",
  "selfLink": "/iaas/api/request-tracker/example-selfLink-alphanumeric-string"
}
```

4. Assign the selfLink variable.

```
selfLink_id='example-selfLink-alphanumeric-string'
```

5. Use the selfLink variable to track the progress of the block device creation.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" $url/iaas/api/request-tracker/$selfLink_id?apiVersion=$api_version | jq "."
```

In the list of resources, the response includes block devices with the block device ID in the path.

```
{
  "progress": 100,
  "message": "success",
  "status": "FINISHED",
  "resources": [
    "/iaas/api/block-devices/example-blockdevice-alphanumeric-string"
  ],
  ...
}
```

6. If you want to retrieve the ID of an existing block device, use an OData filter with the block device name in the request.

```
block_device_name='<your_block_device_name>'

curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/block-devices?$apiVersion=$api_version&$filter=name%20eq%20$block_device_name" | jq "."
```

7. Assign the block device ID variable.

```
block_device_id='example-blockdevice-alphanumeric-string'
```

Create a Block Device

With constraints from an Azure Storage Profile for a managed disk, use the block device specification to deploy a managed disk for a project ID with a two GB capacity and persistence set to false.

```

$ url='https://appliance.domain.com'
$ api_version=' 2021-07-15'
$ project_id='f5357a28-df59-47e0-b983-8a562910d0be'
$ capacity_in_gb=2
$ persistent=false
Deploy the block device.

$ curl -X POST \
$url/iaas/api/block-devices?apiVersion=$api_version \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
  "projectId": "'$project_id'",
  "name": "block-device-example",
  "capacityInGB": "'$capacity_in_gb'",
  "persistent" : "'$persistent'",
  "constraints": [
    {
      "mandatory": "false",
      "expression": "type:managed"
    }
  ]
}'
  | jq "."

```

The response provides a selfLink to the request.

```
{
  "progress": 0,
  "status": "INPROGRESS",
  "name": "Provisioning",
  "id": "22bdaf20-ce48-4a9f-8c1f-f4e74263645f",
  "selfLink": "/iaas/api/request-tracker/22bdaf20-ce48-4a9f-8c1f-f4e74263645f",
  "deploymentId": "cf33c90e-6f6d-48ed-82dd-a6a9f0e6f700"
}
```

Assign the selfLink ID variable.

```
$ selfLink_id='22bdaf20-ce48-4a9f-8c1f-f4e74263645f'
```

Track the progress of the request.

```
$ curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" $url/iaas/api/request-tracker/$selfLink_id?apiVersion=$api_version | jq "."
```

After the request completes successfully, the response provides the block device ID.

```
{
  "progress": 100,
  "message": "success",
  "status": "FINISHED",
  "resources": [
    "/iaas/api/block-devices/41d600c2-429e-4c90-98d4-638e77724101"
  ],
  "name": "Provisioning",
  "id": "22bdaf20-ce48-4a9f-8c1f-f4e74263645f",
  "selfLink": "/iaas/api/request-tracker/22bdaf20-ce48-4a9f-8c1f-f4e74263645f",
  "deploymentId": "cf33c90e-6f6d-48ed-82dd-a6a9f0e6f700"
}
```

Assign the block device ID variable.

```
$ block_device_id='41d600c2-429e-4c90-98d4-638e77724101'
```

Use the block device ID to create a snapshot. See [Create and Manage Azure Disk Snapshots](#).

Create and Manage Azure Disk Snapshots

To create a snapshot of a Azure managed disk, you make a POST request with the block device ID of the managed disk. Using the snapshot ID created, you can list a snapshot or delete a snapshot of a managed disk.

- Verify that all general prerequisites and prerequisites for the Automation Assembler Infrastructure as a Service (IaaS) service have been satisfied. See [Prerequisites for API Use Case Examples](#).
- Verify that you have an Azure managed disk and a block device ID. See [Create a Block Device](#).

1. Assign the block device ID variable.

```
block_device_id='<your_block_device_id>'
```

2. Create a snapshot of the managed disk.

```
curl -X POST \
```

```
  $url/iaas/api/block-devices/$block_device_id/operations/snapshots?
  apiVersion=$api_version \
```

```
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
  "name": "example_name"
}' | jq ."
```

In addition to the required snapshot name, you can include optional snapshot properties that can be used independently or combined as in the following example.

```
curl -X POST \
$url/iaas/api/block-devices/$block_device_id/operations/snapshots?
apiVersion=$api_version \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
  "name": "example_name",
  "snapshotProperties": {
    "incremental": "true",
    "resourceGroupName": "newRG",
    "encryptionSetId" : """$encryption_key"""
  },
}' | jq ."
```

- To create a snapshot that only consists of changes since the last snapshot, set `incremental` to true.
- To specify a target resource group for the snapshot, include the `resourceGroupName` property. You can look up existing resource group names in the Azure portal, or specify a name for a new resource group. If not specified, Automation creates the snapshot in the same resource group as the block device by default.
- To encrypt the snapshot with a customer-managed key, include the `encryptionSetId` property.

To get the `encryptionSetId` property for a particular region ID, use the following API request:

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer
$access_token" $url/iaas/api/fabric-azure-disk-encryption-sets?
regionId=$region_id&apiVersion=$api_version | jq ."
```

Examine the response for the `id` as in the following example.

```
{
  "name": "test-encryption-1.1",
  "id": "/subscriptions/b8ef63a7-a5e3-44fa-8745-1ead33fa1f25/resourceGroups/
DISKRG67970/providers/Microsoft.Compute/diskEncryptionSets/test-encryption-1.1",
  "regionId": "eastus",
  "key": "key1234",
```

```

    "vault": "KeyVault1234"
},

```

Assign the encryption key variable.

```
$encryption_key='/subscriptions/b8ef63a7-a5e3-44fa-8745-1ead33fa1f25/
resourceGroups/DISKRG67970/providers/Microsoft.Compute/diskEncryptionSets/test-
encryption-1.1'
```

3. Examine the response for the selfLink value.

```
{
  "progress": 0,
  "status": "INPROGRESS",
  "name": "Provisioning",
  "id": "example-selfLink-alphanumeric-string",
  "selfLink": "/iaas/api/request-tracker/example-selfLink-alphanumeric-string"
}
```

4. Assign the selfLink variable.

```
selfLink_id='example-selfLink-alphanumeric-string'
```

5. Use the selfLink to track the progress of the snapshot creation.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer
$access_token" $url/iaas/api/request-tracker/$selfLink_id?apiVersion=$api_version |
jq "."
```

The response indicates if the snapshot is successful.

```
{
  "progress": 100,
  "message": "success",
  "status": "FINISHED",
  "resources": [
    "/iaas/api/block-devices/your-block-device-id"
  ],
  ...
}
```

6. To get a snapshot ID, list all snapshots.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer
$access_token" $url/iaas/api/block-devices/$block_device_id/snapshots?
apiVersion=$api_version | jq "."
```

If you created multiple snapshots, the response lists multiple snapshot IDs.

7. Examine the response and select a snapshot ID to assign as a variable.

```
snapshot_id=<your_snapshot_id_1>
```

8. You can list an individual snapshot.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" $url/iaas/api/block-devices/$block_device_id/snapshots/$snapshot_id?apiVersion=$api_version | jq "."
```

9. You can delete a snapshot.

```
curl -X DELETE -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" $url/iaas/api/block-devices/$block_device_id/snapshots/$snapshot_id?apiVersion=$api_version | jq "."
```

Create snapshots of a managed disk

With the block device ID, create multiple snapshots of a managed disk.

```
$ url='https://appliance.domain.com'
$ api_version='2021-07-15'
$ block_device_id='41d600c2-429e-4c90-98d4-638e77724101'

Create a snapshot of the managed disk.

$ curl -X POST \
$url/iaas/api/block-devices/$block_device_id/operations/snapshots?
apiVersion=$api_version \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
  "name": "demo-snapshot-1"
}' | jq "."
```

The response provides a selfLink to the request.

```
{
  "progress": 0,
  "status": "INPROGRESS",
  "name": "Provisioning",
  "id": "66123d15-8e5a-42b0-a0b4-e9ed8e21180a",
  "selfLink": "/iaas/api/request-tracker/66123d15-8e5a-42b0-a0b4-e9ed8e21180a"
```

```
}
```

Assign the selfLink ID variable.

```
$ selfLink_id='66123d15-8e5a-42b0-a0b4-e9ed8e21180a'
```

Track the progress of the request.

```
$ curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token"
$url/iaas/api/request-tracker/$selfLink_id?apiVersion=$api_version | jq "."
```

Create a second snapshot of the managed disk.

```
$ curl -X POST \
$url/iaas/api/block-devices/$block_device_id/operations/snapshots?
apiVersion=$api_version \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
  "name": "demo-snapshot-2"
}' | jq ".."
```

List all the snapshots of the managed disk.

```
$ curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token"
$url/iaas/api/block-devices/$block_device_id/snapshots?apiVersion=$api_version | jq ".."
```

Examine the response to see all snapshot IDs.

```
[

    }
  }
}
```

Update the Custom Properties of a Machine

After deploying a machine, you can use the IaaS APIs to update the machine with custom properties. Custom properties provide you with the flexibility to add any information about the machine that you want.

- Verify that all general prerequisites and prerequisites for the Automation Assembler Infrastructure as a Service (IaaS) service have been satisfied. See [Prerequisites for API Use Case Examples](#).
- Verify that you have the ID of the virtual machine in your deployment. See [Get Deployment Resource IDs](#).

For example, machine IDs are typically autogenerated. By updating the custom properties, you can identify the machine owner and include their contact email or phone information.

1. Assign your virtual machine ID variable.

Assigning this variable is useful if you plan to update the machine again.

```
virtual_machine_id='<your_virtual_machine_id>'
```

2. Update the machine with custom property names and values that you choose.

```
curl -X PATCH \
  $url/iaas/api/machines/$virtual_machine_id?apiVersion=$api_version \
  -H "Authorization: Bearer $access_token" \
  -H 'Content-Type: application/json' \
  -d '{
```

```

"customProperties": {
    "additionalPropName1": "<custom_prop_value_1>",
    "additionalPropName2": "<custom_prop_value_2>",
    "additionalPropName3": "<custom_prop_value_3>"
},
"description": "string",
"tags": "[ { \"key\": \"ownedBy\", \"value\": \"Rainpole\" } ]"
}' | jq "."

```

3. A snippet of the response lists the added custom properties.

Add a Custom Properties to Your Virtual Machine

Update the virtual machine with resource ID 42f49781-1490-4a08-ae21-8baf383a72ac by adding custom properties.

Assign variables.

```
$ url='https://appliance.domain.com'
```

```
$ api_version='2021-07-15'
```

Assign the virtual machine ID.

```
$ virtual_machine_id='42f49781-1490-4a08-ae21-8baf383a72ac'
```

Update the machine with custom properties.

```
$ curl -X PATCH \
$url/iaas/api/machines/$virtual_machine_id?apiVersion=$api_version \
-H "Authorization: Bearer $access_token" \
-H 'Content-Type: application/json' \
-d '{
  "customProperties": {
    "ownerName": "VMuser_Example",
    "ownerEmail": "VMuser_Example@mycompany.com",
    "ownerCell": "123.456.7890"
  },
  "description": "string",
  "tags": "[ { \"key\": \"my.enumeration.type\", \"value\": \"ec2_instance\" } ]"
}' | jq "."
```

A snippet of the response shows that the request was successful.

```

...
"customProperties": {
    "ownerName": "VMUser_Example",
    "ownerEmail": "VMUser_Example@mycompany.com",
    "ownerCell": "123.456.7890"
    "image": "ubuntu",
    "OSType": "LINUX",
    "imageId": "ami-b1234cc5",
    ...
},
...

```

Provision a VLAN Private Network

After creating a network profile with a VLAN transport zone, you can provision a VLAN private network.

- Verify that all general prerequisites and prerequisites for the Automation Assembler Infrastructure as a Service (IaaS) service have been satisfied. See [Prerequisites for API Use Case Examples](#).
- Verify that you have the project ID. See [Create a Project to use in](#).
- Verify that you know the VLAN IDs that you want to use. Comma separated values can be 0 - 4094.

With VLAN IDs in your private network definition, Automation Assembler allocates the cloud template to a network profile with a VLAN transport zone specified. If no VLAN ID is specified, the cloud template is allocated to a network profile with an overlay transport zone.

1. Assign your project ID variable.

```
project_id='<your_project_id>'
```

2. Provision the network with VLAN IDs that you choose.

```

curl -X POST \
    $url/iaas/api/networks?apiVersion=$api_version \
    -H "Authorization: Bearer $access_token" \
    -H 'Content-Type: application/json' \
    -d '{
        "name": "<your_network_name>",
        "description": "<your_description>",
        "projectId": "'$project_id'",
        "customProperties": {
            "networkType": "PRIVATE",
            "vlanIds": "<integer_values_0_to_4094>"
```

```

    }
}

} ' | jq "."

```

The response includes a selfLink value.

```

{
  "progress": 0,
  "status": "INPROGRESS",
  "name": "Provisioning",
  "id": "example-selfLink-alphanumeric-string",
  "selfLink": "/iaas/api/request-tracker/example-selfLink-alphanumeric-string"
}

```

3. Assign the selfLink variable.

```
selfLink_id='example-selfLink-alphanumeric-string'
```

4. Use the selfLink variable to track the request.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/request-tracker/$selfLink_id | jq "."
```

Provision a VLAN Private Network

Provision a VLAN private network for a project ID

Assign variables.

```
$ url='https://appliance.domain.com'
$ api_version=' 2021-07-15'
```

Assign the project ID.

```
$ project_id='5944aacb-91de-4541-bb9e-ef2a5403f81b'
```

Provision the VLAN private network.

```
curl -X POST \
$url/iaas/api/networks?apiVersion=$api_version \
-H "Authorization: Bearer $access_token" \
-H 'Content-Type: application/json' \
-d '{
  "name": "example-vlan-network",
  "description": "Example VLAN Network created using API",
  "projectId": "'$project_id'"}
```

```
"customProperties": {
    "networkType": "PRIVATE",
    "vlanIds": "1004, 1005"
}
}' | jq ".."
```

The response includes a selfLink.

```
{
    "progress": 0,
    "status": "INPROGRESS",
    "name": "Provisioning",
    "id": "dab1fe2f-4104-4fce-b534-e7ab5c172788",
    "selfLink": "/iaas/api/request-tracker/dab1fe2f-4104-4fce-b534-e7ab5c172788",
    "deploymentId": "8964a3f6-e829-40ad-b07c-0177abb7b4f4"
}
```

Assign the selfLink variable.

```
selfLink_id='dab1fe2f-4104-4fce-b534-e7ab5c172788'
```

Use the selfLink variable to track the request.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token"
"$url/iaas/api/request-tracker/$selfLink_id | jq .."
```

When the request completes successfully, the response shows the network has been created.

```
{
    "progress": 100,
    "message": "success",
    "status": "FINISHED",
    "resources": [
        "/iaas/api/networks/3f3b4f87-3e0d-48e8-a484-a8f2890977df"
    ],
    "name": "example-vlan-network Allocation",
    "id": "1cca9d9c-1e93-40d6-8bab-fa92dd89566a",
    "selfLink": "/iaas/api/request-tracker/1cca9d9c-1e93-40d6-8bab-fa92dd89566a",
    "deploymentId": "8b8eef00-e159-4ba9-9e78-09089a3f5786"
}
```

How do I use a placement policy to spread VMs by memory

How do I use a placement policy to spread VMs by memory

If you want to balance your deployed resources across multiple cloud zones, you can use the IaaS API to define the placement policy in a project and its cloud zones. When you deploy a cloud template that uses the project, VMware Aria Automation allocates new VMs to zones and clusters with the most free memory, effectively spreading them for better memory usage.

Prerequisites for defining a placement policy

- Verify that all general prerequisites and prerequisites for the Automation Assembler Infrastructure as a Service (IaaS) service have been satisfied. See [Prerequisites for API Use Case Examples](#).

How to specify spread by memory in your project

This example shows how to find the project with cloud zones where you want to place your VMs. Then using the project ID, you update the project with "placementPolicy": "SPREAD_MEMORY" to spread VM memory use across the cloud zones.

For information about project-level placement policies, see [How do project-level placement policies affect resource allocation in VMware Aria Automation](#).

Get all projects.

```
curl -X GET -H 'Accept: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/projects?apiVersion=$api_version" | jq "."
```

A snippet of the response shows a project with its assigned cloud zones. The project ID 6c2f2d0d-ecee-42e3-90be-7bb66d6da2f9 has two zones with zone IDs:

- 3c2bbe36-bf8e-4484-9c31-ce552422aaaf1
- 8992bdf0-136f-401c-822a-e22dae67259b

```
{
  "administrators": [],
  "members": [],
  "viewers": [],
  "zones": [
    {

}

```

Use the project ID to update the placement policy and spread memory over the two cloud zones.

```
curl -X PATCH \
"$url/iaas/api/projects/6c2f2d0d-ecee-42e3-90be-7bb66d6da2f9?apiVersion=$api_version"
-H 'Content-Type: application/json'
-H "Authorization: Bearer $access_token"
-d '{
  "placementPolicy": "SPREAD_MEMORY"
}' | jq "."

```

How to specify spread by memory in cloud zones

This example shows how to use the cloud zone IDs in the project ID 6c2f2d0d-ecee-42e3-90be-7bb66d6da2f9 to check free memory in compute resources. Provided that free memory is available, you update the cloud zones with "placementPolicy": "SPREAD_MEMORY".

For information about placement policies in Automation Assembler cloud zones, see [Learn more about Automation Assembler cloud zones](#).

To check available memory in zone ID 3c2bbe36-bf8e-4484-9c31-ce552422aaf1, list compute resources.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token"
"$url/iaas/api/zones/3c2bbe36-bf8e-4484-9c31-ce552422aaf1/computes?
apiVersion=$api_version" | jq "."

```

The response shows two clusters with available memory:

- ESO_PKS_VC01_Cluster03 has 747 Gbytes available memory.
- ESO_PKS_VC01_Cluster04 has 397 Gbytes available memory.

```

}' | jq "."

```

Protecting Sensitive Data

By using the Automation Assembler IaaS API to mark certain data as sensitive in a request body, you can store the data in encrypted form, and ensure that only the encrypted form of data is visible in the response. Automation decrypts the data only when the actual value is needed, for example before sending a request to the cloud.

Data encryption works for certain types of data and is limited to the following use cases:

- When provisioning resources such as machines, load balancers, disks, or networks, the following types of data support encryption:
 - Custom property values for all types of resources.
 - Remote access passwords for machines.
 - Sensitive parts of the cloud config for machines.
- When creating or updating projects, custom properties support encryption.
- When updating a deployed machine, custom properties support encryption.

NOTE

Data encryption is only supported for deployed machines. It is not supported for discovered machines.

- When creating or updating image profiles, cloud config supports encryption. This means that you can mark parts of the cloud config script as sensitive. For example if the script includes passwords, you can mark the passwords as sensitive.

How to provision a machine with sensitive data

To mark data as sensitive, you add sensitive values with a prefix and suffix. The following example shows how to provision a new machine with sensitive values such as custom properties and a remote access password. This machine is also provisioned with a project that includes an encrypted custom property, so that the custom property is added to the machine.

1. In Automation Assembler, create a cloud account. Add a cloud zone to the cloud account and add a flavor mapping and image mapping to the cloud zone.
2. In your browser or HTTP client application, verify that all general prerequisites and prerequisites for the Automation Assembler Infrastructure as a Service (IaaS) service have been satisfied. See [Prerequisites for API Use Case Examples](#).
3. Create a project with the cloud zone that you created using the Automation Assembler UI. Include a sensitive custom property for the Active Directory (AD) password. In this way, when users related to the project provision resources with the project, they have the same AD password.

The following example shows the AD password enclosed with the ((sensitive: prefix and the)) suffix to mark it as sensitive.

```
curl -X POST \
"$url/iaas/api/projects?apiVersion=$api_version"
-H 'Content-Type: application/json'
-H "Authorization: Bearer $access_token"
-d '{
  "name" : "example-project",
  "customProperties": {
    "activeDirectoryPassword": ((sensitive:My-password123!))
  }
}' | jq "."
```

A snippet of the response lists the project ID.

```
...
{
  "name": "example-project",
  "description": "This is an example project",
  "id": "5944aacb-91de-4541-bb9e-ef2a5403f81b",
  "organizationId": "8327d53f-91ea-420a-8613-ba8f3149db95",
  ...
}
```

4. Provision a virtual machine with sensitive data.

The following example includes the custom property `costCenterPassword` and a password for remote access, with values that are both marked as sensitive using the ((sensitive: prefix and the)) suffix. The request body also includes the ID of the project with the encrypted AD password.

```
curl -X POST \
"$url/iaas/api/machines?apiVersion=$api_version"
```

```

-H 'Content-Type: application/json'
-H "Authorization: Bearer $access_token"
-d '{
    "name" : "example-vm",
    "image" : "ubuntu",
    "flavor" : "small",
    "projectId" : "5944aacb-91de-4541-bb9e-ef2a5403f81b",
    "customProperties": {
        "costCenterPassword": "((sensitive:Pass4costCtr$$$$))"
    "remoteAccess": {
        "authentication": "usernamePassword",
        "username": "example-user",
        "password": "((sensitive:example-sensitive-pass!123))"
    }
}
}' | jq "."

```

NOTE

The password for remote access is marked sensitive as an example. If left unmarked, the remote access password is encrypted because it is sensitive by default.

- After successfully provisioning the machine, issue a GET /iaas/api/machines request to obtain information about the machine.

In a snippet of the response, values for the custom property costCenterPassword and remote access password are encrypted and appear in their encrypted form with the ((secret:v1: prefix as in the following example.

```

..."customProperties": {
    ...
    "costCenterPassword": "((secret:v1:AAHeSZhRynh8+NSdswAdsfdfsgSDffhbh))",
    ...
},
...
"bootConfig": {
    "content": "#cloud-config\nusers:\n- default\n- name: example-user\n  ...\\n  passwd:\n  ((secret:v1:AAFPdqFQBijBkGdklseiHSN28ckjSghjngj))\\n..."
}
...

```

Automation converts the remote access information in the request into a cloud config script in the response. The encrypted password appears as a content value in the bootConfig .

Verify that the remote access password works

Even though the password is encrypted in the Automation database, you can use the user name and plain text password from the request to log in to the machine because the password is decrypted before it is sent to the cloud.

NOTE

You can choose to verify that your remote access password works only if the cloud provider allows remote access. For example, Azure might allow remote access while GCP or AWS might not.

To test your password, use the IP address of the newly provisioned machine such as 192.168.12.1234 and the user name such as example-user. Log in to the remote machine with:

```
$ ssh example-user@192.168.12.1234
```

When prompted for the password, copy and paste the plain text password from the request or example-sensitive-pass!123. A successful login verifies that the machine was provisioned with the remote access password provided in the request.

Properties that Support Encryption

Image profiles, projects and all types of provisioned entities can include sensitive information. The table below lists all endpoints that support encryption and the parts of the request body that can contain sensitive data.

Endpoint	You can apply encryption to:	Example Input
Create/update/list machines NOTE Data encryption is only supported for deployed machines. It is not supported for discovered machines.	<ul style="list-style-type: none"> • customProperties: value • nics: customProperties: value • Sensitive parts of bootConfig: content • remoteAccess: password 	<pre>{ "name": "machine1", "customProperties": { "username": "guest", "password": "((sensitive:mypass))" } }</pre>
Create/update/list image profiles	Sensitive parts of imageMapping: value: cloudConfig	<pre>{ "imageMapping" : { "ubuntu": { "id": "#awsUbuntuId", "cloudConfig": "#cloud-config\nchpasswd:\nlist: \nuser1:((sensitive:password1))" } }, }</pre>

Table continued on next page

Continued from previous page

Endpoint	You can apply encryption to:	Example Input
		<pre> "name" : "aws-image- profile", "regionId": "{{awsRegionId}}" } </pre>
Create/update/list projects	customProperties: value	<pre> { "name": "project1", "customProperties": { "vidm-password": "((sensitive:mypass))" } } </pre>
Create/list load balancers	<ul style="list-style-type: none"> • customProperties: value • nics: customProperties: value 	<pre> { "name": "load-balancer1", "nics": { "customProperties": { "dhcp-server- password": "((sensitive:mypass))" } } } </pre>
Create/list networks	customProperties: value	<pre> { "name": "network1", "customProperties": { "dhcp-server-password": "((sensitive:mypass))" } } </pre>
Create/list security groups	customProperties: value	<pre> { "name": "security-group1", } </pre>

Table continued on next page

Continued from previous page

		<pre>"customProperties": { "some-password": "((sensitive:mypass))" }</pre>
Create/list block device	customProperties: value	<pre>{ "name": "device1", "customProperties": { "some-password": "((sensitive:mypass))" } }</pre>
Create/list compute gateway	customProperties: value	<pre>{ "name": "gateway1", "customProperties": { "some-password": "((sensitive:mypass))" } }</pre>

Querying with the Automation APIs

Querying with the APIs

By adding query options to an API request, you control the amount of output returned by the server and make the response easier to interpret. The API service uses the options specified to transform the data by filtering or paginating before returning the results.

You can use the following query options in your API requests. The options do not apply to all endpoints.

\$top	Number of records to get. For more information, see Using Pagination and Count .
\$skip	Number of records to skip. For more information, see Using Pagination and Count .
\$count	If set to true, shows the total number of records. If used with a filter, shows the number of records matching the filter. For more information, see Using Pagination and Count .
\$select	Names the subset of properties to list in the response.

Table continued on next page

Continued from previous page

\$filter	<p>Filters results by a predicate expression with operators such as, eq, ne, and, and or. For specialized filtering examples, see:</p> <ul style="list-style-type: none"> • Filtering Resources by Region ID • Filtering Operations for Projects • Filtering for Machine Status
----------	--

Endpoints that support all query options

To query for any of the following endpoints, you can use all options. Examples show how to construct a request using the \$filter option with a logical or operation.

NOTE

Automation APIs do not support filtering for nested properties with a "." in the property name.

For example, you can filter for a property with the name createdByEmail as in the following example:

```
$filter=customProperties.createdByEmail%20eq%20'user@mycompany.com'
```

However, API filtering does not support a property with the name my.createdByEmail as in the following example:

```
$filter=customProperties.my.createdByEmail%20eq%20'user@mycompany.com'
```

Endpoint	Example
Machine	<pre>\$url/iaas/api/machines? \$filter=name%20ne%20'example- name'%20or%20customProperties.osType%20eq%2 0'example-os'</pre>
Cloud Account	<pre>\$url/iaas/api/cloud-accounts? \$filter=name%20ne%20'example-cloud- account'%20or%20customProperties.isExternal% 20eq%20>false'</pre>
Fabric Azure Storage Account	<pre>\$url/iaas/api/fabric-azure-storage- accounts/?\$filter=name%20ne%20'example- name'%20or%20type%20eq%20'example-type'</pre>
Fabric Compute	<pre>\$url/iaas/api/fabric-computes? \$filter=name%20ne%20'example- name'%20or%20customProperties.isExternal%20 eq%20>false'</pre>
Fabric Image	<pre>\$url/iaas/api/fabric-images? \$filter=name%20ne%20'example- name'%20or%20osFamily%20eq%20'example-os'</pre>
Fabric Network	<pre>\$url/iaas/api/fabric-networks? \$filter=name%20ne%20'example- name'%20or%20externalId%20eq%20'example-id'</pre>
Fabric Network (vSphere)	<pre>\$url/iaas/api/fabric-networks-vsphere? \$filter=name%20ne%20'example- name'%20or%20externalId%20eq%20'example-id'</pre>

Table continued on next page

Continued from previous page

Endpoint	Example
Fabric vSphere Datastores	\$url/iaas/api/fabric-vsphere-datastores? \$filter=name%20ne%20'example-name'%20or%20externalId%20eq%20'example-id'
Fabric vSphere Storage Policies	\$url/iaas/api/fabric-vsphere-storage-policies?\$filter=name%20ne%20'example-name'%20or%20externalId%20eq%20'example-id'

Querying for endpoints with a specified ID

To query for an endpoint with specified ID, you can only use the `$select` option. Examples show how to construct a request.

Endpoint	Example
Cloud Account by ID	\$url/iaas/api/cloud-account/{id}? \$select=name
Machine by ID	\$url/iaas/api/machines/{id}?\$select=name
Fabric Azure Storage Account by ID	\$url/iaas/api/fabric-azure-storage-accounts/{id}?\$select=name
Fabric Image by ID	\$url/iaas/api/fabric-images/{id}? \$select=name
Fabric Network by ID	\$url/iaas/api/fabric-networks/{id}? \$select=name
Fabric Network (vSphere) by ID	\$url/iaas/api/fabric-networks-vsphere/{id}? \$select=name
Fabric vSphere Datastores by ID	\$url/iaas/api/fabric-vsphere-datastores/{id}?\$select=name
Fabric vSphere Storage Policies by ID	\$url/iaas/api/fabric-vsphere-storage-policies/{id}?\$select=name

Querying for a partial match

To query for the partial match of a name that starts with, ends with, or is contained within another name, the `$filter` options are the same for most IaaS endpoints but are different for `iaas/api/projects` and `iaas/api/deployments` endpoints. Examples show how to construct the partial match filters for the different endpoint types.

Filter Operation	Query with <code>iaas/api/projects</code> or <code>iaas/api/deployments</code>	Query with most IaaS endpoints
Name starts with <code>foo</code>	<code>?\$filter=startswith(name, 'foo')</code>	<code>\$filter=name%20eq%20'foo*'</code>
Name ends with <code>foo</code>	<code>?\$filter=endswith(name, 'foo')</code>	<code>\$filter=name%20eq%20'*foo'</code>
<code>foo</code> contained within the name	<code>?\$filter=substringof('foo', name)</code>	<code>\$filter=name%20eq%20'*foo*'</code>

Querying for deployments

To query for deployments, you can use all options except `$select`. The following example shows how to use the `$filter` option to list deployments that are not named `example-name` or have `projectId='example-id'`.

```
GET $url/iaas/api/deployments?$filter=name%20ne%20'example-
name'%20or%20projectId%20eq%20'example-id'
```

Using Pagination and Count

Pagination controls the number of elements or the range of elements returned in an API response. When the count flag is specified, the response shows the total number of records. Use parameters in combination to traverse all elements in a result.

To paginate a response, you use the following parameters.

<code>\$top=N</code>	Selects only the first N elements of the set. N must be a positive integer. Specifying N limits the maximum number of elements that the server returns in the response. The default IaaS API page size is 100. If <code>\$top</code> is left unspecified, pagination selects the first 100 elements. If you want the output to include elements beyond the first 100 elements, specify a top value greater than 100.
<code>\$skip=N</code>	Skips N elements and selects only the remaining elements starting with element N+1.

Pagination examples

The following examples show how to combine parameter values to control the elements returned in a vSphere deployment with 45 cloud accounts.

If you want to...	Use this request
List the first 20 cloud accounts, or 1–20	<pre>curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer \$access_token" "\$url/iaas/api/cloud-accounts?apiVersion=\$api_version&\$filter=cloudAccountType%20eq%20%27vsphere%27&\$top=20&\$skip=0" jq "."</pre>
List the second set of 20 cloud accounts, or 21–40	<pre>curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer \$access_token" "\$url/iaas/api/cloud-accounts?apiVersion=\$api_version&\$filter=cloudAccountType%20eq%20%27vsphere%27&\$top=20&\$skip=20" jq "."</pre>
List the third set of 20 cloud accounts, or 41–45	<pre>curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer \$access_token" "\$url/iaas/api/cloud-accounts?apiVersion=\$api_version&\$filter=cloudAccountType%20eq%20%27vsphere%27&\$top=20&\$skip=40" jq "."</pre>

Count example

The following example shows how to count the AWS cloud accounts.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token"
"$url/iaas/api/cloud-accounts?$filter=cloudAccountType%20eq%20aws%27&$count=true" | jq
."
```

Filtering Resources by Region ID

You can use a filter in the IaaS APIs to identify resources provisioned in a cloud account of a particular region. By specifying the resources for which you want information such as network and security, compute, storage, and tags content, you limit the API response to provide only the information that you want.

You can also use filtering to identify and automatically update resources. For example, if you have automated builds on an vSphere private cloud account, you can use filtering to identify the image profiles associated with a region of the cloud account and automatically update those profiles in Automation.

Obtaining the externalRegionId and cloudAccountId

To get information about a resource that is in a region of a cloud account, you filter by its externalRegionId and its cloudAccountId. The following example shows how to obtain the IDs for a vSphere cloud account and use them to construct a generic query. It assumes that all general prerequisites and prerequisites for the Automation Assembler Infrastructure as a Service (IaaS) service have been satisfied. See [Prerequisites for API Use Case Examples](#).

1. List vSphere cloud accounts.

```
curl -X GET "$url/iaas/api/cloud-accounts?
apiVersion=$api_version'&'$filter='cloudAccountType%20eq%20'vsphere'" -H 'Content-
Type: application/json' -H "Authorization: Bearer $access_token" | jq "."
```

2. Examine the response to obtain the cloud account ID and region ID for the vSphere account that you want.

```
...

  "regions": {
    "hrefs": [
      "/iaas/api/regions/277e3cd9fe87527557cab268cae5a"
    ]
  }
},
```

...

3. Assign the cloud account ID and region ID variables.

```
cloud_account_id='e0f23c91d5ecca75-7f703c5265a63d87-7e3d8d60a55d1306cc791422547ead9153c3bdf1c802400819ad45a341cba1f3-c39814fe67b8247557cab2652647d'
region_id='277e3cd9fe87527557cab268cae5a'
```

4. List regions with the region ID and associated with the cloud account ID.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/regions/?apiVersion=$api_version&'$filter'"="id%20eq%20'$region_id'"%20and%20cloudAccountId%20eq%20'$cloud_account_id'"' | jq ".."
```

5. Examine the response to obtain the external region ID.

...

```
{
  "externalRegionId": "Datacenter:datacenter-2",
  "name": "VC60-Datacenter",
  "cloudAccountId": "e0f23c91d5ecca75-7f703c5265a63d87-7e3d8d60a55d1306cc791422547ead9153c3bdf1c802400819ad45a341cba1f3-c39814fe67b8247557cab2652647d",
  "id": "277e3cd9fe87527557cab268cae5a",
  "updatedAt": "2022-04-02",
}
```

...

6. Assign the external region ID variable.

```
external_region_id='Datacenter:datacenter-2'
```

Using the externalRegionId and cloudAccountId, you can construct a generic filter to use in any IaaS API that queries for resources.

```
$filter="externalRegionId%20eq%20'$external_region_id'%20and%20cloudAccountId%20eq%20'$cloud_account_id'"'
```

Constructing a query for a VMC cloud account

The VMC cloud account consists of an AWS cloud account facade and associated internal vSphere and NSX cloud accounts. To construct the query for a resource in the VMC cloud account, you use the cloudAccountId of the associated vSphere cloud account and not the cloudAccountId of the VMC cloud account.

The following example shows how to obtain the cloudAccountId and externalRegionId and use them to construct a generic query. It assumes that you know the name of the VMC cloud account and that all general prerequisites and prerequisites for the Automation Assembler Infrastructure as a Service (IaaS) service have been satisfied. See [Prerequisites for API Use Case Examples](#).

1. Assign the cloud account name variable.

```
cloud_account_name='<my_vmc_cloud_account>'
```

2. List VMC cloud accounts with your VMC cloud account name.

```
curl -X GET "$url/iaas/api/cloud-accounts?
apiVersion=$api_version&'$filter'"="cloudAccountType%20eq%20'vmc'%20and%20name%20eq%20'$cloud_account_name'"' -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" | jq '.."
```

3. Examine the response to obtain the cloud account ID for the associated vSphere cloud account.

Under `_links`, two associated cloud accounts are listed. The first cloud account is the vSphere cloud account. The second is the NSX cloud account.

...

```

    "_links": {
        "regions": {
            "hrefs": [
                "/iaas/api/regions/5a8da7fe-63d9-4f82-84e8-f47bfdcef43c"
            ]
        },
        "associated-cloud-accounts": {
            "hrefs": [
                "/iaas/api/cloud-accounts/df59d7cd-d3ee-4bc3-
bf4a-8a4027cefb05",
                "/iaas/api/cloud-accounts/6993943b-82bc-4ec7-
bad6-65f2f595da7e"
            ]
        },
        "self": {
            "href": "/iaas/api/cloud-accounts/95be1cc2-
c70a-4311-9f18-6218786ac51b"
        }
    }

```

...

4. To assign the cloud account ID variable, use the associated vSphere cloud account.

```
assoc_cloud_account_id='df59d7cd-d3ee-4bc3-bf4a-8a4027cefb05'
```

5. List regions in the associated vSphere cloud account.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer
$access_token" "$url/iaas/api/regions/?
apiVersion=$api_version&'$filter'"=cloudAccountId%20eq%20'$assoc_cloud_account_id''
" | jq "."
```

6. Examine the response to obtain the external region ID.

...

```
{
    "externalRegionId": "Datacenter:datacenter-3",
    "cloudAccountId": "df59d7cd-d3ee-4bc3-bf4a-8a4027cefb05",
    "id": "e572c96b-9084-4c37-b74d-bf61f0b08e79",
```

```

"updatedAt": "2022-04-02",
"organizationId": "33a92056-18f0-469c-a088-9c8eae4e4888",
"orgId": "33a92056-18f0-469c-a088-9c8eae4e4888",
"_links": {
  "self": {
    "href": "/iaas/api/regions/e572c96b-9084-4c37-b74d-bf61f0b08e79"
  },
  "cloud-account": {
    "href": "/iaas/api/cloud-accounts/df59d7cd-d3ee-4bc3-
bf4a-8a4027cefb05"
  }
}
}

...

```

7. Assign the external region ID variable.

```
external_region_id='Datacenter:datacenter-3'
```

Using the externalRegionId and cloudAccountId for the associated vSphere cloud account, you can construct a generic filter to use in any IaaS API that queries for resources in the VMC cloud account.

```
$filter="externalRegionId%20eq%20'$external_region_id'%20and%20cloudAccountId%20eq%20'$ass
oc_cloud_account_id'"
```

Resource Query Examples

The following examples show how to incorporate the filter into resource queries.

Resource	Query
Security Group	\$url/iaas/api/security-groups? \$filter="externalRegionId%20eq%20'\$externa l_region_id'%20and%20cloudAccountId%20eq%2 0'\$cloud_account_id'"
Security Group (NSX only)	\$url/iaas/api/security-groups? \$filter="externalRegionId%20eq%20'global'% 20and%20cloudAccountId%20eq%20'\$cloud_acco unt_id'"
Region	\$url/iaas/api/regions? \$filter="externalRegionId%20eq%20'\$externa l_region_id'%20and%20cloudAccountId%20eq%2 0'\$cloud_account_id'"

Filtering for Machine Status

To filter for machines with deployed or discovered status, you can use the IaaS APIs. A machine with the discovered status is in the cloud and has not yet been onboarded. A machine with the deployed status has been onboarded or provisioned from Automation.

If a machine has a discovered status, you can bring it into VMware Aria Automation management using the onboarding tool. See [Onboard selected machines as a single deployment](#).

After onboarding, the machine has a deployed status and is associated with the deployment. Then you can manage it in the same way as any other provisioned machine.

To query for deployed or discovered status, you use the following parameters.

\$filter=deploymentId eq '*' \$filter=deploymentId ne '*' Returns all machines that are deployed and under Automation management. Deployed machines have a deployment ID. Returns all machines that are discovered in the cloud. Machines without the deployment ID property are not deployed.	
---	--

Machine filter examples

The following examples show how to list deployed or discovered machines.

If you want to...	Use this request
List all deployed machines	curl -X GET "\$url/iaas/api/machines? apiVersion=\$api_version&"\$filter='\"deploy mentId%20eq%20'\"' -H 'Content-Type: application/json' -H "Authorization: Bearer \$access_token" jq \"."

Table continued on next page

Continued from previous page

If you want to...	Use this request
List all discovered machines	<pre>curl -X GET "\$url/iaas/api/cloud-accounts?apiVersion=\$api_version&"\$filter='deploy mentId%20ne%20'*' -H 'Content-Type: application/json' -H "Authorization: Bearer \$access_token" jq """</pre>

Filtering Operations for Projects

To restrict the output from a project endpoint, you include a filter in the `GET /project-service/api/projects` request. The API service uses the operation to filter for a collection of projects to paginate, order, or count your results.

Filter operation examples

The following examples show how to incorporate filter operations into project queries.

Operation	Query
equal	<code>\$url/project-service/api/projects? \$filter=name%20eq%20'00-TestProject'</code>
not equal	<code>\$url/project-service/api/projects? \$filter=name%20ne%20'00-TestProject'</code>
logical and	<code>\$url/project-service/api/projects? \$filter=name%20eq%20'00- TestProject'%20and%20sharedResources%20eq%2 0true</code>
logical or	<code>\$url/project-service/api/projects? \$filter=name%20eq%20'00- TestProject'%20or%20sharedResources%20eq%20 false</code>
logical negation	<code>\$url/project-service/api/projects? \$filter=not%20startswith(name, '00')</code>
starts with	<code>\$url/project-service/api/projects? \$filter=startswith(name, '00')</code>
substring of	<code>\$url/project-service/api/projects? \$filter=substringof('00', name)</code>
ends with	<code>\$url/project-service/api/projects? \$filter=endswith(name, '00')</code>
length	<code>\$url/project-service/api/projects? \$filter=length(name)%20eq%205</code>
index of	<code>\$url/project-service/api/projects? \$filter=indexof(name, '00')%20eq%200</code>
substring from	<code>\$url/project-service/api/projects? \$filter=substring(name, 1)%20eq%20'0-Te'</code>

Table continued on next page

Continued from previous page

Operation	Query
substring from to	\$url/project-service/api/projects? \$filter=substring(name, 1, 2)%20eq%20'0-'
to lower	\$url/project-service/api/projects? \$filter=tolower(name)%20eq%20'00-testproject'
to upper	\$url/project-service/api/projects? \$filter=toupper(name)%20eq%20'00-TESTPROJECT'
concatenate	\$url/project-service/api/projects? \$filter=concat(concat(name, ','), description)%20eq%20'test project,test project description'
trim	\$url/project-service/api/projects? \$filter=trim(name)%20eq%20'00-TestProject'

Related query examples

The following examples show how to use related query options to paginate, order, or count your results.

If you want to...	Use this request
List the first twenty items	curl -X GET \$url/project-service/api/projects?\$top=20 -H 'Content-Type: application/json' -H "Authorization: Bearer \$access_token" jq ".."
Skip the first ten items in the collection	curl -X GET \$url/project-service/api/projects?\$skip=10 -H 'Content-Type: application/json' -H "Authorization: Bearer \$access_token" jq ".."
List the items in ascending order with <code>asc</code> or descending order with <code>desc</code> . If the type of order is not specified, the list defaults to ascending order.	<p>For ascending order:</p> <pre>curl -X GET \$url/project-service/api/projects?\$skip=0\$orderBy=name%20asc -H 'Content-Type: application/json' -H "Authorization: Bearer \$access_token" jq ".."</pre> <p>For descending order:</p> <pre>curl -X GET \$url/project-service/api/projects?\$skip=0\$orderBy=name%20desc -H 'Content-Type: application/json' -H "Authorization: Bearer \$access_token" jq ".."</pre>
List the total number of items in the collection.	curl -X GET \$url/project-service/api/projects?\$count=true -H 'Content-Type: application/json' -H "Authorization: Bearer \$access_token" jq ".."

Setting up Automation Assembler using APIs

Setting up Automation Assembler using APIs

As a Automation Assembler administrator, you can use the Infrastructure as a Service (IaaS) APIs to set up connections with your cloud account vendor and integration applications in VMware Aria Automation.

Adding Cloud Accounts

You use the IaaS APIs to create cloud accounts for various cloud platforms. Automation Assembler uses permissions configured in the cloud accounts to collect data from regions or data centers, and to deploy cloud templates to those regions.

After adding a cloud account, you use the cloud account ID to create a cloud zone, flavor mappings, image mappings, network, profiles, or storage profiles.

Add an Amazon Web Services Cloud Account

To create an Amazon Web Services cloud account with or without cloud zones, you make a POST request. The request body includes the parameters specific to Amazon Web Services that are required to create the cloud account.

- Verify that all general prerequisites and prerequisites for the Automation Assembler Infrastructure as a Service (IaaS) service have been satisfied. See [Prerequisites for API Use Case Examples](#).
- Verify that you have the Amazon Web Services access key ID and the Amazon Web Services secret access key for the new cloud account.

- Assign the Amazon Web Services account variables.

```
aws_access_key_id='<your_aws_access_key_id>'  
aws_secret_access_key='<your_aws_secret_access_key>'
```

- Submit a request to create an Amazon Web Services cloud account without default cloud zones.

When the parameter `createDefaultZones` is left unspecified, the cloud account is created without default cloud zones by default.

```
curl -X POST \  
      "$url/iaas/api/cloud-accounts?apiVersion=$api_version" \  
      -H 'Content-Type: application/json' \  
      -H "Authorization: Bearer $access_token" \  
      -d '{  
        "privateKeyId": "'$aws_access_key_id'",  
        "cloudAccountType": "aws",  
        "name": "<your_aws_cloud_account>",  
        "description": "This is a demo AWS cloud account without cloud zones",  
        "regionIds": [ "<your_region_id1>", "<your_region_id2>" ],  
        "privateKey": "'$aws_secret_access_key'"  
      }' | jq "."
}
```

- Submit a request to create an Amazon Web Services cloud account with default cloud zones.

```

curl -X POST \
"$url/iaas/api/cloud-accounts?apiVersion=$api_version" \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
  "privateKeyId": "'$aws_access_key_id'",
  "cloudAccountType": "aws",
  "name": "<your_aws_cloud_account>",
  "description": "This is a demo AWS cloud account with default cloud zones",
  "regionIds": [ "<your_region_id1>", "<your_region_id2>" ],
  "createDefaultZones": true,
  "privateKey": "'$aws_secret_access_key'"
}' | jq "."

```

4. To obtain your cloud account ID, examine the response.
5. Assign the cloud account ID variable to your cloud account ID.

```
cloud_account_id='<your_cloud_account_id>'
```

6. List all cloud accounts.

```
curl -X GET $url/iaas/api/cloud-accounts?apiVersion=$api_version -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" | jq "."
```

7. To look up the cloud account you created, list the cloud account with your cloud account ID.

```
curl -X GET $url/iaas/api/cloud-accounts/$cloud_account_id?apiVersion=$api_version -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" | jq "."
```

The response shows the cloud account name and ID for the Amazon Web Services cloud account you created.

Create an Amazon Web Services Cloud Account

Assign the required variables.

```
$ url='https://appliance.domain.com'
$ api_version='2021-07-15'
$ aws_access_key_id='FEDCBA5JJ2F43TUVW7XA'
$ aws_secret_access_key='XYZfGo0/Vb5XPezeC58QRSvLMN0wsHhuB2IbEJxL'
```

Create a cloud account named `demo-aws-account` without default cloud zones.

```
$ curl -X POST \
"$url/iaas/api/cloud-accounts?apiVersion=$api_version" \
```

```
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
  "privateKeyId": "'$aws_access_key_id'",
  "cloudAccountType": "aws",
  "name": "demo-aws-account",
  "description": "This is a demo AWS cloud account without cloud zones",
  "regionIds": [ "us-east-1", "us-west-1" ],
  "privateKey": "'$aws_secret_access_key'"
}' | jq "."

```

A snippet of the response from your request shows the account ID.

```
...
"tags": [],
"name": "demo-aws-account",
"id": "c8c3c9fdb449475-7f703c5265a63d87-
f8e705d89b2569e1aac66c6d00bf4fc7ef4b1c44100f0e944af31eb8ba3d2a5a-
f4226a20b65c4675574bc5fbff6c0",
"updatedAt": "2022-04-02",
"organizationId": "8327d53f-91ea-420a-8613-ba8f3149db95",
...

```

Add a vSphere Cloud Account

To create a vSphere cloud account, you make a POST request. The request body includes the parameters specific to vSphere that are required to create the cloud account.

- Verify that all general prerequisites and prerequisites for the Automation Assembler Infrastructure as a Service (IaaS) service have been satisfied. See [Prerequisites for API Use Case Examples](#).
- Verify that you have the following parameters for the new cloud account:
 - vSphere host name
 - vSphere user name
 - vSphere password
- Verify that you have an existing vSphere, NSX-T, NSX-V, or VMC cloud account that you want to associate with the new cloud account and obtain the cloud account ID.

- List all cloud accounts.

```
curl -X GET $url/iaas/api/cloud-accounts?apiVersion=$api_version -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" | jq "."

```

- Examine the response to obtain the cloud account ID such as the `id` value in this example.

```
...

```

```
"name": "vsphere-account-example",
```

```

"id": "b9fa1b42c767de7558ceff3b78004",
"updatedAt": "2022-04-02",
"orgId": "f670fdfc-66d6-4689-9793-d524e7066d1e",
...

```

The following procedure shows how to create a vSphere cloud account that supports a trusted certificate. To obtain a trusted certificate, you submit a request to validate asynchronously with the vSphere cloud account specification. When the validation request completes successfully, you use the certificate ID from the response to obtain the trusted certificate that you submit when you create the vSphere cloud account.

1. List all cloud proxies.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/data-collectors?apiVersion=$api_version" | jq ".."
```

2. To obtain the data collector ID, examine the response.

3. Assign the data collector ID variable.

```
data_collector_id='<your_datacollector_id>'
```

4. Assign the vSphere account variables.

```
vsphere_host_name='<your_vsphere_host_name>'  
vsphere_user='<your_vsphere_user_name>'  
vsphere_password='<your_vsphere_password>'
```

5. List external region IDs from a vSphere cloud account.

```
curl -X POST \  
"$url/iaas/api/cloud-accounts-vsphere/region-enumeration?apiVersion=$api_version" \  
-H 'Content-Type: application/json' \  
-H "Authorization: Bearer $access_token" \  
-d '{  
    "cloudAccountType": "vsphere",  
    "username": "'$vsphere_user'",  
    "password": "'$vsphere_password'",  
    "hostName": "'$vsphere_host_name'",  
    "dcid": "'$data_collector_id'",  
    "acceptSelfSignedCertificate": "false"  
}' | jq ".."
```

6. To obtain the external region ID, examine the response and assign the region ID variable.

```
vsphere_region_id='<your_vsphere_region_id>'
```

7. Submit a request to validate asynchronously with the vSphere cloud account specification.

```
curl -X POST -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/cloud-accounts-vsphere?apiVersion=$api_version&validateOnly" | jq "."
```

The response includes a selfLink.

```
{
  "progress": 0,
  "status": "INPROGRESS",
  "name": "Cloud account specification validation",
  "id": "example-selfLink-alphanumeric-string",
  "selfLink": "/iaas/api/request-tracker/example-selfLink-alphanumeric-string"
}
```

8. Assign the selfLink variable.

```
selfLink_id='example-selfLink-alphanumeric-string'
```

9. Use the selfLink variable to track the request.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/request-tracker/$selfLink_id?apiVersion=$api_version" | jq "."
```

When the validation request completes successfully, the response includes a resource with the certificate ID.

```
{
  "progress": 0,
  "message": "valid certificate found",
  "status": "SUCCEEDED",
  "resources": [
    "/iaas/api/certificates/example-certificate-id-string"
  ],
  "name": "Cloud account specification validation",
  "id": "example-selfLink-alphanumeric-string",
  "selfLink": "/iaas/api/request-tracker/example-selfLink-alphanumeric-string"
}
```

10. Assign the certificate ID variable.

```
certificate_id='example-certificate-id-string'
```

11. Submit a request to get the certificate information.

```
PEM_for_X509Certificate='curl -X GET -H "Content-Type: application/json" -H "Authorization: Bearer $access_token" "$url/iaas/api/certificates/$certificate_id?apiVersion=$api_version" | jq ".")'
```

12. Assign the ID of the existing cloud account to associate with the new cloud account.

```
existing_cloud_account_ID='<your_existing_cloud_account_ID>'
```

13. Include the certificate in the request to create a vSphere cloud account with default cloud zones.

To create a vSphere cloud account without default cloud zones, use "createDefaultZones":false.

```
curl -X POST \
"$url/iaas/api/cloud-accounts-vsphere?apiVersion=$api_version" \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
  "name": "demo-vsphere-account",
  "description": "This is a demo vSphere account with default cloud zones",
  "username": "'$vsphere_user'",
  "password": "'$vsphere_password'",
  "hostName": "'$vsphere_host_name'",
  "acceptSelfSignedCertificate":false,
  "associatedCloudAccountIds": "'$existing_cloud_account_ID'",
  "createDefaultZones":true,
  "dcId": "'$data_collector_id'",
  "regions": [
    {
      "name": "'$vsphere_region_id'",
      "ExternalRegionId": "'$vsphere_region_id'"
    }
  ],
  "tags": [
    {
      "key": "env",
      "value": "dev"
    }
  ]
}'
```

```
[ ,  
  "certificateInfo":{  
    "certificate": "'$PEM_for_X509Certificate'"  
  }  
} ' | jq ".."
```

NOTE

The following example shows how to create a vSphere cloud account with multiple cloud account IDs. However, the payload can only include a single NSX-P-Cloud endpoint and a single VMC endpoint.

```
"associatedCloudAccountIds": "[\"'$existing_NSXT_cloud_account_ID'\",  
\"'$existing_VMC_cloud_account_ID'\",  
\"'$existing_vSphere_cloud_account_ID'\"]",
```

14. List all cloud accounts.

```
curl -X GET $url/iaas/api/cloud-accounts?apiVersion=$api_version -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" | jq ".."
```

15. Examine the response and verify that the name and ID of the vSphere cloud account you created is listed.

Create a vSphere Cloud Account

This example creates a cloud account with default cloud zones.

Assign the required variables.

```
$ url='https://appliance.domain.com'  
$ api_version=' 2021-07-15'
```

List all cloud proxies.

```
$ curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/data-collectors?apiVersion=$api_version" | jq ".."
```

A snippet of the response from your request shows the data collector IDs.

```
...  
 {  
   "dcId": "60740040-f3cd-4694-96da-15e547242bf7",  
   "ipAddress": "10.108.78.154",  
   "name": "example-prod-corp-rdc",  
   "hostName": "corp-v783-dhcp-79-85.eng.mycompany.com",  
   "status": "ACTIVE"  
 },  
 ...
```

Assign the data collector ID variable.

```
$ data_collector_id='60740040-f3cd-4694-96da-15e547242bf7'
```

Assign the vSphere account variables.

```
$ vsphere_host_name='corp-v783-dhcp-79-85.eng.mycompany.com'
```

```
$ vsphere_user='admin@mycompany.com'
```

```
$ vsphere_password='my_vsphere_password'
```

List external region IDs from your vSphere cloud account.

```
$ curl -X POST \
"$url/iaas/api/cloud-accounts-vsphere/region-enumeration?apiVersion=$api_version" \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
  "cloudAccountType": "vsphere",
  "username": "'$vsphere_user'",
  "password": "'$vsphere_password'",
  "hostName": "'$vsphere_host_name'",
  "dcid": "'$data_collector_id'",
  "acceptSelfSignedCertificate": "false"
}' | jq ."
```

A snippet of the response shows the region ID to use.

```
...
{
  "externalRegionIds": [
    "Datacenter:datacenter-2"
  ]
}
```

Assign the region ID variable.

```
$ vsphere_region_id='Datacenter:datacenter-2'
```

Submit request to validate asynchronously with the vSphere cloud account specification.

```
$ curl -X POST -H 'Content-Type: application/json' -H "Authorization: Bearer
$access_token" "$url/iaas/api/cloud-accounts-vsphere?apiVersion=$api_version&validateOnly"
| jq ."
```

A snippet of the response shows the selfLink.

```
{
  "progress": 0,
  "status": "INPROGRESS",
  "name": "Cloud account specification validation",
  "id": "bbcdee18-a77d-46f8-b068-4013e80e2b55",
  "selfLink": "/.../request-tracker/bbcdee18-a77d-46f8-b068-4013e80e2b55"
}
```

Assign the selfLink variable.

```
$ selfLink_id='bbcdee18-a77d-46f8-b068-4013e80e2b55'
```

Submit a request to track the request with the selfLink.

```
$ curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/request-tracker/$selfLink_id?apiVersion=$api_version" | jq ".">
```

When the request succeeds, the response shows the resource with the certificate ID.

```
{
  "progress": 0,
  "message": "valid certification path to requested target found",
  "status": "SUCCEEDED",
  "resources": [
    "/iaas/api/certificates/7fe4c108-64ff-4347-92de-b0790bdala3c?apiversion=2021-07-15"
  ],
  "name": "Cloud account specification validation",
  "id": "bbcdee18-a77d-46f8-b068-4013e80e2b55",
  "selfLink": "/iaas/api/request-tracker/bbcdee18-a77d-46f8-b068-4013e80e2b55"
}
```

Assign the certificate ID variable.

```
$ certificate_id='7fe4c108-64ff-4347-92de-b0790bdala3c'
```

To get certificate information, submit a request with the certificate ID.

```
$ PEM_for_X509Certificate='curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/certificates/$certificate_id?apiVersion=$api_version" | jq ".")'
```

Assign the ID of the existing cloud account to associate with the new cloud account.

```
$ existing_cloud_account_id ='b9fa1b42c767de7558ceff3b78004'
```

Create a cloud account named demo-vsphere-account with default cloud zones.

```
$ curl -X POST \
```

```

"$url/iaas/api/cloud-accounts-vpshere?apiVersion=$api_version" \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
  "name": "demo-vsphere-account",
  "description": "This is a demo vSphere account with default cloud zones",
  "username": "'$vsphere_user'",
  "password": "'$vsphere_password'",
  "hostName": "'$vsphere_host_name'",
  "acceptSelfSignedCertificate":false,
  "associatedCloudAccountIds": "'$existing_cloud_account_id'",
  "createDefaultZones":true,
  "dcId": "'$data_collector_id'",
  "regions": [
    {
      "name": "'$vsphere_region_id'",
      "ExternalRegionId": "'$vsphere_region_id'"
    }
  ],
  "tags": [
    {
      "key": "env",
      "value": "dev"
    }
  ],
  "certificateInfo":{
    "certificate": "'$PEM_for_X509Certificate'"
  }
}' | jq "."
A snippet of the response from your request shows the account ID.
...
  "tags": []

Add an NSX-T or NSX-V Cloud Account

To create an NSX-T or NSX-V cloud account, you make a POST request. The request body includes the NSX-specific parameters required to create the cloud account.

- Verify that all general prerequisites and prerequisites for the Automation Assembler Infrastructure as a Service (IaaS) service have been satisfied. See [Prerequisites for API Use Case Examples](#).
- Verify that you have the following parameters for the new cloud account:
 - NSX host name
 - NSX user name
 - NSX password

As an alternative to using the `cloud-accounts` API call, you can use a `cloud-accounts-nsx-t` or `cloud-accounts-nsx-v` API call to list NSX-T or NSX-V cloud accounts respectively.

1. List all cloud proxies.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer
$access_token" "$url/iaas/api/data-collectors?api_version=$api_version" | jq "."

```

2. Examine the response and assign the data collector variable.

```
data_collector_id='<your_datacollector_id>'
```

3. Assign the NSX account variables.

```
nsx_host_name='<your_nsx_host_name>'
nsx_username='<your_nsx_user_name>'
nsx_password='<your_nsx_password>'
```

4. If you have a vSphere cloud account that you want to associate with the NSX cloud account, assign the ID of the vSphere cloud account to the `vsphere_cloud_account_id` variable. See [Add a Cloud Account](#).

```
vsphere_cloud_account_id='<your_vsphere_cloud_account_id>'
```

5. Submit a request to create an NSX-V cloud account. To add an NSX-T cloud account, use `"cloudAccountType": "nsxt"`. This example includes the `vsphere_cloud_account_id` variable.

```
curl -X POST \
"$url/iaas/api/cloud-accounts?apiVersion=$api_version" \
-H 'Content-Type: application/json' \
```

```

-H "Authorization: Bearer $access_token" \
-d '{
  "cloudAccountType": "nsxv",
  "privateKeyId": "'$nsx_username'",
  "privateKey": "'$nsx_password'",
  "associatedCloudAccountIds": [
    "'$vsphere_cloud_account_id'"
  ],
  "cloudAccountProperties": {
    "hostName": "'$nsx_host_name'",
    "acceptSelfSignedCertificate": "true",
    "dcId": "'$data_collector_id'",
    "privateKeyId": "'$nsx_username'",
    "privateKey": "'$nsx_password'"
  },
  "tags": [
    {
      "key": "env",
      "value": "prod"
    }
  ],
  "name": "<your_nsx_cloud_account>",
  "description": "Example NSX cloud account description"
}' | jq "."

```

6. To obtain the NSX cloud account ID, examine the response.

7. Assign the NSX cloud account ID variable.

```
nsx_cloud_id='<your_nsx_cloud_id>'
```

8. List all cloud accounts.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer
$access_token" "$url/iaas/api/cloud-accounts?apiVersion=$api_version" | jq "."
```

9. List all NSX-T cloud accounts using the `cloud-accounts-nsxt` API call.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/cloud-accounts-nsx-t?apiVersion=$api_version" | jq "."
```

10. List all NSX-V cloud accounts using the `cloud-accounts-nsx-v` API call.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/cloud-accounts-nsx-v?apiVersion=$api_version" | jq "."
```

11. Examine the response and verify that the name and ID of the NSX cloud account you created is listed.

NOTE

The ID of the associated vSphere cloud account appears under `_links` and `hrefs` as in the following code snippet example.

```
...
{
  "name": "nsxv manager",
  "id": "515684ccebafe75-7f703c5265a63d87-e78aab87e9c8d5cd4cd1da1a285403f0f4e77a5240720d093e147b830b172542-d5a5e16bdc3eec75572358fd24ab6",
  "updatedAt": "2022-04-02",
  "organizationId": "f670fdfc-66d6-4689-9793-d524e7066d1e",
  "orgId": "f670fdfc-66d6-4689-9793-d524e7066d1e",
  "_links": {
    "associated-cloud-accounts": {
      "hrefs": [
        "/iaas/api/cloud-accounts/515684ccebafe75-7f703c5265a63d87-e78aab87e9c8d5cd4cd1da1a285403f0f4e77a5240720d093e147b830b172542-23b5c527d7083675572f5099a8da0"
      ]
    },
    "self": {
      "href": "/iaas/api/cloud-accounts/515684ccebafe75-7f703c5265a63d87-e78aab87e9c8d5cd4cd1da1a285403f0f4e77a5240720d093e147b830b172542-d5a5e16bdc3eec75572358fd24ab6"
    }
  }
}
```

Create an NSX-V Cloud Account

This example creates an NSX-V cloud account that includes an existing vSphere cloud account.

Assign the required variables.

```
$ url='https://appliance.domain.com'
$ api_version='2021-07-15'
```

List all cloud proxies.

```
$ curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/data-collectors?api_version=$api_version" | jq "."
```

A snippet of the response from your request shows the data collector IDs.

```
...
{
  "dcId": "cd7d1eb4-573f-4150-8206-de3d536490ca",
  "ipAddress": "10.139.116.60",
  "name": "localhost.localdom",
  "hostName": "localhost.localdom",
  "status": "ACTIVE"
},
...
...
```

Assign the data collector ID variable.

```
$ data_collector_id='cd7d1eb4-573f-4150-8206-de3d536490ca'
```

Assign the NSX account variables.

```
$ nsx_host_name='nsx-manager.mycompany.local'
$ nsx_username='admin'
$ nsx_password='my_nsx_password'
```

Assign the account variables for your existing vSphere cloud account.

```
$ vsphere_cloud_account_id='515684ccebafe75-7f703c5265a63d87-e78aab87e9c8d5cd4cd1da1a285403f0f4e77a5240720d093e147b830b172542-23b5c527d7083675572f5099a8da0'
```

Create an NSX-V cloud account named demo-nsxv-account.

```
$ curl -X POST \
"$url/iaas/api/cloud-accounts?apiVersion=$api_version" \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
  "cloudAccountType": "nsxv",
  "privateKeyId": "'$nsx_username'",
  "privateKey": "'$nsx_password'",
  "associatedCloudAccountIds": [
    '$vsphere_cloud_account_id'
  ]
}'
```

```
[,
"cloudAccountProperties": {
  "hostName": "'$nsx_host_name'",
  "acceptSelfSignedCertificate": "true",
  "dcId": "'$data_collector_id'",
  "privateKeyId": "'$nsx_username'",
  "privateKey": "'$nsx_password'"
},
"tags": [
  {
    "key": "env",
    "value": "prod"
  }
],
"name": "demo-nsxv-account",
"description": "Example NSX cloud account description"
}' | jq "."

```

A snippet of the response from your request shows the account ID.

```
...
"tags": [],

```

Add a VMware Cloud on AWS Cloud Account with a Proxy

Add a VMC Cloud Account with a Proxy

Adding a VMware Cloud on AWS cloud account with a proxy requires manual deployment of a cloud proxy VM. Then you make a POST request with a request body that includes the data collector ID along with parameters specific to VMware Cloud on AWS.

- Verify that all general prerequisites and prerequisites for the Automation Assembler Infrastructure as a Service (IaaS) service have been satisfied. See [Prerequisites for API Use Case Examples](#).

- Verify that a cloud proxy VM has been manually deployed.
- Verify that you have the following parameters for the new cloud account:
 - VMC API token.
 - SDDC name.
 - vCenter private IP.
 - NSX Manager IP.
 - vCenter user name.
 - vCenter password.
 - vCenter data center ID.

1. List all cloud proxies.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/data-collectors?api_version=$api_version" | jq "."
```

2. Examine the response and assign the data collector variable.

```
data_collector_id='<your_datacollector_id>'
```

3. Assign the account variables for the VMC cloud account.

```
vmc_api_token='<your_vmc_api_token>'  
vmc_sddc_name='<your_vmc_sddc_name>'  
vmc_vcenter_private_ip='<your_vcenter_private_ip>'  
vmc_nsx_manager_ip='<your_nsx_manager_ip>'  
vmc_vcenter_username='<your_vcenter_username>'  
vmc_vcenter_password='<your_vcenter_password>'  
vmc_vcenter_datacenter_id='<your_datacenter_id>'
```

4. Submit a request to create a VMC cloud account.

```
curl -X POST \  
"$url/iaas/api/cloud-accounts?apiVersion=$api_version" \  
-H "Authorization: Bearer $access_token" \  
-H 'Content-Type: application/json' \  
-d '{  
  "name": "vmc-endpoint",  
  "description": "VMC cloud account",  
  "cloudAccountType": "vmc",  
  "privateKeyId": """$vmc_vcenter_username""",  
  "privateKey": """$vmc_vcenter_password""",  
  "cloudAccountProperties": {  
    "sddcId": """$vmc_sddc_name""",
```

```

    "apiKey": """$vmc_api_token""",
    "hostName": """$vmc_vcenter_private_ip""",
    "nsxHostName": """$vmc_nsx_manager_ip""",
    "dcId": """$vmc_data_collector_id""",
    "acceptSelfSignedCertificate": "false"
},
"regionIds": [
    """$vmc_vcenter_datacenter_id"""
]
} ' | jq "."

```

The response includes a selfLink value.

5. Assign the selfLink variable.

```
selfLink_id='example-selfLink-alphanumeric-string'
```

6. Use the selfLink variable to track the request.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/request-tracker/$selfLink_id" | jq "."

```

The VMware Cloud on AWS cloud account is created when the response shows "status": "FINISHED".

Create a VMC Cloud Account with a Proxy

This example creates a VMware Cloud on AWS cloud account with a cloud proxy VM that has been manually deployed.

Assign the required variables.

```
$ url='https://appliance.domain.com'
$ api_version='2021-07-15'
```

List all cloud proxies.

```
$ curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/data-collectors?api_version=$api_version" | jq "."

```

A snippet of the response from your request shows the data collector IDs.

...

```
{
    "dcId": "cd7d1eb4-573f-4150-8206-de3d536490ca",
    "ipAddress": "10.139.116.60",
    "name": "localhost.localdom",
    "hostName": "localhost.localdom",
```

```

    "status": "ACTIVE"
},
}

...
Assign the data collector ID variable.

$ data_collector_id='cd7d1eb4-573f-4150-8206-de3d536490ca'

Assign the variables for the VMC cloud account.

$ vmc_data_collector_id=a1235a7f-d49f-4365-8ed9-2d7d0805e4bc
$ vmc_api_token=ab392fba-32a8-49a5-a084-d422fa32c5b8
$ vmc_sddc_name=MYCOM-PRD-NSXT-M7GA-052019
$ vmc_vcenter_private_ip=10.70.57.196
$ vmc_nsx_manager_ip=10.70.57.131
$ vmc_vcenter_username=cloudadmin@vmc.local
$ vmc_vcenter_password=aBcqCW+m4+XEQg7
$ vmc_vcenter_datacenter_id=Datacenter:datacenter-1

Create a VMC cloud account named demo-vmc-account.

$ curl -X POST \
"$url/iaas/api/cloud-accounts?apiVersion=$api_version" \
-H "Authorization: Bearer $access_token" \
-H 'Content-Type: application/json' \
-d '{
  "name": "demo-vmc-account",
  "description": "VMC cloud account",
  "cloudAccountType": "vmc",
  "privateKeyId": """$vmc_vcenter_username""",
  "privateKey": """$vmc_vcenter_password""",
  "cloudAccountProperties": {
    "sddcId": """$vmc_sddc_name""",
    "apiKey": """$vmc_api_token""",
    "hostName": """$vmc_vcenter_private_ip""",
    "nsxHostName": """$vmc_nsx_manager_ip""",
    "dcId": """$vmc_data_collector_id""",
    "acceptSelfSignedCertificate": "false"
}
}
```

```

},
"regionIds": [
    """$vmc_vcenter_datacenter_id"""
]
}' | jq "."

```

The response includes a selfLink variable.

```
{
    "progress": 0,
    "status": "INPROGRESS",
    "name": "Cloud account creation/update",
    "id": "0dc374ba-08ec-4422-8615-24f4f94ef5aa",
    "selfLink": "/iaas/api/request-tracker/0dc374ba-08ec-4422-8615-24f4f94ef5aa"
}
```

Assign the selfLink variable.

```
selfLink_id='0dc374ba-08ec-4422-8615-24f4f94ef5aa'
```

Use the selfLink variable to track the request.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token"
"$url/iaas/api/request-tracker/$selfLink_id" | jq "."
```

When the request completes successfully, the response shows the cloud account ID at the end of the resources path.

```
{
    "progress": 100,
    "status": "FINISHED",
    "resources": [
        "/iaas/api/cloud-accounts/e6af1aa6-dc7a-4847-8adc-c4c73727e5b3"
    ],
    "name": "Cloud account creation/update",
    "id": "a85d1476-1b11-45b0-8d14-91951385c95d",
    "selfLink": "/iaas/api/request-tracker/a85d1476-1b11-45b0-8d14-91951385c95d"
}
```

Add a Microsoft Azure Cloud Account

To create a Microsoft Azure cloud account, you make a POST request. The request body includes parameters specific to Microsoft Azure that are required to create the cloud account.

- Verify that all general prerequisites and prerequisites for the Automation Assembler Infrastructure as a Service (IaaS) service have been satisfied. See [Prerequisites for API Use Case Examples](#).

- Verify that you have the following parameters for the new cloud account:
 - Microsoft Azure subscription ID
 - Microsoft Azure tenant ID
 - Microsoft Azure client application ID
 - Microsoft Azure client application secret key

As an alternative to using the `cloud-accounts` API call, you can use a `cloud-accounts-azure` API call that creates a Microsoft Azure cloud account with fewer input parameters.

- Assign the Microsoft Azure account variables.

```
azure_subscription_id='<your_azure_subscription_id>'  
azure_tenant_id='<your_azure_tenant_id>'  
azure_client_application_id='<your_azure_client_application_id>'  
azure_client_application_secret_key='<your_azure_client_application_secret_key>'
```

- Submit a request to create a Microsoft Azure cloud account with default cloud zones.

```
curl -X POST \  
"$url/iaas/api/cloud-accounts?apiVersion=$api_version" \  
-H 'Content-Type: application/json' \  
-H "Authorization: Bearer $access_token" \  
-d '{  
  "cloudAccountType": "azure",  
  "privateKeyId": "'$azure_client_application_id'",  
  "privateKey": "'$azure_client_application_secret_key'",  
  "cloudAccountProperties": {  
    "userLink": "'$azure_subscription_id'",  
    "azureTenantId": "'$azure_tenant_id'"  
  },  
  "regionIds": ["<your_region_id>"],  
  "createDefaultZones": true,  
  "name": "<your_azure_cloud_account>",  
  "description": "This is a demo Azure cloud account",  
} ' | jq ".")
```

- Submit a request to create a Microsoft Azure cloud account with the `cloud-accounts-azure` API call.

```
curl -X POST \  
"$url/iaas/api/cloud-accounts-azure?apiVersion=$api_version" \  
-H 'Content-Type: application/json' \  
-d '{  
  "cloudAccountType": "azure",  
  "privateKeyId": "'$azure_client_application_id'",  
  "privateKey": "'$azure_client_application_secret_key'",  
  "cloudAccountProperties": {  
    "userLink": "'$azure_subscription_id'",  
    "azureTenantId": "'$azure_tenant_id'"  
  },  
  "regionIds": ["<your_region_id>"],  
  "createDefaultZones": true,  
  "name": "<your_azure_cloud_account>",  
  "description": "This is a demo Azure cloud account",  
} ' | jq ".")
```

```

-H "Authorization: Bearer $access_token" \
-d '{
  "name": "<your_azure_cloud_account>",
  "description": "This is a demo Azure cloud account",
  "subscriptionId": "'$azure_subscription_id'",
  "tenantId": "'$azure_tenant_id'",
  "clientApplicationId": "'$azure_client_application_id'",
  "clientApplicationSecretKey": "'$azure_client_application_secret_key'",
  "regionIds": [ "<your_region_id1>", "<your_region_id2>" ],
  "createDefaultZones": true,
  "tags": [ { "key": "env", "value": "dev" } ]
}' | jq "."

```

4. List all cloud accounts.

```
curl -X GET $url/iaas/api/cloud-accounts?apiVersion=$api_version -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" | jq "."
```

5. Examine the response and verify that the name and ID of the Microsoft Azure cloud account you created is listed.

Create a Microsoft Azure Cloud Account

Assign the required variables.

```

$url='https://appliance.domain.com'
$api_version='2021-07-15'
$azure_subscription_id='r1e31415-4a08-4072-be4a-19de37d12345'
$azure_tenant_id='s39138ca-3abc-4b4a-a4d6-cd92d9dd62f0'
$azure_client_application_id='te21wxyz-b183-42ac-cd84-3c4a2459b9a9'
$azure_client_application_secret_key='udv61Y8MwpP5ABCDFsztP3ABCDEaLMNOPQRmDEUeiI0='
Create a cloud account named demo-azure-account.

```

```

$ curl -X POST \
"$url/iaas/api/cloud-accounts?apiVersion=$api_version" \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
  "cloudAccountType": "azure",
  "privateKeyId": "'$azure_client_application_id'"
}'

```

```

"privateKey": '$azure_client_application_secret_key',
"cloudAccountProperties": {
    "userLink": '$azure_subscription_id',
    "azureTenantId": '$azure_tenant_id'
},
"regionIds": ["eastus"],
"createDefaultZones": true,
"name": "demo-azure-account",
"description": "This is a demo Azure cloud account",
}' | jq "."

```

A snippet of the response from your request shows the account ID.

```

...

```

Add a Google Cloud Platform Cloud Account

To create a Google Cloud Platform (GCP) cloud account, you make a POST request. The request body includes parameters specific to Google Cloud Platform that are required to create the cloud account.

- Verify that all general prerequisites and prerequisites for the Automation Assembler Infrastructure as a Service (IaaS) service have been satisfied. See [Prerequisites for API Use Case Examples](#).
- Verify that you have the following parameters for the new cloud account:
 - GCP project ID
 - GCP private key ID
 - GCP private key
 - GCP client email

1. Assign the GCP account variables.

```

gcp_project_id='<your_gcp_project_id>'
gcp_private_key_id='<your_gcp_private_key_id>'
gcp_private_key='<your_gcp_private_key>'
gcp_client_email='<your_gcp_client_email>'

```

2. Submit a request to create a GCP cloud account with default cloud zones.

```
curl -X POST \
"$url/iaas/api/cloud-accounts?apiVersion=$api_version" \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
  "cloudAccountType": "gcp",
  "privateKeyId": "'$gcp_private_key_id'",
  "privateKey": "'$gcp_private_key'",
  "cloudAccountProperties": {
    "projectId": "'$gcp_project_id'",
    "clientEmail": "'$gcp_client_email'"
  },
  "regionIds": ["<your_region_id>"],
  "createDefaultZones": true,
  "name": "<your_gcp_cloud_account>",
  "description": "This is a demo GCP cloud account",
} ' | jq "."
```

3. List all cloud accounts.

```
curl -X GET $url/iaas/api/cloud-accounts?apiVersion=$api_version -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" | jq "."
```

4. Examine the response and verify that the name and ID of the GCP cloud account you created is listed.

Create a Google Cloud Platform Cloud Account

Assign the required variables.

```
$ url='https://appliance.domain.com'
$ api_version='2021-07-15'
$ gcp_project_id='Example-e2e'
$ gcp_private_key_id='defg3c20c85abcde6a95b44222c4c1d68554b87e'
$ gcp_private_key='-----BEGIN PRIVATE KEY-----\nMIIEvQIBADANBgkqhkiG9w0BAQEFAA

Integrating with other applications

To fully automate your organization setup, you can use the IaaS APIs to list, create, update, and delete VMware Aria Automation integrations with other applications programmatically.

Using different input variables, you can create integrations with external systems such as GitHub, Ansible, and external IPAM providers. The following table lists all supported integrations.

Integration	Type	What do I need to create an integration?	Additional Product Documentation
Active Directory	activedirectory	<ul style="list-style-type: none"> LDAP connection to Active Directory server. Project configured with appropriate cloud zones, and image and flavor mappings to use with the Active Directory integration. 	How do I create an Active Directory integration in Automation Assembler
Ansible	ansible	<ul style="list-style-type: none"> Ansible control machine running Ansible version 2.6.0 or later. Read/write access to the directory where the Ansible inventory file is located. Deactivated host key. Vault password set. 	Configure Ansible Open Source integration in Automation Assembler
Ansible Tower	ansible.tower	Credentials and templates in Ansible Tower configured to use with deployments.	Configure Ansible Tower Integration in Automation Assembler
Bitbucket	org.bitbucket	Personal access API token for Bitbucket.	Configure Bitbucket integration in Automation Assembler
GitHub	com.github.saas	Personal access API token for GitHub. See https://docs.gitlab.com/ee/user/profile/personal_access_tokens.html	Configure GitHub integration in Automation Assembler
GitLab	com.gitlab.saas	Personal access API token for GitLab.	Configure GitLab cloud template integration in Automation Assembler
IPAM	ipam	<ul style="list-style-type: none"> IPAM provider package. Administrator credentials for the account with the external IPAM provider. 	How to configure an external IPAM integration in VMware Aria Automation
Puppet	puppet	Puppet master name and hostname or IP address of the master.	Configure Puppet Enterprise integration in Automation Assembler
Red Hat OpenShift	cmx.openshift-endpoint	Red Hat OpenShift server configured.	Configure Red Hat OpenShift Integration in Automation Assembler

Table continued on next page

Continued from previous page

Integration	Type	What do I need to create an integration?	Additional Product Documentation
		NOTE If needed, you can create an OpenShift cluster with a cloud template that VMware provides. See https://flings.vmware.com/red-hat-openshift-container-platform-as-a-service-on-vrealize-automation-cloud .	
SaltStack	saltstack	<ul style="list-style-type: none"> • Salt master used in the Automation Config integration that contains the Master Plugin. • Automation Config service administrator role in VMware Aria Automation. • Automation Assembler service administrator role in VMware Aria Automation. 	Create an Automation Config integration in VMware Aria Automation
SDDC Manager	sddc	SDDC manager 4.1 or later installed.	Configure a VMware SDDC Manager integration
Terraform Runtime	terraform.runtime	Terraform runtime environment. See Preparing an Automation Assembler Terraform runtime environment .	Preparing for Terraform configurations in Automation Assembler
VMware Enterprise PKS	cmx.pks-endpoint	<ul style="list-style-type: none"> • Pivotal Container Service (PKS) server configured with UAA authentication. • Cloud administrator credentials. 	Configure VMware Tanzu Kubernetes Grid Integrated Edition Integration in v Automation Assembler
VMware Aria Automation Orchestrator	vro	<ul style="list-style-type: none"> • VMware Aria Automation Orchestrator configured. 	Configure a VMware Aria Automation

Table continued on next page

Integration	Type	What do I need to create an integration?	Additional Product Documentation
		<ul style="list-style-type: none"> VMware Aria Automation Orchestrator URL Cloud Extensibility proxy deployed. 	Orchestrator integration in Automation Assembler
VMware Aria Operations	vrops	<p>A local or non-local VMware Aria Operations login account with read-only privileges to the vCenter adapter instance of the vSphere endpoint.</p> <p>NOTE For non-local account login, username format is <code>username@domain@authenticated-source</code>, for example <code>jdoe@company.com@workspaceone</code></p>	Integrating with VMware Aria Operations

Create an Integration with Github

To create an integration with GitHub, you make a POST request. The request body includes properties specific to GitHub.

- Verify that all general prerequisites and prerequisites for the Automation Assembler Infrastructure as a Service (IaaS) service have been satisfied. See [Prerequisites for API Use Case Examples](#).
- Verify that you have a personal access token for authentication to GitHub. See https://docs.gitlab.com/ee/user/profile/personal_access_tokens.html.

1. Assign variables for GitHub.

```
private_key='<your_GitHub_personal_access_token>'
```

2. Submit a request to create a GitHub integration.

```
curl -X POST \
"$url/iaas/api/integrations?apiVersion=$api_version" \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
  "integrationType": "com.github.saas",
  "name": "<your_github_integration>",
  "privateKey": "'$private_key'"
}'
```

```
"integrationProperties": {
    "url": "https://api.github.com"
},
} ' | jq ."
```

The response includes a selfLink.

```
{
    "progress": 0,
    "status": "INPROGRESS",
    "name": "Integration creation/update",
    "id": "example-selfLink-alphanumeric-string",
    "selfLink": "/iaas/api/request-tracker/example-selfLink-alphanumeric-string"
}
```

3. Assign the selfLink variable.

```
selfLink_id='example-selfLink-alphanumeric-string'
```

4. Use the selfLink variable to track the request.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/request-tracker/$selfLink_id?apiVersion=$api_version" | jq ."
```

When the request completes successfully, the response includes a resource with the integration ID.

```
{
    "progress": 100,
    "status": "FINISHED",
    "resources": [
        "/iaas/api/integrations/example-integration-id-string"
    ],
    "name": "Integration creation/update",
    "id": "example-selfLink-alphanumeric-string",
    "selfLink": "/iaas/api/request-tracker/example-selfLink-alphanumeric-string"
}
```

5. Assign the integration ID variable.

```
integration_id='example-integration-alphanumeric-string'
```

6. Use the integration ID variable to list the integration.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/integrations/$integration_id?apiVersion=$api_version" | jq ".."
```

7. Examine the response and verify that the name and ID of the integration that you created is listed.

Create a GitHub integration

Assign the required variables.

```
$ url='https://appliance.domain.com'
$ api_version='2021-07-15'
$ private_key='8bc9401b5d28f4ec126929af0dc4e99dd0792b0f'
```

Create the integration.

```
$ curl -X POST \
"$url/iaas/api/integrations?apiVersion=$api_version" \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
  "integrationType": "com.github.saas",
  "name": "Git integration example",
  "privateKey": "'$private_key'",
  "integrationProperties": {
    "url": "https://api.github.com"
  },
}' | jq ".."
```

The response includes a selfLink.

```
{
  "progress": 0,
  "status": "INPROGRESS",
  "name": "Integration creation/update",
  "id": "a0c5eb3a-9ffa-4bfb-b63b-c77510bcc597",
  "selfLink": "/iaas/api/request-tracker/a0c5eb3a-9ffa-4bfb-b63b-c77510bcc597"
}
```

Assign the selfLink variable

```
selfLink_id='a0c5eb3a-9ffa-4bfb-b63b-c77510bcc597'
```

Use the `selfLink` variable to track the request.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token"
"$url/iaas/api/request-tracker/$selfLink_id?apiVersion=$api_version" | jq "."
```

When the request completes successfully, the response includes a resource with the integration ID.

```
{
  "progress": 100,
  "status": "FINISHED",
  "resources": [
    "/iaas/api/integrations/e5dda941-bb17-4f19bd15-7db0b8eab88c"
  ],
  "name": "Integration creation/update",
  "id": "a0c5eb3a-9ffa-4bfb-b63b-c77510bcc597",
  "selfLink": "/iaas/api/request-tracker/a0c5eb3a-9ffa-4bfb-b63b-c77510bcc597"
}
```

Assign the integration ID variable

```
integration_id='e5dda941-bb17-4f19bd15-7db0b8eab88c'
```

Use the integration ID variable to list the integration.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token"
"$url/iaas/api/integrations/$integration_id?apiVersion=$api_version" | jq "."
```

When the request completes successfully, a snippet of the response shows integration details.

```
...
{
  "integrationType": "com.github.saas",
  "integrationProperties": (
    "url": "https://api.github.com"
  ),
  "name": "Git integration example",
  "id": "e5dda941-bb17-4f19bd15-7db0b8eab88c",
  "createdAt": "2022-04-02",
  "updatedAt": "2022-04-02",
  "orgId": "ce811934-eala-4f53-6bec-4656ca7d126",
  "_links": {
    "self": {
      "href": "/iaas/api/integrations/e5dda941-bb17-4f19bd15-7db0b8eab88c"
```

```

    }
}

}
...

```

Delete an Integration

To delete an integration, you make a DELETE request with the ID of the integration.

- Verify that all general prerequisites and prerequisites for the Automation Assembler Infrastructure as a Service (IaaS) service have been satisfied. See [Prerequisites for API Use Case Examples](#).
- Verify that you have the ID of the integration that you want to delete. See [Create an Integration with Github](#).

The following procedure shows how to delete an integration including an optional step to list the integration details before deleting the integration. It is a good practice to check the details of the integration so that you delete the correct integration.

1. Assign your integration ID variable.

```
integration_id='<your_integration_id>'
```

2. List the integration before deleting.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/integrations/$integration_id?apiVersion=$api_version" | jq ".
```

3. Examine the response to verify the integration details, such as integration name and integration type.

4. Submit a request to delete the integration.

```
curl -X DELETE -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/integrations/$integration_id?apiVersion=$api_version" | jq ".
```

The response includes a selfLink.

```
{
  "progress": 0,
  "status": "INPROGRESS",
  "name": "Integration deletion",
  "id": "example-selfLink-alphanumeric-string",
  "selfLink": "/iaas/api/request-tracker/example-selfLink-alphanumeric-string"
}
```

5. Assign the selfLink variable.

```
selfLink_id='example-selfLink-alphanumeric-string'
```

6. Use the selfLink variable to track the request.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/request-tracker/$selfLink_id | jq ."
```

When the request completes successfully, the response shows the status as FINISHED.

```
{
  "progress": 100,
  "message": "Deleted",
  "status": "FINISHED",
  "name": "Integration deletion",
  "id": "example-selfLink-alphanumeric-string",
  "selfLink": "/iaas/api/request-tracker/example-selfLink-alphanumeric-string"
}
```

Delete an integration

Assign the required variables.

```
$ url='https://appliance.domain.com'
$ api_version='2021-07-15'
$ integration_id='e5dda941-bb17-4f19bd15-7db0b8eab88c'
```

Delete the integration.

```
curl -X DELETE -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/integrations/$integration_id?apiVersion=$api_version" | jq ."
```

The response includes a selfLink.

```
{
  "progress": 0,
  "status": "INPROGRESS",
  "name": "Integration deletion",
  "id": "fe472e75-f346-4de7-bbc4-5edddefd9dfa",
  "selfLink": "/iaas/api/request-tracker/fe472e75-f346-4de7-bbc4-5edddefd9dfa"
}
```

Assign the selfLink variable

```
selfLink_id='fe472e75-f346-4de7-bbc4-5edddefd9dfa'
```

Use the selfLink variable to track the request.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/request-tracker/$selfLink_id | jq ."
```

When the request completes successfully, the response shows the status as FINISHED.

```
{
  "progress": 100,
  "message": "Deleted",
  "status": "FINISHED",
  "name": "Integration deletion",
  "id": "fe472e75-f346-4de7-bbc4-5eddddefd9dfa",
  "selfLink": "/iaas/api/request-tracker/fe472e75-f346-4de7-bbc4-5eddddefd9dfa"
}
```

How do I import an IPAM package

To import an IPAM package using the IaaS API, you reserve enough space for the package then you make multiple PATCH requests to import smaller pieces of the package. After importing all the pieces, you use a POST request to upload the file onto the server.

- Verify that all general prerequisites and prerequisites for the Automation Assembler IaaS API have been satisfied. See [Prerequisites for API Use Case Examples](#).
- Verify that you know the size of the package that you want to upload. If the package is large, divide it into smaller packages. The following example divides the large package into smaller packages that are each 9000000 bytes in size.
`split -b 9000000 <your_package>.zip <your_package>.zip_split`
- If using the API to complete the IPAM integration with a cloud account, verify that you have the following parameters for your cloud account:
 - *privateKeyId* used to create your cloud account.
 - *privateKey* used to create your cloud account.
 - *hostName* used to create your cloud account.
 - *faasProviderEndpointID* is your cloud account ID.

The IaaS API implements the TUS RFC protocol which provides a mechanism for resumable file uploads. By dividing a large package into smaller ZIP packages and importing the packages individually, you ensure that you will not exceed the server's file size limit with your upload.

For more information about the TUS RFC protocol, see <https://github.com/tus/tus-resumable-upload-protocol/blob/main/protocol.md>.

This procedure shows how to import your IPAM package using the integrations IPAM APIs. Then you complete the integration using the Automation Assembler UI or the integrations API.

1. Reserve space for the package with `Upload-Length` equal to the size of the package in bytes.

```
curl -X POST \
"$url/iaas/api/integrations-ipam/package-import?apiVersion=$api_version" \
-H "Authorization: Bearer $access_token" \
-H "Upload-Length: <package_size_in_bytes>" \
-H "Tus-Resumable: 1.0.0" | jq "."
```

Examine the response header to get the location for the package.

NOTE

You must complete the package import process before the location reservation expires in approximately two hours.

2. Assign a variable for the location ID.

```
location_id = '<package_location>'
```

3. Import the first small package with Upload-Offset equal to zero.

```
curl -X PATCH \
"$url/iaas/api/integrations-ipam/package-import/$location_id/?"
apiVersion=$api_version" \
-H "Authorization: Bearer $access_token" \
-H "Tus-Resumable: 1.0.0" \
-H "Content-Type: application/offset+octet-stream" \
-H "Upload-Offset: 0" | jq "."
```

A successful response returns 204 No Content and includes an upload offset number. Use that number in the PATCH request for the next package.

4. Import the next small package.

- You must import the small packages in a sequential order.
- Upload-Offset is the offset value from the response header of the previous PATCH request.

```
curl -X PATCH \
"$url/iaas/api/integrations-ipam/package-import/$location_id/?"
apiVersion=$api_version" \
-H "Authorization: Bearer $access_token" \
-H "Tus-Resumable: 1.0.0" \
-H "Content-Type: application/offset+octet-stream" \
-H "Upload-Offset: <upload_offset_from_previous_response>" | jq "."
```

Verify that the successful response returns 204 No Content and a larger upload offset number. Continue making PATCH requests with the upload offset numbers from the previous response until all the smaller packages have been imported.

NOTE

If you do not know the current upload offset number, make a HEAD request with the location ID.

```
curl -X HEAD \
"$url/iaas/api/integrations-ipam/package-import/$location_id/?"
apiVersion=$api_version" \
-H "Authorization: Bearer $access_token" \
-H "Tus-Resumable: 1.0.0" | jq "."
```

Use the upload offset number in the response for the next PATCH request.

5. After all the small packages have been imported, upload the file.

The input body includes:

- `bundleId` for the location ID.
- "option": "OVERWRITE" to overwrite any existing package.

```
curl -X POST \
```

```
"$url/iaas/api/integrations-ipam/package-import?apiVersion=$api_version" \
-H "Authorization: Bearer $access_token" \
-H "Content-Type: application/json" \
-H "Tus-Resumable: 1.0.0" \
-d '{
  "bundleId": "$location_id",
  "option" : "OVERWRITE"
}'
```

```
| jq ."
```

A successful response includes the Provider ID, Provider name, and Provider version. To complete an IPAM integration, you can use the Automation Assembler UI or the integrations endpoint in the IaaS API.

6. To complete an integration using the Automation Assembler UI, select **Infrastructure > Integrations > Add integration > IPAM**. On the **New Integration** page that appears, select **Manage IPAM Providers** and choose the package with the Provider name and Provider version from the API response.
7. To complete an integration using the API:

- a) Assign a variable for the provider ID.

```
provider_id = '<provider_id_from_package_upload>'
```

- b) Create a new IPAM integration.

```
curl -X POST \
```

```
"$url/iaas/api/integrations?apiVersion=$api_version" \
-H "Authorization: Bearer $access_token" \
-H "Content-Type: application/json" \
-d '{
  "integrationProperties": {
    "providerId" : "'$provider_id'",
    "faasProviderEndpointId": "<your_provider_endpoint_ID>",
    "privateKeyId": "<your_privateKeyId>",
    "privateKey": "<your_privateKey>",
    "hostName": "<your_hostName>",
    "dcId": "onprem"
  }
},
```

```

"customProperties": {"isExternal": "true"},  

"integrationType": "ipam",  

"associatedCloudAccountIds": [],  

"associatedMobilityCloudAccountIds": {},  

"privateKey": "<your_privateKey>",  

"privateKeyId": "<your_privateKeyId>"  

} | jq "."

```

The response includes a self link to track the request.

- c) Assign the selfLink variable.

```
selfLink_id='<example_selfLink_alphanumeric_string>'
```

- d) Use the selfLink variable to track the request.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer  

$access_token" "$url/iaas/api/request-tracker/$selfLink_id?  

apiVersion=$api_version" | jq "."

```

The integration is created with the response includes "status": "FINISHED".

Import an IPAM Package

This example shows how to import an Infoblox IPAM package with a total size of 73342782 bytes. To import incrementally using smaller packages, you divide the larger package into smaller packages. This example assumes that you have divided the package into multiple smaller packages each 9000000 bytes in size.

After importing the IPAM package, you create an integration with a cloud account using the the Automation Assembler UI or the integrations endpoint in the IaaS API. This example shows how to integrate the uploaded IPAM package with a cloud account that has the following parameters:

- faasProviderEndpointId: "f46337e9-e0c2-4ada-9244-766a8e54da48"
- hostName: "infoblox.sof-mbu.eng.mycompany.com"
- privateKey: "Password!23"
- privateKeyId: "administrator@mycompany.local"

Assign variables.

```
$ url='https://appliance.domain.com'  

$ api_version=' 2021-07-15'
```

Reserve space for the package.

```
$ curl -X POST \  

"$url/iaas/api/integrations-ipam/package-import?apiVersion=$api_version" \  

-H "Authorization: Bearer $access_token" \  

-H "Upload-Length: 73342782" \  

-H "Tus-Resumable: 1.0.0" | jq "."
```

Examine the response to get the location ID.

```
status: 201
body: empty
headers: {location:/iaas/api/integrations-ipam/package-import/8a81db06-f27f-4ccb-a7c5-960c35107ed6, ...}
```

Assign the location ID variable.

```
$ location_id='8a81db06-f27f-4ccb-a7c5-960c35107ed6'
```

Import the first package with a content length of 9000000 bytes and a zero upload offset value.

```
$ curl -X PATCH \
"$url/iaas/api/integrations-ipam/package-import/$location_id/?apiVersion=$api_version" \
-H "Authorization: Bearer $access_token" \
-H "Content-Length: 9000000" \
-H "Tus-Resumable: 1.0.0" \
-H "Content-Type: application/offset+octet-stream" \
-H "Upload-Offset: 0" | jq "."
```

Examine the header in the response to get the upload offset value.

```
status: 204
body: empty
headers: {upload-offset:9000000, ...}
```

Import the next package.

```
$ curl -X PATCH \
"$url/iaas/api/integrations-ipam/package-import/$location_id/?apiVersion=$api_version" \
-H "Authorization: Bearer $access_token" \
-H "Content-Length: 9000000" \
-H "Tus-Resumable: 1.0.0" \
-H "Content-Type: \"application/offset+octet-stream\"" \
-H "Upload-Offset: 9000000" | jq "."
```

Examine the header in the response again to get the next upload offset value.

```
status: 204
body: empty
headers: {upload-offset:18000000, ...}
```

Import the next package.

```
$ curl -X PATCH \
```

```
"$url/iaas/api/integrations-ipam/package-import/$location_id/?apiVersion=$api_version" \
-H "Authorization: Bearer $access_token" \
-H "Content-Length: 9000000" \
-H "Tus-Resumable: 1.0.0" \
-H "Content-Type: application/offset+octet-stream" \
-H "Upload-Offset: 18000000" | jq "."
Repeat the process to get the upload offset value from the header response and use that value to import the next package.
```

After importing the final small package, upload the complete package.

```
$ curl -X POST \
"$url/iaas/api/integrations-ipam/package-import?apiVersion=$api_version" \
-H "Authorization: Bearer $access_token" \
-H "Tus-Resumable: 1.0.0" \
-d '{
  "bundleId": "$location_id",
  "option" : "OVERWRITE"
}
| jq "."
A successful response includes the provider ID, provider name, and the provider version
```

```
{
  "providerId": "86801580-9042-49b6-879d-5a7361d33519",
  "providerName": "Infoblox",
  "providerVersion": "1.6"
  "logoIcon": "iVBORw...",
...
}
```

To create an IPAM integration using the Automation Assembler UI, select **Infrastructure > Integrations > Add integration > IPAM**. On the **New Integration** page that appears, select **Manage IPAM Providers** and choose the package with the Provider name **Infoblox** and Provider version **1.6**.

To create an IPAM integration using the API, assign the provider ID variable.

```
$ provider_id = "86801580-9042-49b6-879d-5a7361d33519"
```

Create the integration.

```
$ curl -X POST \
"$url/iaas/api/integrations?apiVersion=$api_version" \
```

```

-H "Authorization: Bearer $access_token" \
-H "Content-Type: application/json" \
-d '{
  "integrationProperties": {
    "providerId" : "'$provider_id'",
    "faasProviderEndpointId": "f46337e9-e0c2-4ada-9244-766a8e54da48",
    "privateKeyId": "administrator@mycompany.local",
    "privateKey": "Password!23",
    "hostName": "infoblox.sof-mbu.eng.mycompany.com",
    "dcId": "onprem"
  },
  "customProperties": {"isExternal": "true"},
  "integrationType": "ipam",
  "associatedCloudAccountIds": [],
  "associatedMobilityCloudAccountIds": {},
  "privateKey": "Password!23",
  "privateKeyId": "administrator@mycompany.local"
} | jq "."

```

Examine the response.

```
{
  "progress": 0,
  "status": "INPROGRESS",
  "name": "Integration creation/update",
  "id": "117ff057-9e26-4f0c-ae7b-eb9fcc1c15cc",
  "selfLink": "/iaas/api/request-tracker/117ff057-9e26-4f0c-ae7b-eb9fcc1c15cc"
}
```

Assign the selfLink variable.

```
$ selfLink_id='117ff057-9e26-4f0c-ae7b-eb9fcc1c15cc'
```

Use the selfLink for tracking.

```
$ curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/request-tracker/$selfLink_id?apiVersion=$api_version" | jq "."
```

The integration is complete when the response includes "status": "FINISHED".

```
{
  "progress": 100,
  "status": "FINISHED",
  "resources": [
    "/iaas/api/integrations/9df2b0a8-2ce6-4465-bf39-04290965da9e" ],
    "name": "Integration creation/update",
    "id": "117ff057-9e26-4f0c-ae7b-eb9fcc1c15cc",
    "selfLink": "/iaas/api/request-tracker/117ff057-9e26-4f0c-ae7b-eb9fcc1c15cc"
  ]
}
```

Using Automation Assembler APIs to Build your Resource Infrastructure

Using Automation Assembler APIs to Build your Resource Infrastructure

You use the Automation Assembler APIs to add a project and set up an infrastructure for the team members in Automation so that new workloads can be provisioned.

Create a Cloud Zone

To create a cloud zone, you first make GET request to obtain a region ID with a cloud account ID as input. Then you make a POST request with the region ID.

- Verify that all general prerequisites and prerequisites for the Automation Assembler Infrastructure as a Service (IaaS) service have been satisfied. See [Prerequisites for API Use Case Examples](#).
- Verify that you have the cloud account ID for the cloud account you added. See [Add an Cloud Account](#) .

1. Assign the cloud account ID variable.

```
cloud_account_id='<your_cloud_account_id>'
```

2. Look up the IDs for the region named us-east-1 that is associated with the cloud account.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/regions/?apiVersion=$api_version&'$filter'"=externalRegionId%20eq%20'us-east-1'%20and%20cloudAccountId%20eq%20'$cloud_account_id''" | jq ".
```

3. To obtain a region ID, examine the response.

4. Assign the region ID variable.

```
region_id='<your_region_id>'
```

5. Create a cloud zone.

```
curl -X POST -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" -d '{ "name": "Demo-zone-1", "description": "This zone is for Demo", "regionId": "'$region_id'", "placementPolicy": "DEFAULT" }' "$url/iaas/api/zones?apiVersion=$api_version" | jq "."
```

6. To obtain a cloud zone ID, examine the response.

7. Assign the zone ID variable.

```
zone_id='<your_cloud_zone_id>'
```

8. List all cloud zones.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/zones?apiVersion=$api_version" | jq "."
```

9. List the cloud zone with your cloud zone ID.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/zones/$zone_id?apiVersion=$api_version" | jq "."
```

10. Examine the output to verify that the cloud zone you created is listed.

Create a Cloud Zone

Assign variables, specify a cloud account and look up IDs for the region named `us-east-1` associated with the cloud account.

```
$ url='https://appliance.domain.com'
$ api_version='2021-07-15'
$ cloud_account_id='c8c3c9bfdb449475-7f703c5265a63d87-
f8e705d89b2569e1aac66c6d00bf4fc7ef4b1c44100f0e944af31eb8ba3d2a5a-
f4226a20b65c4675574bc5fbff6c0'

$ curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/regions/?apiVersion=$api_version&$filter='externalRegionId%20eq%20'us-
east-1'%20and%20cloudAccountId%20eq%20'$cloud_account_id'" | jq "."
```

A snippet of the response from your request shows your cloud account ID with a region ID.

```
...
"externalRegionId": "us-east-1",
"cloudAccountId": "c8c3c9bfdb449475-7f703c5265a63d87-
f8e705d89b2569e1aac66c6d00bf4fc7ef4b1c44100f0e944af31eb8ba3d2a5a-
f4226a20b65c4675574bc5fbff6c0",
"id": "4965d34c3bfe0275574bc5fd858e8",
"updatedAt": "2022-04-02",
...
```

Specify a region ID and create a cloud zone.

```
$ region_id='4965d34c3bfe0275574bc5fd858e8'

$ curl -X POST -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" -d '{ "name": "Demo-zone-1", "description": "This zone is for Demo", "regionId": "'$region_id'", "placementPolicy": "DEFAULT" }' "$url/iaas/api/zones?apiVersion=$api_version" | jq "."
```

A snippet of the response from your request shows the zone ID.

```
...
"name": "Aws / us-east-1",
"id": "4965d34c3bfe0275574bc5fd8782a",
"updatedAt": "2022-04-02",
...
```

Create a Cloud Zone with a Folder

When creating a cloud zone, you can specify a folder with a path that relates to a datacenter, so that when you deploy a machine you deploy it to that folder.

- Verify that all general prerequisites and prerequisites for the Automation Assembler Infrastructure as a Service (IaaS) service have been satisfied. See [Prerequisites for API Use Case Examples](#).

NOTE

Users with the following RBAC permissions can also use the folder API to create a cloud zone:

- provisioning_cloud-zones_read
- provisioning_cloud-zones_manage

- Verify that you have the cloud account ID for the cloud account with the folder that you want to use. See [Add a Cloud Account](#).

To create a cloud zone with a folder, you first obtain an external region ID with a cloud account ID as input. Only the vSphere, VMC, and VCF cloud accounts support folders. Then you use the Folders API to get the external ID for the folder to specify.

The following procedure shows how to find a folder that you can use when creating a cloud zone.

- Assign the cloud account ID variable.

```
cloud_account_id='<your_cloud_account_id>'
```

- List the info for the cloud account.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/cloud-accounts/$cloud_account_id/?apiVersion=$api_version" | jq ".
```

- To find the region where you want to create a cloud zone, examine the enabledRegions section of the response and note the external region ID and its ID.

- Assign the external region ID variable.

```
external_region_id='<your_external_region_id>'  
region_id='<your_region_id>'
```

- List all folders associated with the external region and the cloud account.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/folders?externalRegionId=$external_region_id&cloudAccountId=$cloud_account_id/?apiVersion=$api_version" | jq "."
```

NOTE

Query parameters are optional:

- By providing the cloud account ID, you filter the folders by cloud account.
- By providing the external region ID, you filter the folders by datacenter.

6. Examine the response and note the external ID of the folder that you want to use.
Any of the folders listed in the response can be used in the cloud specification.

7. Assign the external ID variable.

```
external_id='<your_external_id>'
```

8. To create a cloud zone with a folder in the datacenter, specify the external ID as the value for the folder.

```
curl -X POST \
"$url/iaas/api/zones?apiVersion=$api_version" \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
  "regionId": "'$region_id'",
  "name": "<cloud_zone_with_folder>",
  "folder": "'$external_id'"
} | jq ."'
```

The response shows the folder and cloud zone ID.

Any resources that are deployed in the cloud zone are deployed to the folder.

Create a Cloud Zone with a Folder

Assign variables and specify an ID for a vSphere cloud account.

```
$ url='https://appliance.domain.com'
$ api_version='2021-07-15'
$ cloud_account_id='2636b316-b514-47f3-93b8-78f18df51a29'
```

List the information for the vSphere cloud account.

```
$ curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" \
"$url/iaas/api/cloud-accounts/$cloud_account_id/?apiVersion=$api_version" | jq ."'
```

Examine the response to find the region where you want to create a cloud zone. A snippet of the response shows the enabledRegions with an external region ID and your cloud account ID.

...

```
"enabledRegions": [
  {
    "externalRegionId": "Datacenter:datacenter-3",
    "name": "SDDC-Datacenter",
    "cloudAccountId": "2636b316-b514-47f3-93b8-78f18df51a29",
```

```
"id": "8d633554-90ca-4f8a-8a0f-1cd3cd90a522",
"updatedAt": "2022-04-02",
```

...

Assign the external region ID variable.

```
$ external_region_id= 'Datacenter:datacenter-3'
$ region_id= '8d633554-90ca-4f8a-8a0f-1cd3cd90a522'
```

List folders associated with the external region and cloud account.

```
$ curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token"
"$url/iaas/api/folders?
externalRegionId=$external_region_id&cloudAccountId=$cloud_account_id?&
apiVersion=$api_version" | jq "."
```

A snippet of the response shows the folders associated with the external region and the cloud account. The external ID is the value that you assign to the folder when creating the cloud zone.

...

```
"cloudAccountIds": [
    "2636b316-b514-47f3-93b8-78f18df51a29"

]
"externalId": "dbuyukliiska",
"name": "dbuyukliiska",
"id": "3863f2cc-0340-483f-b24e-d351b7c53c8c",
"createdAt": "2022-04-02",
"updatedAt": "2022-04-02",
```

...

Assign the external ID.

```
$ external_id='dbuyukliiska'
```

Create a cloud zone with a specified folder.

```
curl -X POST \
"$url/iaas/api/zones?apiVersion=$api_version" \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
    "regionId": "'$region_id'",
    "name": "Demo-zone-with-folder-1",
```

```
"folder": "'$external_id'"  
} | jq ".."
```

A snippet of the response from your request shows the folder and cloud zone ID.

```
...  
"folder": "dbuyukliiska",  
"externalRegionId": "Datacenter:datacenter-3",  
"cloudAccountId": "2636b316-b514-47f3-93b8-78f18df51a29",  
"name": "Demo-zone-with-folder-1",  
"id": "258bccb1-a337-4b63-9a8a-44a414761d93",  
"updatedAt": "2021-11-22",  
...  
...
```

Create a Project to use in Automation Assembler

As a Automation Assembler administrator, you make a POST request with a project name to create a project. Then you add members and cloud zones to the project so that project members can deploy cloud templates to the associated zones.

- Verify that all general prerequisites and prerequisites for the Automation Assembler Infrastructure as a Service (IaaS) service have been satisfied. See [Prerequisites for API Use Case Examples](#).
- Verify that the project roles that you plan to assign have sufficient permissions to perform project-related tasks.

NOTE

A user with the project administrator or project member role can perform a limited number of project-related tasks. For a complete list of tasks and roles required, see [Organization and service user roles in VMware Aria Automation](#).

- Prepare parameters including the project name, description, and email addresses for administrators, members, or viewers.

1. Assign the project name variable.

```
project_name='<your_project_name>'  
your_project_name is a name that you choose.
```

2. Create a project.

```
curl -X POST \  
"$url/iaas/api/projects?apiVersion=$api_version"  
-H 'Content-Type: application/json'  
-H "Authorization: Bearer $access_token"  
-d '{  
  "name" : "'$project_name'",  
  "description" : "your-description",
```

```
"administrators" : [{ "email" : "<admin_email>", ["type" : <"user" | "group">] }],  
"members" : [{ "email" : "<member_email>", ["type" : <"user" | "group">] }],  
"viewers" : [{ "email" : "<viewer_email>", ["type" : <"user" | "group">] }],  
}' | jq "."
```

- *admin_email*, *member_email*, and *viewer_email* are email addresses of an administrator, member, and viewer user or name of the group in the project.
- The type parameter is optional. It assigns the administrator, member, or viewer to a user or group type. If unspecified, the value defaults to user.

3. Get a list of projects and filter for the project with *your_project_name*.

```
curl -X GET -H 'Accept: application/json' -H "Authorization: Bearer $access_token"  
"$url/iaas/api/projects?  
apiVersion=$api_version&'$filter'"=name%20eq%20'$project_name'" | jq "."
```

4. Examine the response and record the ID of your newly created project.

Create a Project to use in Automation Assembler

Create a project named Example-Assembler-project with administrators, members, and viewers at mycompany.com. This example assumes that Example-project does not exist.

```
$ url='https://appliance.domain.com'  
$ api_version=' 2021-07-15'  
$ project_name='Example-Assembler-project'  
Create a project for Automation Assembler.  
  
$ curl -X POST \  
"$url/iaas/api/projects?apiVersion=$api_version" \  
-H 'Content-Type: application/json' \  
-H "Authorization: Bearer $access_token" \  
-d '{  
    "name" : "'$project_name'",  
    "description" : "This is an example project for Automation Assembler",  
    "administrators" : [{"email" : "admin1@mycompany.com", "type" : "user"}],  
    "members" : [{"email" : "member1@mycompany.com", "type" : "user"}],  
    "viewers" : [{"email" : "viewer1@mycompany.com", "type" : "user"}]  
' | jq "."
```

The response shows the administrators, members, and viewers related to the project and the project ID.

```
{  
    "administrators": [
```

```
{
  "email": "admin1@mycompany.com",
  "type": "user"
},
"members": [
  {
    "email": "member1@mycompany.com",
    "type": "user"
  }
],
"viewers": [
  {
    "email": "viewer1@mycompany.com",
    "type": "user"
  }
],
"sharedResources": true,
"name": "Example-Assembler-project",
"description": "This is an example project for Automation Assembler",
"id": "5944aacb-91de-4541-bb9e-ef2a5403f81b",
"orgId": "8327d53f-91ea-420a-8613-ba8f3149db95"
}
```

Add a cloud zone to your project. See [Add a Cloud Zone to Your Project](#). If you want to add an administrator or user, see [Add Users to Your Project](#).

Add Users to Your Project

As a Automation Assembler user with the project administrator role, you can use PATCH requests to add users and assign roles in your project.

- Verify that all general prerequisites and prerequisites for the Automation Assembler Infrastructure as a Service (IaaS) service have been satisfied. See [Prerequisites for API Use Case Examples](#).
- Verify that you have the project administrator role in your project and you have the project ID. See [Create a Project to use in](#).
- Prepare parameters including additional email addresses for administrators, members, or viewers that you want to add to the project.

1. Assign the project ID variable.

```
project_id='<your_project_id>'
```

your_project_id is the ID of the new project you created.

2. List the details of your project.

```
curl -X GET -H 'Accept: application/json' -H "Authorization: Bearer $access_token" \
"$url/iaas/api/projects/$project_id?apiVersion=$api_version" | jq ".."
```

3. Examine the response to see the administrators and users who are already in your project.

4. Submit a request to add a new administrator that includes the existing administrator for the project.

NOTE

If the call does not include existing administrators for the project, the PATCH request removes those administrators from the project. Specifying the administrator type is optional.

```
curl -X PATCH \
"$url/iaas/api/projects/$project_id?apiVersion=$api_version" \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
  "administrators" : [
    {"email" : "<your_new_administrator_email>", "type" : "user"}, 
    {"email" : "<existing_administrator>", "type" : "user"}
  ]
}' | jq ".."
```

5. Submit a request to add a new member that includes the existing users for the project.

NOTE

If the call does not include existing members for the project, the PATCH request removes those members from the project. Specifying the member type is optional.

```
curl -X PATCH \
"$url/iaas/api/projects/$project_id?apiVersion=$api_version" \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
  "members" : [
    {"email" : "<your_new_member_email>", "type" : "user"}, 
    {"email" : "<existing_member>", "type" : "user"}
  ]
}' | jq ".."
```

```
} ' | jq ".."
```

Add Users to Your Automation Assembler Project

For the project Example-Assembler-project, add another administrator and member at mycompany.com.

```
$ url='https://appliance.domain.com'  
$ api_version='2021-07-15'  
$ project_id='5944aacb-91de-4541-bb9e-ef2a5403f81b'
```

List the details of your project.

```
$ curl -X GET -H 'Accept: application/json' -H "Authorization: Bearer $access_token"  
"$url/iaas/api/projects/$project_id?apiVersion=$api_version" | jq ".."
```

A snippet of the response shows existing administrators, members, and viewers.

...

```
"administrators": [  
    {  
        "email": "admin1@mycompany.com",  
        "type": "user"  
    },  
    "members": [  
        {  
            "email": "member1@mycompany.com",  
            "type": "user"  
        },  
        "viewers": [  
            {  
                "email": "viewer1@mycompany.com",  
                "type": "user"  
            },  
            ...
```

Add the administrator. Include the existing administrator admin1@mycompany.com in the PATCH request.

```
$ curl -X PATCH \
"$url/iaas/api/projects/$project_id?apiVersion=$api_version" \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
  "administrators" : [
    {"email" : "newadministrator@mycompany.com", "type" : "user"},
    {"email" : "admin1@mycompany.com", "type" : "user"}
  ]
}' | jq "."
```

Add the member. Include the existing member `member1@mycompany.com` in the PATCH request.

```
$ curl -X PATCH \
"$url/iaas/api/projects/$project_id?apiVersion=$api_version" \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
  "members" : [
    {"email" : "newmember@mycompany.com", "type" : "user"},
    {"email" : "member1@mycompany.com", "type" : "user"}
  ]
}' | jq "."
```

The response shows the project with administrators, members, and viewers, including the new administrator and new member.

```
{
  "administrators": [
    {
      "email": "newadministrator@mycompany.com",
      "type": "user"
    },
    {
      "email": "admin1@mycompany.com",
      "type": "user"
    }
}
```

```

] ,
"members": [
{
  "email": "newmember@mycompany.com",
  "type": "user"
},
{
  "email": "member1@mycompany.com",
  "type": "user"
}
],
"viewers": [
{
  "email": "viewer1@mycompany.com",
  "type": "user"
}
],
"sharedResources": true,
"name": "Example-Assembler-project",
"description": "This is an example project for Automation Assembler",
"id": "5944aacb-91de-4541-bb9e-ef2a5403f81b",
"orgId": "8327d53f-91ea-420a-8613-ba8f3149db95"
}
]
}

```

Add a Cloud Zone to Your Project

As a Automation Assembler administrator, you use the `PATCH /iaas/api/projects` request to attach a cloud zone to a project.

- Verify that all general prerequisites and prerequisites for the Automation Assembler Infrastructure as a Service (IaaS) service have been satisfied. See [Prerequisites for API Use Case Examples](#).
- Verify that you have added a project and you have the project ID. See [Create a Project to use in](#).

If the project already has cloud zones attached, review them to ensure that all zones needed for the project are included in the PATCH request to add a new cloud zone.

1. Assign the project ID variable.

```
project_id='<your_project_id>'  
your_project_id is the ID of the new project you created.
```

2. List all cloud zones.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer  
$access_token" "$url/iaas/api/zones?apiVersion=$api_version" | jq "."
```

- 3.** To obtain a cloud zone ID, examine the response and find the ID of the zone that you want to attach to your project.
For a snippet of the response, see [Create a Cloud Zone](#).

4. Assign the cloud zone variable.

```
zone_id='<your_zone_id>'
```

5. List the details of your project.

```
curl -X GET -H 'Accept: application/json' -H "Authorization: Bearer $access_token"  
"$url/iaas/api/projects/$project_id?apiVersion=$api_version" | jq "."
```

6. Examine the response to see the zones already attached to your project.

- 7. Submit a request to attach and configure a new cloud zone that includes the ID of existing cloud zones for the project.**

NOTE

If the call does not include existing cloud zones that are already attached to the project, the PATCH request removes those cloud zones from the project.

```
curl -X PATCH \  
"$url/iaas/api/projects/$project_id?apiVersion=$api_version" \  
-H 'Content-Type: application/json' \  
-H "Authorization: Bearer $access_token" \  
-d '{  
    "zoneAssignmentConfigurations" : [  
        {  
            "zoneId" : "'$zone_id'",  
            "priority": 1,  
            "maxNumberInstances": 50  
        },  
        {  
            "zoneId" : "<existing_cloud_zone_id>",  
            "priority": 2,  
            "maxNumberInstances": 100  
        }  
    ]
```

```
} ' | jq "."
```

Attach a Cloud Zone to Your Project

For the new project Example-project, add a cloud zone.

```
$ url='https://appliance.domain.com'
$ api_version='2021-07-15'
$ project_id='5944aacb-91de-4541-bb9e-ef2a5403f81b'
```

List all cloud zones.

```
$ curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token"
"$url/iaas/api/zones?apiVersion=$api_version" | jq "."
```

Examine the response to find the cloud zone you want and assign the zone ID variable.

```
$ zone_id='4965d34c3bfe0275574bc5fd8782a'
```

List the details of your project.

```
$ curl -X GET -H 'Accept: application/json' -H "Authorization: Bearer $access_token"
"$url/iaas/api/projects/$project_id?apiVersion=$api_version" | jq "."
```

A snippet of the response shows an existing cloud zone.

...

```
"zones": [
{
  "zoneId": "3cc2ecb989eee87557b0d532d4bb0",
  "priority": 0,
  "maxNumberInstances": 0
}
```

...

Add the new cloud zone. Include the existing cloud zone 3cc2ecb989eee87557b0d532d4bb0 in the PATCH request.

```
$ curl -X PATCH \
"$url/iaas/api/projects/$project_id?apiVersion=$api_version" \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
  "zoneAssignmentConfigurations": [
    {
      "zoneId": "'$zone_id'"
    }
  ]
}'
```

```

    "priority": 1,
    "maxNumberInstances": 50
},
{
  "zoneId" : "3cc2ecb989eee87557b0d532d4bb0",
  "priority": 2,
  "maxNumberInstances": 100
}
]
} ' | jq "."

```

The response after adding a cloud zone lists the project with its administrators, members, and zone.

```
{
  "administrators": [
    {
      "email": "admin1@mycompany.com"
    }
  ],
  "members": [
    {
      "email": "user1@mycompany.com"
    }
  ],
  "zones": [
    {
      "zoneId": "4965d34c3bfe0275574bc5fd8782a",
      "priority": 1,
      "maxNumberInstances": 50
    },
    {
      "zoneId": "3cc2ecb989eee87557b0d532d4bb0",
      "priority": 2,
      "maxNumberInstances": 100
    }
  ]
}
```

```

    }
  ],
  "sharedResources": true,
  "name": "Example-project",
  "description": "This is an example project",
  "id": "5944aacb-91de-4541-bb9e-ef2a5403f81b",
  "organizationId": "8327d53f-91ea-420a-8613-ba8f3149db95",
  "orgId": "8327d53f-91ea-420a-8613-ba8f3149db95",
  "_links": {
    "self": {
      "href": "/iaas/api/projects/edfd6f26-5d82-428f-96b0-b10ac5e4aca9"
    }
  }
}
}

```

Create Flavor Mappings

To create a flavor mapping, you make a POST request with a region ID associated with a cloud account. The cloud account can be an AWS, vSphere, Azure, or GCP cloud account.

- Verify that all general prerequisites and prerequisites for the Automation Assembler Infrastructure as a Service (IaaS) service have been satisfied. See [Prerequisites for API Use Case Examples](#).
- Verify that you have the cloud account ID for the new cloud account that you added. See [Adding Cloud Accounts](#).

Cloud vendors use flavors, or instance types, to express standard deployment sizings such as small (1 CPU, 2 GB RAM) or large (2 CPU, 8 GB RAM) for compute resources. When you build a cloud template, you pick a flavor that fits your needs and map a flavor name to a value for each account or region.

The same API calls create a flavor profile for an AWS, vSphere, Azure, or GCP cloud account. However, the flavor mapping used to create the flavor profile varies for each type of cloud account. This procedure provides the steps to create a flavor profile for an AWS cloud account. Additional examples show how to create flavor profiles for vSphere and Azure cloud accounts.

1. Assign the cloud account ID variable.

```
cloud_account_id='<your_cloud_account_id>'
```

2. Look up region IDs associated with the cloud account and in the external region ID us-east-1.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/regions/?apiVersion=$api_version&'$filter'"=externalRegionId%20eq%20'us-east-1'%20and%20cloudAccountId%20eq%20'$cloud_account_id''" | jq "."
```

3. Examine the response to find the ID for the region that you want.

4. Assign the region ID variable.

```
region_id='<your_region_id>'
```

5. List all fabric flavors.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/fabric-flavors/?apiVersion=$api_version" | jq "."
```

6. To select fabric flavor names with resources that fit your needs, examine the response.

7. Create a flavor profile for an AWS account that uses the fabric flavor names in your flavor mapping.

```
curl -X POST \
  $url/iaas/api/flavor-profiles?apiVersion=$api_version \
  -H 'Content-Type: application/json' \
  -H "Authorization: Bearer $access_token" \
  -d '{
    "name": "<your_flavor_profile>",
    "description": "Example AWS Compute flavors",
    "flavorMapping": {
      "small": {
        "name": "<flavor_name1_from_response>"
      },
      "medium": {
        "name": "<flavor_name2_from_response>"
      },
      "large": {
        "name": "<flavor_name3_from_response>"
      }
    },
    "regionId": "'$region_id'"
  }' | jq "."
```

8. To obtain the flavor profile ID, examine the response.

9. Assign the flavor profile ID variable.

```
flavor_profile_id='<your_flavor_profile_id>'
```

10. Look up the flavor profile you created with your flavor profile ID.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" $url/iaas/api/flavor-profiles/$flavor_profile_id?
apiVersion=$api_version | jq "."
```

The response shows the name and ID for the flavor profile you created.

NOTE

Using the external region ID and the cloud account ID, you can also filter for the flavor profile with a query that does not require the flavor profile ID. See [Filtering Resources by Region ID](#).

Create flavor mappings for different cloud accounts

Create a flavor mapping for an AWS cloud account.

1. Assign the required variables including the cloud account ID for an AWS cloud account.

```
$ url='https://appliance.domain.com'
$ api_version=' 2021-07-15'
$ cloud_account_id='c8c3c9bfdb449475-7f703c5265a63d87-5fa34c478df36b060e1ca3551254c4033
01
3bf3283908e4661cd1c6fb2f8b9ae-ce5aad01092b47558644f6b6615d'
```

2. Look up region IDs associated with the cloud account and in the external region ID us-east-1.

```
$ curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer
$access_token" "$url/iaas/api/regions/?apiVersion=$api_version&'$filter'"=externalRegionId%20eq%20'us-
east-1'%20and%20cloudAccountId%20eq%20'$cloud_account_id'"' | jq "."
```

A snippet of the response shows the region ID.

```
...
{
  "externalRegionId": "us-east-1",
  "cloudAccountId": "c8c3c9bfdb449475-7f703c5265a63d87-5fa34c478df36b060e1ca3551254c4033013bf3283908e4661
cd1c6fb2f8b9ae-ce5aad01092b47558644f6b6615d",
  "id": "37d6c1acf4a8275586468873c739",
  "updatedAt": " 2022-04-02",
}
```

3. Assign the AWS region ID.

```
$ aws_region_id='37d6c1acf4a8275586468873c739'
```

4. List all fabric flavors.

```
$ curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer
$access_token" "$url/iaas/api/fabric-flavors/?apiVersion=$api_version" | jq "."
```

A snippet of the response shows a fabric flavor name with its resource size.

```
...
{
  "id": "t2.micro",
  "name": "t2.micro",
  "cpuCount": 1,
  "memoryInMB": 1024,
```

```

    "storageType": "EBS",
    "networkType": "Low to Moderate"
  },
  ...
5. Select fabric flavor names with resources that fit your needs and create an AWS flavor profile named aws-flavor-profile.
$ curl -X POST \
$url/iaas/api/flavor-profiles?apiVersion=$api_version \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
  "name": "aws-flavor-profile",
  "description": "Example AWS Compute flavors",
  "flavorMapping": {
    "small": {
      "name": "t2.micro"
    },
    "medium": {
      "name": "t2.medium"
    },
    "large": {
      "name": "t2.large"
    }
  },
  "regionId": "'$aws_region_id'"
}' | jq "."

```

A snippet of the response shows the flavor profile ID.

```

...
  "externalRegionId": "us-east-1",
  "name": "aws-flavor-profile",
  "description": "Example AWS Compute flavors",
  "id": "835249077934b47558eca5963e068",
  "updatedAt": "2022-04-02",

```

...

Create a flavor mapping for a vSphere cloud account.

1. Assign the required variables including the cloud account ID for a vSphere cloud account.

```
$ url='https://appliance.domain.com'
$ api_version=' 2021-07-15'
$ cloud_account_id='c8c3c9bfdb449475-7f703c5265a63d87-5fa34c478df36b060e1ca3551254c4033
01
3bf3283908e4661cd1c6fb2f8b9ae-ce5aad01092b47558644f6b6615d'
```

2. Look up region IDs associated with the cloud account and in the external region ID Datacenter:datacenter-2.

```
$ curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer
$access_token" "$url/iaas/api/regions/?apiVersion=$api_version&'$filter'"=externalRegionId%20eq%20'Datacenter:datacenter-2'
%20and%20cloudAccountId%20eq%20'$cloud_account_id'"' | jq ".
```

A snippet of the response shows the region ID.

...

```
"externalRegionId": "Datacenter:datacenter-2",
"cloudAccountId": "c8c3c9bfdb449475-7f703c5265a63d87-
d06bf79904ce5096492a2a2fc557fb0457d7d3c5b5e7ae20b29957788812bb3d-

"id": "2aaaf79b789eee8755724592b06d39",
"updatedAt": " 2022-04-02",
...
```

3. Assign the vSphere region ID.

```
$ vsphere_region_id='2aaaf79b789eee8755724592b06d39'
```

4. Create a vSphere flavor profile named vcenter-flavor-profile.

```
$ curl -X POST \
```

```
$url/iaas/api/flavor-profiles?apiVersion=$api_version \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
  "name": "vcenter-flavor-profile",
  "description": "Example vSphere Compute flavors",
  "flavorMapping": {
    "small": {
      "cpuCount": 1,
      "memoryInMB": 1024
    }
  }
}'
```

```

} ,
"medium": {
  "cpuCount":2,
  "memoryInMB": 2048
},
"large": {
  "cpuCount":4,
  "memoryInMB": 4096
}
},
"regionId":"'${vsphere_region_id}'"
} ' | jq "."

```

A snippet of the response shows the flavor profile ID.

```

...
"externalRegionId": "Datacenter:datacenter-2",
"name": "vcenter-flavor-profile",
"description": "Example vSphere Compute flavors",
"id": "cfb7246505319275572e9e68372d0",
"updatedAt": " 2022-04-02",
...

```

Create a flavor mapping with an Azure cloud account ID.

1. Assign the required variables including the cloud account ID for an Azure cloud account.

```

$ url='https://appliance.domain.com'
$ api_version=' 2021-07-15'
$ cloud_account_id='c8c3c9bfd449475-7f703c5265a63d87-5fa34c478df36b060e1ca3551254c4033
01
3bf3283908e4661cd1c6fb2f8b9ae-ce5aad01092b47558644f6b6615d'

```

2. Look up region IDs associated with the cloud account and in the external region ID us-east-1.

```

$ curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer
$access_token" "$url/iaas/api/regions/?apiVersion=$api_version&'$filter'"=externalRegionId%20eq%20'us-
east-1'%20and%20cloudAccountId%20eq%20'$cloud_account_id''" | jq "."

```

A snippet of the response shows the region ID.

```

...
    "externalRegionId": "us-east-1",
    "cloudAccountId":
"c8c3c9bfdb449475-7f703c5265a63d87-5fa34c478df36b060e1ca3551254c4033013bf3283908e4661
cd1c6fb2f8b9ae-ce5aad01092b47558644f6b6615d",
    "id": "37d6c1acf4a8275586468873c739",
    "updatedAt": " 2022-04-02",
...

```

3. Assign the Azure region ID.

```
$ azure_region_id='37d6c1acf4a8275586468873c739'
```

4. List all fabric flavors.

```
$ curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer
$access_token" "$url/iaas/api/fabric-flavors/?apiVersion=$api_version" | jq "."
```

A snippet of the response shows a fabric flavor name with its resource size.

```
...
```

```
{
    "id": "Standard_A0",
    "name": "Standard_A0",
    "cpuCount": 1,
    "memoryInMB": 768,
    "bootDiskSizeInMB": 1047552,
    "dataDiskSizeInMB": 20480,
    "dataDiskMaxCount": 1
},
```

```
...
```

5. Select fabric flavor names with resources that fit your needs and create an Azure flavor profile named `azure-flavor-profile`.

```
$ curl -X POST \
$url/iaas/api/flavor-profiles?apiVersion=$api_version \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
    "name": "azure-flavor-profile",
    "description": "Example Azure Compute flavors",
    "flavorMapping": {
        "small": {

```

```

    "name": "Standard_A0"
  },
  "medium": {
    "name": "Standard_A1"
  },
  "large": {
    "name": "Standard_A2"
  }
},
"regionId": "'$azure_region_id'"
} ' | jq "."

```

A snippet of the response shows the flavor profile ID.

```

...
"externalRegionId": "us-east-1",
"name": "azure-flavor-profile",
"description": "Example Azure Compute flavors",
"id": "4965d34c3bfe0275574bc6e505b78",
"updatedAt": "2022-04-02",
...

```

Create Image Mappings

To create an image mapping, you make a POST request with a region ID associated with a cloud account. The cloud account can be an AWS, vSphere, Azure, or GCP cloud account.

- Verify that all general prerequisites and prerequisites for the Automation Assembler Infrastructure as a Service (IaaS) service have been satisfied. See [Prerequisites for API Use Case Examples](#).
- Verify that you have the cloud account ID for the new cloud account that you added. See [Adding Cloud Accounts](#).

Cloud vendors use images to configure a VM based on OS settings, such as an ubuntu-16 configuration. When you build a cloud template, you pick an image that fits your needs and map an image name to a value for each account or region. You can also add constraints and configuration scripts to further control resource placement.

The same API calls create an image profile for an AWS, vSphere, Azure, or GCP cloud account. The following example shows how to create an image profile for a vSphere cloud account with the external region ID Datacenter:datacenter-3.

- Assign the cloud account ID variable.

```
cloud_account_id='<your_cloud_account_id>'
```

- Look up region IDs associated with the cloud account and in the external region ID.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/regions/?apiVersion=$api_version&'$filter'"=externalRegionId%20eq%20'Datacenter:datacenter-3'%20and%20cloudAccountId%20eq%20'$cloud_account_id''" | jq ".."
```

3. Examine the response to find the ID for the region that you want.

4. Assign the region ID variable.

```
region_id='<your_region_id>'
```

5. Create an image profile with an image mapping that specifies the OVA/OVF links.

```
curl -X POST \
    $url/iaas/api/image-profiles?apiVersion=$api_version \
    -H 'Content-Type: application/json' \
    -H "Authorization: Bearer $access_token" \
    -d '{
        "name": "<your_image_profile>",
        "description": "<your_image_profile_description>",
        "imageMapping": {
            "ubuntu": {
                "externalId": "https://cloud-images.ubuntu.com/releases/16.04/
release-20220305/ubuntu-16.04-server-cloudimg-amd64.ova"
            }
        },
        "regionId": "'$region_id'"
    }' | jq ".."
```

6. To obtain the image profile ID, examine the response.

Create image mapping

Assign the required variables including a cloud account ID.

```
$ url='https://appliance.domain.com'
$ api_version=' 2021-07-15'
$ cloud_account_id='ff4e7585-4197-41fb-89cb-179ef4d24779'
```

Look up region IDs associated with the cloud account and in the external region ID Datacenter:datacenter-3.

```
$ curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/regions/?apiVersion=$api_version&'$filter'"=externalRegionId%20eq%20'Datacenter:datacenter-3'%20an
d%20cloudAccountId%20eq%20'$cloud_account_id''" | jq ".."
```

A snippet of the response shows the region ID.

```
...
  "externalRegionId": "Datacenter:datacenter-3",
  "name": "w01-vc08-DC",
  "cloudAccountId": "ff4e7585-4197-41fb-89cb-179ef4d24779",
  "id": "9b148b38-fc7c-4560-b413-5f47b30e57d8",
...
```

Assign the region ID.

```
$ region_id='9b148b38-fc7c-4560-b413-5f47b30e57d8'
```

Create an image profile named example-image-profile.

```
$ curl -X POST \
$url/iaas/api/image-profiles?apiVersion=$api_version \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
  "name": "example-image-profile",
  "description": "Example image profile",
  "imageMapping": {
    "ubuntu": {
      "externalId": "https://cloud-images.ubuntu.com/releases/16.04/release-20220305/ubuntu-16.04-server-cloudimg-amd64.ova"
    }
  },
  "regionId": "'$region_id'"
}' | jq ."
```

A snippet of the response shows the image profile ID.

```
...
  "externalRegionId": "Datacenter:datacenter-3",
  "cloudAccountId": "ff4e7585-4197-41fb-89cb-179ef4d24779",
  "name": "example-image-profile",
  "id": "f670fdfc-66d6-4689-9793-d524e7066d1e-9b148b38-fc7c-4560-b413-5f47b30e57d8",
...
```

Working with Networks

As a Automation Assembler administrator, you can use the IaaS APIs to create network profiles and get information about data collected and networks.

Create Network Profiles

To create a network profile, you make a POST request with a region ID associated with a cloud account.

- Verify that all general prerequisites and prerequisites for the Automation Assembler Infrastructure as a Service (IaaS) service have been satisfied. See [Prerequisites for API Use Case Examples](#).
- Verify that you have the cloud account ID for the new cloud account that you added. See [Adding Cloud Accounts](#).

A Automation Assembler network profile describes the behavior of the network to be deployed. For example, a network might need to be Internet facing versus internal only. Networks and their profiles are cloud-specific.

For information on network profiles, see [Learn more about network profiles in VMware Aria Automation](#).

The networks in this example are used for provisioning to existing or public networks. If you are working with on-demand or deployment networks, see [Using the Network APIs](#).

If you are provisioning to a private network, or outbound networks with one-way access to upstream networks, you create a network profile with isolation enabled by either subnet or security group. See [Create a Network Profile with Isolation](#).

If you want to add firewall rules to all machines provisioned with a network profile, you create a network profile with security groups. See [Create a Network Profile with Security Groups](#).

1. Assign the cloud account ID variable.

```
cloud_account_id='<your_cloud_account_id>'
```

2. Look up regions associated with the cloud account ID and with the region name us-east-1.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/regions/?apiVersion=$api_version&'$filter'"=name%20eq%20'us-east-1'%20and%20cloudAccountId%20eq%20'$cloud_account_id'"' | jq "."
```

3. Examine the response to find the ID for the region that you want.

4. Assign the region ID variable.

```
region_id='<your_region_id>'
```

5. Filter for fabric networks associated with the cloud account ID and in the external region ID us-east-1.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/fabric-networks?apiVersion=$api_version&'$filter'"="externalRegionId%20eq%20'us-east-1'%20and%20cloudAccountId%20eq%20'$cloud_account_id'"' | jq "."
```

For details on how to construct a filter, see [Filtering Resources by Region ID](#).

6. Examine the response to find the IDs for the public networks that you want to include in your network profile.

7. Create a network profile.

```
curl -X POST \
      $url/iaas/api/network-profiles?apiVersion=$api_version \
      -H 'Content-Type: application/json' \
      -H "Authorization: Bearer $access_token" \
      -d '{
```

```

"name": "<your-network-profile>",
"description": "Example Network Profile",
"regionId": "'$region_id'",
"fabricNetworkIds": [
    "<network_id1_from_response>",
    "<network_id2_from_response>"
],
"tags": [ { "key": "env", "value": "prod" } ]
}' | jq "."

```

8. To obtain the network profile ID, examine the response.

9. Assign the network profile ID variable.

```
network_profile_id='<your_network_profile_id>'
```

10. Look up the network profile you created with your network profile ID.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" $url/iaas/api/network-profiles/$network_profile_id?apiVersion=$api_version | jq "."
```

The response shows the name and ID for the network profile you created.

Create a network profile

Assign the required variables including a cloud account ID.

```
url='https://appliance.domain.com'
$ api_version='2021-07-15'
$ cloud_account_id='c8c3c9bfdb449475-7f703c5265a63d87-5fa34c478df36b060e1ca3551254c403301
3bf3283908e4661cd1c6fb2f8b9ae-ce5aad01092b47558644f6b6615d'
```

Look up region IDs associated with the cloud account and in the external region ID us-east-1.

```
$ curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/regions/?apiVersion=$api_version&$filter='externalRegionId%20eq%20'us-east-1'%20and%20cloudAccountId%20eq%20'$cloud_account_id'" | jq "."
```

A snippet of the response shows the region ID.

```
...
"externalRegionId": "us-east-1",
"cloudAccountId":
"c8c3c9bfdb449475-7f703c5265a63d87-5fa34c478df36b060e1ca3551254c4033013bf3283908e4661cd1c6
fb2f8b9ae-ce5aad01092b47558644f6b6615d",
"id": "37d6c1acf4a8275586468873c739",
```

```
"updatedAt": "2022-04-02",
```

...

Assign the region ID.

```
$ region_id='37d6c1acf4a8275586468873c739'
```

Filter for fabric networks associated with the cloud account ID and in the external region ID us-east-1.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" $url/iaas/api/fabric-networks?apiVersion=$api_version | jq "."
```

A snippet of the response shows the fabric network ID for a public network that you can include in your network profile.

...

```
"isPublic": true,
"isDefault": true,
"cidr": "172.31.16.0/20",
"externalRegionId": "us-east-1",
"tags": [
  {
    "key": "vmware.enumeration.type",
    "value": "ec2_subnet"
  }
],
"cloudAccountIds": [
  "c8c3c9bfdb449475-7f703c5265a63d87-f8e705d89b2569e1aac66c6d00bf4fc7ef4b1c44100f0e944af31eb8ba3d2a5a-5a45a4b9d5c72475575931611aa28",

    "d43efed364ef18755759316540e3f"
  ],
  "tags": [ { "key": "env", "value": "prod" } ]
}' | jq ".'
```

A snippet of the response shows the network profile ID.

```
...
{
  "name": "example-network-profile",
  "description": "Example Network Profile",
  "id": "9cb2d111c768927558f043ec13d70",
  "updatedAt": " 2022-04-02",
...
}
```

Create a Network Profile with Isolation

To create either private networks without access to outside networks or outbound networks with one-way access to upstream networks, you create a network profile with isolation and specify the isolation type.

- Verify that all general prerequisites and prerequisites for the Automation Assembler Infrastructure as a Service (IaaS) service have been satisfied. See [Prerequisites for API Use Case Examples](#).
- Verify that you have the cloud account ID for the new cloud account that you added. See [Adding Cloud Accounts](#).
- Verify that you have the region ID for the regions you want to include in the profile. See the procedure in [Create Network Profiles](#).
- For simplicity, examples use `us-east-1` as the external region ID.
- Verify that you have the IDs for the non-public fabric networks you want to include in the profile. See the procedure in [Create Network Profiles](#).

This procedure provides the steps to create a network that supports isolation using a subnet, and includes optional steps that show how to create the network using an external subnet, security groups, or a VLAN transport zone. The network profile that uses a VLAN transport zone only supports private networks.

1. Assign the cloud account ID variable.

```
cloud_account_id='<your_cloud_account_id>'
```

2. Assign the region ID variable.

```
region_id='<your_region_id>'
```

3. Filter for network domains associated with the cloud account ID and in the external region ID us-east-1.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/network-domains?apiVersion=$api_version&'$filter='externalRegionId%20eq%20'us-east-1'%20and%20cloudAccountId%20eq%20'$cloud_account_id'" | jq "."
```

4. Examine the response to find the IDs for the network domain that you want to include in your network profile. If you are creating a network profile with a VLAN transport zone, select a network domain that has the custom property "__transportZoneTrafficType": "VLAN_BACKED".

5. Create a network profile that supports isolation using a subnet and IDs for a non-public network.

```
curl -X POST \
$url/iaas/api/network-profiles?apiVersion=$api_version \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
  "name": "<your-network-profile-with-isolation-by-subnet>",
  "description": "Example Network Profile",
  "regionId": "'$region_id'",
  "isolationType" : "SUBNET",
  "isolationNetworkDomainId" : "<network_domain_id_from_response>",
  "isolatedNetworkCIDRPrefix" : "27",
  "fabricNetworkIds": [
    "<non_public_network_id1>",
    "<non_public_network_id2>"
  ],
  "tags": [ { "key": "env", "value": "prod" } ]
}' | jq "."
```

The response shows the name and ID for the network profile you created.

6. Create a network profile that supports isolation using an external subnet.

```
curl -X POST \
$url/iaas/api/network-profiles?apiVersion=$api_version \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
```

```

"name": "<your-network-profile-with-isolation-by-external-subnet>",
"description": "Example Network Profile",
"regionId": "'$region_id'",
"isolationType" : "SUBNET",
"isolationNetworkDomainId" : "<network_domain_id_from_response>",
"isolatedNetworkCIDRPrefix" : "27",
"isolationExternalFabricNetworkId": "<non_public_network_id1>",
"fabricNetworkIds": [
    "<non_public_network_id1>",
    "<non_public_network_id2>"
],
"tags": [ { "key": "env", "value": "prod" } ]
}' | jq "."

```

The response shows the name and ID for the network profile you created.

7. Create a network profile that supports isolation using security groups.

```

curl -X POST \
$url/iaas/api/network-profiles?apiVersion=$api_version \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
    "name": "<your-network-profile-with-isolation-by-security-group>",
    "description": "Example Network Profile",
    "regionId": "'$region_id'",
    "isolationType" : "SECURITY_GROUP",
    "fabricNetworkIds": [
        "<non_public_network_id1>",
        "<non_public_network_id2>"
    ],
    "tags": [ { "key": "env", "value": "prod" } ]
}' | jq "."

```

The response shows the name and ID for the network profile you created.

Create various types of network profiles with isolation

The following examples include the requests used to create a network profiles that support isolation using:

- A subnet.
- An external subnet.
- Security groups.
- A VLAN transport zone.

Assign the required variables including a cloud account ID and a region ID.

```
$ url='https://appliance.domain.com'
$ api_version='2021-07-15'
$ cloud_account_id='c8c3c9bfdb449475-7f703c5265a63d87-5fa34c478df36b060e1ca3551254c403301
3bf3283908e4661cd1c6fb2f8b9ae-ce5aad01092b47558644f6b6615d'
$ region_id='37d6c1acf4a8275586468873c739'
```

Filter for network domains associated with the cloud account ID and in the external region ID us-east-1.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token"
"$url/iaas/api/network-domains?
apiVersion=$api_version"&"$filter='externalRegionId%20eq%20'us-
east-1'%20and%20cloudAccountId%20eq%20'$cloud_account_id'" | jq "."
```

A snippet of the response shows the ID for a network domain that you can include in your network profile.

```
...
{
  "externalId": "vpc-4511a53d",
  "name": "rainpole-dev",
  "id": "233df662ec3b4875575931653ef00",
  "createdAt": "2022-04-02",
  "updatedAt": "2022-04-02",

}
...
```

Create a Network Profile with Security Groups

To create a network profile with security groups, you make a POST request and provide security group IDs.

- Verify that all general prerequisites and prerequisites for the Automation Assembler Infrastructure as a Service (IaaS) service have been satisfied. See [Prerequisites for API Use Case Examples](#).
- Verify that you have the cloud account ID for the new cloud account that you added. See [Adding Cloud Accounts](#).
- Verify that you have the region ID for the regions you want to include in the profile. See the procedure in [Create Network Profiles](#).
- Verify that you have the IDs for the networks you want to include in the profile. See the procedure in [Create Network Profiles](#).

You create a network profile with security groups so that you can add firewall rules to all machines provisioned with that network profile.

- Assign the region ID variable.

```
region_id='<your_region_id>'
```

- Filter for security groups associated with the cloud account ID and in the external region ID us-east-1.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer
$access_token" "$url/iaas/api/security-groups?
apiVersion=$api_version&'$filter='externalRegionId%20eq%20'us-
east-1'%20and%20cloudAccountId%20eq%20'$cloud_account_id'" | jq "."

```

- Examine the response to find the IDs for the security groups that you want to include in your network profile.

4. Create a network profile with security groups using network IDs for a non-public network.

```
curl -X POST \
  $url/iaas/api/network-profiles?apiVersion=$api_version \
  -H 'Content-Type: application/json' \
  -H "Authorization: Bearer $access_token" \
  -d '{
    "name": "example-network-profile-with-security-groups",
    "description": "Example Network Profile",
    "regionId": "'$region_id'",
    "fabricNetworkIds": [
      "<network_id1>",
      "<network_id1>"
    ],
    "securityGroupIds": [
      "<security_group_id1_from_response>",
      "<security_group_id2_from_response>"
    ],
    "tags": [ { "key": "env", "value": "prod" } ]
}' | jq "."

```

The response shows the name and ID for the network profile you created.

Create a network profile with security groups

Assign the required variables including a cloud account ID and a region ID.

```
$ url='https://appliance.domain.com'

$ api_version='2021-07-15'

$ cloud_account_id='c8c3c9bfdb449475-7f703c5265a63d87-5fa34c478df36b060e1ca3551254c403301
3bf3283908e4661cd1c6fb2f8b9ae-ce5aad01092b47558644f6b6615d'

$ region_id='37d6c1acf4a8275586468873c739'
```

Filter for security groups associated with the cloud account ID and in the external region ID us-east-1.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token"
"$url/iaas/api/security-groups?
apiVersion=$api_version&'$filter='externalRegionId%20eq%20'us-
east-1'%20and%20cloudAccountId%20eq%20'$cloud_account_id'" | jq "."

```

A snippet of the response shows the ID for a security group that you can include in your network profile.

```

"updatedAt": " 2022-04-02",
...

```

Using the Network APIs

As a Automation Assembler administrator, you must understand the difference between using the fabric network APIs and the network APIs.

You use the fabric network APIs such as `/iaas/api/fabric-networks/` to get information about existing networks that you use to create a network profile.

You use the network APIs such as `/iaas/api/networks/` to get information about on-demand networks that are provisioned with a deployment. If provisioned, you can check these networks in the Automation Assembler UI by going to **Resources** > **Deployments**.

To see a list of both public and on-demand networks in the Automation Assembler UI, go to **Infrastructure** > **Resources** > **Networks**.

Creating Storage Profiles

Using different input variables, you can use the Automation Assembler IaaS API to create storage profiles for AWS, vSphere, or Azure cloud accounts.

A Automation Assembler storage profile describes the kind of storage to be deployed. Storage is usually profiled according to characteristics such as service level or cost, performance, or purpose, such as backup.

As a cloud administrator, you organize your storage profiles under cloud-specific regions. One cloud account can have multiple regions, with multiple storage profiles under each. Using a storage profile, you define your storage for the region.

Storage profiles include disk customizations, and a means of identifying the type of storage by capability tags. Tags are matched against provisioning service request constraints to create the desired storage at deployment time.

Create an Amazon Web Services Storage Profile

To create a storage profile, you make a POST request with a region ID associated with a cloud account. The request body includes an Amazon Web Services fabric volume type.

- Verify that all general prerequisites and prerequisites for the Automation Assembler Infrastructure as a Service (IaaS) service have been satisfied. See [Prerequisites for API Use Case Examples](#).

- Verify that you have the cloud account ID for the new cloud account that you added. See [Adding Cloud Accounts](#).

As an alternative to using the `storage-profiles` API call to create an Amazon Web Services storage profile, you can also use the `storage-profiles-aws` API call. Optional procedure steps show how to use the `storage-profiles-aws` API call. The example only includes the steps required to create an Amazon Web Services storage profile using the `storage-profiles` API call.

- Assign the cloud account ID variable.

```
aws_cloud_account_id='<your_cloud_account_id>'
```

- Look up region IDs associated with the cloud account and in the external region ID `us-east-1`.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/regions/?apiVersion=$api_version&'$filter'"=externalRegionId%20eq%20'us-east-1'%20and%20cloudAccountId%20eq%20'$aws_cloud_account_id'"' | jq ".."
```

- Examine the response to find the ID for the region that you want.

- Assign the region ID variable.

```
aws_region_id='<your_region_id>'
```

- List all Amazon Web Services fabric volume types.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/fabric-aws-volume-types/?apiVersion=$api_version" | jq ".."
```

- To select a volume type, examine the response.

- Create a storage profile for the selected region.

```
curl -X POST \
    $url/iaas/api/storage-profiles?apiVersion=$api_version \
    -H 'Content-Type: application/json' \
    -H "Authorization: Bearer $access_token" \
    -d '{
        "defaultItem": false,
        "supportsEncryption": false,
        "tags": [ { "key": "env", "value": "dev" } ],
        "diskProperties": {
            "deviceType": "ebs",
            "volumeType": "<volume_type_from_response>",
            "iops": "400"
        },
        "regionId": "'$region_id'",
        "name": "<your-aws-storage-profile>",
    }'
```

```
"description": "Example AWS storage profile"
} ' | jq "."
```

8. Create a storage profile for the selected region using the `storage-profiles-aws` API call.

```
curl -X POST \
$url/iaas/api/storage-profiles-aws?apiVersion=$api_version \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
  "defaultItem": false,
  "supportsEncryption": false,
  "tags": [ { "key": "env", "value": "dev" } ],
  "deviceType": "ebs",
  "volumeType": "<volume_type_from_response>",
  "iops": "1000",
  "regionId": "'$region_id'",
  "name": "<your-aws-storage-profile>",
  "description": "Example AWS storage profile"
}' ' | jq "."
```

9. To obtain the storage profile ID, examine the response.

10. Assign the storage profile ID variable.

```
aws_storage_profile_id='<your_storage_profile_id>'
```

11. Look up the storage profile you created with your storage profile ID.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" $url/iaas/api/storage-profiles/$aws_storage_profile_id?
apiVersion=$api_version | jq "."
```

The response shows the name and ID for the storage profile you created.

NOTE

Using the external region ID and the cloud account ID, you can also filter for the storage profile with a query that does not require the storage profile ID. See [Filtering Resources by Region ID](#).

12. List all storage profiles using the `storage-profiles-aws` API call.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" $url/iaas/api/storage-profiles-aws?apiVersion=$api_version | jq "."
```

13. Delete an Amazon Web Services storage profile. Alternatively, you can use the `storage-profiles-aws` API call.

```
curl -X DELETE -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" $url/iaas/api/storage-profiles/$aws_storage_profile_id?apiVersion=$api_version | jq ".."
```

Create an Amazon Web Services storage profile

Assign the required variables including the cloud account ID for an Amazon Web Services cloud account.

```
$ url='https://appliance.domain.com'
```

```
$ api_version='2021-07-15'
```

```
$ aws_cloud_account_id='c8c3c9bfb449475-7f703c5265a63d87-5fa34c478df36b060e1ca3551254c4033013bf3283908e4661cd1c6fb2f8b9ae-ce5aad01092b47558644f6b6615d'
```

Look up region IDs associated with the cloud account and in the external region ID us-east-1.

```
$ curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/regions/?apiVersion=$api_version&$filter='externalRegionId%20eq%20'us-east-1'%20and%20cloudAccountId%20eq%20'$aws_cloud_account_id'" | jq ".."
```

Create a vSphere Storage Profile

To create a vSphere storage profile, you make a POST request with a region ID. Optional request body input includes a vSphere storage policy and a vSphere datastore.

- Verify that all general prerequisites and prerequisites for the Automation Assembler Infrastructure as a Service (IaaS) service have been satisfied. See [Prerequisites for API Use Case Examples](#).
- Verify that you have the cloud account ID for the new cloud account that you added. See [Adding Cloud Accounts](#).

As an alternative to using the `storage-profiles` API call to create a vSphere storage profile, you can also use the `storage-profiles-vsphere` API call. Optional procedure steps show how to use the `storage-profiles-vsphere` API call. The example only includes the steps required to create a vSphere storage profile using the `storage-profiles` API call.

1. Assign the cloud account ID variable.

```
vsphere_cloud_account_id='<your_cloud_account_id>'
```

2. Look up region IDs associated with the cloud account and in the external region ID

Datacenter:datacenter-10.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/regions/?apiVersion=$api_version&$filter"="externalRegionId%20eq%20'Datacenter:datacenter-10'%20and%20cloudAccountId%20eq%20'$vsphere_cloud_account_id'" | jq "."
```

3. Examine the response to find the ID for the region that you want.

4. Assign the region ID variable.

```
vsphere_region_id='<your_region_id>'
```

5. If using a vSphere storage policy, list all vSphere storage policies. If using a default storage policy, skip this step.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/fabric-vsphere-storage-policies/?apiVersion=$api_version" | jq "."
```

Examine the response and assign the vSphere storage policy ID.

```
vsphere_storage_policy_id='<your_vsphere_storage_policy_id>'
```

6. If using a vSphere datastore, list all vSphere datastores. If provisioning any datastore or cluster, skip this step.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/fabric-vsphere-datastores/?apiVersion=$api_version" | jq "."
```

Examine the response and assign the vSphere datastore ID.

```
vsphere_datastore_id='<your_vsphere_datastore_id>'
```

7. Create a vSphere storage profile.

```
curl -X POST \
      $url/iaas/api/storage-profiles?apiVersion=$api_version \
      -H 'Content-Type: application/json' \
```

```
-H "Authorization: Bearer $access_token" \
-d '{
  "name": "<your-vsphere-storage-profile>",
  "description": "Example vSphere storage profile",
  "defaultItem": true,
  "supportsEncryption": true,
  "tags": [ { "key" : "env", "value": "dev" } ],
  "diskProperties": {
    "provisioningType": "thin",
    "independent": "true",
    "persistent": "true",
    "sharesLevel": "low",
    "shares": "500",
    "limitIops": "500"
  },
  "diskTargetProperties": {
    "storagePolicyId": "'$vsphere_storage_policy_id'",
    "datastoreId": "'$vsphere_datastore_id'",
    "regionId": "'$vsphere_region_id'"
  }
}' | jq "."

```

8. To obtain the storage profile ID, examine the response.

9. Assign the storage profile ID variable.

```
vsphere_storage_profile_id='<your_storage_profile_id>'
```

10. Look up the storage profile you created with your storage profile ID.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" $url/iaas/api/storage-profiles/$vsphere_storage_profile_id?apiVersion=$api_version | jq "."
```

The response shows the name and ID for the storage profile you created.

NOTE

Using the external region ID and the cloud account ID, you can also filter for the storage profile with a query that does not require the storage profile ID. See [Filtering Resources by Region ID](#).

11. List all storage profiles using the `storage-profiles-vsphere` API call.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" $url/iaas/api/storage-profiles-vsphere?apiVersion=$api_version | jq "."

```

12. Delete a vSphere storage profile. Alternatively, you can use the `storage-profiles-vsphere` API call..

```
curl -X DELETE -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" $url/iaas/api/storage-profiles/$vsphere_storage_profile_id?apiVersion=$api_version | jq "."

```

Create vSphere storage profile

Assign the required variables including the cloud account ID for a vSphere cloud account.

```
$ url='https://appliance.domain.com'
```

```
$ api_version=' 2021-07-15'
```

```
$ vsphere cloud account id='515684ccebafe75-7f703c5265a63d87-e78aab87e9c8d5cd4cd1da1a285403f0f4e77a5240720d093e147b830b172542-23b5c527d7083675572f5099a8da0'
```

Look up region IDs associated with the cloud account and in the external region ID Datacenter:datacenter-10.

```
$ curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/regions/?apiVersion=$api_version&'$filter'"=externalRegionId%20eq%20'Datacenter:datacenter-10'%20and%20cloudAccountId%20eq%20'$vsphere_cloud_account_id'"' | jq "."

```

A snippet of the response shows the region ID.

```
...

```

```
"externalRegionId": "Datacenter:datacenter-10",
  "cloudAccountId":
"c8c3c9bfbdb449475-7f703c5265a63d87-809fe6fef311fdd63aa6dac546574aa898213265e988e34cc851db19b8c05b96-f405bb370210c875572d26445252e",
  "id": "cfb7246505319275572d26466a749",

```

Create a vSphere Storage Profile for a First Class Disk

To create a vSphere Storage Profile that supports First Class Disk (FCD) storage, you make a POST request with a region ID and you include first class as the disk type property. Optional request body input includes a vSphere storage policy and a vSphere datastore.

- Verify that all general prerequisites and prerequisites for the Automation Assembler Infrastructure as a Service (IaaS) service have been satisfied. See [Prerequisites for API Use Case Examples](#).
- Verify that you have the cloud account ID for the vSphere cloud account that you added. See [Add a Cloud Account](#).

1. Assign the cloud account ID variable.

```
vsphere_cloud_account_id='<your_cloud_account_id>'
```

2. Look up region IDs associated with the cloud account and in the external region ID Datacenter:datacenter-3.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/regions/?"
```

```
apiVersion=$api_version"&"$filter""=externalRegionId%20eq%20'Datacenter:datacenter-3'
%20and%20cloudAccountId%20eq%20'$vsphere_cloud_account_id'"'"' | jq "."
```

3. Examine the response to find the ID for the region that you want.

4. Assign the region ID variable.

```
vsphere_region_id='<your_region_id>'
```

5. If using a vSphere storage policy, list all vSphere storage policies. If using a default storage policy, skip this step.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer
$access_token" "$url/iaas/api/fabric-vsphere-storage-policies?/
apiVersion=$api_version" | jq "."
```

Examine the response and assign the vSphere storage policy ID.

```
vsphere_storage_policy_id='<your_vsphere_storage_policy_id>'
```

6. If using a vSphere datastore, list all vSphere datastores. If provisioning any datastore or cluster, skip this step.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer
$access_token" "$url/iaas/api/fabric-vsphere-datastores/?apiVersion=$api_version" |
jq "."
```

Examine the response and assign the vSphere datastore ID.

```
vsphere_datastore_id='<your_vsphere_datastore_id>'
```

7. Create a vSphere Storage Profile with the FCD property.

```
curl -X POST \
      $url/iaas/api/storage-profiles?apiVersion=$api_version \
      -H 'Content-Type: application/json' \
      -H "Authorization: Bearer $access_token" \
      -d '{
        "name": "<your_vsphere_storage_profile_with_FCD>",
        "description": "Example First Class Disk vSphere Storage Profile",
        "defaultItem": true,
        "provisioningType": "thin",
        "diskType": "firstClass",
        "regionId": "'$vsphere_region_id'",
        "tags": [ { "key": "type", "value": "fcd" } ]
      }' | jq "."
```

8. Examine the response.

- "defaultItem": true indicates that this storage profile is the default for the region.
- Tags help you to locate, manage, and work with the infrastructure resources.

Create vSphere Storage Profile with FCD storage

Assign the required variables including the cloud account ID for a vSphere cloud account.

```
$ url='https://appliance.domain.com'
$ api_version='2022-04-02'
$ vsphere_cloud_account_id='683c647b-413d-4673-a236-08b3694cd652'
```

Look up region IDs associated with the cloud account and in the external region ID Datacenter:datacenter-3.

```
$ curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token"
"$url/iaas/api/regions/?"
apiVersion=$api_version"&'$filter'"=externalRegionId%20eq%20'Datacenter:datacenter-10'%20a
nd%20cloudAccountId%20eq%20'"$vsphere_cloud_account_id""' | jq "."
```

A snippet of the response shows the region ID.

...

```
"externalRegionId": "Datacenter:datacenter-3",
"name": "Example external region name",
"cloudAccountId": "683c647b-413d-4673-a236-08b3694cd652",
"id": "0f182edc-1155-4df1-a53a-2c46be7bc373",
```

...

Assign the vSphere region ID.

```
$ vsphere_region_id='0f182edc-1155-4df1-a53a-2c46be7bc373'
```

If using a vSphere storage policy, perform the following steps.

1. List all vSphere storage policies.

```
$ curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer
$access_token" "$url/iaas/api/fabric-vsphere-storage-policies/?"
apiVersion=$api_version" | jq "."
```

A snippet of the response shows the storage policy.

...

```
"externalId": "f31f2442-8247-4517-87c2-8d69d7a6c696",
"name": "Management Storage Policy - Stretched",
"description": "Management Storage policy used for VMC stretched cluster",
"id": "4aad51f0b02b5275572d264d28490",
```

...

2. Examine the response to assign the vSphere storage policy ID.

```
$ vsphere_storage_policy_id='4aad51f0b02b5275572d264d28490'
```

If provisioning a specific datastore or cluster, perform the following steps.

1. List all vSphere datastores.

```
$ curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/fabric-vsphere-datastores/?apiVersion=$api_version" | jq ."
```

A snippet of the response shows the datastore.

```
...
    "externalId": "WorkloadDatastore",
    "name": "WorkloadDatastore",
    "id": "c4f1dd4741d05e75572d264dcc590",
    "createdAt": "2022-04-02",
    "updatedAt": "2022-04-02",
...

```

2. Examine the response to assign the vSphere datastore ID.

```
$ vsphere_datastore_id='c4f1dd4741d05e75572d264dcc590'
```

Create a vSphere Storage Profile named vsphere-storage-profile-with-FCD.

```
$ curl -X POST \
$url/iaas/api/storage-profiles?apiVersion=$api_version \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
    "name": "vsphere-storage-profile-with-FCD",
    "description": "Example First Class Disk vSphere Storage Profile",
    "defaultItem": true,
    "provisioningType": "thin",
    "diskType": "firstClass",
    "regionId": "'$vsphere_region_id'",
    "tags": [ { "key": "type", "value": "fcd" } ]
}' | jq ."
```

Included with storage profile ID, a snippet of the response shows the tags that you defined for the storage profile.

```
{
    "defaultItem": true,
    "tags": [
        {
            "key": "type",
            "value": "fcd"
        }
    ]
}
```

```

    }
],
"provisioningType": "thin",
"externalRegionId": "Datacenter:datacenter-3",
"cloudAccountId": "683c647b-413d-4673-a236-08b3694cd652",
"diskType": "firstClass",
"name": "vsphere-storage-profile-with-FCD",
"description": "Example First Class Disk vSphere Storage Profile",
"id": "6037ac02-83e0-41bb-ba6e-ed5784ae1101",
"createdAt": " 2022-04-02",
"updatedAt": " 2022-04-02",
...

```

Use the tags to create a First Class Disk. See [Create a First Class Disk](#).

Create a Microsoft Azure Storage Profile

To create a Microsoft Azure storage profile, you make a POST request with a region ID. The request body includes a Microsoft Azure fabric storage account ID.

- Verify that all general prerequisites and prerequisites for the Automation Assembler Infrastructure as a Service (IaaS) service have been satisfied. See [Prerequisites for API Use Case Examples](#).
- Verify that you have the cloud account ID for the new cloud account that you added. See [Adding Cloud Accounts](#).

As an alternative to using the `storage-profiles` API call to create a Microsoft Azure storage profile, you can also use the `storage-profiles-azure` API call. Optional procedure steps show how to use the `storage-profiles-azure` API call. The example only includes the steps required to create a Microsoft Azure storage profile using the `storage-profiles` API call.

1. Assign the cloud account ID variable.

```
azure_cloud_account_id='<your_cloud_account_id>'
```

2. Look up region IDs associated with the cloud account.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/regions/?apiVersion=$api_version&$filter='externalRegionId%20eq%20'us-east-1'%20and%20cloudAccountId%20eq%20'$zaure_cloud_account_id''" | jq ".
```

3. Examine the response to find the ID for the region that you want.
4. Assign the region ID variable.

```
azure_region_id='<your_region_id>'
```

5. List all Azure fabric storage accounts.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/fabric-azure-storage-accounts/?apiVersion=$api_version" | jq "."

```

6. To select a storage account ID, examine the response.

7. Create a storage profile for the selected region.

```
curl -X POST \
    $url/iaas/api/storage-profiles?apiVersion=$api_version \
    -H 'Content-Type: application/json' \
    -H "Authorization: Bearer $access_token" \
    -d '{
        "defaultItem": false,
        "supportsEncryption": false,
        "tags": [ { "key": "env", "value": "dev" } ],
        "diskProperties": {
            "azureOsDiskCaching": "None",
            "azureDataDiskCaching": "None"
        },
        "diskTargetProperties": { "storageAccountId": "<storage_account_id_from_response>" },
        "regionId": "'$azure_region_id'",
        "name": "<your-azure-storage-profile>",
        "description": "Example Azure storage profile"
    }' | jq "."

```

8. Create a storage profile for the selected region using the storage-profiles-azure API call.

```
curl -X POST \
    $url/iaas/api/storage-profiles-azure?apiVersion=$api_version \
    -H 'Content-Type: application/json' \
    -H "Authorization: Bearer $access_token" \
    -d '{
        "defaultItem": false,
        "supportsEncryption": false,
        "osDiskCaching": "None",
        "dataDiskCaching": "None",
        "storageAccountId": "<storage_account_id_from_response>",
    }'

```

```
"regionId": "'$azure_region_id'",  
"name": "<your-azure-storage-profile>",  
"description": "Example Azure storage profile"  
"tags": [ { "key": "env", "value": "dev" } ]  
}' | jq ".."
```

9. To obtain the storage profile ID, examine the response.

10. Assign the storage profile ID variable.

```
azure_storage_profile_id='<your_storage_profile_id>'
```

11. Look up the storage profile you created with your storage profile ID.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer  
$access_token" $url/iaas/api/storage-profiles/$azure_storage_profile_id?  
apiVersion=$api_version | jq ".."
```

The response shows the name and ID for the storage profile you created.

NOTE

Using the external region ID and the cloud account ID, you can also filter for the storage profile with a query that does not require the storage profile ID. See [Filtering Resources by Region ID](#).

12. List all Azure storage profiles using the `storage-profiles-azure` API call.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer  
$access_token" $url/iaas/api/storage-profiles-azure?apiVersion=$api_version | jq ".."
```

13. Delete a Microsoft Azure storage profile. Alternatively, you can use the `storage-profiles-azure` API call.

```
curl -X DELETE -H 'Content-Type: application/json' -H "Authorization: Bearer  
$access_token" $url/iaas/api/storage-profiles/$azure_storage_profile_id?  
apiVersion=$api_version | jq ".."
```

Create a Microsoft Azure storage profile

Assign the required variables including the cloud account ID for a Microsoft Azure cloud account.

```
$ url='https://appliance.domain.com'  
  
$ api_version=' 2021-07-15'  
  
$ azure_cloud_account_id='c8c3c9bfdb449475-7f703c5265a63d87-5fa34c478df36b060e1ca3551254  
c4033013bf3283908e4661cd1c6fb2f8b9ae-ce5aad01092b47558644f6b6615d'
```

Look up region IDs associated with the cloud account and in the external region ID us-east-1

```
$ curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token"  
"$url/iaas/api/regions/?apiVersion=$api_version&'$filter'"=externalRegionId%20eq%20'us-  
east-1'%20and%20cloudAccountId%20eq%20'$azure_cloud_account_id'"' | jq '.."
```

A snippet of the response shows the region ID.

```
...
    "externalRegionId": "us-east-1",
    "cloudAccountId":
"c8c3c9bfdb449475-7f703c5265a63d87-5fa34c478df36b060e1ca3551254c4033013bf3283908e4661cd1c6
fb2f8b9ae-ce5aad01092b47558644f6b6615d",
    "id": "37d6c1acf4a8275586468873c739",
    "updatedAt": " 2022-04-02",
...
```

Assign the Azure region ID.

```
$ azure_region_id='37d6c1acf4a8275586468873c739'
```

List all fabric storage accounts.

```
$ curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token"
"$url/iaas/api/fabric-azure-storage-accounts/?apiVersion=$api_version" | jq "."
```

A snippet of the response shows the storage accounts.

```
...
    "externalId": "/subscriptions/b8ef63a7-a5e3-44fa-8745-1ead33fa1f25/resourceGroups/
default-rg/providers/Microsoft.Storage/storageAccounts/azbasicsa80370",
    "name": "azbasicsa80370",
    "id": "f81c26bf-51b1-49cc-865c-de2ab3821c1d",
...
```

Select storage account ID and create an Azure storage profile named `azure-storage-profile`.

```
$ curl -X POST \
$url/iaas/api/storage-profiles?apiVersion=$api_version \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
    "defaultItem": false,
    "supportsEncryption": false,
    "tags": [ { "key": "env", "value": "dev" } ],
    "diskProperties": {
        "azureOsDiskCaching": "None",
        "azureDataDiskCaching": "None"
    },
    "diskTargetProperties": { "storageAccountId": "f81c26bf-51b1-49cc-865c-de2ab3821c1d" },
    "regionId": "'$azure_region_id'",
}
```

```
"name": "azure-storage-profile",
"description": "Example Azure storage profile"
}' | jq "."

```

A snippet of the response shows the storage profile ID.

```
...
"externalRegionId": "us-east-1",
"name": "azure-storage-profile",
"description": "Example Azure storage profile",
"id": "f83d0fd4-45de-4ca7-a699-c98bc141ecaa",
"createdAt": "2022-04-02",
"updatedAt": "2022-04-02",
...

```

Create a Microsoft Azure Storage Profile for a Managed Disk

To create a Microsoft Azure storage profile for a managed disk, you make a POST request with a region ID and include disk properties to specify the managed disk type.

- Verify that all general prerequisites and prerequisites for the Automation Assembler Infrastructure as a Service (IaaS) service have been satisfied. See [Prerequisites for API Use Case Examples](#).
- Verify that you have the cloud account ID for the new cloud account that you added. See [Adding Cloud Accounts](#).

- Assign the cloud account ID variable.

```
azure_cloud_account_id='<your_cloud_account_id>'
```

- Look up region IDs associated with the cloud account and in the external region ID eastus.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/regions/?apiVersion=$api_version&'$filter'"=externalRegionId%20eq%20'eastus'%20and%20cloudAccountId%20eq%20'"$zaure_cloud_account_id"" | jq "."

```

- Examine the response to find the ID for the region that you want.

- Assign the region ID variable.

```
azure_region_id='<your_region_id>'
```

- Create a storage profile for the selected region.

```
curl -X POST \
$url/iaas/api/storage-profiles?apiVersion=$api_version \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
```

```

"defaultItem": false,
"supportsEncryption": false,
"tags": [ { "key": "type", "value": "managed" } ],
"diskProperties": {
    "azureManagedDiskType": "Standard_LRS",
    "azureOsDiskCaching": "ReadWrite",
    "azureDataDiskCaching": "ReadWrite"
},
"regionId": "'$azure_region_id'",
"name": "<your-azure-managed-disk-storage-profile>",
"description": "Example Azure managed disk"
} ' | jq "."

```

6. To obtain the storage profile ID, examine the response.

7. Assign the storage profile ID variable.

```
azure_storage_profile_id='<your_storage_profile_id>'
```

8. Look up the storage profile you created with your storage profile ID.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" $url/iaas/api/storage-profiles/$azure_storage_profile_id?apiVersion=$api_version | jq "."
```

The response shows the name and ID for the storage profile you created.

NOTE

Using the external region ID and the cloud account ID, you can also filter for the storage profile with a query that does not require the storage profile ID. See [Filtering Resources by Region ID](#).

Create a Microsoft Azure storage profile

Assign the required variables including the cloud account ID for a Microsoft Azure cloud account.

```
$ url='https://appliance.domain.com'
$ api_version=' 2021-07-15 '
$ azure_cloud_account_id='c8c3c9bfdb449475-7f703c5265a63d87-5fa34c478df36b060e1ca3551254
c4033013bf3283908e4661cd1c6fb2f8b9ae-ce5aad01092b47558644f6b6615d'
```

Look up region IDs associated with the cloud account and in the external region ID `eastus`

```
$ curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/iaas/api/regions/?apiVersion=$api_version&"'$filter'='externalRegionId%20eq%20'us-east-1'%20and%20cloudAccountId%20eq%20'$azure_cloud_account_id'"'" | jq "."
```

A snippet of the response shows the region ID.

```
...
  "externalRegionId": "eastus",
  "cloudAccountId": "c8c3c9bfdb449475-7f703c5265a63d87-5fa34c478df36b060e1ca3551254c4033013bf3283908e4661cd1c6fb2f8b9ae-ce5aad01092b47558644f6b6615d",
  "id": "20d6c1abc4a8275586468873c721",
  "updatedAt": "2022-04-02",
...
```

Assign the Azure region ID.

```
$ azure_region_id='20d6c1abc4a8275586468873c721'
```

Create a Microsoft Azure storage profile named `azure-with-managed-disks-storage-profile`.

```
$ curl -X POST \
$url/iaas/api/storage-profiles?apiVersion=$api_version \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
  "defaultItem": false,
  "supportsEncryption": false,
  "tags": [ { "key": "type", "value": "managed" } ],
  "diskProperties": {
    "azureManagedDiskType": "Standard_LRS",
    "azureOsDiskCaching": "ReadWrite",
    "azureDataDiskCaching": "ReadWrite"
  },
  "regionId": "'$azure_region_id'",
  "name": "azure-with-managed-disks-storage-profile",
  "description": "Example Azure with managed disks storage profile"
}' | jq ."
```

A snippet of the response shows the storage profile ID.

```
...
  "externalRegionId": "eastus",
  "name": "azure-with-managed-disks-storage-profile",
  "description": "Example Azure with managed disks storage profile",
  "id": "f83d0fd4-45de-4ca7-a699-c20bc121abcd",
```

```
"createdAt": "2022-04-02",
"updatedAt": "2022-04-022021-08-02",
...
```

Managing Your Projects Using the Project APIs

Managing Your Projects

You use the Project APIs to manage projects that can be used in any of the Automation component services. In addition to basic operations such as creating, updating, or deleting projects, you can use the Project APIs to modify principals assigned to a project or modify a project cost.

Create a Project with the Project Service API

Using the Project Service API, you can create a project. You can also modify or delete a project and list all projects in an organization.

- Verify that all general prerequisites and prerequisites for the Project service have been satisfied. See [Prerequisites for API Use Case Examples](#).
- Verify that the project roles that you plan to assign have sufficient permissions to perform project-related tasks.

NOTE

A user with the project administrator or project member role can perform a limited number of project-related tasks. For a complete list of tasks and roles required, see [Organization and service user roles in VMware Aria Automation](#).

- Prepare parameters including the project name, description, and email addresses for administrators, members, or viewers.

Before creating a project, it is a good practice to get a list of projects so that you can verify that the project you plan to create does not exist. Then you create the project with users assigned to project roles.

1. Get a list of projects.

```
curl -X GET -H 'Accept: application/json' -H "Authorization: Bearer $access_token"
"$url/project-service/api/projects?apiVersion=$api_version" | jq "."
```

2. To verify that the project you plan to create is not already listed, examine the response.

3. Assign the project name variable.

```
project_name='<your_project_name>'  
your_project_name is a name that you choose.
```

4. Create a project.

```
curl -X POST \
"$url/project-service/api/projects?apiVersion=$api_version" \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
  "name" : "'$project_name'",
```

```

"description" : "your-description",
"administrators" : [{ "email" : "<admin_email>", ["type" : <"user" | "group">] }],
"members" : [{ "email" : "<member_email>", ["type" : <"user" | "group">] }],
"viewers" : [{ "email" : "<viewer_email>", ["type" : <"user" | "group">] }],
}' | jq "."

```

- *admin_email*, *member_email*, and *viewer_email* are email addresses of an administrator, member, and viewer user or name of the group in the project.
- The type parameter is optional. It assigns the administrator, member, or viewer to a user or group type. If unspecified, the value defaults to user.

Create a Project

Create a project named `Example-project` with administrators, members, and viewers at `mycompany.com`. This example assumes that `Example-project` does not exist.

```

$ url='https://appliance.domain.com'
$ api_version='2019-01-15'
$ project_name='Example-project'

Create a project with an administrator, member, and viewer assigned to user type roles.

$ curl -X POST \
"$url/project-service/api/projects?apiVersion=$api_version" \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
  "name" : "'$project_name'",
  "description" : "This is an example project",
  "administrators" : [{"email" : "adminX@mycompany.com", "type" : "user"}],
  "members" : [{"email" : "memberX@mycompany.com", "type" : "user"}],
  "viewers" : [{"email" : "viewerX@mycompany.com", "type" : "user"}]
}' | jq "."

```

The response shows the administrators, members, and viewers related to the project and the project ID.

```
{
  "id": "094a2fab-7715-4844-94f9-71b45452da27",
  "name": "Example-project",
  "description": "This is an example project",
  "orgId": "f670fdfc-66d6-4689-9793-d524e7066d1e",
}
```

```
"administrators": [
  {
    "email": "adminX@mycompany.com",
    "type": "user"
  }
],
"members": [
  {
    "email": "memberX@mycompany.com",
    "type": "user"
  },
],
"viewers": [
  {
    "email": "viewerX@mycompany.com",
    "type": "user"
  }
],
"supervisors": [],
"constraints": {
  "network": {
    "conditions": []
  }
},
"properties": {},
"cost": {
  "cost": 0,
  "costSyncTime": "2019-05-13T12:47:10.624Z",
  "costUnit": "USD"
},
"operationTimeout": 0,
"sharedResources": true
},
```

...

Add Users to Your Project Using the Project Service API

As a service administrator, you can use a PATCH request to add, modify, or remove a project user.

- Verify that all general prerequisites and prerequisites for the Project service have been satisfied. See [Prerequisites for API Use Case Examples](#).
- Verify that you have the project administrator role in your project and you have the project ID. See [Create a Project with the Project Service API](#).
- Verify that the project roles that you plan to assign have sufficient permissions to perform project-related tasks.

NOTE

A user with the project administrator or project member role can perform a limited number of project-related tasks. For a complete list of tasks and roles required, see [Organization and service user roles in VMware Aria Automation](#).

- Prepare parameters including additional email addresses for administrators, members, or viewers that you want to add to the project.

1. Assign the project ID variable.

```
project_id='<your_project_id>'
```

your_project_id is the ID of the new project you created.

2. List the details of your project.

```
curl -X GET -H 'Accept: application/json' -H "Authorization: Bearer $access_token" "$url/project-service/api/projects/$project_id?apiVersion=$api_version" | jq "."
```

3. Examine the response to see the administrators and users who are already in your project.

4. Submit a request to add a new project administrator.

```
curl -X PATCH \
  "$url/project-service/api/projects/$project_id/principals?apiVersion=$api_version"
  -H 'Content-Type: application/json' \
  -H "Authorization: Bearer $access_token" \
  -d '{
    "modify" : [
      {
        "email" : "<your_new_administrator_email>",
        "role" : "administrator",
        "type" : "user"
      }
    ]
}'
```

```
} ' | jq "."
```

5. Submit a request to add a new project member.

```
curl -X PATCH \
\ "$url/project-service/api/projects/$project_id/principals?apiVersion=$api_version"
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
  "modify" : [
    {
      "email" : "<your_new_member_email>",
      "role" : "member",
      "type" : "user"
    }
  ]
}' | jq "."
```

Add Users to Your Project

For the project Example-project, add a user with the administrator role and a user with the member role at mycompany.com.

```
$ url='https://appliance.domain.com'
$ api_version='2019-01-15'
$ project_id='094a2fab-7715-4844-94f9-71b45452da27'
```

List the details of your project.

```
$ curl -X GET -H 'Accept: application/json' -H "Authorization: Bearer $access_token"
"$url/project-service/api/projects/$project_id?apiVersion=$api_version" | jq ".">
```

The response shows existing administrators, members, and viewers.

```
{
  "id": "094a2fab-7715-4844-94f9-71b45452da27",
  "name": "Example-project",
  "description": "This is an example project",
  "orgId": "f670fdfc-66d6-4689-9793-d524e7066d1e",
  "administrators": [
```

```
{  
    "email": "adminX@mycompany.com",  
    "type": "user"  
}  
  
"members": [  
    {  
        "email": "memberX@mycompany.com",  
        "type": "user"  
    },  
],  
  
"viewers": [  
    {  
        "email": "viewerX@mycompany.com",  
        "type": "user"  
    }  
]  
  
"supervisors": [],  
  
"constraints": {  
    "network": {  
        "conditions": []  
    }  
},  
  
"properties": {},  
  
"cost": {  
    "cost": 0,  
    "costSyncTime": "2019-05-13T12:47:10.624Z",  
    "costUnit": "USD"  
},  
  
"operationTimeout": 0,  
  
"sharedResources": true  
},  
...  
}
```

Add the administrator.

```
curl -X PATCH \
"$url/project-service/api/projects/$project_id/principals?apiVersion=$api_version" \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
  "modify" : [
    {
      "email" : "newadminX@mycompany.com",
      "role" : "administrator",
      "type" : "user"
    }
  ]
}' | jq ".."
```

Add the member.

```
curl -X PATCH \
"$url/project-service/api/projects/$project_id/principals?apiVersion=$api_version" \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
  "modify" : [
    {
      "email" : "newmemberX@mycompany.com",
      "role" : "member",
      "type" : "user"
    }
  ]
}' | jq ".."
```

The response lists the project including the added administrator and added member.

```
{  
  "id": "094a2fab-7715-4844-94f9-71b45452da27",  
  "name": "Example-project",

"sharedResources": true
}

```

Working with Blueprints/Cloud Templates

Working with Blueprints/Cloud Templates

To create and update cloud templates, version cloud templates, and deploy cloud templates, you use the Automation Assembler Blueprint APIs. Blueprint is the term used in the API specifications. In the product, blueprints are renamed to Automation Assembler Templates.

Create and Update a Cloud Template

To create a cloud template, you make a POST request. The request body includes the name of the new cloud template and the project ID of an existing project. To update a cloud template, you make a PUT request that changes one of the properties of the cloud template.

- Verify that all general prerequisites and prerequisites for the Automation Assembler Blueprint service have been satisfied. See [Prerequisites for API Use Case Examples](#).
- Verify that you have a project ID for the project that includes cloud zones configured to support the resource requirements of your cloud template. See [Create a Project to use in](#).

Before creating a cloud template, you get a list of cloud templates to verify that the cloud template you plan to create does not already exist. After a cloud template is created, you can update it to change the cloud template definition.

1. Assign the project ID variable.

```
project_id='<your_project_id>'
```

2. Assign your cloud template name variable.

```
cloud_template_name='<your_cloud_template_name>'
```

your_cloud_template_name is a name that you choose.

3. Get a list of cloud templates.

```
curl -X GET $url/blueprint/api/blueprints -H "Authorization: Bearer $access_token" | jq ".">
```

4. To verify that the cloud template you plan to create is not already listed, examine the response.
5. Validate the cloud template before creating it.

```

curl -X POST \
$url/blueprint/api/blueprint-validation?apiVersion=$api_version \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
  "name" : """$cloud_template_name""",
  "description" : "Basic Cloud Machine cloud template",
  "content" : "formatVersion: 1\ninputs:\n  flavor:\n    type: string\n    title: Flavor\n    description: Flavor Mapping Name\n  image:\n    type: string\n    title: Image\n    description: Image Mapping Name\n  count:\n    type: integer\n    minimum: 1\n    default: 1\n    maximum: 2\n    title: Number of Instances\nresources:\n  BasicCloudMachine:\n    type: Cloud.Machine\n    properties:\n      name: BasicCloudMachine\n      flavor: '$input.flavor'\n      image: '$input.image'\n    count: '$input.count',
  "projectId" : """$project_id""",
  "requestScopeOrg": false
}' | jq "."

```

6. Examine the response to confirm that you see "valid":true.

7. Create a new cloud template.

```

curl -X POST \
$url/blueprint/api/blueprints?apiVersion=$api_version \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
  "name" : """$cloud_template_name""",
  "description" : "Basic Cloud Machine cloud template",
  "content" : "formatVersion: 1\ninputs:\n  flavor:\n    type: string\n    title: Flavor\n    description: Flavor Mapping Name\n  image:\n    type: string\n    title: Image\n    description: Image Mapping Name\n  count:\n    type: integer\n    minimum: 1\n    default: 1\n    maximum: 2\n    title: Number of Instances\nresources:\n  BasicCloudMachine:\n    type: Cloud.Machine\n    properties:\n      name: BasicCloudMachine\n      flavor: '$input.flavor'\n      image: '$input.image'\n    count: '$input.count',
  "projectId" : """$project_id""",
  "requestScopeOrg": false
}' | jq "."

```

8. Examine the response and record the ID of your newly created cloud template.

9. Assign the cloud template ID variable.

```
cloud_template_id='<your_cloud_template_id>'
```

your_cloud_template_id is the ID of the new cloud template that you created.

- To verify that the cloud template has been created, get a list of cloud templates and filter for *your_cloud_template_name*.

```
curl -X GET $url/blueprint/api/blueprints?name=$cloud_template_name -H "Authorization: Bearer $access_token" | jq ".."
```

- To update the cloud template, use a PUT request and specify *your_cloud_template_id*.

```
curl -X PUT \
$url/blueprint/api/blueprints/$cloud_template_id?apiVersion=$api_version \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
  "name" : """$cloud_template_name""",
  "description" : "Basic Cloud Machine cloud template",
  "content" : "formatVersion: 1\ninputs:\n  flavor:\n    type: string\n    title: Flavor\n    description: Flavor Mapping Name\n  image:\n    type: string\n    title: Image\n    description: Image Mapping Name\n  count:\n    type: integer\n    minimum: 1\n    default: 1\n    maximum: 2\n    title: Number of Instances\nresources:\n  BasicCloudMachine:\n    type: Cloud.Machine\n    properties:\n      name: BasicCloudMachine\n      flavor: '$input.flavor'\n      image: '$input.image'\n      count: '$input.count'\n    tags: [\n      {\n        \"key\": \"env\", \n        \"value\": \"prod\"\n      }\n    ]\n",
  "projectId" : """$project_id""",
  "requestScopeOrg": false
}' | jq ".."
```

Create a Cloud Template and Update it

Create a cloud template named `MyExampleCloudTemplate`. This example assumes that `MyExampleCloudTemplate` does not already exist.

Assign variables.

```
$ url='https://appliance.domain.com'
$ api_version='2019-09-12'
$ project_id='394a4ccb-22c6-4ef0-8c75-8b77efbefb51'
$ cloud_template_name='MyExampleCloudTemplate'
```

Validate the cloud template.

```
$ curl -X POST \
$url/blueprint/api/blueprint-validation?apiVersion=$api_version \
```

```

-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
  "name" : """$cloud_template_name""",
  "description" : "Basic cloud machine cloud template",
  "content" : "formatVersion: 1\ninputs:\n  flavor: type: string\n  title: string\n  description: Flavor Mapping Name\n  image: type: string\n  title: string\n  description: Image Mapping Name\n  count: type: integer\n  minimum: 1\n  default: 1\n  maximum: 2\n  title: Number of Instances\nresources:\n  BasicCloudMachine: type: Cloud.Machine\n  properties:\n    name: string\n    flavor: '$input.flavor'\n    image: '$input.image'\n    count: '$input.count'",
  "projectId" : """$project_id""",
  "requestScopeOrg": false
}' | jq "."

```

Examine the response to confirm that "valid":true.

```
{
  "valid": true,
  "validationMessages": []
}
```

Create the cloud template.

```

$ curl -X POST \
$url/blueprint/api/blueprints?apiVersion=$api_version \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
  "name" : """$cloud_template_name""",
  "description" : "Basic cloud machine cloud template",
  "content" : "formatVersion: 1\ninputs:\n  flavor: type: string\n  title: string\n  description: Flavor Mapping Name\n  image: type: string\n  title: string\n  description: Image Mapping Name\n  count: type: integer\n  minimum: 1\n  default: 1\n  maximum: 2\n  title: Number of Instances\nresources:\n  BasicCloudMachine: type: Cloud.Machine\n  properties:\n    name: string\n    flavor: '$input.flavor'\n    image: '$input.image'\n    count: '$input.count'",
  "projectId" : """$project_id""",
  "requestScopeOrg": false
}' | jq "."

```

The response from your request to create the cloud template shows the cloud template ID.

```
{
  "id": "1f170637-81a3-4257-b1cd-b2219ee8034c",
  "createdAt": "2019-10-10T23:43:27.001Z",
  ...
  "selfLink": "/blueprint/api/blueprints/1f170637-81a3-4257-b1cd-b2219ee8034c"
  ...
}
```

Assign the cloud template ID variable.

```
$ cloud_template_id='1f170637-81a3-4257-b1cd-b2219ee8034c'
```

Update the cloud template to set a tag on the machine properties in the cloud template.

```
$ curl -X PUT \
$url/blueprint/api/blueprints/$cloud_template_id?apiVersion=$api_version \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
  "name" : """$cloud_template_name""",
  "description" : "Basic cloud machine cloud template",
  "content" : "formatVersion: 1\ninputs:\n  flavor:\n    type: string\n    title: Flavor\n    description: Flavor Mapping Name\n  image:\n    type: string\n    title: Image\n    description: Image Mapping Name\n  count:\n    type: integer\n    minimum: 1\n    default: 1\n    maximum: 2\n    title: Number of Instances\nresources:\n  BasicCloudMachine:\n    type: Cloud.Machine\n    properties:\n      name: BasicCloudMachine\n      flavor: '$input.flavor'\n      image: '$input.image'\n      count: '$input.count'\n      tags: []
    \\"key\\": \"env\",
    \\"value\\": \"prod\\"
  }',
  "projectId" : """$project_id""",
  "requestScopeOrg": false
}' | jq ."
```

Use the cloud template ID to version and release the cloud template to a catalog.

Setting up Policies

Setting up Policies

As a cloud administrator, you can use the Automation Service Broker APIs to create policies with rules or parameters that you apply to deployments in Automation Service Broker and Automation Assembler.

Create an Approval Policy

To add a layer of governance to deployment requests before they are run, you can create an approval policy using the Policies API. The policy controls who must agree to a deployment or Day 2 action before a request is provisioned.

- Verify that all general prerequisites and prerequisites for the Automation Service Broker Policies service have been satisfied. See [Prerequisites for API Use Case Examples](#).
- Assign an API version variable for the Approvals API.

```
api_version_approval=' 2020-11-01'
```

NOTE

The Approvals APIs and Policies APIs have different API version values. You set the API version value for the Policies APIs when you satisfied the general prerequisites.

- Verify that you know the name of the Cloud Template to which you want to apply the approval policy.

You create an approval policy based on certain deployment criteria, such as deployments created from a specific cloud template. For example, if you specify a cloud template ID, you can create a policy that requires a specified level of approval for deployments created from that cloud template.

The following procedure shows how to use the Approval API to get the cloud template ID and list approval actions for a deployment before creating the approval policy using the Policy API.

- List the cloud templates.

```
curl -X GET \
$url/approval/api/policy/data/blueprints?apiVersion=$api_version_approval \
-H "Authorization: Bearer $access_token" | jq "."

```

- Examine the response to find the ID of the cloud template for the approval policy.

- Assign the cloud template variable.

```
cloudtemplateId = "<your_cloud_template_ID>"
```

- If you do not know the actions to specify in the policy, list the IDs of deployment actions.

```
curl -X GET \
$url/approval/api/policy/data/actions?
apiVersion=$api_version_approval&search=Deployment \
-H "Authorization: Bearer $access_token" | jq "."

```

Note the action IDs.

- Create an approval policy with hard enforcement that is applied to deployments created from the cloud template with `cloudtemplateId`.

- For an approval policy, you specify `"typeId": "com.vmware.policy.approval"`
- `autoApprovalExpiry` specifies the number of days that the approvers have to act before triggering the `autoApprovalDecision`
- `level` specifies the order in which the policy is applied with values 1-99. For example, level 1 approvals are applied first, followed by level 2 approvals and so forth.

```
curl -X POST \

```

```
$url/policy/api/policies?apiVersion=$api_version \
-H "Authorization: Bearer $access_token" \

```

```
-H 'Content-Type: application/json' \
-d '{
  "name": "<your_approval_policy_name>",
  "enforcementType": "HARD",
  "typeId": "com.vmware.policy.approval"
  "definition": {
    "level": <policy_level>,
    "approverType": "USER",
    "approvalMode": "ALL_OF",
    "autoApprovalDecision": "APPROVE",
    "approvers": [
      "USER:<approver1_ID>",
      "USER:<approver2_ID>"
    ],
    "autoApprovalExpiry": <number_of_days>,
    "actions": [
      "<actionID_1>",
      "<actionID_2>",
      "<actionID_3>"
    ]
  },
  "criteria": {
    "matchExpression": [
      {
        "key": "blueprintId",
        "operator": "eq",
        "value": "'$cloudtemplateId'"
      }
    ]
  }
}' | jq "."
```

Create an approval policy

Create a policy named Sample Approval Policy to apply to deployments created from a cloud template named template-1.

Assign variables.

```
$ url='https://appliance.domain.com'
$ api_version='2020-08-25'
$ api_version_approval='2020-11-01'
```

List the cloud templates.

```
curl -X GET \
$url/approval/api/policy/data/blueprints?apiVersion=$api_version_approval \
-H "Authorization: Bearer $access_token" | jq "."
```

Examine the response to find the cloud template named template-1.

...

```
{
  "id": "77265efc-6d06-428e-9fad-3ad8f31441f3",
  "name": "template-1",
  "description": ""
}
```

...

Assign the cloud template ID variable.

```
$ cloudtemplateId = "77265efc-6d06-428e-9fad-3ad8f31441f3"
```

List the deployment actions.

```
curl -X GET \
$url/approval/api/policy/data/actions?apiVersion=$api_version_approval&search=Deployment \
-H "Authorization: Bearer $access_token" | jq "."
```

Examine the response to find the IDs of the deployment actions that you want to specify in your approval policy.

...

```
{
  "id": "Deployment.Create",
  "name": "Create",
  "description": "Create a deployment",
  "resourceType": "Deployment"
```

```

},
...
{
  "id": "Cloud.Azure.Machine.PowerOn",
  "name": "Power On",
  "description": "Power on a machine",
  "resourceType": "Cloud.Azure.Machine"
},
...
{
  "id": "Cloud.Azure.Machine.PowerOff",
  "name": "Power Off",
  "description": "Power off a machine",
  "resourceType": "Cloud.Azure.Machine"
},
...

```

Use the cloud template ID to create the approval policy of level 2 with hard enforcement named Sample Approval Policy. When a deployment is requested, users listed will act as approvers for the actions: provision, power on, and power off an Azure machine. If approvers do not act within three days, then the deployment actions are automatically approved.

```

$ curl -X POST \
$url/policy/api/policies?apiVersion=$api_version \
-H "Authorization: Bearer $access_token" \
-H 'Content-Type: application/json' \
-d '{
  "name": "Sample Approval Policy",
  "enforcementType": "HARD",
  "typeId": "com.vmware.policy.approval"
  "definition": {
    "level": 2,
    "approverType": "USER",
    "approvalMode": "ALL_OF",
    "autoApprovalDecision": "APPROVE",

```

```

"approvers": [
    "USER:mary@mycompany.com",
    "USER:susan@mycompany.com"
],
"autoApprovalExpiry": 3,
"actions": [
    "Deployment.Create",
    "Cloud.Azure.Machine.PowerOn",
    "Cloud.Azure.Machine.PowerOff"
]
},
"criteria": {
    "matchExpression": [
        {
            "key": "blueprintId",
            "operator": "eq",
            "value": "'$cloudtemplateId'"
        }
    ]
}
}' | jq "."

```

The response shows the approval policy.

```
{
    "id": "62ad2f02-0b2a-4ed8-a739-a6c40d761e49",
    "name": "Sample Approval Policy",
    "typeId": "com.vmware.policy.approval",
    "enforcementType": "HARD",
    "orgId": "d2994f92-bd52-45b1-9220-686b20944c2c",
    "definition": {
        "level": 2,
        "approverType": "USER",
        "approvalMode": "ALL_OF",

```

```

"autoApprovalDecision": "APPROVE",
"approvers": [
    "USER:mary@mycompany.com",
    "USER:susan@mycompany.com"
],
"autoApprovalExpiry": 3,
"actions": [
    "Deployment.Create",
    "Cloud.Azure.Machine.PowerOn",
    "Cloud.Azure.Machine.PowerOff"
]
},
"criteria": {
    "matchExpression": [
        {
            "key": "blueprintId",
            "operator": "eq",
            "value": "77265efc-6d06-428e-9fad-3ad8f31441f3"
        }
    ]
},
"createdAt": "2021-11-08T09:45:38.108885Z",
"createdBy": "admin@mycompany.com",
"lastUpdatedAt": "2021-11-08T09:45:38.108885Z",
"lastUpdatedBy": "admin@mycompany.com"
}

```

How to Create Resource Quota Policies

How to Create Resource Quota Policies

To limit the resource consumed by each user, project, or organization, you can create a resource quota policy using the Policies API. Applying the policy ensures that users do not consume all available resources.

With the policy defined, any new deployment requests are evaluated against the resource quota. If a resource request exceeds the quota, the deployment request fails with a message that indicates the reason for the failure. The resource quota does not apply to deployment requests that are already in-progress when the policy is defined.

In cases where multiple policies are defined for a resource at the same scope level, the request is evaluated against the quota with the lowest limit value.

For information about policy scope, see [How do I configure scope in Automation Service Broker policies](#).

The following examples show how to define a resource quota policy with:

- Organization level limits.
- Project level limits.

For both definitions, you use `POST /policy/api/policies` to create the policy with the input parameter "typeId": "com.vmware.policy.resource.quota".

Prerequisites for creating a resource quota policy

- Verify that all general prerequisites and prerequisites for the Automation Service Broker Policies service have been satisfied. See [Prerequisites for API Use Case Examples](#).
- Verify that you know the resource quotas that you want to apply.

Resource quota policy with organizational level limits

This example shows how to define a resource quota policy with hard enforcement and limits on resource consumption by the organization and each user within the organization.

```
curl -k -X POST \
"$url/policy/api/policies?apiVersion=$api_version" \
-H "Authorization: Bearer $access_token" \
-H 'Content-Type: application/json' \
-d '{
  "name": "Sample Resource Quota Policy 1",
  "enforcementType": "HARD",
  "typeId": "com.vmware.policy.resource.quota",

Resource quota policy with project level limits

This example shows how to define a resource quota policy with hard enforcement and limits on resource consumption by a project and each project user.

```

curl -k -X POST \
"$url/policy/api/policies?apiVersion=$api_version" \
-H "Authorization: Bearer $access_token" \
-H 'Content-Type: application/json' \
-d '{
    "name": "Sample Resource Quota Policy 2",
    "enforcementType": "HARD",
    "projectId": "6df55bb1-7444-4c13-9997-4004ba0a321d",
    "scopeCriteria": null,
    "typeId": "com.vmware.policy.resource.quota",
    "definition": {
        "projectLevel": {
            "limits": {
                "cpu": {
                    "value": 50
                },
                ...
            }
        }
    }
}'

```

```
"storage": {  
    "value": 80,  
    "unit": "GB"  
},  
"memory": {  
    "value": 80,  
    "unit": "GB"  
},  
"instances": {  
    "value": 40  
}  
,  
"userLevel": {  
    "limits": {  
        "cpu": {  
            "value": 5  
        },  
        "storage": {  
            "value": 8,  
            "unit": "GB"  
        },  
        "memory": {  
            "value": 8,  
            "unit": "GB"  
        },  
        "instances": {  
            "value": 4  
        }  
    }  
}  
}
```

```
 }' | jq ".."
```

The response shows the resource quota policy with project and project user level limits.

```

Create a Deployment Limit Policy

To limit resource consumption when users deploy cloud templates in Automation Assembler and request catalog items in Automation Service Broker, you can create a limit policy using the Policies API. The policy applies limits to all deployments in an organization by default.

- Verify that all general prerequisites and prerequisites for the Automation Service Broker Policies service have been satisfied. See [Prerequisites for API Use Case Examples](#).
- Assign an API version variable for the Deployment Limit API.

```
api_version_deploymentlimit='2020-11-01'
```

NOTE

The Deployment Limit APIs and Policies APIs have different API version values. You set the API version value for the Policies APIs when you satisfied the general prerequisites. The Deployment Limit APIs are grouped with the Approvals services. See <https://techdocs.broadcom.com/us/en/vmware-cis/aria/aria-automation/8-16/what-is-the-api-and-how-do-i-use-it.html>.

- Verify you know the resource criteria that you want to use to restrict the policy.

You create a deployment limit policy based on certain resource criteria, such as account names, account types, cloud templates, cloud zones, flavors, and many more. For example, if you specify a cloud template ID as the resource criteria, you can restrict the policy so that it only applies limits to deployments created from a specific cloud template.

NOTE

If approval policy or resource quota policy definitions affect deployments within the policy scope, deployment limits are enforced before the other policy types.

The following procedure shows how to use the Deployment limit API to get the cloud template ID before creating the deployment limit policy using the Policy API.

1. List the cloud templates.

```
curl -X GET \
$url/deploymentlimit/api/policy/data/blueprints?
apiVersion=$api_version_deploymentlimit \
-H "Authorization: Bearer $access_token" | jq "."
```

2. Examine the response to find the ID of the cloud template used to create the deployments where you want to limit resource usage.

3. Assign the cloud template variable.

```
cloudtemplateId = "<your_cloud_template_ID>"
```

4. Create a deployment limit policy with hard enforcement that is applied to deployments created from the cloud template with `cloudtemplateId`. For the deployment limit policy, you specify "typeId": "com.vmware.policy.deployment.limit".

```
curl -X POST \
$url/policy/api/policies?apiVersion=$api_version \
-H "Authorization: Bearer $access_token" \
-H 'Content-Type: application/json' \
-d '{
  "name": "<your_limit_policy_name>",
  "enforcementType": "HARD",
  "typeId": "com.vmware.policy.deployment.limit"
  "definition": {
    "deploymentLimits": {
      "cpu": {
        "value": 6
      },
      "memory": {
        "unit": "GB",
        "value": 5
      },
      "instances": {

```

```
"value": 3
},
"storage": {
    "unit": "GB",
    "value": "20
}
},
"deploymentResourceLimits": {
    "resources": [
        {
            "name": "vSphere-Machine-Limits",
            "limits": {
                "cpu": {
                    "value": 2
                },
                "memory": {
                    "unit": "GB",
                    "value": 2
                },
                "storage": {
                    "unit": "GB",
                    "value": "20
                }
            },
            "criteria": {
                "matchExpression": [
                    {
                        "key": "type",
                        "value": "Cloud.vSphere.Machine",
                        "operator": "eq"
                    }
                ]
            }
        }
    ]
}
```

```

        }
    }
]
},
"criteria": {
    "matchExpression": [
        {
            "key": "blueprintId",
            "operator": "eq",
            "value": "'$cloudtemplateId'"
        }
    ]
}
}
|
jq "."

```

Create a deployment limit policy

Create a deployment limit policy named Sample Limit Policy that is applied to limit resource usage in deployments created from a cloud template named template2.

Assign variables.

```
$ url='https://appliance.domain.com'
$ api_version=' 2020-08-25'
$ api_version_deploymentlimit='2020-11-01'
$ orgId='394a4ccb-22c6-4ef0-8c75-8b77efbefb51'
```

List the cloud templates.

```
$ curl -X GET \
$url/deploymentlimit/api/policy/data/blueprints?apiVersion=$api_version_deploymentlimit \
-H "Authorization: Bearer $access_token" | jq "."
```

Examine the response to find the cloud template named template2.

```
...
{
```

```
"id": "3d3c714f-0aeb-423d-a494-97e85e4a8566",
"name": "template2",
"description": "Cloud template for example deployment"
},  
...
```

Assign the cloud template ID variable.

```
$ cloudtemplateId = "3d3c714f-0aeb-423d-a494-97e85e4a8566"
```

Use the cloud template ID to create the deployment limit policy with hard enforcement named Sample Limit Policy. The value for the type ID is fixed as com.vmware.policy.deployment.limit.

```
$ curl -X POST \
$url/policy/api/policies?apiVersion=$api_version \
-H "Authorization: Bearer $access_token" \
-H 'Content-Type: application/json' \
-d '{
  "name": "Sample Limit Policy",
  "enforcementType": "HARD",
  "typeId": "com.vmware.policy.deployment.limit"
  "definition": {
    "deploymentLimits": {
      "cpu": {
        "value": 6
      },
      "memory": {
        "unit": "GB",
        "value": 5
      },
      "instances": {
        "value": 3
      },
      "storage": {
        "unit": "GB",
        "value": "20
      },
    }
  }
}'
```

```
},
"deploymentResourceLimits": {
  "resources": [
    {
      "name": "vSphere-Machine-Limits",
      "limits": {
        "cpu": {
          "value": 2
        },
        "memory": {
          "unit": "GB",
          "value": 2
        },
        "storage": {
          "unit": "GB",
          "value": "20"
        }
      },
      "criteria": {
        "matchExpression": [
          {
            "key": "type",
            "value": "Cloud.vSphere.Machine",
            "operator": "eq"
          }
        ]
      }
    }
  ],
  "criteria": {
    "matchExpression": [

```

```
{  
    "key": "blueprintId",  
    "operator": "eq",  
    "value": "'$cloudtemplateId'"  
}  
]  
}  
}  
}  
| jq "."
```

The response shows the deployment limit policy.

```
{

}

```

Create a Content Sharing Policy

As a Automation Service Broker administrator, you can create a content sharing policy that entitles all Automation Service Broker users in a project to shared content defined in the policy.

- Verify that all general prerequisites and prerequisites for the Automation Service Broker Policies service have been satisfied. See [Prerequisites for API Use Case Examples](#).

NOTE

The Policies API and the Catalog API have the same API version. You set the API version value for both services when you satisfy the prerequisites for the Policies service.

- Assign an API version variable for the Projects API.

```
api_version_projects='2019-01-15'
```

NOTE

The Projects APIs and Policies APIs have different API version values. You set the API version value for the Policies APIs when you satisfied the prerequisites for the Policies service.

The following procedure shows how to use the Policies API to create a content sharing policy that defines shared content for users or groups that are part of the same project. To get the input required for the project, project users, and project groups, you use the Projects API. To get the catalog sources or catalog items to share in the policy, you use the Catalog API.

The steps to get catalog sources or items to share are optional, because a content sharing policy may not share both sources and items. However, the policy must share at least one catalog source or item.

- Get a list of all projects in your organization.

```
curl -X GET "$url/project-service/api/projects?apiVersion=$api_version_projects" -H
"Authorization: Bearer $access_token" | jq ."
```

Examine the response to get the ID of the project for the shared policy. The project must include the users or groups for which you want to entitle content. See [Create a Project with the Project Service API](#).

2. Assign the project ID variable.

```
project_id='<your_project_id>'
```

3. Get a list of users in the project.

```
curl -X GET \
$url/project-service/api/projects/$project_id/principals?
apiVersion=$api_version_projects&expandGroups=true& \
'$filter='"(substringof('{}",tolower(acct)))'" \
-H "Authorization: Bearer $access_token" | jq "."
```

Examine the response to get the user email addresses for the project users. Users selected in the policy are entitled to items shared with the project.

4. Get a list of groups in the project.

```
curl -X GET \
$url/project-service/api/projects/$project_id/groups?
apiVersion=$api_version_projects&page=0 \
'$filter='"(substringof('{}",tolower(displayName)))'" \
-H "Authorization: Bearer $access_token" | jq "."
```

Examine the response to get the group display name for the project users that are part of the group. Groups selected in the policy are entitled to items shared with the project.

5. Get a list of catalog sources for your project.

```
curl -X GET $url/catalog/api/admin/sources?
projectId=$project_id&apiVersion=$api_version -H "Authorization: Bearer
$access_token" | jq "."
```

Examine the response to find catalog sources that you want to share.

6. If you are sharing a catalog source, assign the catalog source ID variable.

```
catalog_source_id='<shared_catalog_source_id>'
```

7. Get a list of catalog items for your project.

```
curl -X GET $url/catalog/api/items?projectId=$project_id&apiVersion=$api_version -H
"Authorization: Bearer $access_token" | jq "."
```

Examine the response to find catalog items that you want to share.

8. If you are sharing a catalog item, the catalog item ID variable.

```
catalog_item_id='<shared_catalog_item_id>'
```

9. Create a content sharing policy with hard enforcement.

- The value for user type is always USER.
- The group's display name is always in the format `groupDisplayName@groupDomain`.

- The typeId for the content sharing policy is always com.vmware.policy.catalog.entitlement.

```
curl -X POST \  
$url/policy/api/policies?apiVersion=$api_version \  
-H "Authorization: Bearer $access_token" \  
-H 'Content-Type: application/json' \  
-d '{  
  "name": "<your_content_sharing_policy_name>",  
  "projectId": "'$project_id'",  
  "definition": {  
    "entitledUsers": [  
      {  
        "userType": "USER",  
        "principals": [  
          {  
            "type": "USER",  
            "referenceId": "<user1_email_address>"  
          },  
          {

```

Create a content sharing policy

Create a policy named Sample Sharing Policy.

Assign variables.

```
$ url='https://appliance.domain.com'
$ api_version=' 2020-08-25'
$ api_version_projects=' 2019-01-15'
```

List the projects in your organization.

```
$ curl -X GET "$url/project-service/api/projects?apiVersion=$api_version_projects" -H
"Authorization: Bearer $access_token" | jq "."

```

Examine the response to find the project that you want to use for the shared content policy.

```
{
    "id": "1d0bcd42-4d8f-4a8f-8b31-f34a4707533e",
    "name": "Example-project",
    "description": "This is an example project",
    "orgId": "f670fdfc-66d6-4689-9793-d524e7066d1e",
    ...
}
```

Assign the project ID.

```
$ project_id='1d0bcd42-4d8f-4a8f-8b31-f34a4707533e'
```

List the users in the project.

```
$ curl -X GET \
$url/project-service/api/projects/$project_id/principals?
apiVersion=$api_version_projects&expandGroups=true& \
'$filter='"(substringof('{}",tolower(acct)))'" \
-H "Authorization: Bearer $access_token" | jq "."
```

A snippet of the response shows the email addresses for the users in the project.

...

```
"content": [
{
  "id": "ab373898-d29b-4e3b-8703-58023cadd140",
  "acct": "user1@mycompany.com",
  "domain": "mycompany.com"
},
]
```

...

Get a list of groups in the project.

```
$ curl -X GET \
$url/project-service/api/projects/$project_id/groups?
apiVersion=$api_version_projects&page=0 \
'$filter='"(substringof('{}",tolower(displayName)))'" \
-H "Authorization: Bearer $access_token" | jq "."
```

A snippet of the response shows the group display name for the users that are part of the group.

...

```
"content": [
{
  "id": "a9da96e7-ba19-47d4-9f38-dd1983e29424",
  "displayName": "test@mycompany.com",
  "groupType": "USER_GROUP",
  "usersCount": 2
},
]
```

...

Get a list of catalog sources for your project.

```
$ curl -X GET $url/catalog/api/admin/sources?projectId=$project_id&apiVersion=$api_version
-H "Authorization: Bearer $access_token" | jq ."
```

Examine the response to find the catalog sources that you want to share.

...

```
"content": [
  {
    "id": "600026c6-3155-4395-a990-580ff1159e82",
    "name": "BpContent-Quality Engineering",
    "description": "For Project-Quality Engineering",
    "typeId": "com.vmw.blueprint",
    "createdAt": "2022-10-12T10:37:01.751799Z",

    "lastUpdatedBy": "system-user",
    "config": {
      "sourceProjectId": "1d0bcd42-4d8f-4a8f-8b31-f34a4707533e"
    },
  ...
]
```

Assign the ID of the catalog source to share.

```
$ catalog_source_id='600026c6-3155-4395-a990-580ff1159e82'
```

Get a list of catalog items for your project.

```
$ curl -X GET $url/catalog/api/admin/items?projectId=$project_id&apiVersion=$api_version
-H "Authorization: Bearer $access_token" | jq ."
```

Examine the response to find the catalog item.

...

```
"content": [
  {
    "id": "b2d0fba7-5f62-3c79-b1b8-a2aa7d38063b",
    "name": "CF-SQAVC67-Centos-MultiMachine",
    "description": "CF-SQAVC67-Centos-MultiMachine vsphere components, disk, networks",
    "sourceId": "600026c6-3155-4395-a990-580ff1159e82",
    "sourceName": "BpContent-Quality Engineering",
  ...
]
```

Assign the ID of the catalog item to share.

```
$ catalog_item_id='b2d0fba7-5f62-3c79-b1b8-a2aa7d38063b'
```

Create a content sharing policy with hard enforcement.

The following example shows the group's display name which is of the format `groupDisplayName@groupDomain` where:

- `groupDisplayName` is `test@mycompany.com`
- `groupDomain` is `mycompany.com`

```
$ curl -X POST \
$url/policy/api/policies?apiVersion=$api_version \
-H "Authorization: Bearer $access_token" \
-H 'Content-Type: application/json' \
-d '{
  "name": "Sample Sharing Policy",
  "projectId": "'$project_id'",
  "definition": {
    "entitledUsers": [
      {
        "userType": "USER",
        "principals": [
          {
            "type": "USER",
            "referenceId": "user1@mycompany.com"
          },
          {
            "type": "PROJECT",
            "referenceId": "'$project_id'"
          },
          {
            "type": "GROUP",
            "referenceId": "test@mycompany.com@mycompany.com"
          }
        ],
        "items": [

```

```

    {
        "id": "'$catalog_source_id'",
        "type": "CATALOG_SOURCE_IDENTIFIER"
    },
    {
        {
            "id": "'$catalog_item_id'",
            "type": "CATALOG_ITEM_IDENTIFIER"
        }
    ]
}
],
},
"enforcementType": "HARD",
"typeId": "com.vmware.policy.catalog.entitlement"
}

```

The response shows the content sharing policy.

```
{
    "id": "0cecca9a-d778-47b5-acdf-c08248406052",
    "name": "Sample Sharing Policy",
    "projectId": "1d0bcd42-4d8f-4a8f-8b31-f34a4707533e",
    "definition": {
        "entitledUsers": [
            {

```

Version and Release a Cloud Template to a VMware Aria Automation Service Broker Catalog

After creating a cloud template, you version and release your cloud template using a POST request. The request body includes the ID of an existing cloud template and the number of the version to release.

- Verify that all general prerequisites and prerequisites for the Automation Assembler Blueprint service have been satisfied. See [Prerequisites for API Use Case Examples](#).

- Verify that you have the cloud template ID for the cloud template you want to version and release. See [Create and Update a Cloud Template](#).
- Verify that you know the version of the cloud template that you want to create and release to the catalog.

By versioning and releasing the cloud template, you mark a cloud template version as ready to be consumed by VMware Aria Automation Service Broker. To show the released cloud template in VMware Aria Automation Service Broker, you must have a catalog source.

1. Assign the cloud template ID variable.

```
cloud_template_id='<your_cloud_template_id>'
```

2. Assign a cloud template version variable.

```
cloud_template_version='<your_cloud_template_version>'
```

your_cloud_template_version is the version that you want to create.

3. To version the cloud template without releasing it, submit the request with "release": false .

```
curl -X POST \
```

```
$url/blueprint/api/blueprints/$cloud_template_id/versions?apiVersion=$api_version \
-H "Authorization: Bearer $access_token" \
-H 'Content-Type: application/json' \
-d '{
  "changeLog": "Creating a version '\"$cloud_template_version\"',",
  "description": "Creating a version from the current draft",
  "release": false,
  "version": '\"'$cloud_template_version'\"'
}' | jq ".."
```

4. Release the cloud template.

```
curl -X POST \
```

```
$url/blueprint/api/blueprints/$cloud_template_id/versions/$cloud_template_version/
actions/release?apiVersion=$api_version \
-H "Authorization: Bearer $access_token" \
-H 'Content-Type: application/json' | jq ".."
```

Version and Release a Cloud Template

Release version 5 of your cloud template with ID 1f170637-81a3-4257-b1cd-b2219ee8034c.

Assign variables.

```
$ url='https://appliance.domain.com'
$ api_version='2019-09-12'
```

```
$ cloud_template_id='1f170637-81a3-4257-b1cd-b2219ee8034c'  
$ cloud_template_version='v5'  
Version the cloud template without releasing it.  
  
$ curl -X POST \  
$url/blueprint/api/blueprints/$cloud_template_id/versions?apiVersion=v5  
-H "Authorization: Bearer $access_token" \  
-H 'Content-Type: application/json' \  
-d '{  
  "changeLog": "Creating a version '$cloud_template_version'",  
  "description": "Creating a version from the current draft",  
  "release": false,  
  "version": "'$cloud_template_version'"  
}' | jq "."
```

Release the cloud template.

```
$ curl -X POST \
  $url/blueprint/api/blueprints/$cloud_template_id/versions/$cloud_template_version/
actions/release?apiVersion=$api_version \
-H "Authorization: Bearer $access_token" \
-H 'Content-Type: application/json' | jq "."
```

A snippet of the response shows the new cloud template version with a RELEASED status.

```
...
"blueprintId": "1f170637-81a3-4257-b1cd-b2219ee8034c",
"name": "MyExampleCloudTemplate",
"description": "Basic Cloud Machine cloud template",
"version": "v5",
"tags": [],
"content": "formatVersion: 1\ninputs:\n  flavor:\n    type: string\n    title: Flavor\n    description: Flavor Mapping Name\n  image:\n    type: string\n    title: Image\n    description: Image Mapping Name\n  count:\n    type: integer\n    minimum: 1\n    default: 1\n    maximum: 2\n    title: Number of Instances\nresources:\n  BasicCloudMachine:\n    type: Cloud.Machine\n    properties:\n      name: BasicCloudMachine\n      flavor: '${input.flavor}'\n      image: '${input.image}'\n      count: '${input.count}'\n      tags: [\n        {\n          \"key\": \"env\",\n          \"value\": \"prod\"\n        }\n      ]\n    ",
"status": "RELEASED",
"versionDescription": "Creating a version from the current draft",
```

```

"versionChangeLog": "Creating a version v5",
"valid": true
}

```

Edit and Version a Custom Form in Your Cloud Template

Edit and Version a Custom Form

After creating a cloud template in Automation Assembler, versioning it, and importing it into your Automation Service Broker content, you can add a custom request form. Then you can use the form designer to edit and version the form, so that you can choose the version and use it later.

- Verify that you have satisfied all general prerequisites and prerequisites for the Automation Service Broker Catalog service. See [Prerequisites for API Use Case Examples](#).
- Verify that you have versioned and released your cloud template in Automation Assembler. See [Version and Release a Cloud Template to a VMware Aria Automation Service Broker Catalog](#).
- Verify that you have imported your cloud template into Automation Service Broker. See [Add Automation Assembler templates to the Automation Service Broker catalog](#).

The following procedure assumes that your Automation Service Broker content includes a versioned Automation Assembler cloud template. Using the Catalog service API, you find the ID of the cloud template and get the cloud template schema for one of the template versions. To create a custom form from the schema, you use the Form Service API. Additional steps show how to customize and version the custom form, and how to list and restore a versioned form.

For more information about Custom Forms, see [Learn more about Automation Service Broker custom forms](#).

1. List the items in your catalog.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/catalog/api/admin/items?apiVersion=$api_version" | jq "."

```

Examine the response to find the catalog ID of the cloud template that you want to use.

2. Assign a variable for the cloud template catalog ID.

```
item_id='<cloud_template_catalog_ID>'
```

3. Get information about the catalog item.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" "$url/catalog/api/admin/items/$item_id?apiVersion=$api_version" | jq "."

```

Examine the result to choose the version of the template that you want to use for the custom form.

4. Assign a variable for the cloud template version ID.

The form that you create and customize a form will be associated with this cloud template version ID.

```
version_id='<your_cloud_template_version_ID>'
```

5. Using the catalog ID and version ID, get the schema for the the cloud template.

```
$ schema='curl -k -X GET \
"$url/catalog/api/admin/items/$item_id/versions/$version_id \
-H "Authorization: Bearer $access_token" \
-H 'Content-Type: application/json' | jq -r .schema'
```

6. Use the schema to create a custom form.

```
curl -k -X POST \
"$url/form-service/api/forms/designer/request?
sourceType=com.vmw.blueprint.version&sourceId=$item_id/
$version_id&formType=requestForm" \
-H "Authorization: Bearer $access_token" \
-H 'Content-Type: application/json' \
-d '$schema' | jq "."
```

You have a current version of your custom form.

7. Customize the form.

- *your_modified_form_json_as_string* Used to update the form field properties. For information about form field properties, see [../using-automation-service-broker/topics/service-broker-custom-forms-service-broker-custom-form-designer-field-properties.dita](#).
- *your_modified_styles_string* Used to update a cascading style sheet written in CSS Syntax Module Level 3. For information about the CSS file format, see [../using-automation-service-broker/topics/service-broker-custom-forms-learn-more-about-service-broker-custom-forms.dita](#).

```
curl -k -X POST \
-H "Authorization: Bearer $access_token" \
-H 'Content-Type: application/json' \
"$url/form-service/api/forms" \
-d '{

"name":"Demo Blueprint / 2.0.0",
"form":"<your_modified_form_json_as_string>",
"styles":"<your_modified_styles_string>",

"status":"ON", // set ON to enable the custom form, OFF to disable
"type":"requestForm",
"sourceId":"$item_id/$version_id",
"sourceType":"com.vmw.blueprint.version"
}' | jq "."
```

A response with the status 201 'Created' indicates a successful form update.

8. To save the current form with a new version name, you version the form.

```
curl -k -X POST \
"$url/form-service/api/forms/versions" \
-H "Authorization: Bearer $token" \
-H 'Content-Type: application/json' \
-d '{
```

```

"name": "<your_form_version_name>",
"sourceId": "$item_id/$version_id",
"sourceType": "com.vmw.blueprint.version",
"formType": "requestForm"
} ' | jq "."

```

The form is saved with version name.

To create more versions, you repeat the steps to customize and version the form. If you customize without versioning, the changes you make are only applied to the current form.

- If you have at least one form version in addition to the current form, you can list and restore the version that you want to use.

- To list form versions:

```

curl -k -X GET \
"$url/form-service/api/forms/versions?
sourceType=com.vmw.blueprint.version&sourceId=$item_id/
$version_id&formType=requestForm" \
-H "Authorization: Bearer $token" \
-H 'Content-Type: application/json' | jq "."

```

The response lists the names of stored form versions and their IDs or `formVersionId`.

- To restore a previously versioned form, use the `formVersionId`:

```

curl -k -X PATCH \
"$url/form-service/api/forms/versions/$formVersionId/restore" \
-H "Authorization: Bearer $token" \
-H 'Content-Type: application/json' | jq "."

```

Edit and Version a Custom Form

Edit the custom form for a cloud template with the name `Demo Blueprint`. Then version the custom form it so that you can save it to use later.

Assign variables.

```

$url='https://appliance.domain.com'
$api_version='2020-08-25'

```

List the items in your catalog.

```

curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token"
"$url/catalog/api/admin/items?apiVersion=$api_version" | jq "."

```

Examine the response to find the cloud template named `Demo Blueprint` and get the catalog ID.

[

{

```
"id": "890275e3-cbc6-3778-af0d-d9eddf4664a0",
"name": "Demo Blueprint",
"description": "",
"sourceId": "d4c24bba-68cc-4923-9155-338c4bf3e663",
"sourceName": "template-content-source",
"type": {
  "id": "com.vmw.blueprint",
  "link": "/catalog/api/types/com.vmw.blueprint",
  "name": "VMware Aria Automation Templates"
},
"createdAt": "2023-05-03T15:15:02.805617Z",
"createdBy": "user@mycompany.com",
"lastUpdatedAt": "2023-05-03T15:15:02.805617Z",
"iconId": "1495b8d9-9428-30d6-9626-10ff9281645e",
"bulkRequestLimit": 1
}
]
```

Assign the item ID variable with the catalog ID of the cloud template.

```
$ item_id='890275e3-cbc6-3778-af0d-d9eddf4664a0'
```

Get catalog information about the cloud template.

```
$ curl -X GET \
"$url/catalog/api/admin/items/$item_id?apiVersion=$api_version" \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" | jq .content
```

A snippet of the response lists the imported versions.

```
[

{
  "id": "2.0.0",
  "description": "Added numberInput field",
  "createdAt": "2023-03-29T06:19:48.748349Z",
  "externalId": "/blueprint/api/blueprints/bbbb30b8-a73a-44bb-92db-27a504e0ec85"
},
```

```
{  
  "id": "1.0.0",  
  "description": "Added stringInput field",  
  "createdAt": "2023-03-29T06:19:30.845516Z",  
  "externalId": "/blueprint/api/blueprints/bbbb30b8-a73a-44bb-92db-27a504e0ec85"  
}  
]
```

The cloud template in this example has two versions in the catalog. To get the schema and create a custom form for version 2.0.0, assign a variable.

```
$ version_id='2.0.0'
```

Use the catalog ID and the version ID to get the schema for the cloud template.

```
$ schema='curl -k -X GET \
"$url/catalog/api/admin/items/$item_id/versions/$version_id \
-H "Authorization: Bearer $access_token" \
-H 'Content-Type: application/json' | jq -r .schema'
```

Use the schema to create a custom form.

```
$ curl -k -X POST \
"$url/form-service/api/forms/designer/request?
sourceType=com.vmw.blueprint.version&sourceId=$item_id/$version_id&formType=requestForm" \
-H "Authorization: Bearer $access_token" \
-H 'Content-Type: application/json' \
-d '$schema' | jq ."
```

The response shows the schema for Demo Blueprint version 2.0.0. It also shows the form ID or 4e383140-51a4-44a7-afcd-26296079596d.

```
{  
  "tenant": "733178c1-0620-478c-96b4-2b04ece1478d",

\"scriptAction\",\"parameters\":[]},\"constraints\":{\"required\":true},\"stringInput\":
{\"label\":\"stringInput\",\"type\":{\"dataType\":\"string\",\"isMultiple\":false},
\"constraints\":{\"required\":true}},\"deploymentName\":{\"label\":\"Deployment Name\",
\"type\":{\"dataType\":\"string\",\"isMultiple\":false},\"constraints\":
{\"required\":true,\"max-value\":900}}},\"options\":{\"externalValidations\":[]}}",
"sourceType": "com.vmw.blueprint.version",
"sourceId": "890275e3-cbc6-3778-af0d-d9eddf4664a0/2.0.0",
"type": "requestForm",
"status": "ON",
"formFormat": "JSON",
"styles": ""
}

```

Update the form schema to change the visibility of the Deployment Name from true to false.

```

$ curl -k -X POST \
-H "Authorization: Bearer $access_token" \
-H 'Content-Type: application/json' \
"$url/form-service/api/forms" \
-d '{
"name":"Demo Blueprint / 2.0.0",

"form": {"layout": {"pages": [{"id": "page_general", "sections": [
{"id": "section_project", "fields": [
{"id": "project", "display": "dropDown", "signpostPosition": "right-middle", "state": {
"visible": true, "read-only": false}], {"id": "section_deploymentName", "fields": [
{"id": "deploymentName", "display": "textField", "state": {"visible": false, "read-
only": false}, "signpostPosition": "right-middle"}]]}], "schema": {"project": {
"label": "Project", "type": {"dataType": "string", "isMultiple": false}, "valueList": [
{id": "projects", "type": "scriptAction"}, {"constraints": {"required": true}}, {"deploymentName": {
"label": "Deployment Name", "type": {"dataType": "string", "isMultiple": false}, "constraints": {
"required": true, "max-value": 900}}}, {"options": {"externalValidations": []}}}

"status": "ON", // set ON to enable the custom form, OFF to disable
"type": "requestForm",
"sourceId": "$item_id/$version_id",
"sourceType": "com.vmw.blueprint.version"
}'

```

If you want to see the updated form, use the form ID from the schema.

```

curl -k -X GET "$url/form-service/api/forms/4e383140-51a4-44a7-afcd-26296079596d" \
-H "Authorization: Bearer $token" \
-H 'Content-Type: application/json' | jq "."

```

Version the form and give it a name that will help you to identify it in a list later.

```
$ curl -k -X POST \
"$url/form-service/api/forms/versions" \
-H "Authorization: Bearer $token" \
-H 'Content-Type: application/json' \
-d '{
  "name": "Version1_Deployment_Visibility_FALSE",
  "sourceId": "$item_id/$version_id",
  "sourceType": "com.vmw.blueprint.version",
  "formType": "requestForm"
}' | jq ."
```

You can repeatedly update and version the form.

- Each time you update the form, you are updating the current version.
- Each time you version the form, you save the updated form with a new name.

If you want to restore a version of the form, list your form versions to find the version of the form that you want.

```
$ curl -k -X GET \
"$url/form-service/api/forms/versions?
sourceType=com.vmw.blueprint.version&sourceId=$item_id/$version_id&formType=requestForm" \
-H "Authorization: Bearer $token" \
-H 'Content-Type: application/json'
```

The response includes the IDs and names of the custom forms.

```
[{"id": "4bfdd822-8975-4883-a8b2-22396ddf9395",
  "createdDate": "2023-05-17T14:54:07.187+0000",
  "createdBy": "user@mycompany.com",
  "name": "Version1_Deployment_Visibility_FALSE"}, {"id": "bed58877-e408-41ce-ad20-3bc48c569d84",
  "createdDate": "2023-05-17T14:39:16.267+0000",
  "createdBy": "user@mycompany.com",
  "name": "Version2_TextField_Added"}]
```

]

Assign the ID of the form you want to restore to the form version ID variable.

```
$ formVersionID='4bfdd822-8975-4883-a8b2-22396ddf9395'
```

Restore the form.

```
$ curl -k -X PATCH \
"$url/form-service/api/forms/versions/$formVersionId/restore" \
-H "Authorization: Bearer $token" \
-H 'Content-Type: application/json'
```

You have learned how to create, update, version, and restore a custom form.

Remove a Cloud Template Version from a VMware Aria Automation Service Broker Catalog

If you want to remove a cloud template version, you make a POST request. The body of the input indicates the version to remove.

- Verify that all general prerequisites and prerequisites for the Automation Assembler Blueprint service have been satisfied. See [Prerequisites for API Use Case Examples](#).
- Verify that you have the cloud template ID for the cloud template you want to remove. See [Create and Update a Cloud Template](#).
- Verify that you have the cloud template version that you want to remove from the catalog. See [Version and Release a Cloud Template to a VMware Aria Automation Service Broker Catalog](#).

If you have a versioned and released cloud template in VMware Aria Automation Service Broker, it appears in the catalog source. If you do not want that cloud template version to be available for deployment, you must remove it from the catalog.

1. Assign the cloud template ID variable.

```
cloud_template_id='<your_cloud_template_id>'
```

2. Assign the cloud template version variable.

```
cloud_template_version='<your_cloud_template_version>'  
your_cloud_template_version is the version that you want to remove.
```

3. Remove a version of your cloud template from the catalog.

```
curl -X POST \
$url/blueprint/api/blueprints/$cloud_template_id/versions/$cloud_template_version/
action/unrelease?apiVersion=$api_version \
-H "Authorization: Bearer $access_token" \
-H 'Content-Type: application/json' | jq "."

```

4. To see the change in the Automation Service Broker UI, select the **Content & Policies** tab.

- a) Select **Content Sources**.
- b) Select the name of the content source with your cloud template.
- c) On the Content Source Details screen that appears, click **Save and Import**.

The cloud template version you specified is removed from the Automation Service Broker catalog. Any other released cloud template versions remain listed.

Remove a Cloud Template Version

Remove version 5 of your cloud template with ID fa6b42d5-ac46-451d-8917-b2f7e527b785.

Assign variables.

```
$ url='https://appliance.domain.com'
$ api_version='2019-09-12'
$ cloud_template_id='fa6b42d5-ac46-451d-8917-b2f7e527b785'
$ cloud_template_version='v5'
```

Remove the cloud template version.

```
$ curl -X POST \
    $url/blueprint/api/blueprints/$cloud_template_id/versions/$cloud_template_version/
    action/unrelease?apiVersion=$api_version \
    -H "Authorization: Bearer $access_token" \
    -H 'Content-Type: application/json' | jq "."
A snippet of the response shows the cloud template version with a VERSIONED status.
```

```
...
"blueprintId": "1f170637-81a3-4257-b1cd-b2219ee8034c",
"name": "MyExampleCloudTemplate",
"description": "Basic Cloud Machine cloud template",
"version": "v5",
"tags": [],
"content": "formatVersion: 1\ninputs:\n  flavor: type: string\n  title: Flavor\n  description: Flavor Mapping Name\n  image: type: string\n  title: Image\n  description: Image Mapping Name\n  count: type: integer\n  minimum: 1\n  default: 1\n  maximum: 2\n  title: Number of Instances\nresources:\n  BasicCloudMachine:\n    type: Cloud.Machine\n    properties:\n      name: BasicCloudMachine\n      flavor: '${input.flavor}'\n      image: '${input.image}'\n      count: '${input.count}'\n      tags: [\n        {\n          \"key\": \"env\", \n          \"value\": \"prod\"\n        }\n      ]\n    "
  "status": "VERSIONED",
  "versionDescription": "Creating a version from the current draft",
  "versionChangeLog": "Creating a version v5",
  "valid": true
}
```

Test Your Cloud Template Deployment

To test the deployment of a cloud template, you use the Blueprint APIs to make a POST request with the cloud template ID as input.

- Verify that all general prerequisites and prerequisites for the Automation Assembler Blueprint service have been satisfied. See [Prerequisites for API Use Case Examples](#).
- Verify that the flavor mapping and image mapping specified in the released Automation cloud template version exist in your cloud account. See [Create Flavor Mappings](#) and [Create Image Mappings](#).
- Verify that you have the ID for the cloud template you want to deploy. See [Create and Update a Cloud Template](#).

Before deploying a cloud template, you can test the syntax and placement of your cloud template to ensure deployment viability. If errors are reported in the test, you must fix the errors and test again before deploying the cloud template.

1. Assign the cloud template ID variable.

```
cloud_template_id='<your_cloud_template_id>'
```

2. Assign image mapping and flavor mapping variables for the cloud template you intend to deploy.

```
image_mapping='<your_image_mapping_name>'  
flavor_mapping='<your_flavor_mapping_name>'
```

The image mapping specifies the OS image for a VM. The flavor mapping specifies the CPU count and RAM of a VM.

3. Test the cloud template deployment.

```
curl -X POST \  
$url/blueprint/api/blueprint-requests?apiVersion=$api_version \  
-H "Authorization: Bearer $access_token" \  
-H 'Content-Type: application/json' \  
-d '{  
    "simulate":true,  
    "blueprintId": """$cloud_template_id""",  
    "inputs": {  
        "count": 2,  
        "image": """$image_mapping""",  
        "flavor": """$flavor_mapping"""  
    }  
}' | jq ."
```

4. Examine the response and assign the cloud template request ID.

```
cloud_template_request_id='<your_cloud_template_request_id>'
```

5. Get the status of the test request.

```
curl -X GET \
    $url/blueprint/api/blueprint-requests/$cloud_template_request_id?
apiVersion=$api_version \
-H "Authorization: Bearer $access_token" | jq ".."
```

Test a Deployment

For a cloud template with ID 1f170637-81a3-4257-b1cd-b2219ee8034c, test the deployment with image mapping set to `ubuntu` and flavor mapping set to `small`.

Assign variables.

```
$ url='https://appliance.domain.com'
$ api_version='2019-09-12'
$ cloud_template_id='1f170637-81a3-4257-b1cd-b2219ee8034c'
$ image_mapping='ubuntu'
$ flavor_mapping='small'
```

Test the cloud template deployment.

```
$ curl -X POST \
    $url/blueprint/api/blueprint-requests?apiVersion=$api_version \
    -H "Authorization: Bearer $access_token" \
    -H 'Content-Type: application/json' \
    -d '{
        "simulate":true,
        "blueprintId": """$cloud_template_id""",
        "inputs": {
            "count": 2,
            "image": """$image_mapping""",
            "flavor": """$flavor_mapping"""
        }
    }' | jq ".."
```

A snippet of the response shows the cloud template request ID.

```
{
    "id": "5c33355e-fc52-4a30-97c3-3752cf9b644e",
    "createdAt": "2019-10-11T00:11:55.544Z",
    ...
}
```

```
"blueprintId": "1f170637-81a3-4257-b1cd-b2219ee8034c",
```

...

Assign the cloud template request ID variable.

```
$ cloud_template_request_id='5c33355e-fc52-4a30-97c3-3752cf9b644e'
```

Request the status of the deployment.

```
$ curl -X GET \
```

```
  $url/blueprint/api/blueprint-requests/$cloud_template_request_id?apiVersion=$api_version
\
```

```
  -H "Authorization: Bearer $access_token" | jq "."
```

A snippet of the response shows the status of the deployment test request.

...

```
"blueprintId": "1f170637-81a3-4257-b1cd-b2219ee8034c",
```

```
"inputs": {
```

```
  "count": 2,
```

```
  "image": "ubuntu",
```

```
  "flavor": "small"
```

```
},
```

```
"status": "FINISHED",
```

...

If your test deployment is successful, you are ready to deploy your cloud template.

Deploy Your Cloud Template

To request the deployment of a cloud template, you use the Blueprint APIs to make a POST request with the cloud template ID as input.

- Verify that all general prerequisites and prerequisites for the Automation Assembler Blueprint service have been satisfied. See [Prerequisites for API Use Case Examples](#).
- Verify that you have a project ID for the project that includes cloud zones configured to support the resource requirements of your cloud template. See [Create a Project to use in](#).
- Verify that the flavor mapping and image mapping specified in the released Automation cloud template version exist in your cloud account. See [Create Flavor Mappings](#) and [Create Image Mappings](#).
- Verify that you have the ID for the cloud template you want to deploy. See [Create and Update a Cloud Template](#).
- Verify that you have tested your cloud template deployment to ensure deployment viability. See [Test Your Cloud Template Deployment](#).

The prerequisites of this task call for verifying that you have the cloud template ID of the cloud template you want to deploy. In addition, this procedure includes an optional step to deploy a cloud template without a cloud template ID by providing contents inline instead.

1. Assign the cloud template ID variable.

```
cloud_template_id='<your_cloud_template_id>'
```

2. To deploy a cloud template, assign variables for image mapping and flavor mapping.

```
image_mapping='<your_image_mapping_name>'  
flavor_mapping='<your_flavor_mapping_name>'
```

The image mapping specifies the OS image for a VM. The flavor mapping specifies the CPU count and RAM of a VM.

3. Request a deployment of a cloud template.

```
curl -X POST \  
$url/blueprint/api/blueprint-requests?apiVersion=$api_version \  
-H "Authorization: Bearer $access_token" \  
-H 'Content-Type: application/json' \  
-d '{  
    "description": "requesting deployment from cloud template",  
    "blueprintId": """$cloud_template_id""",  
    "inputs": {  
        "count": 2,  
        "image": """$image_mapping""",  
        "flavor": """$flavor_mapping"""  
    }  
}' | jq "."
```

4. Examine the response to get the cloud template request ID and the deployment ID.

5. Assign the cloud template request ID and the deployment ID.

```
cloud_template_request_id='<your_cloud_template_request_id>'  
deployment_id='<your_deployment_id>'
```

6. If you do not have a cloud template ID, you can also request a cloud template deployment with contents inline.

- a) Validate the cloud template before creating it.

```
curl -X POST \  
$url/blueprint/api/blueprint-validation?apiVersion=$api_version \  
-H 'Content-Type: application/json' \  
-H "Authorization: Bearer $access_token" \  
-d '{
```

```

"name" : "'\"$cloud_template_id\"'",

"description" : "Basic Cloud Machine cloud template",

"content" : "formatVersion: 1\ninputs:\n  flavor: string\n  type: string\n  title: Flavor\n  description: Flavor Mapping Name\n  image: string\n  type: string\n  title: Image\n  description: Image Mapping Name\n  count: integer\n  type: integer\n  minimum: 1\n  default: 1\n  maximum: 2\n  title: Number of Instances\nresources:\n  BasicCloudMachine: BasicCloudMachine\n  type: Cloud.Machine\n  properties:\n    name: BasicCloudMachine\n    flavor: '${input.flavor}'\n    image: '${input.image}'\n  count: '${input.count}'",

"projectId" : "'\"$project_id\"'",

"requestScopeOrg": false

}' | jq "."

```

b) Examine the response to confirm that you see "valid":true.

c) Request the cloud template deployment.

```

curl -X POST \
$url/blueprint/api/blueprint-requests \
-H "Authorization: Bearer $access_token" \
-H 'Content-Type: application/json' \
-d '{
  "description": "requesting deployment from inline cloud template",
  "projectId": "'\"$project_id\"'",
  "inputs": {
    "count": "2",
    "image": "'\"$image_mapping\"'",
    "flavor": "'\"$flavor_mapping\"'"
  },
  "content" : "formatVersion: 1\ninputs:\n  flavor: string\n  type: string\n  title: Flavor\n  description: Flavor Mapping Name\n  image: string\n  type: string\n  title: Image\n  description: Image Mapping Name\n  count: integer\n  type: integer\n  minimum: 1\n  default: 1\n  maximum: 2\n  title: Number of Instances\nresources:\n  BasicCloudMachine: BasicCloudMachine\n  type: Cloud.Machine\n  properties:\n    name: BasicCloudMachine\n    flavor: '${input.flavor}'\n    image: '${input.image}'\n  count: '${input.count}'"
}' | jq "."

```

7. Look up the status of the cloud template deployment.

```

curl -X GET \
$url/api/blueprint-requests/$cloud_template_request_id?apiVersion=$api_version \

```

```
-H "Authorization: Bearer $access_token" | jq "."
```

Deploy a Cloud Template

For a cloud template with ID 1f170637-81a3-4257-b1cd-b2219ee8034c, request the deployment with image mapping set to `ubuntu` and flavor mapping set to `small`.

Assign variables.

```
$ url='https://appliance.domain.com'
$ api_version='2019-09-12'
$ cloud_template_id='1f170637-81a3-4257-b1cd-b2219ee8034c'
$ image_mapping='ubuntu'
$ flavor_mapping='small'
```

Request the deployment of a cloud template.

```
$ curl -X POST \
$url/blueprint/api/blueprint-requests?apiVersion=$api_version \
-H "Authorization: Bearer $access_token" \
-H 'Content-Type: application/json' \
-d '{
  "description": "requesting deployment from cloud template",
  "blueprintId": """$cloud_template_id""",
  "inputs": {
    "count": 2,
    "image": """$image_mapping""",
    "flavor": """$flavor_mapping"""
  }
}' | jq "."
```

A snippet of the response shows the cloud template request ID, the deployment ID, and the cloud template ID.

```
{
  "id": "889f95a8-79a3-4b2f-b19e-32d1536dd69a",
  "createdAt": "2019-10-11T00:11:55.544Z",
  ...
  "projectName": "Example-project",
  "deploymentId": "15454178-63fc-42ea-b4ad-7ed8a5cdb128",
```

```
"requestTrackerId": "889f95a8-79a3-4b2f-b19e-32d1536dd69a",
...
"blueprintId": "1f170637-81a3-4257-b1cd-b2219ee8034c",
...
```

Assign the cloud template request ID variable.

```
$ cloud_template_request_id='889f95a8-79a3-4b2f-b19e-32d1536dd69a'
```

Request the status of the deployment.

```
$ curl -X GET \
$url/blueprint/api/blueprint-requests/$cloud_template_request_id?apiVersion=$api_version
\

-H "Authorization: Bearer $access_token" | jq "."
```

A snippet of the response shows the cloud template request ID and the cloud template ID with the status of the deployment request. If the deployment fails, the failure message indicates the reason for the failure.

```
{
  "id": "889f95a8-79a3-4b2f-b19e-32d1536dd69a"
  ...
  "blueprintId": "1f170637-81a3-4257-b1cd-b2219ee8034c",
  "inputs": {
    "count": 2,
    "image": "ubuntu",
    "flavor": "small"
  },
  "status": "FINISHED",
  ...
}
```

Use the deployment ID to look up resource information for your deployment.

Specify SCSI disk placement using the Automation API

Specify SCSI disk placement

When attaching a disk object to a vSphere VM, you can specify the SCSI controller and the logical unit number (LUN) disk properties so that you can identify the disk when taking day 2 actions.

- Verify that all general prerequisites and prerequisites for the Automation Assembler Infrastructure as a Service (IaaS) service have been satisfied. See [Prerequisites for API Use Case Examples](#).

To attach a disk to a VM, you need the block device ID of the disk and the ID of the VM. The following procedure includes steps to:

- List all machines in your environment to find the ID of the vSphere VM that you want to attach a disk to.

- List all block devices in your environment to find the disk you want to attach.
- Attach the disk specifying the SCSI controller and LUN.

1. List all the machines in your environment.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" $url/iaas/api/machines?apiVersion=$api_version | jq "."
```

To identify the vSphere VM where you want to attach your disk, look for the name and the region ID in the response. The `self:href` path includes the machine ID.

```

        resize",  
        "/iaas/api/machines/0355cee4-5d88-36b6-9a87-5f37b5baa6e2/disks",  
        "/iaas/api/machines/0355cee4-5d88-36b6-9a87-5f37b5baa6e2/disks/{id}"  
    ]  
},  
"disks": {  
    "hrefs": [  
        "/iaas/api/machines/0355cee4-5d88-36b6-9a87-5f37b5baa6e2/disks/  
        effb94a6-41ad-3553-bb9a-22896785a283",  
        "/iaas/api/machines/0355cee4-5d88-36b6-9a87-5f37b5baa6e2/disks/  
        0815ed4c-0a33-3058-a5f5-3032a426ded4",  
        "/iaas/api/machines/0355cee4-5d88-36b6-9a87-5f37b5baa6e2/disks/  
        3804a2b2-99fc-3fca-bd2f-f0cf3845b54"  
    ]  
},  
"self": {  
    "href": "/iaas/api/machines/0355cee4-5d88-36b6-9a87-5f37b5baa6e2"  
}
```

```

        }
    }
},

```

In this response example, the machine ID is 0355cee4-5d88-36b6-9a87-5f37b5baa6e2.

2. Assign the machine ID.

```
machine_id='example-machineID-alphanumeric-string'
```

3. List the block devices in your environment.

```
curl -X GET -H "Content-Type: application/json" -H "Authorization: Bearer $access_token" $url/iaas/api/block-devices?apiVersion=$api_version | jq "."
```

Examine the response to find the block device that you want to attach. The block device must be available and in the same external region as the vSphere VM. The `self:href` path includes the block device ID.

```
...
```

```
{
  "capacityInGB": 30,
  "status": "AVAILABLE",
  "type": "HDD",
  "persistent": false,
  "externalRegionId": "Datacenter:datacenter-2",
  "cloudAccountIds": [
    "e0f23c91d5ecca75-7f703c5265a63d87-e78aab87e9c8d5cd4cd1da1a285403f0f4e77a5240720d093e147b830b172542-6b4f9990d36ee87558f04e6e8e0ca"
  ],

  "name": "Hard disk 1",
  "id": "02c39b60-32f5-4a7e-9317-88bf8a3fe20c",
  "createdAt": "2022-04-02",
  "updatedAt": "2022-04-02",
  "organizationId": "f670fdfc-66d6-4689-9793-d524e7066d1e",
  "orgId": "f670fdfc-66d6-4689-9793-d524e7066d1e",
}
```

```

"_links": {
    "cloud-accounts": {
        "hrefs": [
            "/iaas/api/cloud-accounts/e0f23c91d5ecca75-7f703c5265a63d87-
e78aab87e9c8d5cd4cd1dala285403f0f4e77a5240720d093e147b830b172542-6b4f9990d36ee87558f0
4e6e8e0ca"
        ]
    },
    "operations": {
        "hrefs": [
            "/iaas/api/block-devices/02c39b60-32f5-4a7e-9317-88bf8a3fe20c?
capacityInGB={capacityInGB}"
        ]
    },
    "self": {
        "href": "/iaas/api/block-devices/02c39b60-32f5-4a7e-9317-88bf8a3fe20c"
    }
}
},
...

```

In this response example, the block device ID is 02c39b60-32f5-4a7e-9317-88bf8a3fe20c.

4. Assign the block device ID variable.

```
block_device_id='example-blockdeviceID-alphanumeric-string'
```

5. Attach the disk to the VM, specifying both the SCSI controller number and the LUN disk properties.

- For the SCSI controller number, you can specify any of four values: `SCSI_Controller_0`, `SCSI_Controller_1`, `SCSI_Controller_2`, `SCSI_Controller_3`.
- For the LUN, you can specify any integer value from 0 through 15. Unit 0 is the boot disk. Disks with higher LUN values attach after disks with lower LUN values.

NOTE

If you do not specify a LUN, the disk attaches to the first available unit number. If you specify neither the SCSI controller nor the LUN, the disk attaches to the first available SCSI controller and first available unit number.

This request example uses `"scsiController": "SCSI_Controller_0"` and `"unitNumber": "0"`.

```
curl -X POST \
$url/iaas/api/machines/$machine_id/disks?apiVersion=$api_version \
-H 'Content-Type: application/json' \
```

```
-H "Authorization: Bearer $access_token" \
-d '{
  "blockDeviceId": "'$block_device_id'",
  "scsiController": "SCSI_Controller_0",
  "name": "BootDisk",
  "description": "Unit 0 is the boot disk",
  "unitNumber": "0"
}' | jq ."
```

The response includes a selfLink value.

```
{
  "progress": 0,
  "status": "INPROGRESS",
  "name": "Provisioning",
  "id": "example-selfLink-alphanumeric-string",
  "selfLink": "/iaas/api/request-tracker/example-selfLink-alphanumeric-string"
}
```

6. Assign the selfLink variable.

```
selfLink_id='example-selfLink-alphanumeric-string'
```

7. Use the selfLink variable to track the progress of the disk attachment.

```
curl -X GET -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" $url/iaas/api/request-tracker/$selfLink_id?apiVersion=$api_version | jq ."
```

After the request completes successfully, the response includes a list of resources with a machine that has your machine ID in the path.

```
{
  "progress": 100,
  "message": "success",
  "status": "FINISHED",
  "resources": [
    "/iaas/api/machines/example-machineID-alphanumeric-string"
  ],
  ...
}
```

8. To specify SCSI controller and LUN when attaching additional disks, repeat [specify-scsi-disk-placement.dita#STEP_F289E615-2FDA-40EE-91CE-BF6FC23768E9-en](#) to [specify-scsi-disk-placement.dita#STEP_58521BE8-A047-41CE-BD9B-DADED3CF2C7A-en](#).

If you deploy a cloud template that includes a VM with multiple vSphere disk objects, the disks are assigned to the SCSI controller and LUN that you specified. In this way, you can identify the disks when taking day 2 actions such as formatting or resizing a disk.

How to Create Custom Naming Templates

How to Create Custom Naming Templates

If you enroll in custom naming in the Automation Assembler UI, you can create custom naming templates for your organization or project using the IaaS API. Custom naming provides a way for you to name deployed resources using conventions that you define.

If you create a custom name using `POST /iaas/api/naming`, any project that does not already have a template applied can use the naming template. An organization-level naming template applies to any project that is added to an organization.

A maximum of two resource naming templates can be applied to a project: one project-level naming template and one organization-level naming template. Each can have multiple resource types. If naming templates exist at both the project and organization level, the project uses the naming convention used in the project-level naming template.

NOTE

If you created a project and specified a custom naming template as part of a previous project definition, that template is deprecated when you enroll in custom naming. To replace that template, create a custom name at the project level and add a new naming template.

The following examples show how to define custom naming templates for an organization and a project.

Prerequisites for creating a custom name

- Verify that all general prerequisites and prerequisites for the Automation Assembler Infrastructure as a Service (IaaS) service have been satisfied. See [Prerequisites for API Use Case Examples](#).
- Verify that you have enrolled in Custom Naming. For information about enrolling in custom naming, see [Custom naming deployed resources in Automation Assembler](#).
- Verify that you know your organization ID. If you do not know your organization ID, perform the following steps:
 1. Log in to the organization console of your VMware Aria Automation appliance, for example `https://appliance.domain.com/csp/gateway/portal/`
 2. Click the drop-down arrow by your name to display the organization ID below the organization name.
 3. Right click the icon next to the organization ID to copy the long string.
- If you are adding a project-level template, verify that you know the name and ID of the project that you want to assign to the template. For information on how to get a list of projects, see [Create a Project to use in](#) .

How to create a custom name with organization scope

This example shows how to define an organization-level custom name with a naming template for a machine resource type in "orgId": "8327d53f-91ea-420a-8613-ba8f3149db95".

```
curl -X POST \
"$url/iaas/api/naming?apiVersion=$api_version" \
-H "Authorization: Bearer $access_token" \
```

```

-H 'Content-Type: application/json' \
-d '{
  "name": "org-level custom name",
  "description": "Example organization-level custom name",
  "projects": [
    {
      "defaultOrg": true,
      "active": true,
      "projectName": "*",
      "projectId": "*",
      "orgId": "8327d53f-91ea-420a-8613-ba8f3149db95"
    }
  ],
  "templates": [
    {
      "uniqueName": true,
      "staticPattern": "",
      "counters": [],
      "incrementStep": 1,
      "pattern": "myvm-${##}",
      "startCounter": 1,
      "resourceTypeName": "Machine",
      "resourceType": "COMPUTE",
      "resourceDefault": true
    }
  ]
}' | jq "."

```

The response shows the organization-level custom name with the custom name ID.

```
{
  "name": "org-level custom name",
  "description": "Example organization-level custom name",
  "id": "6ca7be62-627b-41f0-9505-fc29c1349a85",
}
```

```

"_links": {
    "self": {
        "href": "/iaas/api/naming/6ca7be62-627b-41f0-9505-fc29c1349a85"
    }
}

```

How to create a custom name with project scope

This example shows how to define a project-level custom name with naming templates for network and machine resource types, and assigned to a project that has not already been added to a custom name with project scope.

```

curl -X POST \
"$url/iaas/api/naming?apiVersion=$api_version" \
-H "Authorization: Bearer $access_token" \
-H 'Content-Type: application/json' \
-d '{
    "name": "proj-level custom name",
    "description": "Example project-level custom name",
    "projects": [
        {
            "defaultOrg": false,
            "active": true,
            "projectName": "Example-CA-project",
            "projectId": "5944aacb-91de-4541-bb9e-ef2a5403f81b",
            "orgId": "8327d53f-91ea-420a-8613-ba8f3149db95"
        }
    ],
    "templates": [
        {
            "uniqueName": true,
            "staticPattern": "",
            "counters": [],
            "incrementStep": 1,
            "pattern": "myCoproject-${{##}}"
        }
    ]
}'

```

```

"startCounter": 1,
"resourceTypeName": "Network",
"resourceType": "NETWORK",
"resourceDefault": true
},
{
"uniqueName": true,
"staticPattern": "",
"counters": [],
"incrementStep": 1,
"pattern": "myCoproject-${{##}}",
"startCounter": 1,
"resourceTypeName": "Machine",
"resourceType": "COMPUTE",
"resourceDefault": true
}
]
} | jq "."

```

The response shows the project-level custom name with the custom name ID.

```
{
  "name": "proj-level custom name",
  "description": "Example project-level custom name",
  "id": "9afa9636-9536-4867-a325-fc70eb073a86",
  "_links": {
    "self": {
      "href": "/iaas/api/naming/9afa9636-9536-4867-a325-fc70eb073a86"
    }
  }
}
```

Requesting a Deployment from a Catalog Item Using Automation Service Broker APIs

Requesting a Deployment from a Catalog Item

To create catalog items and request deployments, you use the Automation Service Broker Catalog and Deployment APIs.

In this use case, you create a catalog source with a project that you previously used to create a cloud template, so that you can request a deployment from the catalog item. Optionally, if you want to expire your deployment, you can create a lease policy.

Create a Catalog Source and List Discovered Items

To create a catalog source, you make a POST request with a project ID that has a cloud template version released to the project.

- Verify that all general prerequisites and prerequisites for the Automation Service Broker Catalog service have been satisfied. See [Prerequisites for API Use Case Examples](#).
- Verify that you have the ID for a project that has the cloud template versioned and released to it. See the prerequisites section of [Create and Update a Cloud Template](#).

Because you are requesting the deployment of a cloud template from the catalog, this example lists the steps required to create a Automation Assembler Templates source type.

1. Assign the project ID variable.

```
project_id='<your_project_id>'
```

2. List all your catalog sources.

```
curl -X GET \
$url/catalog/api/admin/sources?apiVersion=$api_version \
-H "Authorization: Bearer $access_token" | jq "."
```

3. Examine the response to confirm that the name of the catalog source that you plan to create is not listed.

4. List all catalog source types.

```
curl -X GET \
$url/catalog/api/types?apiVersion=$api_version \
-H "Authorization: Bearer $access_token" | jq "."
```

5. Examine the response to find the catalog source type that you want to create.

6. Assign the catalog item type ID variable for the Automation Assembler Templates source type.

```
catalog_type_id='com.vmw.blueprint'
```

7. Create a catalog source for your cloud template.

```
curl -X POST \
$url/catalog/api/admin/sources?apiVersion=$api_version \
-H "Authorization: Bearer $access_token" \
-H "Content-Type: application/json" \
-d '{
  "config": {
    "sourceProjectId": "'$project_id'"
  }
},
```

```

"typeId":'$catalog_type_id',
"name":<your_catalog_source_name>
}' | jq "."

```

8. To obtain the catalog source ID, examine the response.
9. List all items discovered in the project.

```

curl -X GET \
$url/catalog/api/admin/items?projectId=$project_id&apiVersion=$api_version \
-H "Authorization: Bearer $access_token" | jq "."

```

10. To obtain the catalog item ID, examine the response.
11. Assign the cloud template name variable.

```
cloud_template_name='<your_cloud_template_name_that_was_released_to_catalog>'
```

12. To get the catalog item ID, you can also list discovered items by name.

```

curl -X GET \
$url/catalog/api/admin/items?
projectId=$project_id&search=$cloud_template_name&apiVersion=$api_version \
-H "Authorization: Bearer $access_token" | jq "."

```

Create a catalog source and list discovered items

Create a catalog source for a cloud template named BasicCloudMachine.

Assign variables.

```

$ url='https://appliance.domain.com'
$ api_version=' 2020-08-25'
$ project_id='394a4ccb-22c6-4ef0-8c75-8b77efbefb51'

```

List all available sources in your catalog.

```

$ curl -X GET \
$url/catalog/api/admin/sources?apiVersion=$api_version \
-H "Authorization: Bearer $access_token" | jq "."

```

Examine the response to confirm that the name of the catalog source that you plan to create is not listed. The following snippet shows that you cannot create a catalog source with the name Catalog Source from Blueprintecho s.

```

...
{
  "id": "753d24a3-e2b0-4d5e-bba6-9e32e5964c69",
  "name": "Catalog Source from Blueprintecho s",
}
...
```

List all available catalog source types.

```
$ curl -X GET \
$url/catalog/api/types?apiVersion=$api_version \
-H "Authorization: Bearer $access_token" | jq "."
```

Examine the response to find the ID for a Automation Assembler Templates source type.

```
...
{
  "id": "com.vmw.blueprint",
  "name": "Automation Assembler Template",
  "baseUri": "http://catalog-service:8000/catalog/api/provider/blueprint",
  "createdBy": "deploymentservice",
}
```

Assign the source type to the catalog item type variable.

```
$ catalog_type_id='com.vmw.blueprint'
```

Create a catalog source of the Automation Assembler Templates source type.

```
$ curl -X POST \
$url/catalog/api/admin/sources?apiVersion=$api_version \
-H "Authorization: Bearer $access_token" \
-H "Content-Type: application/json" \
-d '{
  "config": {
    "sourceProjectId": "'$project_id'"
  },
  "typeId": "'$catalog_type_id'",
  "name": "Catalog Source from Automation Assembler Templates"
}' | jq "."
```

A snippet of the response shows the catalog source ID.

```
{
  "id": "753d24a3-e2b0-4d5e-bba6-9e32e5964c69",
  "name": "Catalog Source from Automation Assembler Templates",
  "typeId": "com.vmw.blueprint",
  "createdAt": "2021-11-08T22:02:33.553Z",
}
```

Assign the catalog source ID.

```
$ catalog_source_id='753d24a3-e2b0-4d5e-bba6-9e32e5964c69'
```

List items discovered in your project.

```
$ curl -X GET \
$url/catalog/api/admin/items?projectId=$project_id&apiVersion=$api_version \
-H "Authorization: Bearer $access_token" | jq "."
```

A snippet of the response shows the catalog item ID with your cloud template name.

```
{
  "id": "718917c0-1e02-3141-8142-11da5acaed8f",
  "name": "BasicCloudMachine",
  "description": "Basic Cloud Machine cloud template",
  "sourceId": "753d24a3-e2b0-4d5e-bba6-9e32e5964c69",
  ...
}
```

Assign the catalog item ID.

```
$ catalog_item_id='718917c0-1e02-3141-8142-11da5acaed8f'
```

Before requesting a deployment, you use the `catalog_source_id` to create entitlement for the catalog source. Or you can use the `catalog_item_id` to create entitlement for the cloud template item. See [Create a Content Sharing Policy](#).

Request Deployment

To request a deployment from a catalog item, you make a POST request with a project ID that has a cloud template version released to the project. The request body includes the ID of the catalog item from which you are requesting the deployment, and the version of the released cloud template.

- Verify that all general prerequisites and prerequisites for both the Automation Service Broker Catalog service and the Automation Service Broker Deployment service have been satisfied. See [Prerequisites for API Use Case Examples](#).
- Verify that the flavor mapping and image mapping specified in the released cloud template version exist in your cloud account. See [Create Flavor Mappings](#) and [Create Image Mappings](#).
- Verify that you have the ID for a project that has the cloud template versioned and released to it. See the prerequisites section of [Create and Update a Cloud Template](#).
- Verify that you have the ID of the catalog item from which you plan to request a deployment. See [Create a Catalog Source and List Discovered Items](#).
- Verify that you have the version of a cloud template released to the project that you want to request for deployment. See [Version and Release a Cloud Template to a VMware Aria Automation Service Broker Catalog](#).
- Verify that you have created an entitlement for your catalog item or create one using [Create a Content Sharing Policy](#).

1. Assign the project ID variable.

```
project_id='<your_project_id>'
```

2. Assign the catalog item ID variable.

```
catalog_item_id='<your_catalog_item_id>'
```

3. List the available versions of the catalog item that can be requested.

```
curl -X GET \
$url/catalog/api/items/$catalog_item_id/versions \
-H "Authorization: Bearer $access_token" | jq "."
```

4. Examine the response to verify the version of the item that you want has been published to the catalog.
5. Assign the catalog item version.

```
catalog_item_version='<your_catalog_item_version>'
```

6. Assign your deployment name variable.

```
deployment_name='<your_deployment_name>'
```

If your deployment name includes spaces, use double quotes as in the following example.

```
deployment_name="This deployment name includes spaces"
```

- a) To ensure that the deployment name you plan to use does not already exist, list all deployments.

```
curl -X GET \
-G --data-urlencode "name=$deployment_name" \
$url/deployment/api/deployments?apiVersion=$api_version \
-H "Authorization: Bearer $access_token" | jq "."
```

- b) Examine the response. If your deployment name appears, create a new name and reassign your deployment name variable.

7. To deploy a cloud template, assign variables for image mapping and flavor mapping.

```
image_mapping='<your_image_mapping_name>'
```

```
flavor_mapping='<your_flavor_mapping_name>'
```

The image mapping specifies the OS image for a VM. The flavor mapping specifies the CPU count and RAM of a VM.

8. Request the deployment from a catalog item.

```
curl -X POST \
$url/catalog/api/items/$catalog_item_id/request?apiVersion=$api_version \
-H "Authorization: Bearer $access_token" \
-H 'Content-Type: application/json' \
-d '{
  "deploymentName": """$deployment_name""",
  "projectId": """$project_id""",
  "inputs": {
    "count": 1,
    "image": """$image_mapping"""
  }
}'
```

```

    "flavor": "$flavor_mapping"
},
"version": "$catalog_item_version"
}' | jq "."

```

The `inputs` field includes values for request time variables such as size, image, or password.

9. To obtain the deployment ID, examine the response.
10. Assign the deployment ID variable.

```
deployment_id='<your_deployment_id>'
```

11. Get the status of the deployment.

```
curl -X GET \
$url/deployment/api/deployments/$deployment_id?apiVersion=$api_version \
-H "Authorization: Bearer $access_token" | jq "."

```

Request Deployment of a Cloud Template from a Catalog Item

Request the deployment of a cloud template with catalog item ID `718917c0-1e02-3141-8142-11da5acaed8f`. When requesting the deployment, set image mapping set to `ubuntu` and flavor mapping set to `small`.

Assign variables.

```
$ url='https://appliance.domain.com'
$ api_version='2020-08-25'
$ project_id='394a4ccb-22c6-4ef0-8c75-8b77efbefb51'
$ catalog_item_id='718917c0-1e02-3141-8142-11da5acaed8f'
```

List available versions.

```
$ curl -X GET \
$url/catalog/api/items/$catalog_item_id/versions \
-H "Authorization: Bearer $access_token" | jq "."

```

A snippet of the response shows version numbers.

```
...
{
  "id": "v2",
  "description": "Creating a version from the current draft",
  "createdAt": "2021-11-08T19:33:04.445Z"
},
```

```
{
  "id": "v1",
  "description": "Creating a version from the current draft",
  "createdAt": "2021-11-08T19:25:43.327Z"
}
```

...

Assign the catalog item version number.

```
$ catalog_item_version='v2'
```

Assign a deployment name and check to ensure that it does not already exist.

```
$ deployment_name="Example Deployment of Cloud Template"
```

```
$ curl -X GET \
```

```
-G --data-urlencode "name=$deployment_name" \
$url/deployment/api/deployments?apiVersion=$api_version \
-H "Authorization: Bearer $access_token" | jq "."
```

A snippet of the response shows existing deployments. Example Deployment of Cloud Template is not listed.

```
{
  "id": "c14e787f-60ee-4cce-a5b5-c9440bf181ab",
  "name": "Not Example Deployment",
  "orgId": "c9258a19-fef0-4431-a999-d711e1741c60",
  "catalogItemId": "947b9db2-cf89-3b83-8035-bbcf83bd4c34",
```

...

To deploy a cloud template, you must assign image mapping and flavor mapping variables.

```
$ image_mapping='ubuntu'
```

```
$ flavor_mapping='small'
```

Request a deployment from the catalog item.

```
$ curl -X POST \
```

```
$url/catalog/api/items/$catalog_item_id/request?apiVersion=$api_version \
-H "Authorization: Bearer $access_token" \
-H 'Content-Type: application/json' \
-d '{
  "deploymentName": "$deployment_name",
  "projectId": "$project_id",
```

```

"inputs": {
    "count":1,
    "image": "$image_mapping",
    "flavor": "$flavor_mapping"
},
"version": "$catalog_item_version"
} | jq "."

```

The response provides the deployment ID.

```
{
  "deploymentId": "3721d9e2-fce3-48eb-96e5-d8f381354610",
  "deploymentName": "Example Deployment of Cloud Template"
}
```

Assign the deployment ID.

```
$ deployment_id='3721d9e2-fce3-48eb-96e5-d8f381354610'
```

Get the deployment status.

```
$ curl -X GET \
$url/deployment/api/deployments/$deployment_id?apiVersion=$api_version"
-H "Authorization: Bearer $access_token" | jq "."

```

A snippet of the response shows the deployment status.

```
,
  "projectId": "394a4ccb-22c6-4ef0-8c75-8b77efbefb51",
  "status": "CREATE_SUCCESSFUL"
}
```

Create a Lease Policy

To create a lease policy for your deployment, you make a POST request with a project ID that has a cloud template version released to the project.

- Verify that all general prerequisites and prerequisites for the Automation Service Broker Policies service have been satisfied. See [Prerequisites for API Use Case Examples](#).
- Verify that you have the ID for a project that has the cloud template versioned and released to it. See the prerequisites section of [Create and Update a Cloud Template](#).

Creating a lease policy is optional. For example, you can create a lease policy to specify when you want a deployment to expire. You specify the policy with either a soft or hard lease enforcement type.

- If specified with soft enforcement, the policy can be overridden and will have lower priority than policies with hard enforcement.

- If specified with hard enforcement, the policy must be enforced. If strict enforcement is not possible, for example in cases of conflicting policies, the policy can be overridden but Automation Service Broker will report an error.

1. Assign the project ID variable.

```
project_id='<your_project_id>'
```

2. Assign a lease policy with soft enforcement to your project.

```
curl -X POST \
$url/policy/api/policies?apiVersion=$api_version \
-H "Authorization: Bearer $access_token" \
-H 'Content-Type: application/json' \
-d '{
  "name": "<your_lease_policy_name>",
  "projectId": "'$project_id'",
  "definition": {
    "leaseGrace": 1,
    "leaseTermMax": 10,
    "leaseTotalTermMax": 100
  },
  "enforcementType": "SOFT",
  "typeId": "com.mycompany.policy.deployment.lease"
}' | jq "."

```

Create a lease policy with soft enforcement

Assign variables.

```
$ url='https://appliance.domain.com'
$ api_version=' 2020-08-25'
$ project_id='394a4ccb-22c6-4ef0-8c75-8b77efbefb51'
```

Create the soft lease policy named Sample Lease.

```
$ curl -X POST \
$url/policy/api/policies?apiVersion=$api_version \
-H "Authorization: Bearer $access_token" \
-H 'Content-Type: application/json' \
-d '{
```

```

"name": "Sample Lease",
"projectId": "'$project_id'",
"definition": {
    "leaseGrace": 1,
    "leaseTermMax": 10,
    "leaseTotalTermMax": 100
},
"enforcementType": "SOFT",
"typeId": "com.vmware.policy.deployment.lease"
}' | jq "."

```

The response shows the lease policy.

```
{
  "id": "49893797-208c-4322-8ed5-061467674d54",
  "name": "Sample Lease",
  "typeId": "com.mycompany.policy.deployment.lease",
  "enforcementType": "SOFT",
  "orgId": "c9258a19-fef0-4431-a999-d711e1741c60",
  "projectId": "394a4ccb-22c6-4ef0-8c75-8b77efbefb51",
  "definition": {
    "leaseGrace": 1,
    "leaseTermMax": 10,
    "leaseTotalTermMax": 100
},
  "createdAt": "2021-11-08T02:29:07.936Z",
  "createdBy": "admin@mycompany.com",
  "lastUpdatedAt": "2021-11-08T02:29:07.936Z",
  "lastUpdatedBy": "admin@mycompany.com"
}
```

Working with Deployments and Resources

Working with Deployments and Resources

To work with deployments, you use the Automation Assembler and Automation Service Broker Deployment APIs. You also use the Automation Service Broker Deployment APIs to manage or get information about resources in your deployment.

These use cases include examples of procedures you can follow to reconfigure your deployment after initial cloud template deployment. The first example deploys a new cloud template with a deployment ID. In subsequent examples, you use the deployment ID to update the deployment or reconfigure the cloud template components.

If you want to onboard a machine that was deployed outside of Automation Assembler, you use the Relocation Service APIs to create an onboarding plan so that you can onboard the machine. Onboarding use cases show how to create an onboarding plan and onboard a machine with or without a cloud template.

Deploy a Cloud Template with Contents Inline

To request a deployment of a cloud template with contents inline, you use the Blueprint APIs to make a POST request with a project ID. Before requesting the deployment, you use the Deployment API to ensure that the deployment name does not already exist.

- Verify that all general prerequisites and prerequisites for the Automation Service Broker Deployment service have been satisfied. See [Prerequisites for API Use Case Examples](#).
- Verify that you have the ID for a project that is associated with the deployment that you are managing. See [Request Deployment](#).
- Verify that the flavor mapping and image mapping specified in the cloud template to be deployed exist in your cloud account. See [Create Flavor Mappings](#) and [Create Image Mappings](#).
- Verify that the cloud zone that you are deploying into is associated with your project. See [Add a Cloud Zone to Your Project](#).
- Verify that a network profile is configured for the cloud account associated with the project. See [Create Network Profiles](#).
- Assign an API version variable for the Blueprint API.

```
api_version_blueprint=' 2019-09-12 '
```

NOTE

The Automation Service Broker Deployment service and the Automation Assembler Blueprint service have different API version values. You set the API version value for the Automation Service Broker Deployment service when you satisfied the general prerequisites.

In this example, you deploy a cloud template by providing contents inline instead of providing a cloud template ID. The new cloud template has different content from previously deployed cloud templates including a load balancer component, a virtual machine component, and a network component. For information about deploying a cloud template by providing a cloud template ID, see [Deploy Your Cloud Template](#).

1. Assign the project ID variable.

```
project_id='<your_project_id>'
```

2. Assign your deployment name variable.

```
deployment_name='<your_deployment_name>'
```

If your deployment name includes spaces, use double quotes as in the following example.

```
deployment_name="This deployment name includes spaces"
```

- a) To ensure that the deployment name you plan to use does not already exist, list all deployments.

```
curl -X GET \
-G --data-urlencode "name=$deployment_name" \
$url/deployment/api/deployments?apiVersion=$api_version \
-H "Authorization: Bearer $access_token" | jq "."
```

- b) To verify that the deployment name does not already exist, examine the response. If your deployment name appears, create a new name and reassign your deployment name variable.
3. To deploy a cloud template, assign variables for image mapping and flavor mapping.

```
image_mapping='<your_image_mapping_name>'  
flavor_mapping='<your_flavor_mapping_name>'
```

The image mapping specifies the OS image for a VM. The flavor mapping specifies the CPU count and RAM of a VM.

4. Request deployment of a cloud template with contents inline.

```
curl -X POST \  
$url/blueprint/api/blueprint-requests?apiVersion=$api_version_blueprint \  
-H "Authorization: Bearer $access_token" \  
-H 'Content-Type: application/json' \  
-d '{  
    "deploymentName": """$deployment_name""",  
    "description": "requesting deployment with contents inline",  
    "projectId": """$project_id""",  
    "inputs": {  
        "flavor": """$flavor_mapping""",  
        "image" : """$image_mapping"""  
    },  
    "content" : "formatVersion: 1\ninputs:\n  flavor:\n    type: string\n    title: Flavor\n    description: Flavor Mapping Name\n  image:\n    type: string\n    title: Image\n    description: Image Mapping Name\nresources:\n  cloud-vm:\n    type: Cloud.AWS.EC2.Instance\n    properties:\n      name: cloudvm\n      flavor: '$input.flavor'\n      image: '$input.image'\n      networks:\n        - name: '$resource.Cloud_Network_1.name'\n          network: '$resource.Cloud_Network_1.id'\n          Provider_LoadBalancer_1:\n            type: Cloud.LoadBalancer\n            properties:\n              name: OC-LB\n              routes:\n                - protocol: HTTP\n                  port: '80'\n                  instanceProtocol: HTTP\n                  instancePort: '80'\n                  healthCheckConfiguration:\n                    protocol: HTTP\n                    port: '80'\n                    urlPath: /index.html\n                    intervalSeconds: 60\n                    timeoutSeconds: 5\n              unhealthyThreshold: 5\n              healthyThreshold: 2\n              network: '$resource.Cloud_Network_1.name'\n              instances:\n                - '$resource[\"cloud-vm\"].id'\n            internetFacing: false\n            Cloud_Network_1:\n              type: Cloud.Network\n              properties:\n                name: provider\n                networkType: public\n"  
  }' | jq ."
```

5. To obtain the cloud template request ID and the deployment ID, examine the response.
6. Assign the cloud template request ID variable.

```
cloud_template_request_id='<your_cloud_template_request_id>'
```

7. Get the status of the request.

```
curl -X GET \
$url/blueprint/api/blueprint-requests/$cloud_template_request_id?
apiVersion=$api_version_blueprint \
-H "Authorization: Bearer $access_token" | jq "."
```

Deploy a Cloud Template with Contents Inline

Request a deployment named Deployment with Cloud Template Contents Inline. When requesting the deployment, set image mapping set to ubuntu and flavor mapping set to small.

Assign variables.

```
$ url='https://appliance.domain.com'
$ api_version=' 2020-08-25'
$ api_version_blueprint=' 2019-09-12'
$ project_id='394a4ccb-22c6-4ef0-8c75-8b77efbefb51'
$ deployment_name="Deployment with Cloud Template Contents Inline"
```

To request deployment, you must assign image mapping and flavor mapping variables.

```
$ image_mapping='ubuntu'
$ flavor_mapping='small'
```

Request deployment of a cloud template with contents inline.

```
$ curl -X POST \
$url/blueprint/api/blueprint-requests?apiVersion=$api_version_blueprint \
-H "Authorization: Bearer $access_token" \
-H 'Content-Type: application/json' \
-d '{
  "deploymentName": """$deployment_name""",
  "description": "requesting deployment with contents inline",
  "projectId": """$project_id""",
  "inputs": {
    "flavor": """$flavor_mapping""",
    "image" : """$image_mapping"""
  },
  "content" : "formatVersion: 1\ninputs:\n  flavor:\n    type: string\n    title: Flavor\n  description: Flavor Mapping Name\n  image:\n    type: string\n    title: Image\n  description: Image Mapping Name\nresources:\n  cloud-vm:\n    type:
```

```

Cloud.AWS.EC2.Instance\n    properties:\n        name: cloudvm\n        flavor: '$\n{input.flavor}'\n        image: '$\n{input.image}'\n        networks:\n            - name: '$\n{resource.Cloud_Network_1.name}'\n            network: '$\n{resource.Cloud_Network_1.id}'\n        Provider_LoadBalancer_1:\n            type: Cloud.LoadBalancer\n            properties:\n                name: OC-LB\n                routes:\n                    - protocol: HTTP\n                        port: '80'\n                        instanceProtocol: HTTP\n                        instancePort: '80'\n                        healthCheckConfiguration:\n                            protocol: HTTP\n                            port: '80'\n                            urlPath: /index.html\n                            intervalSeconds: 60\n                            timeoutSeconds: 5\n                            unhealthyThreshold: 5\n                            healthyThreshold: 2\n                            network: '$\n{resource.Cloud_Network_1.name}'\n            instances:\n                - '$\n{resource["cloud-vm"].id}'\n            internetFacing: false\n        Cloud_Network_1:\n            type: Cloud.Network\n            properties:\n                name: provider\n                networkType: public\n'
}' | jq "."

```

A snippet of the response provides the cloud template request ID and the deployment ID.

```

...
{
    "type": "blueprint-request",
    "id": "bec37f54-3de5-451d-b484-a110c0ed8772",
...
{
    "projectId": "394a4ccb-22c6-4ef0-8c75-8b77efbefb51",
    " projectName": "example-project",
    "deploymentId": "5551a299-8b67-45e3-909e-a638d11b0d9f",
    "requestTrackerId": "bec37f54-3de5-451d-b484-a110c0ed8772",
    "deploymentName": "Deployment with Cloud Template Contents inline",
...
}

```

Assign the cloud template request ID.

```
$ cloud_template_request_id='bec37f54-3de5-451d-b484-a110c0ed8772'
```

Get the deployment status.

```
$ curl -X GET \
$url/blueprint/api/blueprint-requests/$cloud_template_request_id?
apiVersion=$api_version_blueprint \
-H "Authorization: Bearer $access_token" | jq "."

```

A snippet of the response shows the deployment status.

```

...
{
    "inputs": {
        "image": "ubuntu",
        "flavor": "small"
    },
    "status": "FINISHED",
}

```

...

You can use the deployment ID to perform other operations on your deployment. Other operations include, changing the lease on your deployment, fetching deployment resources, reconfiguring a load balancer, or adding a disk to a machine and power it off.

Look up Deployment Details

To look up deployment details such as the resources provisioned for each deployment, you use the Deployment APIs to make a GET request that displays all available resources. Then you use the resource ID in the output to make a GET request that returns the details of a particular resource.

- Verify that all general prerequisites and prerequisites for the Automation Service Broker Deployment service have been satisfied. See [Prerequisites for API Use Case Examples](#).
- Verify that you have a deployment ID for the deployment that you requested. See [Deploy Your Cloud Template](#).

1. Assign the deployment ID variable.

```
deployment_id='<your_deployment_id>'
```

2. Display all the available resources that are provisioned in your deployment.

```
curl -X GET \
  $url/deployment/api/deployments/$deployment_id?
  expand=resources&apiVersion=$api_version \
  -H "Authorization: Bearer $access_token" | jq "."
```

3. Examine the response to find the ID of the resource for which you want details.

4. Assign the deployment resource ID.

```
deployment_resource_id='<your_deployment_resource_id>'
```

5. Display the details of that resource.

```
curl -X GET \
  $url/deployment/api/deployments/$deployment_id/resources/$deployment_resource_id?
  apiVersion=$api_version \
  -H "Authorization: Bearer $access_token" | jq "."
```

6. List the deployment events.

```
curl -X GET \
  $url/deployment/api/deployments/$deployment_id/events?apiVersion=$api_version \
  -H "Authorization: Bearer $access_token" | jq "."
```

In case of deployment failures, listing deployment events can help with debugging.

Look up the details of a provisioned resource in your deployment

Display the resources provisioned in your deployment.

Assign variables.

```
$ url='https://appliance.domain.com'
$ api_version=' 2020-08-25'
$ deployment_id='15454178-63fc-42ea-b4ad-7ed8a5cdb128'
```

Look up deployment details.

```
$ curl -X GET \
$url/deployment/api/deployments/$deployment_id?expand=resources&apiVersion=$api_version \
-H "Authorization: Bearer $access_token" | jq "."
A snippet of the response shows the details for each resource details including a deployment resource ID.
```

...

```
"resources": [
{
  "id": "3994a33e-bd93-4eea-87f1-f99ff17717ce",
  "name": "BasicCloudMachine[0]",
...

```

Assign the deployment resource ID variable for the BasicCloudMachine resource.

```
$ deployment_resource_id='3994a33e-bd93-4eea-87f1-f99ff17717ce'
```

Display the details of that resource.

```
$ curl -X GET \
$url/deployment/api/deployments/$deployment_id/resources/$deployment_resource_id?
apiVersion=$api_version \
-H "Authorization: Bearer $access_token" | jq "."
A snippet of the response shows the details of the single resource.
```

{

```
"id": "3994a33e-bd93-4eea-87f1-f99ff17717ce",
"name": "BasicCloudMachine[0]",
"type": "Cloud.Machine",
"dependsOn": [],
"createdAt": " 2021-11-08T17:56:09.463Z",
"properties": {
  "id": "/resources/compute/3114189206b1763d",
  "name": "BasicCloudMachine",
...

```

```

"service": "EC2",
"storage": {
  "disks": [
    {
      "name": "boot-disk",
      "type": "HDD",
      ...
    }
  ],
  ...
  "networks": [
    {
      "name": "BasicCloudMachine_nic",
      "address": "172.16.1.98",
      "assignment": "dynamic"
    }
  ],
  ...
  "__ext:ComputeReservationTaskState:STARTED:SELECTED": "true",
  "__ext:ComputeAllocationTaskState:STARTED:START_COMPUTE_ALLOCATION": "true"
},
"state": "OK"
}

```

List events from the deployment.

```

$ curl -X GET \
$url/deployment/api/deployments/$deployment_id/events?apiVersion=$api_version \
-H "Authorization: Bearer $access_token" | jq "."

```

A snippet of the response shows successful events.

```

...
  "totalTasks": 3,
  "status": "SUCCESSFUL",
  "inputs": {
    "count": 2,
    "image": "ubuntu",
    "flavor": "small"
  }
}

```

```
}
```

```
...
```

Get Deployment Resource IDs

To get IDs of the resources in your deployment, you use the Deployment APIs to make a GET request.

- Verify that all general prerequisites and prerequisites for the Automation Service Broker Deployment service have been satisfied. See [Prerequisites for API Use Case Examples](#).
- Verify that you have the ID of the deployment you want to reconfigure. See [Deploy a Cloud Template with Contents Inline](#).

To perform operations on the load balancer or virtual machine in your deployment, you need the IDs of those resources.

1. Assign your deployment ID variable.

```
deployment_id='<your_deployment_id>'
```

2. List the resources in your deployment.

```
curl -X GET \
$url/deployment/api/deployments/$deployment_id/resources?apiVersion=$api_version \
-H "Authorization: Bearer $access_token" | jq "."
```

3. Examine the response.

- Find the resource named `Provider_LoadBalancer_1` and copy the value to assign to the load balancer ID.
- Find the resource named `cloud-vm` and copy the value to assign to the virtual machine ID.

4. Assign variables for the resources.

```
load_balancer_id='<your_load_balancer_id>'  
virtual_machine_id='<your_virtual_machine_id>'
```

Get Deployment Resource IDs

Get the resource IDs for your deployment with ID 5551a299-8b67-45e3-909e-a638d11b0d9f.

Assign variables.

```
$ url='https://appliance.domain.com'  
$ api_version=' 2020-08-25'  
$ deployment_id='5551a299-8b67-45e3-909e-a638d11b0d9f'
```

List the resources in your deployment.

```
$ curl -X GET \
$url/deployment/api/deployments/$deployment_id/resources?apiVersion=$api_version \
```

```
-H "Authorization: Bearer $access_token" | jq "."
```

A snippet of the response shows the ID for the resource `Provider_LoadBalancer_1` and the ID for the resource `cloud-vm`.

```
...
{
  "id": "d5b4569d-2234-4fc4-a594-45e6b0251588",
  "name": "Provider_LoadBalancer_1",
  "type": "Cloud.LoadBalancer",
...
{
  "id": "42f49781-1490-4a08-ae21-8baf383a72ac",
  "name": "cloud-vm",
  "type": "Cloud.AWS.EC2.Instance",
...
}
```

Assign the load balancer ID and virtual machine ID variables.

```
$ load_balancer_id='d5b4569d-2234-4fc4-a594-45e6b0251588'
$ virtual_machine_id='42f49781-1490-4a08-ae21-8baf383a72ac'
```

Use the load balancer ID to reconfigure your load balancer. Use the virtual machine ID to add a disk to the VM and power off the VM.

Change the Lease on Your Deployment

To change the lease on your deployment, you use the Deployment APIs to make a POST request with a new lease expiration date.

- Verify that all general prerequisites and prerequisites for the Automation Service Broker Deployment service have been satisfied. See [Prerequisites for API Use Case Examples](#).
- Verify that you have the ID of the deployment you want to reconfigure. See [Deploy a Cloud Template with Contents Inline](#).

The lease on your deployment is set to never expire by default. The following procedure shows how to add a lease expiration date. It also includes an optional step that shows how to reset the lease on your deployment back to never expire.

1. Assign your deployment ID variable.

```
deployment_id='<your_deployment_id>'
```

2. Get a list of actions available for your deployment.

```
curl -X GET \
$url/deployment/api/deployments/$deployment_id/actions?apiVersion=$api_version \
```

```
-H "Authorization: Bearer $access_token" | jq "."
```

3. Examine the response.

- Confirm that you see the action "name": "ChangeLease".
- "valid":true indicates that the action is valid for the deployment.

4. Assign the action ID variable for the action "name": "ChangeLease".

```
action_id='Deployment.ChangeLease'
```

5. List the deployment actions for the action ID .

```
curl -X GET \
$url/deployment/api/deployments/$deployment_id/actions/$action_id?
apiVersion=$api_version \
-H "Authorization: Bearer $access_token" | jq "."
```

6. Examine the response. The schema field shows the format of the input for an action on the deployment.

7. To change the lease on the deployment, assign the lease expiry date using the format specified in the schema as in the following example.

```
lease_expiry_date=2021-05-15T23:11:00Z
```

8. Change the lease expiration date.

```
curl -X POST \
$url/deployment/api/deployments/$deployment_id/requests \
-H "Authorization: Bearer $access_token" \
-H 'Content-Type: application/json' \
-d '{
  "actionId": "Deployment.ChangeLease",
  "inputs": {
    "Lease Expiration Date": """$lease_expiry_date"""
  }
}' | jq "."
```

9. Examine the response and assign the request ID.

```
request_id='<your_request_id>'
```

10. Check the status of the request.

```
curl -X GET \
$url/deployment/api/requests/$request_id?apiVersion=$api_version \
-H "Authorization: Bearer $access_token" | jq "."
```

If the request is successful, the response shows "status": "SUCCESSFUL".

11. To change the lease on the deployment back to never expire, use the same `action_id='Deployment.ChangeLease'` but leave inputs empty.

```
curl -X POST \
  $url/deployment/api/deployments/$deployment_id/requests \
  -H "Authorization: Bearer $access_token" \
  -H 'Content-Type: application/json' \
  -d '{
    "actionId": "Deployment.ChangeLease",
    "inputs": {}
}' | jq ".."
```

Use the request ID from the response to check the status of the request. The lease is changed when the response shows "status": "SUCCESSFUL".

Change the Lease on Your Deployment

Change the lease on your deployment with ID 5551a299-8b67-45e3-909e-a638d11b0d9f.

Assign variables.

```
$ url='https://appliance.domain.com'
$ api_version='2020-08-25'
$ deployment_id='5551a299-8b67-45e3-909e-a638d11b0d9f'
```

List the actions available for your deployment.

```
$ curl -X GET \
  $url/deployment/api/deployments/$deployment_id/actions?apiVersion=$api_version \
  -H "Authorization: Bearer $access_token" | jq ".."
```

A snippet of the response shows `Deployment.ChangeLease`.

```
...
{
```

```
"id": "Deployment.ChangeLease",
"name": "ChangeLease",
"displayName": "Change Lease",
"description": "Set a deployment's expiration date",
"valid": true,
"actionType": "RESOURCE_ACTION"
```

```
}
```

```
...
```

Assign the action ID variable.

```
$ action_id='Deployment.ChangeLease'
```

To get the schema for your action, list the deployment actions by ID.

```
$ curl -X GET \
```

```
$url/deployment/api/deployments/$deployment_id/actions/$action_id?&apiVersion=$api_version \
```

```
-H "Authorization: Bearer $access_token" | jq "."
```

A snippet of the response provides the schema for the lease expiration date.

```
...
```

```
"properties": {  
    "Deployment expires in": {  
        "type": "string",  
        "readOnly": true,  
        "default": "9d 21h 27m"  
    },  
    "Lease Expiration Date": {  
        "type": "string",  
        "title": "Lease Expiration Date",  
        "description": "The lease can be extended by up to 90d 0h 0m",  
        "format": "date-time",  
        "formatMinimum": "2021-02-12T21:47:00Z",  
        "formatMaximum": "2021-05-20T19:15:00Z",  
        "default": "2021-02-22T19:15:00Z"  
    }  
}
```

```
...
```

Assign the lease expiry date variable in the propert format.

```
$ lease_expiry_date=2021-05-15T23:11:00Z
```

Submit a request to change the lease expiration.

```
$ curl -X POST \
```

```
$url/deployment/api/deployments/$deployment_id/requests \n  
-H "Authorization: Bearer $access_token" \n  
-H 'Content-Type: application/json' \n
```

```
-d '{
  "actionId": "Deployment.ChangeLease",
  "inputs": {
    "Lease Expiration Date": """$lease_expiry_date"""
  }
}' | jq "."

```

A snippet of the response shows request ID.

```
...
{
  "id": "6b9b5534-0d84-4f07-9941-5c3cc26f7e3b",
  "name": "Change Lease",
  "deploymentId": "5551a299-8b67-45e3-909e-a638d11b0d9f",
}
...
```

Assign the request ID variable.

```
$ request_id='6b9b5534-0d84-4f07-9941-5c3cc26f7e3b'
```

Check the status of the request.

```
$ curl -X GET \
$url/deployment/api/requests/$request_id?apiVersion=$api_version \
-H "Authorization: Bearer $access_token" | jq "."

```

A snippet of the response shows that the request was successful.

```
...
{
  "actionId": "Deployment.ChangeLease",
  "completedTasks": 1,
  "totalTasks": 1,
  "status": "SUCCESSFUL"
}
```

Delete Your Deployment

To delete a deployment, you use the Automation Service Broker Deployment API and if needed, the Automation Assembler IaaS API. You make a DELETE request to remove the deployment and clean up the associated resources from the cloud provider.

- Verify that all general prerequisites and prerequisites for the Automation Service Broker Deployment service have been satisfied. See [Prerequisites for API USE Case Examples](#).
- Verify that you have the Automation Assembler administrator service role.
- Verify that you know the deployment that you want to delete.
- Assign an API version variable for the IaaS API.

```
api_version_iaas='2021-07-15'
```

NOTE

The Automation Service Broker Deployment service and the Automation Assembler Infrastructure as a Service (IaaS) service have different API version values. You set the API version value for the Automation Service Broker Deployment service when you satisfied the general prerequisites.

If using the Automation Service Broker Deployment service fails to delete the deployment, you can use the Automation Assembler IaaS service to force the deletion. The following procedure shows how to delete a deployment when both API services are used.

1. List all deployments.

```
curl -X GET "$url/deployment/api/deployments?apiVersion=$api_version" -H "Authorization: Bearer $access_token" | jq "."
```

2. Examine the response to find the name and ID of the deployment that you want to delete.

3. Assign your deployment ID variable.

```
deployment_id='<your_deployment_id>'
```

4. Get a list of actions for the deployment.

```
curl -X GET \
"$url/deployment/api/deployments/$deployment_id/actions?apiVersion=$api_version" \
-H "Authorization: Bearer $access_token" | jq "."
```

5. Examine the response.

- Confirm that you see the action "id": "Deployment.Delete".
- "valid":true indicates that the action is valid for the deployment.

6. Delete the deployment.

```
curl -X DELETE \
"$url/deployment/api/deployments/$deployment_id?apiVersion=$api_version" \
-H "Authorization: Bearer $access_token" | jq "."
```

7. Examine the response for the ID of the deletion request.

8. Assign the ID to the request ID variable.

```
request_id='<delete_request_id>'
```

9. Get the status of the deployment request.

```
curl -X GET \
"$url/deployment/api/requests/$request_id?apiVersion=$api_version" \
-H "Authorization: Bearer $access_token" | jq "."
```

10. Examine the response.

- If the response shows "status": "SUCCESSFUL", then the delete request succeeded.

- If the response shows "status": "FAILED" then the delete request may have failed due to a dependency such as an unreleased IP in an AD account. If you are certain that you want to remove the deployment and all related resources, you can choose to ignore the deletion failures and submit a delete request that uses the Automation Assembler IaaS service.
11. If you want to force deletion, use `forceDelete=true` in the Automation Assembler IaaS service request to delete the deployment.
- ```
curl -X DELETE \
"$url/iaas/api/deployments/$deployment_id?
forceDelete=true&apiVersion=$api_version_iaas" \
-H "Authorization: Bearer $access_token" | jq "."
```
12. Repeat steps 7, 8, and 9.
13. Examine the response to verify that "status": "SUCCESSFUL" appears.

## Delete Your Deployment

This example shows how to delete a deployment with the Automation Service Broker Deployment service and when that deletion fails, force the deletion with the Automation Assembler IaaS service.

Assign variables.

```
$ url='https://appliance.domain.com'
$ api_version=' 2020-08-25'
$ api_version_iaas=' 2021-07-15'
```

List all deployments.

```
curl -X GET "$url/deployment/api/deployments?apiVersion=$api_version" -H "Authorization:
Bearer $access_token" | jq "."
```

Examine the response to find the deployment that you want to delete.

```
{
 "id": "164f2d4e-1755-491e-b0a0-583f0ed4ae3e",
 "name": "example_deployment",
 "description": "",
 ...
},
```

Assign your deployment variable.

```
deployment_id='164f2d4e-1755-491e-b0a0-583f0ed4ae3e'
```

List the actions available for your deployment.

```
$ curl -X GET \
"$url/deployment/api/deployments/$deployment_id/actions?apiVersion=$api_version" \
-H "Authorization: Bearer $access_token" | jq "."
```

A snippet of the response shows the action "id": "Deployment.Delete" with "valid": true so you can delete the deployment.

```
...
{
 "id": "Deployment.Delete",
 "name": "Delete",
 "displayName": "Delete",
 "description": "Delete a deployment",
 "valid": true,
 "actionType": "RESOURCE_ACTION"
}
```

Delete the deployment.

```
curl -X DELETE \
"$url/deployment/api/deployments/$deployment_id?apiVersion=$api_version" \
-H "Authorization: Bearer $access_token" | jq "."
A snippet of the response shows the ID which is the request ID.
```

```
...
{
 "id": "d9541db3-2806-42aa-bde0-fb870d114833",
 "name": "Delete",
 "requestedBy": "user@mycompany.com",
 "actionId": "Deployment.Delete",
 "deploymentId": "164f2d4e-1755-491e-b0a0-583f0ed4ae3e",
 "resourceIds": [
 ...
],
 "status": "PENDING",
 ...
}
Assign the request ID variable.
```

```
$ request_id='d9541db3-2806-42aa-bde0-fb870d114833'
```

Check the status of the request.

```
$ curl -X GET \
"$url/deployment/api/requests/$request_id?apiVersion=$api_version" \
```

```
-H "Authorization: Bearer $access_token" | jq "."
```

A snippet of the response shows that the request failed.

```
{
 "id": "d9541db3-2806-42aa-bde0-fb870d114833",
 "name": "Delete",
 "requestedBy": "user@mycompany.com",
 "actionId": "Deployment.Delete",
 "deploymentId": "164f2d4e-1755-491e-b0a0-583f0ed4ae3e",
 "resourceIds": [
 ...
],
 "status": "FAILED",
 ...
}
```

If you are certain that you want to delete the deployment, force the deletion using the Automation Assembler IaaS service.

```
curl -X DELETE \
"$url/iaas/api/deployments/$deployment_id?forceDelete=true&apiVersion=$api_version_iaas" \
-H "Authorization: Bearer $access_token" | jq "."
```

Examine the response to get the new request ID.

```
{
 "progress": 0,
 "status": "INPROGRESS",
 "name": "Delete",
 "id": "a1b674a2-09aa-4b14-9459-35ddddbb9bbc1",
 "selfLink": "/iaas/api/request-tracker/a1b674a2-09aa-4b14-9459-35ddddbb9bbc1"
...
}
```

Assign the new request ID.

```
$ new_request_id='a1b674a2-09aa-4b14-9459-35ddddbb9bbc1'
```

Use the Automation Service Broker Deployment service to check the status of the request.

```
$ curl -X GET \
"$url/deployment/api/requests/$new_request_id?apiVersion=$api_version" \
-H "Authorization: Bearer $access_token" | jq "."
```

Examine the response to verify that the action is in progress.

```
{
 "id": "a1b674a2-09aa-4b14-9459-35ddddb9bbc1",
 "name": "Delete",
 "requestedBy": "user@mycompany.com",
 "actionId": "Deployment.Delete",
 "deploymentId": "164f2d4e-1755-491e-b0a0-583f0ed4ae3e",
 "resourceIds": [
 ...
],
 "status": "INPROGRESS",
 ...
}
```

Continue to check the status of the request.

```
$ curl -X GET \
"$url/deployment/api/requests/$new_request_id?apiVersion=$api_version" \
-H "Authorization: Bearer $access_token" | jq "."
```

The response shows when the deployment deletion request is successful.

```
{
 "id": "a1b674a2-09aa-4b14-9459-35ddddb9bbc1",
 "name": "Delete",
 "requestedBy": "user@mycompany.com",
 "actionId": "Deployment.Delete",
 "deploymentId": "164f2d4e-1755-491e-b0a0-583f0ed4ae3e",
 "resourceIds": [
 ...
],
 "status": "SUCCESSFUL",
 ...
}
```

## Reconfigure Load Balancer

To reconfigure the load balancer in your deployment, you use the Deployment APIs to make a POST request with the ID of the load balancer to update.

- Verify that all general prerequisites and prerequisites for the Automation Service Broker Deployment service have been satisfied. See [Prerequisites for API Use Case Examples](#).
- Verify that you have the ID of the deployment you want to reconfigure. See [Deploy a Cloud Template with Contents Inline](#).

- Verify that you have the ID of the load balancer in your deployment. See [Get Deployment Resource IDs](#).

- Assign your deployment ID variable.

```
deployment_id='<your_deployment_id>'
```

- Assign your load balancer ID variable.

```
load_balancer_id='<your_load_balancer_id>'
```

- Get a list of actions available for the load balancer in your deployment.

```
curl -X GET \
 $url/deployment/api/deployments/$deployment_id/resources/$load_balancer_id/actions?
 apiVersion=$api_version \
 -H "Authorization: Bearer $access_token" | jq "."
```

- Examine the response.

- Confirm that you see the action "name": "LoadBalancer.Reconfigure".
- "valid":true indicates that the action is valid for the deployment resource.

- Assign the action ID variable for the reconfigure action "name": "LoadBalancer.Reconfigure".

```
reconfigure_action_id='Cloud.LoadBalancer.LoadBalancer.Reconfigure'
```

- List the resource actions for the action ID .

```
curl -X GET \
 $url/deployment/api/deployments/$deployment_id/resources/$load_balancer_id/actions/
 $reconfigure_action_id?apiVersion=$api_version \
 -H "Authorization: Bearer $access_token" | jq "."
```

- Examine the response. The schema field shows the format of the input for an action on the load balancer resource.

- Reconfigure the load balancer with input inline.

```
curl -X POST \
 $url/deployment/api/deployments/$deployment_id/resources/$load_balancer_id/requests
 \
 -H "Authorization: Bearer $access_token" \
 -H 'Content-Type: application/json' \
 -d '{
 "actionId": "Cloud.LoadBalancer.LoadBalancer.Reconfigure",
 "inputs": {
 "routes": [
 {
 "port": "81",
 "protocol": "TCP",
 }
]
 }
 }'
```

```

 "instancePort": "81",
 "instanceProtocol": "TCP",
 "healthCheckConfiguration": {
 "port": "81",
 "urlPath": "/index.html",
 "protocol": "HTTP",
 "timeoutSeconds": 5,
 "intervalSeconds": 60,
 "healthyThreshold": 2,
 "unhealthyThreshold": 5
 }
 }
]
}
}

}' | jq "."

```

**9. Examine the response and assign the request ID.**

```
request_id='<your_request_id>'
```

**10. Check the status of the request.**

```
curl -X GET \
$url/deployment/api/requests/$request_id?apiVersion=$api_version \
-H "Authorization: Bearer $access_token" | jq "."

If the request is successful, the response shows "status": "SUCCESSFUL".
```

## Reconfigure the Load Balancer in Your Deployment

For your deployment with ID 5551a299-8b67-45e3-909e-a638d11b0d9f, reconfigure the load balancer with resource ID d5b4569d-2234-4fc4-a594-45e6b0251588.

Assign variables.

```
$ url='https://appliance.domain.com'
$ api_version='2020-08-25'
$ deployment_id='5551a299-8b67-45e3-909e-a638d11b0d9f'
```

Assign the load balancer ID.

---

```
$ load_balancer_id='d5b4569d-2234-4fc4-a594-45e6b0251588'
```

List the actions available for the load balancer resource.

```
$ curl -X GET \
 $url/deployment/api/deployments/$deployment_id/resources/$load_balancer_id/actions?
 apiVersion=$api_version \
 -H "Authorization: Bearer $access_token" | jq "."
```

A snippet of the response shows LoadBalancer.Reconfigure action.

...

{

```
 "id": "Cloud.LoadBalancer.LoadBalancer.Reconfigure",
 "name": "LoadBalancer.Reconfigure",
 "displayName": "Reconfigure",
 "description": "Reconfigure Load Balancer",
 "valid": true,
 "actionType": "RESOURCE_ACTION"
}
```

...

Assign the action ID variable.

```
$ reconfigure_action_id='Cloud.LoadBalancer.LoadBalancer.Reconfigure'
```

To get the schema for your action, list the resource actions by ID.

```
$ curl -X GET \
 $url/deployment/api/deployments/$deployment_id/resources/$load_balancer_id/actions/
 $reconfigure_action_id?apiVersion=$api_version" \
 -H "Authorization: Bearer $access_token" | jq "."
```

A snippet of the response provides the schema for the load balancing action.

...

```
"schema": {
 "type": "object",
 "title": "Reconfigure Load Balancer",
 "description": "Request schema for updating routes of load balancer resource",
 "properties": {
 "routes": {
 "type": "array",
 "items": {
 "type": "object"
 }
 }
 }
}
```

```

"type": "object",
"properties": {
 "protocol": {
 "type": "string",
 "title": "Protocol",
 "description": "The communication protocol for an incoming request to the load balancer. HTTP, HTTPS, or TCP.",
 "enum": [
 "HTTP",
 "HTTPS",
 "TCP"
]
 },
 "port": {
 "type": "string",
 "title": "Port",
 "description": "The listening port for an incoming request to the load balancer.",
 "pattern": "^\\d+$"
 },
 "instanceProtocol": {
 "type": "string",
 "title": "Instance protocol",
 "description": "The communication protocol used between the load balancer and the machines in the pool. HTTP, HTTPS, or TCP.",
 "enum": [
 "HTTP",
 "HTTPS",
 "TCP"
]
 }
}
...

```

Submit a request to reconfigure the load balancer with new route properties.

```

$ curl -X POST \
$url/deployment/api/deployments/$deployment_id/resources/$load_balancer_id/requests \

```

```

-H "Authorization: Bearer $access_token" \
-H 'Content-Type: application/json' \
-d '{
 "actionId": "Cloud.LoadBalancer.LoadBalancer.Reconfigure",
 "inputs": {
 "routes": [
 {
 "port": "81",
 "protocol": "TCP",
 "instancePort": "81",
 "instanceProtocol": "TCP",
 "healthCheckConfiguration": {
 "port": "81",
 "urlPath": "/index.html",
 "protocol": "HTTP",
 "timeoutSeconds": 5,
 "intervalSeconds": 60,
 "healthyThreshold": 2,
 "unhealthyThreshold": 5
 }
 }
]
 }
}' | jq "."

```

A snippet of the response shows request ID.

```

...
{
 "id": "7342a348-65e0-4376-9472-94be56b928a9",
 "name": "Reconfigure",
 "deploymentId": "13c04d0a-fd81-4bcc-99b1-ac499fb1821d",
...

```

Assign the request ID variable.

```
$ request_id='342a348-65e0-4376-9472-94be56b928a9'
```

Check the status of the request.

```
$ curl -X GET \
$url/deployment/api/requests/$request_id?apiVersion=$api_version" \
-H "Authorization: Bearer $access_token" | jq "."
```

A snippet of the response shows that the request was successful.

```
...
{
 "actionId": "Cloud.LoadBalancer.LoadBalancer.Reconfigure",
 "completedTasks": 1,
 "totalTasks": 1,
 "status": "SUCCESSFUL",
}
```

## Add a Disk to a Machine and Power It Off

To add a disk to a machine in your deployment, you use the Deployment APIs to make a POST request with the ID of the virtual machine to update. To power off the machine, you make a POST request and specify the action to perform.

- Verify that all general prerequisites and prerequisites for the Automation Service Broker Deployment service have been satisfied. See [Prerequisites for API Use Case Examples](#).
- Verify that you have the ID of the deployment you want to reconfigure. See [Deploy a Cloud Template with Contents Inline](#).
- Verify that you have the ID of the virtual machine in your deployment. See [Get Deployment Resource IDs](#).

1. Assign your deployment ID variable.

```
deployment_id='<your_deployment_id>'
```

2. Assign your virtual machine ID variable.

```
virtual_machine_id='<your_virtual_machine_id>'
```

3. Get a list of actions available for the virtual machine in your deployment.

```
curl -X GET \
$url/deployment/api/deployments/$deployment_id/resources/$virtual_machine_id/actions \
-H "Authorization: Bearer $access_token" | jq "."
```

4. Examine the response.

- Confirm that you see the action `Add.Disk` with `"valid":true`. Copy the value to assign to the add disk action ID.
- Confirm that you see the action `PowerOff` with `"valid":true`. Copy the value to assign to the power off action ID.

`"valid":true` indicates that each action is valid for the deployment resource.

5. Assign variables for the resources.

```
add_disk_action_id='<your_add_disk_id>'
poweroff_machine_action_id='<your_poweroff_action_id>'
```

**6. List the resource actions for the add disk action ID.**

```
curl -X GET \
$url/deployment/api/deployments/$deployment_id/actions/$reconfigure_action_id?
apiVersion=$api_version \
-H "Authorization: Bearer $access_token" | jq "."
```

**7. Examine the response. The schema field shows the format of the input for an action on the virtual machine resource.**

**8. Attach a disk of size 1 GB to the machine.**

```
curl -X POST \
$url/deployment/api/deployments/$deployment_id/resources/$virtual_machine_id/
requests \
-H "Authorization: Bearer $access_token" \
-H 'Content-Type: application/json' \
-d '{
 "actionId": "Cloud.AWS.EC2.Instance.Add.Disk",
 "inputs": {
 "name": "disk1",
 "capacityGb": 1,
 "type": "Cloud.Volume"
 }
}' | jq "."
```

**9. Examine the response and assign the request ID.**

```
request_id='<your_request_id>'
```

**10. Check the status of the request.**

```
curl -X GET \
$url/deployment/api/requests/$request_id?apiVersion=$api_version \
-H "Authorization: Bearer $access_token" | jq "."
```

If the request is successful, the response shows "status": "SUCCESSFUL".

**11. List the resource actions for the power off action ID.**

```
curl -X GET \
$url/deployment/api/deployments/$deployment_id/resources/$virtual_machine_id/
```

```
actions/$poweroff_machine_action_id?apiVersion=$api_version \
-H "Authorization: Bearer $access_token" | jq ".."
```

12. Examine the response. No schema field indicates that no inputs field is required for this action on the virtual machine resource.
13. Power off the machine.

```
curl -X POST \
$url/deployment/api/deployments/$deployment_id/resources/$virtual_machine_id/
requests \
-H "Authorization: Bearer $access_token" \
-H 'Content-Type: application/json' \
-d '{
 "actionId": "Cloud.AWS.EC2.Instance.PowerOff"
}' | jq ".."
```

14. Examine the response and assign the request ID.

```
request_id='<your_request_id>'
```

15. Check the status of the request.

```
curl -X GET \
$url/deployment/api/requests/$request_id?apiVersion=$api_version \
-H "Authorization: Bearer $access_token" | jq ".."
```

If the request is successful, the response shows "status": "SUCCESSFUL".

## Add a Disk and Power Off Your Virtual Machine

For your deployment with ID 5551a299-8b67-45e3-909e-a638d11b0d9f, reconfigure the virtual machine with resource ID 42f49781-1490-4a08-ae21-8baf383a72ac by adding a disk and powering it off.

Assign variables.

```
$ url='https://appliance.domain.com'
$ api_version='2020-08-25'
$ deployment_id='5551a299-8b67-45e3-909e-a638d11b0d9f'
```

Assign the virtual machine ID.

```
$ virtual_machine_id='42f49781-1490-4a08-ae21-8baf383a72ac'
```

List the actions available for the virtual machine resource.

```
$ curl -X GET \
$url/deployment/api/deployments/$deployment_id/resources/$virtual_machine_id/actions?
apiVersion=$api_version \
```

```
-H "Authorization: Bearer $access_token" | jq "."
```

A snippet of the response shows the actions to Add.Disk and PowerOff.

```
...
{
 "id": "Cloud.AWS.EC2.Instance.Add.Disk",
 "name": "Add.Disk",
 "displayName": "Add Disk",
 "description": "Add a disk to the machine",
 "valid": true,
 "actionType": "RESOURCE_ACTION"
},
...
{
 "id": "Cloud.AWS.EC2.Instance.PowerOff",
 "name": "PowerOff",
 "displayName": "Power Off",
 "description": "Power off a machine",
 "valid": true,
 "actionType": "RESOURCE_ACTION"
},
...

```

Assign the action ID variables to add a disk and power off the virtual machine.

```
$ add_disk_action_id='Cloud.AWS.EC2.Instance.Add.Disk'
```

```
$ power_off_action_id='Cloud.AWS.EC2.Instance.PowerOff'
```

Get the add disk action for the virtual machine resource.

```
$ curl -X GET \
 $url/deployment/api/deployments/$deployment_id/resources/$virtual_machine_id/actions/
$add_disk_action_id?apiVersion=$api_version \
-H "Authorization: Bearer $access_token" | jq "."
```

A snippet of the response provides the schema to add a disk.

```
...
{
 "properties": {
 "name": {
 "type": "string"
 }
 }
}
```

```

 "type": "string",
 "title": "Name",
 "description": "Disk Name",
 "minLength": 1
 },
 "capacityGb": {
 "type": "integer",
 "title": "Size(GB)",
 "description": "Disk Capacity in GB",
 "minimum": 1
 },
 "type": {
 "type": "string",
 "title": "Type",
 "description": "Disk Resource Type.",
 "readOnly": true,
 "default": "Cloud.Volume"
 },
...

```

Follow the schema and submit a request to add a 1 GB disk to the virtual machine.

```

$ curl -X POST \
$url/deployment/api/deployments/$deployment_id/resources/$virtual_machine_id/requests \
-H "Authorization: Bearer $access_token" \
-H 'Content-Type: application/json' \
-d '{
 "actionId": "Cloud.AWS.EC2.Instance.Add.Disk",
 "inputs": {
 "name": "disk1",
 "capacityGb": 1,
 "type": "Cloud.Volume"
 }
}' | jq "."

```

A snippet of the response shows request ID.

```
...
"id": "17dec8d9-2e2a-4c29-9067-ce41c37be7a3",
"name": "Add Disk",
"deploymentId": "5551a299-8b67-45e3-909e-a638d11b0d9f",
...
```

Assign the request ID variable.

```
$ request_id='17dec8d9-2e2a-4c29-9067-ce41c37be7a3'
```

Check the status of the request.

```
$ curl -X GET \
$url/deployment/api/requests/$request_id?apiVersion=$api_version \
-H "Authorization: Bearer $access_token" | jq "."
A snippet of the response shows that the request was successful.
```

```
...
"actionId": "Cloud.AWS.EC2.Instance.Add.Disk",
"completedTasks": 3,
"totalTasks": 3,
"status": "SUCCESSFUL",
}
```

Get the power off action for the virtual machine resource.

```
$ curl -X GET \
$url/deployment/api/deployments/$deployment_id/resources/$virtual_machine_id/actions/
$poweroff_machine_action_id?apiVersion=$api_version \
-H "Authorization: Bearer $access_token" | jq "."
The complete response shows that there is no schema for the power off action.
```

```
{
"id": "Cloud.AWS.EC2.Instance.PowerOff",
"name": "PowerOff",
"displayName": "Power Off",
"description": "Power off a machine",
"dependents": [
"Provider_LoadBalancer_1"
],
```

```
"valid": true,
"actionType": "RESOURCE_ACTION"
}
Power off the virtual machine.

$ curl -X POST \
$url/deployment/api/deployments/$deployment_id/resources/$virtual_machine_id/requests \
-H "Authorization: Bearer $access_token" \
-H 'Content-Type: application/json' \
-d '{
 "actionId": "Cloud.AWS.EC2.Instance.PowerOff"
}' | jq ".
```

A snippet of the response shows request ID.

```
...
 "id": "ab7d3aec-f850-4b0e-9c1c-47378c182a00",
 "name": "Power Off",
 "deploymentId": "5551a299-8b67-45e3-909e-a638d11b0d9f",
...
```

Assign the request ID variable.

```
$ request_id='ab7d3aec-f850-4b0e-9c1c-47378c182a00'
```

Check the status of the request.

```
$ curl -X GET \
$url/deployment/api/requests/$request_id?apiVersion=$api_version \
-H "Authorization: Bearer $access_token" | jq ".
```

A snippet of the response shows that the request was successful.

```
...
 "actionId": "Cloud.AWS.EC2.Instance.PowerOff",
 "completedTasks": 1,
 "totalTasks": 1,
 "status": "SUCCESSFUL",
 "inputs": {}
}
```

## Viewing Billable Objects

### Viewing Billable Objects

As an Automation Assembler or Automation Service Broker administrator, you can use the Automation Service Broker Deployment APIs to view billable objects that are used in your organization.

### Prerequisites for viewing billable objects

- Verify that all general prerequisites and prerequisites for the Automation Service Broker Deployment service have been satisfied. See [Prerequisites for API Use Case Examples](#).

### How to get a summary of billable objects

The following request retrieves a categorized summary or total count of VMware Aria Automation billable objects in your organization.

```
curl -X GET \
$url/deployment/api/billing-metrics?apiVersion=$api_version \
-H 'Accept: application/json' \
-H "Authorization: Bearer $access_token" | jq "."
```

The following sample response shows all billable objects.

```
{
 "billingMetrics": [
 {
 "id": "vSphereManagedVMCount",
 "displayName": "vSphere Managed VM Count",
 "value": 19
 },
 {
 "id": "vSphereCpuCount",
 "displayName": "vSphere CPU Count",
 "value": 20
 },
 {
 "id": "vSphereCpuCoreCount",
 "displayName": "vSphere CPU Core Count",
 "value": 52
 }
]
}
```

```

 "id": "vmcManagedVMCount",
 "displayName": "VMC Managed VM Count",
 "value": 0
},
{
 "id": "vmcCpuCount",
 "displayName": "VMC CPU Count",
 "value": 0
},
{
 "id": "vmcCpuCoreCount",
 "displayName": "VMC CPU Core Count",
 "value": 0
},
{
 "id": "publicCloudManagedVMCount",
 "displayName": "Public Cloud Managed VM Count",
 "value": 58
}
]
}

```

### **How to get information about billable objects**

By applying the filter billable=true, the following request limits the amount of output from the call to include only the billable objects that are in your organization.

```

curl -X GET \
"$url/deployment/api/resources?apiVersion=$api_version&billable=true" \
-H 'Accept: application/json' \
-H "Authorization: Bearer $access_token" \
| jq "."

```

The following sample response snippet provides the details about one of the billable objects.

```
{
 "content": [

```

```
{
 "id": "9bc16a26-bd81-4660-9aa6-6eadfe72456d",
 "name": "Cloud_Machine_1-mcm1157065-230404373562",
 "type": "Cloud.AWS.EC2.Instance",

## Onboarding virtual machines

### Onboarding machines

To onboard machines that are not yet managed by an Automation Assembler project, you use the Onboarding APIs.

The onboarding process begins with creating an onboarding plan that locates the machines to be onboarded and creates a deployment for those machines when the plan runs. When you add deployments to the plan, you have the option of adding the deployment with a cloud template that allows all day 2 actions on the deployment.

### Onboard machines as a single deployment

As an administrator, you can use the Onboarding APIs to onboard unmanaged machines as a single Automation Assembler deployment so that you can manage the machines. To onboard machines, you:

- Verify that all general prerequisites and prerequisites for the Onboarding service have been satisfied. See [Prerequisites for API Use Case Examples](#).
- Verify that you have the ID for the cloud account with cloud zones where the machines to be onboarded are located. See [Adding Cloud Accounts](#) and [Create a Cloud Zone](#).
- Verify that you have the ID for a project with at least one user and with access to the cloud zones. See [Create a Project to use in Automation Assembler](#)
  
- Create an onboarding plan.
- Query for unmanaged machines.
- Create a bulk deployment that adds the unmanaged machines.
- Run the plan.

When you run the plan you can check the plan progress to see if the plan completes successfully and onboards the machines.

The following procedure shows how to onboard machines and create a deployment in VMware Aria Automation without using a cloud template. This is the fastest way to onboard machines. However, to run the **Update** day 2 action on the deployment after onboarding, you must create the deployment with a cloud template. See [How do I add a cloud template to my onboarding plan](#).

1. Create your onboarding plan without placements.

In this example,

- project ID: 4c4f8a47-d746-43f4-b88c-ea94ac8bd573
- cloud account ID: 0cbc8179-d202-4a30-9460-c25d2653a677

```
curl -X POST \
$url/relocation/onboarding/plan \
-H "Authorization: Bearer $access_token" \
-H 'Content-Type: application/json' \
-d '{
 "name": "'<your_plan_name>'",
 "projectId": "4c4f8a47-d746-43f4-b88c-ea94ac8bd573",
 "endpointIds": [
 "0cbc8179-d202-4a30-9460-c25d2653a677"
],
}'
```

```
"usePlacements": false
}' | jq "."
```

**NOTE**

To create an onboarding plan with placements, set "usePlacements": true. With placement turned on, the onboarded workload considers resource limits defined in your project cloud zones or resource quota policy and takes longer to run.

Examine the response to verify the status, the project ID, the cloud ID, and to get the documentSelfLink, for example:

```
{
 "status": "OK",
 "nextRefreshTimeMicros": 0,
 "refreshIntervalMicros": 0,
 "name": "Plan-782",
 "projectId": "4c4f8a47-d746-43f4-b88c-ea94ac8bd573",
 "endpointIds": [
 "0cbc8179-d202-4a30-9460-c25d2653a677"
],
 ...
 "documentSelfLink": "/relocation/onboarding/plan/d2010bcd-34f6-4fac-9d67-f7f4c6ec686a"
 ...
}
```

The value for the documentSelfLink is used for the planLink in subsequent steps.

2. Use the planLink to discover the compute resources representing unmanaged machines.

```
curl -X POST \
 $url/relocation/api/wo/query-unmanaged-machine \
 -H "Authorization: Bearer $access_token" \
 -H 'Content-Type: application/json' \
 -d '{
 "planLink": "/relocation/onboarding/plan/d2010bcd-34f6-4fac-9d67-f7f4c6ec686a"
 "expandFields": [
 "id",
 "documentSelfLink",
 "name",
 "computeResourceType"
]
 }'
```

```

 "powerState",
 "address",
 "creationTimeMicros",
 "expandedTags",
 "tagLinks",
 "endpointLinks"
],
 "optionExcludePlanMachines": true
}' | jq "."

```

Examine the response to get the snippet for unmanaged machines with "powerState": "ON", for example:

```

...
"/resources/compute/8bff887d-56fd-3752-bb99-d3f32a35abde": {
 "address": "10.10.10.17",
 "creationTimeMicros": 1717409843457000,
 "documentSelfLink": "/resources/compute/dd646fdc-e6db-3b16-a72e-d1c905f7a9c8",
 "endpointLinks": "/resources/endpoints/aa6a5445-e63a-4659-a277-00073a2645c8",
 "expandedTags": [],
 "id": "5017d984-aa61-e00e-dfa6-a986403c01b8",
 "name": "Machine-76",
 "powerState": "ON",
 "tagLinks": []
}

"/resources/compute/9bc16a26-bd81-4660-9aa6-6eadfe72456d": {
 "address": "10.10.2.243",
 "creationTimeMicros": 1717409843457000,
 "documentSelfLink": "/resources/compute/8615bbfe-ea90-420a-a1cf-8048ba4271d4",
 "endpointLinks": "/resources/endpoints/2d57f1c4-fbe0-46ce-a061-3a5f1396f37b",
 "expandedTags": [],
 "id": "a6f324e4-101c-33f6-ac51-d9aaaa020123",
 "name": "Machine-25",
 "powerState": "ON",
 "tagLinks": []
}

```

```
}...
```

### 3. Use the planLink, documentSelfLink, and name to create a single deployment for the unmanaged machines.

```
curl -X POST \
 $url/relocation/onboarding/task/create-deployment-bulk \
 -H "Authorization: Bearer $access_token" \
 -H 'Content-Type: application/json' \
 -d '{
 "planLink": "/relocation/onboarding/plan/d2010bcd-34f6-4fac-9d67-f7f4c6ec686a",
 "deployments": [
 {
 "name": "'<your_deployment_name>'",
 "resources": [
 {
 "link": "/resources/compute/dd646fdc-e6db-3b16-a72e-
d1c905f7a9c8",
 "name": "Machine-76"
 },
 {
 "link": "/resources/compute/8615bbfe-ea90-420a-
a1cf-8048ba4271d4",
 "name": "Machine-25"
 }
]
 }
]
 }' | jq ".."
```

The response shows that the discovered machines have been assigned to the deployment.

```
{
 "planLink": "/relocation/onboarding/plan/d2010bcd-34f6-4fac-9d67-f7f4c6ec686a",
 "deployments": [
 {
 "planLink": "/relocation/onboarding/plan/d2010bcd-34f6-4fac-9d67-
f7f4c6ec686a",
 "name": "Deployment-562",
```

```

 "resources": [
 {
 "link": "/resources/compute/dd646fdc-e6db-3b16-a72e-d1c905f7a9c8",
 "name": "Machine-76"
 },
 {
 "link": "/resources/compute/8615bbfe-ea90-420a-a1cf-8048ba4271d4",
 "name": "Machine-25"
 }
],
 "tenantLink": "/core/tenants/dc96003b28356c75",
 "documentVersion": 0,
 "documentUpdateTimeMicros": 0,
 "documentExpirationTimeMicros": 0
}
],
"tenantLink": "/core/tenants/dc96003b28356c75"
}

```

**4. Use the planLink to run the plan and onboard the machines.**

```

curl -X POST \
$url/relocation/api/wo/execute-plan \
-H "Authorization: Bearer $access_token" \
-H 'Content-Type: application/json' \
-d '{
 "planLink": "/relocation/onboarding/plan/d2010bcd-34f6-4fac-9d67-f7f4c6ec686a"
}' | jq "."

```

**5. Use the planLink to the check the run.**

```

curl -X GET \
$url/relocation/onboarding/plan/d2010bcd-34f6-4fac-9d67-f7f4c6ec686a \
-H "Authorization: Bearer $access_token" \
-H 'Content-Type: application/json'

```

```
| jq "."
```

The status in the response changes as the plan moves through executing or updating. If the run fails, the status shows "status": "error".

```
{
 "status": "OK",
 "nextRefreshTimeMicros": 0,
 "refreshIntervalMicros": 0,
 "name": "Plan-782",
 "projectId": "4c4f8a47-d746-43f4-b88c-ea94ac8bd573",
 "endpointIds": [
 "0cbc8179-d202-4a30-9460-c25d2653a677"
],
 "createdBy": "example_admin@example_company.com",
 "enableExtensibilityEvents": true,
 "organizationId": "174adb59-8132-46f0-9cd8-2b2361e9cb2c",
 "customProperties": {},
 "usePlacements": false,
 "isQuick": false,
 "tenantLink": "/core/tenants/dc96003b28356c75",
 "documentVersion": 0,
 "documentKind":
 "com:vmware:relocation:services:onboarding:plan:OnboardingPlanService:OnboardingPlansState",
 "documentSelfLink": "/relocation/onboarding/plan/d2010bcd-34f6-4fac-9d67-f7f4c6ec686a",
 "documentUpdateTimeMicros": 1718190629415000,
 "documentUpdateAction": "POST",
 "documentExpirationTimeMicros": 0,
 "documentAuthPrincipalLink": "/core/authz/users/example_admin@example_company.com"
}
```

## How do I add a cloud template to my onboarding plan

When creating an onboarding plan, you can attach an existing VMware cloud template (VCT) to the deployment. The cloud template allows you to iteratively update the deployment and avoid the need to delete onboarded resources and create new ones while gradually scaling out your deployment.

With a cloud template attached to your deployment, you can run all day 2 actions including the **Update** day 2 action provided that the YAML of the selected cloud template accepts user input.

### NOTE

You can choose any cloud template but depending on the cloud template details, an **Update** day 2 action might delete and re-create original resources.

By attaching a cloud template with resource mapping, you can create an onboarding deployment that maps VMs to template resources in the same way as the deployment that was originally provisioned in VMware Aria Automation using the same cloud template. The only restriction is that the onboarding deployment must have the same number of machines as the selected cloud template and the admin must specify the VM to template resource mapping.

A deployment that uses a cloud template with resource mapping includes the **Update** day 2 action if the selected template accepts user input and the update only applies changes to existing resources. It will not re-create the original resources unless there are major changes between the current version of cloud template and original deployment. Onboarded deployments can also be iteratively updated without deletion and re-creation of the onboarded machines.

### Prerequisites for adding deployments with a cloud template

- Verify that all general prerequisites and prerequisites for the Onboarding service have been satisfied. See [Prerequisites for API Use Case Examples](#).
- Verify that you have the `planLink` for an existing onboarding plan. For example, to list onboarding plans use `GET /relocation/api/onboarding/plan`. See [Onboard machines as a single deployment](#).
- Verify that you have the IDs and names of the resources that you are planning to onboard. For example, to list unmanaged machines, use `POST /relocation/api/wo/query-unmanaged-machine`. See [Onboard machines as a single deployment](#).
- Verify that the VMware cloud template that you plan to attach exists. For example, to list cloud templates use `GET /blueprint/api/blueprints`. See [Create and Update a Cloud Template](#).
- If adding a cloud template with mapping, verify that you have the correct template component name to link to each machine. For example:
  - To get template component names, use `GET /blueprint/api/blueprints/<blueprint_id>` where `blueprint_id` is the ID for your cloud template. In the response, the `blueprint` content field lists the machine component names.
  - To list unmanaged machines, use `POST /relocation/api/wo/query-unmanaged-machine`.

Example payloads include the following input:

- **planLink for existing onboarding plan**

```
"planLink": "/relocation/onboarding/plan/d2010bcd-34f6-4fac-9d67-f7f4c6ec686a"
```

- **Template to attach if onboarding with template but without mapping**

```
"name": "singleMachines"
"link": "/blueprint/api/blueprints/b79612a9-6e2f-4b48-a775-88eb7676dc2c"
```

- **Template to attach if onboarding with template and with mapping**

```
"template": {
 "name": "vc01",
 "link": "/blueprint/api/blueprints/74bbcdae-b945-4a95-ac86-8bed0a75e2c2",
 "components": {
 "/resources/compute/bf07d26a-38cd-392e-b3d6-0004cf36168a":
 "Cloud_vSphere_Machine_1",
 "/resources/compute/cc628c21-5531-414d-a09e-5f35916ce689":
 "Cloud_vSphere_Machine_2"
 }
}
```

## **How do I add a deployment with a cloud template**

The following example adds a deployment with the template `singleMachine` to bring the VMs `East-centos-small-000011` and `est` under management.

```
curl -X POST \
$url/relocation/onboarding/task/create-deployment-bulk \
-H "Authorization: Bearer $access_token" \
-H 'Content-Type: application/json' \
-d '{
 "deployments": [
 {
 "resources": [
 {
 "link": "/resources/compute/b82870f1-575b-308b-ac2e-874fad85703b",
 "name": "East-centos-small-000011",
 "tagLinks": []
 },
 ...
]
 }
]
}'
```

```

 {
 "link": "/resources/compute/e12fefb6-2d0a-3ee1-bb7f-1ceceb3d1ca6",
 "name": "est",
 "tagLinks": []
 }
],
 "template": {
 "name": "singleMachine",
 "link": "/blueprint/api/blueprints/b79612a9-6e2f-4b48-
a775-88eb7676dc2c"
 }
}
],
"planLink": "/relocation/onboarding/plan/d2010bcd-34f6-4fac-9d67-f7f4c6ec686a"
}' | jq "."

```

### **How do I add a deployment with a cloud template and mapping**

The following example adds a deployment with the template vc01 to bring:

- VMs VM-20 and VM-21 under management with:
  - VM-20 mapped to Cloud\_vSphere\_Machine\_1 in the template.
  - VM-21 mapped to Cloud\_vSphere\_Machine\_2 in the template.
- VMs VM-0014 and VM-0015 under management with:
  - VM-0014 mapped to Cloud\_vSphere\_Machine\_1 in the template.
  - VM-0015 mapped to Cloud\_vSphere\_Machine\_2 in the template.

```

curl -X POST \
$url/relocation/onboarding/task/create-deployment-bulk \
-H "Authorization: Bearer $access_token" \
-H 'Content-Type: application/json' \
-d '{

## Working with Pipelines

### Working with Pipelines

As a Automation Pipelines administrator, you can use the Automation Pipelines APIs to model your software release process. The following API examples show how to add an endpoint to use in a pipeline task, run the pipeline, and verify results.

### Create an Endpoint

To create an endpoint, you make a POST request with the endpoint properties. Then you use the ID of the endpoint created to validate it.

- Verify that all general prerequisites and prerequisites for the Automation Pipelines service have been satisfied. See [Prerequisites for API Use Case Examples](#).
- Verify that you have the ID for the project that you want to use for your endpoint. See [Create a Project with the Project Service API](#).

The following procedure shows how to create a Jenkins endpoint to use in your pipeline. To create a Jenkins endpoint, you must provide the URL of the Jenkins server and the admin password. Before using it in a pipeline, you validate the endpoint to verify that it can connect to the Jenkins server.

1. Assign the project ID variable.

```
project_id='<your_project_id>'
```

2. Create a Jenkins endpoint.

```
curl -X POST \
 $url/codestream/api/endpoints?apiVersion=$api_version \

```

```

-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
 "name": "<your_endpoint_name>",
 "description": "",
 "isRestricted": false,
 "properties": {
 "url": "<your_Jenkins_server_URL>",
 "username": "admin",
 "password": "<admin_passwd_for_Jenkins_server>",
 "folderPath": "",
 "pollInterval": 2,
 "retryCount": 2,
 "retryWaitSeconds": 3
 },
 "type": "jenkins",
 "project": "'$project_id'"
}' | jq "."

```

**3. Examine the response and assign the endpoint ID variable.**

```
endpoint_id='<your_endpoint_id>'
```

**4. To verify that the endpoint can connect to the Jenkins server, validate the endpoint.**

```

$ curl -X POST \
$url/codestream/api/endpoint-validation?apiVersion=$api_version \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
 "project": "'$project_id'",
 "kind": "ENDPOINT",
 "id": "'$endpoint_id'",
 "name": "<your_endpoint_name>",
 "type": "jenkins",
 "properties": {

```

```

"url": "<your_Jenkins_server_URL>",
"username": "admin",
"password": "<admin_passwd_for_Jenkins_server>",
"folderPath": "",
"pollInterval": 2,
"retryCount": 2,
"retryWaitSeconds": 3
}
} | jq "."

```

Examine the response to verify that the endpoint is valid.

## Create a Jenkins endpoint

Create a Jenkins endpoint named `jenkins-example`.

Assign variables.

```

$ url='https://appliance.domain.com'
$ api_version='2019-10-17'
$ project_id='MyProject1'

```

Create the Jenkins endpoint.

```

$ curl -X POST \
$url/codestream/api/endpoints?apiVersion=$api_version \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
 "name": "jenkins-example",
 "description": "",
 "isRestricted": false,
 "properties": {
 "url": "http://example-jenkins-server.mycompany.com:8080",
 "username": "admin",
 "password": "1146Examplea3eJenkin5d004Pa55word",
 "folderPath": "",
 "pollInterval": 2,
 }
}'

```

```

 "retryCount": 2,
 "retryWaitSeconds": 3
 },
 "type": "jenkins",
 "project": "'$project_id'"
}' | jq "."

```

The response from your request shows the endpoint ID.

```
{
 "project": "MyProject1",
 "kind": "ENDPOINT",
 "id": "85723b0b-a819-435e-8d71-f8f834cdbaa2",
 "name": "jenkins-example",
 "description": "",
 "updatedBy": "adminuser@mycompany.com",
 "createdAt": "2022-08-03T08:57:10.033+0000",
 "updatedAt": "2022-11-04T11:14:49.315+0000",
 "_link": "/codestream/api/endpoints/85723b0b-a819-435e-8d71-f8f834cdbaa2",
...
}
```

Assign the endpoint ID variable.

```
$ endpoint_id='85723b0b-a819-435e-8d71-f8f834cdbaa2'
```

Validate the endpoint.

```
$ curl -X POST \
$url/codestream/api/endpoint-validation?apiVersion=$api_version \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
 "project": "'$project_id'",
 "kind": "ENDPOINT",
 "id": "'$endpoint_id'",
 "name": "jenkins-example",
 "type": "jenkins",
```

```

"properties": {
 "url": "http://example-jenkins-server.mycompany.com:8080",
 "username": "admin",
 "password": "1146Examplea3eJenkin5d004Pa55word",
 "folderPath": "",
 "pollInterval": 2,
 "retryCount": 2,
 "retryWaitSeconds": 3
}
} | jq "."

```

The status message in the response verifies that the endpoint is valid.

```
{
 "output": {},
 "status": "COMPLETED",
 "statusMessage": "Valid Jenkins Endpoint",
 "duration": 0
}
```

Create a pipeline with a Jenkins task that uses the endpoint.

## Create and Enable a Pipeline

To create a pipeline, you make a POST request and provide the endpoint ID. Then you use the ID of the pipeline created in a PATCH request to enable it.

- Verify that all general prerequisites and prerequisites for the Automation Pipelines service have been satisfied. See [Prerequisites for API Use Case Examples](#).
- Verify that you have the ID for the project that you used for your endpoint. See [Create a Project with the Project Service API](#).
- Verify that you know the name of the Jenkins endpoint that you created. See [Create an Endpoint](#).

The following procedure shows how to create a pipeline with a Jenkins task using the Jenkins endpoint that you created. Then you enable the pipeline to run.

1. Assign the project ID variable.

```
project_id='<your_project_id>'
```

2. Assign the endpoint name variable.

```
endpoint_name='<your_endpoint_name>'"
```

3. Create the pipeline with a Jenkins task.

- For job, provide the job on the Jenkins server that your pipeline will run.

- For parameters, provide the parameters that will be passed to the job.

```
curl -X POST \n\n $url/codestream/api/pipelines?apiVersion=$api_version \n -H 'Content-Type: application/json' \n -H "Authorization: Bearer $access_token" \n -d '{\n \"project\": \"'$project_id'\",\n \"kind\": \"PIPELINE\", \n \"name\": \"'<your_pipeline_name>'\", \n \"concurrency\": 10,\n \"stageOrder\": [\"Stage0\"],\n \"stages\": {\n \"Stage0\": {\n \"taskOrder\": [\"Task0\"],\n \"tags\": [],\n \"tasks\": {\n \"Task0\": {\n \"type\": \"Jenkins\", \n \"ignoreFailure\": false,\n \"preCondition\": \"\", \n \"input\": {\n \"job\": \"'<your_job_name>'\", \n \"jobFolder\": \"\", \n \"parameters\": {\n \"'<your_parameters>'\": \"\"\n }\n },\n \"endpoints\": {\n \"jenkinsServer\": \"'$endpoint_name'\" \n },\n \"tags\": [],\n \"_configured\": true\n }\n }\n }\n }\n}
```

```

 }
 }
}

}' | jq "."

```

A snippet of the response shows the pipeline ID with the pipeline disabled. Assign a variable for the pipeline ID.

`pipeline_id='<your_pipeline_id>'`

#### 4. Enable the pipeline.

```

curl -X PATCH \
$url/codestream/api/pipelines/$pipeline_id?apiVersion=$api_version \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{"state": "ENABLED"}' | jq "."

```

The response shows the pipeline state changed to "state": "ENABLED".

## Create and Enable a Pipeline

Using the endpoint named `jenkins-example` that you created, create a pipeline named `jenkinspipeline` with a Jenkins task.

Assign variables.

```

$ url='https://appliance.domain.com'
$ api_version=' 2019-10-17'
$ project_id='MyProject1'
$ endpoint_name='jenkins-example'

```

Create the pipeline with a Jenkins task.

```

$ curl -X POST \
$url/codestream/api/pipelines?apiVersion=$api_version \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
 "project": "'$project_id'",
 "kind": "PIPELINE",
 "name": "jenkinspipeline",
 "concurrency": 10,
}

```

```

"stageOrder": ["Stage0"],
"stages": {
 "Stage0": {
 "taskOrder": ["Task0"],
 "tags": [],
 "tasks": {
 "Task0": {
 "type": "Jenkins",
 "ignoreFailure": false,
 "preCondition": "",
 "input": {
 "job": "Build-DemoApp",
 "jobFolder": "",
 "parameters": {
 "vRCSTestExecutionId": ""
 }
 },
 "endpoints": {
 "jenkinsServer": "'$endpoint_name'"
 },
 "tags": [],
 "_configured": true
 }
 }
 }
}
} ' | jq "."

```

A snippet of the response shows the pipeline ID and shows the state of the pipeline as disabled.

```
{
 "project": "MyProject1",
 "kind": "PIPELINE",
 "id": "2677aa61-578a-4465-a653-a3c787fed3be",
}
```

```

"name": "jenkinspipeline",
"createdBy": "adminuser@mycompany.com",
"updatedBy": "adminuser@mycompany.com",
"createdAt": "2022-11-04T11:20:09.905+0000",
"updatedAt": "2022-11-04T11:23:40.971+0000",
"_link": "/codestream/api/pipelines/2677aa61-578a-4465-a653-a3c787fed3be",
...
"rollbacks": [],
"tags": [],
"state": "DISABLED"
}

```

Assign a variable for the pipeline ID.

```
$ pipeline_id="2677aa61-578a-4465-a653-a3c787fed3be"
```

Enable the pipeline.

```
$ curl -X PATCH \
$url/codestream/api/pipelines/$pipeline_id?apiVersion=$api_version \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{"state": "ENABLED"}' | jq "."
```

A snippet of the response shows the state of the pipeline is enabled.

```
{
"project": "MyProject1",
"kind": "PIPELINE",
"id": "2677aa61-578a-4465-a653-a3c787fed3be",
"name": "jenkinspipeline",
"createdBy": "adminuser@mycompany.com",
"updatedBy": "adminuser@mycompany.com",
"createdAt": "2022-11-04T11:20:09.905+0000",
"updatedAt": "2022-11-04T11:24:50.693+0000",
"_link": "/codestream/api/pipelines/2677aa61-578a-4465-a653-a3c787fed3be",
...
"rollbacks": []}
```

```

 "tags": [],
 "state": "ENABLED"
}

```

Run your pipeline.

## Run and Monitor your Pipeline

To run your pipeline and verify that it completes successfully, you make a POST request with the pipeline ID and monitor the run.

- Verify that all general prerequisites and prerequisites for the Automation Pipelines service have been satisfied. See [Prerequisites for API Use Case Examples](#).
- Verify that you have the ID for the pipeline that you created. See [Create and Enable a Pipeline](#).

1. Assign the pipeline ID variable.

```
pipeline_id='<your_pipeline_id>'
```

2. Run your pipeline.

```
curl -X POST \
 $url/codestream/api/pipelines/$pipeline_id/executions?apiVersion=$api_version \
 -H 'Content-Type: application/json' \
 -H "Authorization: Bearer $access_token" \
 -d '{
 "comments": "",
 "input": {}
}' | jq "."

```

3. Examine the response and assign the execution ID variable.

```
execution_id='<your_execution_id>'
```

4. Monitor the run.

```
$ curl -X GET $url/codestream/api/executions/$execution_id?apiVersion=$api_version -H
'Content-Type: application/json' -H "Authorization: Bearer $access_token" | jq "."

```

Continue to monitor the pipeline activity until the response shows:

```
...
{
 "status": "COMPLETED",
 "statusMessage": "Execution Completed."
}
...
```

## Run and Monitor your Pipeline

Using the ID for the pipeline named `jenkinspipeline` that you created, run and monitor the pipeline.

Assign variables.

```
$ url='https://appliance.domain.com'
$ api_version='2019-10-17'
$ pipeline_id='2677aa61-578a-4465-a653-a3c787fed3be'
```

Run your pipeline.

```
$ curl -X POST \
$url/codestream/api/pipelines/$pipeline_id/executions?apiVersion=$api_version \
-H 'Content-Type: application/json' \
-H "Authorization: Bearer $access_token" \
-d '{
 "comments": "",
 "input": {}
}' | jq ."
```

The response from your request shows the execution ID.

```
{
 "executionId": "6fc8e571-418e-4b07-b869-e661fdbdf29f",
 "executionLink": "/codestream/api/executions/6fc8e571-418e-4b07-b869-e661fdbdf29f",
 "executionIndex": 0
}
```

Assign the execution ID variable.

```
$ execution_id='6fc8e571-418e-4b07-b869-e661fdbdf29f'
```

Monitor the run.

```
$ curl -X GET $url/codestream/api/executions/$execution_id?apiVersion=$api_version -H 'Content-Type: application/json' -H "Authorization: Bearer $access_token" | jq ."
```

Continue to monitor the pipeline activity until the response shows the task and run completed successfully.

```
{
 "project": "MyProject1",
 "id": "6fc8e571-418e-4b07-b869-e661fdbdf29f",
 "name": "jenkinspipeline",
 "updatedBy": "adminuser@mycompany.com",
 "updatedAt": "2022-11-04 11:26:25.283",
```

```
